MySQL NDB Cluster 7.5 Release Notes

Abstract

This document contains release notes for the changes in each release of MySQL NDB Cluster that uses version 7.5 of the NDB (NDBCLUSTER) storage engine.

Each NDB Cluster 7.5 release is based on a mainline MySQL Server release and a particular version of the NDB storage engine, as shown in the version string returned by executing SELECT VERSION() in the mysql client, or by executing the ndb_mgm client SHOW or STATUS command; for more information, see MySQL NDB Cluster 7.5.

For general information about features added in NDB Cluster 7.5, see What is New in MySQL NDB Cluster 7.5. For a complete list of all bugfixes and feature changes in MySQL Cluster, please refer to the changelog section for each individual NDB Cluster release.

For additional MySQL 5.7 documentation, see the MySQL 5.7 Reference Manual, which includes an overview of features added in MySQL 5.7 that are not specific to NDB Cluster (What Is New in MySQL 5.7), and discussion of upgrade issues that you may encounter for upgrades from MySQL 5.6 to MySQL 5.7 (Changes Affecting Upgrades to MySQL 5.7). For a complete list of all bugfixes and feature changes made in MySQL 5.7 that are not specific to NDB, see MySQL 5.7 Release Notes.

Updates to these notes occur as new product features are added, so that everybody can follow the development process. If a recent version is listed here that you cannot find on the download page (http://dev.mysql.com/downloads/), the version has not yet been released.

The documentation included in source and binary distributions may not be fully up to date with respect to release note entries because integration of the documentation occurs at release build time. For the most up-to-date release notes, please refer to the online documentation instead.

For legal information, see the Legal Notices.

For help with using MySQL, please visit either the MySQL Forums or MySQL Mailing Lists, where you can discuss your issues with other MySQL users.

For additional documentation on MySQL products, including translations of the documentation into other languages, and downloadable versions in variety of formats, including HTML and PDF formats, see the MySQL Documentation Library.

Document generated on: 2017-01-04 (revision: 10541)

Preface and Legal Notices

This document contains release notes for the changes in each release of MySQL NDB Cluster that uses version 7.5 of the NDB storage engine.

Legal Notices

Copyright © 1997, 2016, Oracle and/or its affiliates. All rights reserved.

This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

If this is software or related documentation that is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, then the following notice is applicable:

U.S. GOVERNMENT END USERS: Oracle programs, including any operating system, integrated software, any programs installed on the hardware, and/or documentation, delivered to U.S. Government end users are "commercial computer software" pursuant to the applicable Federal Acquisition Regulation and agency-specific supplemental regulations. As such, use, duplication, disclosure, modification, and adaptation of the programs, including any operating system, integrated software, any programs installed on the hardware, and/or documentation, shall be subject to license terms and license restrictions applicable to the programs. No other rights are granted to the U.S. Government.

This software or hardware is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications that may create a risk of personal injury. If you use this software or hardware in dangerous applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure its safe use. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software or hardware in dangerous applications.

Oracle and Java are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

Intel and Intel Xeon are trademarks or registered trademarks of Intel Corporation. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. AMD, Opteron, the AMD logo, and the AMD Opteron logo are trademarks or registered trademarks of Advanced Micro Devices. UNIX is a registered trademark of The Open Group.

This software or hardware and documentation may provide access to or information about content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services unless otherwise set forth in an applicable agreement between you and Oracle. Oracle Corporation and its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services, except as set forth in an applicable agreement between you and Oracle.

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at

http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc.

Access to Oracle Support

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit

http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info or visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs if you are hearing impaired.

This documentation is NOT distributed under a GPL license. Use of this documentation is subject to the following terms:

You may create a printed copy of this documentation solely for your own personal use. Conversion to other formats is allowed as long as the actual content is not altered or edited in any way. You shall not publish or distribute this documentation in any form or on any media, except if you distribute the documentation in a manner similar to how Oracle disseminates it (that is, electronically for download on a Web site with the software) or on a CD-ROM or similar medium, provided however that the documentation is disseminated together with the software on the same medium. Any other use, such as any dissemination of printed copies or use of this documentation, in whole or in part, in another publication, requires the prior written consent from an authorized representative of Oracle. Oracle and/or its affiliates reserve any and all rights to this documentation not expressly granted above.

Changes in MySQL NDB Cluster 7.5.5 (5.7.16-ndb-7.5.5) (Not yet released, General Availability)

MySQL Cluster NDB 7.5.5 is a new release of MySQL Cluster NDB 7.5, based on MySQL Server 5.7 and including features in version 7.5 of the NDB storage engine, as well as fixing recently discovered bugs in previous MySQL Cluster releases.

Obtaining MySQL Cluster NDB 7.5. MySQL Cluster NDB 7.5 source code and binaries can be obtained from http://dev.mysql.com/downloads/cluster/.

For an overview of changes made in MySQL Cluster NDB 7.5, see What is New in MySQL NDB Cluster 7.5.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.7 through MySQL 5.7.16 (see Changes in MySQL 5.7.16 (2016-10-12, General Availability)).

Version 5.7.16-ndb-7.5.5 has no changelog entries, or they have not been published because the product version has not been released.

Changes in MySQL NDB Cluster 7.5.4 (5.7.16-ndb-7.5.4) (2016-10-18, General Availability)

MySQL Cluster NDB 7.5.4 is a new release of MySQL Cluster NDB 7.5, based on MySQL Server 5.7 and including features in version 7.5 of the NDB storage engine, as well as fixing recently discovered bugs in previous MySQL Cluster releases.

Obtaining MySQL Cluster NDB 7.5. MySQL Cluster NDB 7.5 source code and binaries can be obtained from http://dev.mysql.com/downloads/cluster/.

For an overview of changes made in MySQL Cluster NDB 7.5, see What is New in MySQL NDB Cluster 7.5.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.7 through MySQL 5.7.16 (see Changes in MySQL 5.7.16 (2016-10-12, General Availability)).

Functionality Added or Changed

· Bugs Fixed

Functionality Added or Changed

• Important Change; Packaging: Naming and organization of the RPMs provided for MySQL Cluster have been changed to align with those released for the MySQL server. All MySQL Cluster RPM package names are now prefixed with mysql-cluster. Data nodes are now installed using the data-node package; management nodes are now installed from the management-server package; and SQL nodes require the server and common packages. Important: SQL nodes must use the mysql-cluster version of these RPMs; the versions released for the standard MySQL server do not provide support for the NDB storage engine. All client programs, including both the mysql client and the ndb_mgm management client, are now included in the client RPM.

For more information, see Installing NDB Cluster from RPM.

• Added the --print-sql-log option for the ndb_restore program included with the MySQL Cluster distribution. This option causes the program to log SQL statements to stdout.

Note that each table being restored in this fashion must have an explicitly defined primary key; the hidden primary key implemented by the NDB storage engine is *not* sufficient for this purpose. (Bug #13511949)

- For fully replicated tables, ndb_desc shows only nodes holding main fragment replicas for partitions; nodes with copy fragment replicas only are ignored. To make this information available in the mysql client, several new tables have been introduced in the ndbinfo information database. These tables are listed here, with brief descriptions:
 - dict_obj_info provides the names and types of database (DICT) objects in NDB, such as tables and indexes, as well as information about parent objects where applicable
 - table distribution status provides NDB table distribution status information
 - table_fragments provides information about the distribution of NDB table fragments
 - table_info provides information about logging, checkpointing, storage, and other options in force for each NDB table
 - table_replicas provides information about fragment replicas

For more information, see The ndbinfo NDB Cluster Information Database. (Bug #81762, Bug #23547643)

- MySQL NDB ClusterJ: To help applications handle database errors better, a number of new features have been added to the ClusterJDatastoreException class:
 - A new method, getCode(), returns code from the NdbError object.
 - A new method, getMysqlCode(), returns mysql_code from the NdbError object.
 - A new subclass, ClusterJDatastoreException.Classification, gives users the ability to decode the result from getClassification(). The method Classification.toString() gives the name of the error classification as listed in NDB Error Classifications.

(Bug #22353594)

Bugs Fixed

- Important Change: The default value of the --ndb-default-column-format server option has been changed from DYNAMIC to FIXED. This has been done for backwards compatibility. Only the default has been changed; setting this option to DYNAMIC continues to cause DYNAMIC to be used for ROW_FORMAT and COLUMN_FORMAT unless overridden. (Bug #24487363)
- Important Change: Event buffer status reporting has been improved by altering the semantics for calculating lag or slippage. Rather than defining this lag as the number of epochs behind, lag is now taken as the number of epochs completely buffered in the event buffer, but not yet consumed by the binlog injector thread. As part of this work, the default value for the ndb_report_thresh_binlog_epoch_slip system variable has been increased from 3 to 10. For more information, see the description of this variable in the documentation, as well as Event Buffer Reporting in the Cluster Log. (Bug #22916457)

References: See also: Bug #22901309.

• NDB Cluster APIs: The term "fragment count type" has been superceded by "partition balance". This change affects NDB_TABLE options for NDB tables as well as in the NDB API. In NDB_TABLE table option syntax, the FRAGMENT_COUNT_TYPE keyword is replaced with PARTITION_BALANCE. In the NDB API, the Table methods getFragmentCountType() and setFragmentCountType() have been renamed to getPartitionBalance() and setPartitionBalance(), respectively; getFragmentCountTypeString() is renamed to getPartitionBalanceString(). In addition, Object::FragmentCountType has been renamed to PartitionBalance, and the names of its enumerated values have been updated to be consistent with the new nomenclature.

For more information on how these changes affect NDB API applications, see the indicated Table and Object member descriptions. For more information on the SQL-level changes made as part of this fix, Setting NDB_TABLE Options in Table Comments. (Bug #81761, Bug #23547525)

References: See also: Bug #83147, Bug #24733331.

- If more than 4096 seconds elapsed while calculating an internal NdbDuration::microSec() value, this could cause an assert warning that the calculation would overflow. We fix this to avoid any overflow or precision loss when converting from the internal "tick" format to microseconds and nanoseconds, by performing the calculation in two parts corresponding to seconds and fractions of a second. (Bug #24695026)
- The serial commit protocol—which commits each operation at each replica individually and serially, and
 is used by the DBTC kernel block (see The DBTC Block) for takeover and when a transaction is judged
 to have timed out during the COMMIT or COMPLETE phase—had no support for LATE_COMMIT, which is
 required for the READ_BACKUP and FULLY_REPLICATED protocols. (Bug #24681305)
- In some cases, ALTER TABLE ... REORGANIZE PARTITION could lead to an unplanned shutdown
 of the cluster. This was due to the fact that, for fully replicated tables. the log part ID was assumed to be
 the same as the partition ID. This worked when FOR_RA_BY_LDM was used, but not necessarily for the
 other partition balancing types. (Bug #24610551)
- Using ALGORITHM=INPLACE when changing any of a table's NDB_TABLE properties (see Setting NDB_TABLE Options in Table Comments) caused the server to fail. (Bug #24584741)
- Following successive ALTER TABLE statements updating NDB_TABLE properties (see Setting NDB_TABLE Options in Table Comments), the current values were not always shown by SHOW CREATE TABLE or ndb_desc. (Bug #24584690)
- Case-insensitivity of keywords such as FULLY_REPLICATED in NDB_TABLE comments was not honored. (Bug #24577931)

- An ALTER TABLE statement attempting to set both FULLY_REPLICATED and PARTITION_BALANCE (see Setting NDB_TABLE Options in Table Comments) failed with a garbled error message. (Bug #24577894)
- A number of dependencies between the binlog injector thread and the NDB utility thread—a recurring source of synchronization and other problems—were removed. The principal changes are listed here:
 - Moved the setup of binlog injector structures from the utility thread to the injector thread itself.
 - Removed sharing of some utility and injector thread structures between these threads.
 - Moved stopping of the utility thread from the injector thread into a common block in which other such threads are stopped.
 - · Removed a number of hacks required by the previous design.
 - Removed some injector mutex locking and injector condition signaling which were made obsolete by the changes already listed.

(Bug #24496910)

References: See also: Bug #22204186.

 A late commit ACK signal used for FULLY_REPLICATED or READ_BACKUP tables caused the associated ApiConnectionRecord to have an invalid state. (Bug #24459817)

References: See also: Bug #24444861.

- Added missing error information for a failure occurring when tables on disk became full. (Bug #24425373)
- When ndbmtd crashed, the resulting error log incorrectly specified the name of the trace for thread 0, appending the nonexistent suffix _t0 to the file name. (Bug #24353408)
- Passing a nonexistent node ID to CREATE NODEGROUP led to random data node failures. (Bug #23748958)
- DROP TABLE followed by a node shutdown and subesequent master takeover—and with the containing local checkpoint not yet complete prior to the takeover—caused the LCP to be ignored, and in some cases, the data node to fail. (Bug #23735996)

References: See also: Bug #23288252.

- Removed an invalid assertion to the effect that all cascading child scans are closed at the time API
 connection records are released following an abort of the main transaction. The assertion was invalid
 because closing of scans in such cases is by design asynchronous with respect to the main transaction,
 which means that subscans may well take some time to close after the main transaction is closed. (Bug
 #23709284)
- Although arguments to the DUMP command are 32-bit integers, ndb_mgmd used a buffer of only 10 bytes when processing them. (Bug #23708039)
- The READ_BACKUP setting was not honored when performing scans on BLOB tables. (Bug #23703536)
- Setting FULLY_REPLICATED=1 (see Setting NDB_TABLE Options in Table Comments) did not
 propagate to the internal BLOB part tables used for BLOB and TEXT columns. (Bug #23703343)
- The READ_BACKUP setting was not applied to unique indexes. (Bug #23702848)

- In ReadCommitted mode, DBSPJ read primary fragment replicas for tables with READ_BACKUP (see Setting NDB_TABLE Options in Table Comments), even when a local fragment was available. (Bug #23633848)
- ALL REPORT MemoryUsage produced incorrect output when fully replicated tables were in use. (Bug #23539805)
- Ordered indexes did not inherit READ_BACKUP (see Setting NDB_TABLE Options in Table Comments) from an indexed table, which meant that ordered index scans continued to be routed to only to primary fragment replicas and never to backup fragment replicas.

Now DBDICT sets this property on ordered indexes from the table property when it distributes this information to instances of DBTC and DBSPJ. (Bug #23522027)

- Updates to a table containing a virtual column could cause the binary logging thread to fail. (Bug #23514050)
- A number of potential buffer overflow issues were found and fixed in the NDB codebase. (Bug #23152979)
- During an online upgrade from a MySQL Cluster NDB 7.3 release to an NDB 7.4 (or later) release,
 the failures of several data nodes running the lower version during local checkpoints (LCPs), and just
 prior to upgrading these nodes, led to additional node failures following the upgrade. This was due to
 lingering elements of the EMPTY_LCP protocol initiated by the older nodes as part of an LCP-plus-restart
 sequence, and which is no longer used in NDB 7.4 and later due to LCP optimizations implemented in
 those versions. (Bug #23129433)
- A SIGNAL_DROPPED_REP handler invoked in response to long message buffer exhaustion was
 defined in the SPJ kernel block, but not actually used. This meant that the default handler from
 SimulatedBlock was used instead in such cases, which shut down the data node. (Bug #23048816)

References: See also: Bug #23251145, Bug #23251423.

When a data node has insufficient redo buffer during a system restart, it does not participate in the
restart until after the other nodes have started. After this, it performs a takeover of its fragments from
the nodes in its node group that have already started; during this time, the cluster is already running and
user activity is possible, including DML and DDL operations.

During a system restart, table creation is handled differently in the DIH kernel block than normally, as this creation actually consists of reloading table definition data from disk on the master node. Thus, DIH assumed that any table creation that occurred before all nodes had restarted must be related to the restart and thus always on the master node. However, during the takeover, table creation can occur on non-master nodes due to user activity; when this happened, the cluster underwent a forced shutdown.

Now an extra check is made during system restarts to detect in such cases whether the executing node is the master node, and use that information to determine whether the table creation is part of the restart proper, or is taking place during a subsequent takeover. (Bug #23028418)

- ndb_restore set the MAX_ROWS attribute for a table for which it had not been set prior to taking the backup. (Bug #22904640)
- Whenever data nodes are added to or dropped from the cluster, the NDB kernel's Event API is notified of this using a SUB_GCP_COMPLETE_REP signal with either the ADD (add) flag or SUB (drop) flag set, as well as the number of nodes to add or drop; this allows NDB to maintain a correct count of SUB_GCP_COMPLETE_REP signals pending for every incomplete bucket. In addition to handling the bucket for the epoch associated with the addition or removal, it must also compensate for any later

incomplete buckets associated with later epochs. Although it was possible to complete such buckets out of order, there was no handling of these, leading a stall in to event reception.

This fix adds detection and handling of such out of order bucket completion. (Bug #20402364)

References: See also: Bug #82424, Bug #24399450.

- When performing online reorganization of tables, unique indexes were not included in the reorganization. (Bug #13714258)
- Under very high loads, neither the receive thread nor any user thread had sufficient capacity to handle
 poll ownership properly. This meant that, as the load and the number of active thread increased, it
 became more difficult to sustain throughput. This fix attempts to increase the priority of the receive
 thread and retains poll ownership if successful.

This fix requires sufficient permissions to be enabled. On Linux systems, this means ensuring that either the data node binary or the user it runs as has permission to change the nice level. (Bug #83217, Bug #24761073)

- Local reads of unique index and blob tables did not work correctly for fully replicated tables using more than one node group. (Bug #83016, Bug #24675602)
- The effects of an ALTER TABLE statement changing a table to use READ_BACKUP were not preserved after a restart of the cluster. (Bug #82812, Bug #24570439)
- Using FOR_RP_BY_NODE or FOR_RP_BY_LDM for PARTITION_BALANCE did not work with fully replicated tables. (Bug #82801, Bug #24565265)
- Changes to READ_BACKUP settings were not propagated to internal blob tables. (Bug #82788, Bug #24558232)
- The count displayed by the c_exec column in the ndbinfo.threadstat table was incomplete. (Bug #82635, Bug #24482218)
- The default PARTITION_BALANCE setting for NDB tables created with READ_BACKUP=1 (see Setting NDB_TABLE Options in Table Comments) has been changed from FOR_RA_BY_LDM to FOR_RP_BY_LDM. (Bug #82634, Bug #24482114)
- The internal function ndbcluster_binlog_wait(), which provides a way to make sure that all events originating from a given thread arrive in the binary log, is used by SHOW BINLOG EVENTS as well as when resetting the binary log. This function waits on an injector condition while the latest global epoch handled by NDB is more recent than the epoch last committed in this session, which implies that this condition must be signalled whenever the binary log thread completes and updates a new latest global epoch. Inspection of the code revealed that this condition signalling was missing, and that, instead of being awakened whenever a new latest global epoch completes (~100ms), client threads waited for the maximum timeout (1 second).

This fix adds the missing injector condition signalling, while also changing it to a condition broadcast to make sure that all client threads are alerted. (Bug #82630, Bug #24481551)

- Fully replicated internal foreign key or unique index triggers could fire multiple times, which led to aborted transactions for an insert or a delete operation. This happened due to redundant deferred constraint triggers firing during pre-commit. Now in such cases, we ensure that only triggers specific to unique indexes are fired in this stage. (Bug #82570, Bug #24454378)
- Backups potentially could fail when using fully replicated tables due to their high usage (and subsequent exhaustion) of internal trigger resources. To compensate for this, the amount of memory reserved in the

NDB kernel for internal triggers has been increased, and is now based in part on the maximum number of tables. (Bug #82569, Bug #24454262)

References: See also: Bug #23539733.

• In the DBTC function executeFullyReplicatedTrigger() in the NDB kernel, an incorrect check of state led in some cases to failure handling when no failure had actually occurred. (Bug #82568, Bug #24454093)

References: See also: Bug #23539733.

When returning from LQHKEYREQ with failure in LQHKEYREF in an internal trigger operation, no check
was made as to whether the trigger was fully replicated, so that those triggers that were fully replicated
were never handled. (Bug #82566, Bug #24453949)

References: See also: Bug #23539733.

- When READ_BACKUP had not previously been set, then was set to 1 as part of an ALTER TABLE ... ALGORITHM=INPLACE statement, the change was not propagated to internal unique index tables or BLOB tables. (Bug #82491, Bug #24424459)
- Distribution of MySQL privileges was incomplete due to the failure of the
 mysql_cluster_move_privileges() procedure to convert the mysql.proxies_priv table to
 NDB. The root cause of this was an ALTER TABLE ... ENGINE NDB statement which sometimes
 failed when this table contained illegal TIMESTAMP values. (Bug #82464, Bug #24430209)
- The internal variable m_max_warning_level was not initialized in storage/ndb/src/kernel/blocks/thrman.cpp. This sometimes led to node failures during a restart when the uninitialized value was treated as 0. (Bug #82053, Bug #23717703)
- Usually, when performing a system restart, all nodes are restored from redo logs and local checkpoints (LCPs), but in some cases some node might require a copy phase before it is finished with the system restart. When this happens, the node in question waits for all other nodes to start up completely before performing the copy phase. Notwithstanding the fact that it is thus possible to begin a local checkpoint before reaching start phase 4 in the DBDIH block, LCP status was initialized to IDLE in all cases, which could lead to a node failure. Now, when performing this variant of a system restart, the LCP status is no longer initialized. (Bug #82050, Bug #23717479)
- After adding a new node group online and executing ALTER TABLE . . . ALGORITHM=INPLACE REORGANIZE PARTITION, partition IDs were not set correctly for new fragments.

In a related change done as part of fixing this issue, ndb_desc -p now displays rows relating to partitions in order of partition ID. (Bug #82037, Bug #23710999)

- When executing STOP BACKUP it is possible sometimes that a few bytes are written to the backup data
 file before the backup process actually terminates. When using ODIRECT, this resulted in the wrong error
 code being returned. Now in such cases, nothing is written to O_DIRECT files unless the alignment is
 correct. (Bug #82017, Bug #23701911)
- When transaction coordinator (TC) connection records were used up, it was possible to handle scans
 only for local checkpoints and backups, so that operations coming from the DBUTIL block—used for
 ALTER TABLE ... REORGANIZE PARTITION and other operations that reorganize metadata—were
 unnecessarily blocked. In addition, such operations were not always retried when TC records were
 exhausted. To fix this issue, a number of operation records are now earmarked for DBUTIL usage,
 as well as for LCP and backup usage so that these operations are also not negatively impacted by
 operations coming from DBUTIL.

For more information, see The DBUTIL Block. (Bug #81992, Bug #23642198)

- Operations performing multiple updates of the same row within the same transaction could sometimes lead to corruption of lengths of page entries. (Bug #81938, Bug #23619031)
- During a node restart, a fragment can be restored using information obtained from local checkpoints (LCPs); up to 2 restorable LCPs are retained at any given time. When an LCP is reported to the DIH kernel block as completed, but the node fails before the last global checkpoint index written into this LCP has actually completed, the latest LCP is not restorable. Although it should be possible to use the older LCP, it was instead assumed that no LCP existed for the fragment, which slowed the restart process. Now in such cases, the older, restorable LCP is used, which should help decrease long node restart times. (Bug #81894, Bug #23602217)
- Optimized node selection (ndb_optimized_node_selection setting) was not respected by ndb_data_node_neighbour when this was enabled. (Bug #81778, Bug #23555834)
- NDB no longer retries a global schema lock if this has failed due to a timeout (default 3000ms) and there
 is the potential for this lock request to participate in a metadata lock-global schema lock deadlock. Now
 in such cases it selects itself as a "victim", and returns the decision to the requestor of the metadata lock,
 which then handles the request as a failed lock request (preferable to remaining deadlocked indefinitely),
 or, where a deadlock handler exists, retries the metadata lock-global schema lock. (Bug #81775, Bug
 #23553267)
- Two issues were found in the implementation of hash maps—used by NDB for mapping a table row's hash value to a partition—for fully replicated tables:
 - 1. Hash maps were selected based on the number of fragments rather than the number of partitions. This was previously undetected due to the fact that, for other kinds of tables, these values are always the same.
 - 2. The hash map was employed as a partition-to-partition map, using the table row's hash value modulus the partition count as input.

This fix addresses both of the problems just described. (Bug #81757, Bug #23544220)

References: See also: Bug #81761, Bug #23547525, Bug #23553996.

• Using mysqld together with --initialize and --ndbcluster led to problems later when attempting to use mysql_upgrade. When running with --initialize, the server does not require NDB support, and having it enabled can lead to issues with ndbinfo tables. To prevent this from happening, using the --initialize option now causes mysqld to ignore the --ndbcluster option if the latter is also specified.

This issue affects upgrades from MySQL Cluster NDB 7.5.2 or 7.5.3 only. In cases where such upgrades fail for the reasons outlined previously, you can work around the issue by deleting all .frm files in the data/ndbinfo directory following a rolling restart of the entire cluster, then running mysql_upgrade. (Bug #81689, Bug #23518923)

References: See also: Bug #82724, Bug #24521927.

• While a mysqld was waiting to connect to the management server during initialization of the NDB handler, it was not possible to shut down the mysqld. If the mysqld was not able to make the connection, it could become stuck at this point. This was due to an internal wait condition in the utility and index statistics threads that could go unmet indefinitely. This condition has been augmented with a maximum timeout of 1 second, which makes it more likely that these threads terminate themselves properly in such cases.

In addition, the connection thread waiting for the management server connection performed 2 sleeps in the case just described, instead of 1 sleep, as intended. (Bug #81585, Bug #23343673)

- ALTER TABLE ... ALGORITHM=INPLACE on a fully replicated table did not copy the associated trigger ID, leading to a failure in the DBDICT kernel block. (Bug #81544, Bug #23330359)
- The list of deferred tree node lookup requests created when preparing to abort a DBSPJ request were
 not cleared when this was complete, which could lead to deferred operations being started even after the
 DBSPJ request aborted. (Bug #81355, Bug #23251423)

References: See also: Bug #23048816.

Error and abort handling in Dbspj::execTRANSID_AI() was implemented such that its abort()
method was called before processing of the incoming signal was complete. Since this method sends
signals to the LDM, this partly overwrote the contents of the signal which was later required by
execTRANSID_AI(). This could result in aborted DBSPJ requests cleaning up their allocated resources
too early, or not at all. (Bug #81353, Bug #23251145)

References: See also: Bug #23048816.

- The read backup feature added in MySQL Cluster NDB 7.5.2 that makes it possible to read from backup replicas was not used for reads with lock, or for reads of BLOB tables or unique key tables where locks were upgraded to reads with lock. Now the TCKEYREQ and SCAN_TABREQ signals use a flag to convey information about such locks making it possible to read from a backup replica when a read lock was upgraded due to being the read of the base table for a BLOB table, or due to being the read for a unique key. (Bug #80861, Bug #23001841)
- Primary replicas of partitioned tables were not distributed evenly among node groups and local data managers.

As part of the fix for this issue, the maximum number of node groups supported for a single MySQL Cluster, which was previously not determined, is now set at 48 (MAX_NDB_NODE_GROUPS). (Bug #80845, Bug #22996305)

- Several object constructors and similar functions in the NDB codebase did not always perform sanity checks when creating new instances. These checks are now performed under such circumstances. (Bug #77408, Bug #21286722)
- An internal call to malloc() was not checked for NULL. The function call was replaced with a direct write. (Bug #77375, Bug #21271194)
- NDB Cluster APIs: Reuse of transaction IDs could occur when Ndb objects were created and deleted concurrently. As part of this fix, the NDB API methods lock_ndb_objects() and unlock ndb objects are now declared as const. (Bug #23709232)
- NDB Cluster APIs: When the management server was restarted while running an MGM API application that continuously monitored events, subsequent events were not reported to the application, with timeouts being returned indefinitely instead of an error.

This occurred because sockets for event listeners were not closed when restarting mgmd. This is fixed by ensuring that event listener sockets are closed when the management server shuts down, causing applications using functions such as ndb_logevent_get_next() to receive a read error following the restart. (Bug #19474782)

NDB Cluster APIs: To process incoming signals, a thread which wants to act as a receiver must acquire
polling rights from the transporter layer. This can be requested and assigned to a separate receiver
thread, or each client thread can take the receiver role when it is waiting for a result.

When the thread acting as poll owner receives a sufficient amount of data, it releases locks on any other clients taken while delivering signals to them. This could make them runnable again, and the operating system scheduler could decide that it was time to wake them up, which happened at the expense of the poll owner threads, which were in turn excluded from the CPU while still holding polling rights on it. After this fix, polling rights are released by a thread before unlocking and signalling other threads. This makes polling rights available for other threads that are actively executing on this CPU.

This change increases concurrency when polling receiver data, which should also reduce latency for clients waiting to be woken up. (Bug #83129, Bug #24716756)

• NDB Cluster APIs: libndbclient and libmysqlclient exported conflicting symbols, resulting in a segmentation fault in debug builds on Linux. To fix this issue, the conflicting symbols in libndbclient.so are no longer publicly visible. Due to this change, the version number for libndbclient.so has been raised from 6.0.0 to 6.1.0. (Bug #83093, Bug #24707521)

References: See also: Bug #80352, Bug #22722555.

• NDB Cluster APIs: When NDB schema object ownership checks are enabled by a given NdbTransaction, objects used by this transaction are checked to make sure that they belong to the NdbDictionary owned by this connection. An attempt to create a NdbOperation, NdbScanOperation, or NdbIndexScanOperation on a table or index not belonging to the same connection fails.

This fix corrects a resource leak which occurred when the operation object to be created was allocated before checking schema object ownership and subsequently not released when the object creation failed. (Bug #81949, Bug #23623978)

References: See also: Bug #81945, Bug #23623251.

• NDB Cluster APIs: NDB API objects are allocated in the context of an Ndb object, or of an NdbTransaction object which is itself owned by an Ndb object. When a given Ndb object is destroyed, all remaining NdbTransaction objects are terminated, and all NDB API objects related to this Ndb object should be released at this time as well. It was found, when there remained unclosed NdbTransaction objects when their parent Ndb object was destroyed, leaks of objects allocated from the NdbTransaction objects could occur. (However, the NdbTransaction objects themselves did not leak.)

While it is advisable (and, indeed, recommended) to close an NdbTransaction explicitly as soon as its lifetime ends, the destruction of the parent Ndb object should be sufficient to release whatever objects are dependent on it. Now in cases such as described previously, the Ndb destructor checks to ensure that all objects derived from a given Ndb instance are truly released. (Bug #81945, Bug #23623251)

• NDB Cluster APIs: In some of the NDB API example programs included with the MySQL Cluster distribution, ndb_end() was called prior to calling the Ndb_cluster_connection destructor. This caused a segmentation fault in debug builds on all platforms. The example programs affected have also been extensively revised and refactored. See NDB API Examples, for more information. (Bug #80352, Bug #22722555)

References: See also: Bug #83093, Bug #24707521.

Changes in MySQL NDB Cluster 7.5.3 (5.7.13-ndb-7.5.3) (2016-07-08, Release Candidate)

MySQL Cluster NDB 7.5.3 is a new release of MySQL Cluster NDB 7.5, based on MySQL Server 5.7 and including features in version 7.5 of the NDB storage engine, as well as fixing recently discovered bugs in previous MySQL Cluster releases.

Obtaining MySQL Cluster NDB 7.5. MySQL Cluster NDB 7.5 source code and binaries can be obtained from http://dev.mysql.com/downloads/cluster/.

For an overview of changes made in MySQL Cluster NDB 7.5, see What is New in MySQL NDB Cluster 7.5.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.7 through MySQL 5.7.13 (see Changes in MySQL 5.7.13 (2016-06-02, General Availability)).

- Functionality Added or Changed
- · Bugs Fixed

Functionality Added or Changed

• Important Change: It is now possible to set READ_BACKUP for an existing table online using an SQL statement such as ALTER TABLE ... ALGORITHM=INPLACE, COMMENT="NDB_TABLE=READ_BACKUP=1". See Setting NDB_TABLE Options in Table Comments, for further information about the READ_BACKUP option. (Bug #80858, Bug #23001617)

References: See also: Bug #18435416.

- Added three new tables to the ndbinfo information database to provide running information about locks and lock attempts in an active MySQL Cluster. These tables, with brief descriptions, are listed here:
 - cluster_locks: Current lock requests which are waiting for or holding locks; this information can be useful when investigating stalls and deadlocks. Analogous to cluster operations.
 - locks_per_fragment: Counts of lock claim requests, and their outcomes per fragment, as well as total time spent waiting for locks successfully and unsuccessfully. Analogous to operations_per_fragment and memory_per_fragment.
 - server_locks: Subset of cluster transactions—those running on the local mysqld, showing a connection ID per transaction. Analogous to server operations.

For more information, see The ndbinfo NDB Cluster Information Database.

• The NDB storage engine now supports generated columns (see CREATE TABLE and Generated Columns) as well as indexes on stored generated columns.

Indexes on virtual generated columns of NDB tables are not supported.

ALTER TABLE statements that add stored generated columns to NDB tables cannot be performed online.

Bugs Fixed

• The ndbinfo cpustat_1sec and cpustat_20sec tables did not provide any history information. (Bug #23520271)

• During shutdown, the mysqld process could sometimes hang after logging NDB Util: Stop ... NDB Util: Wakeup. (Bug #23343739)

References: See also: Bug #21098142.

 During expansion or reduction of a hash table, allocating a new overflow page in the DBACC kernel block caused the data node to fail when it was out of index memory. This could sometimes occur after a large table had increased or decreased very rapidly in size. (Bug #23304519)

References: This issue is a regression of: Bug #13436216.

- When tracking time elapsed from sending a SCAN_FRAGREQ signal to receiving a corresponding SCAN_FRAGCONF, the assumption was made in the DBTC kernel block that a SCAN_FRAGCONF can occur only after sending a SCAN_FRAGREQ or SCAN_NEXTREQ signal, which is not always the case: It it is actually possible that a local query handler can, immediately after sending a SCAN_FRAGCONF, send an additional SCAN_FRAGCONF signal upon reporting that the scan is closed. This problem is fixed by ensuring that the timer value is initialized each time before use. (Bug #81907, Bug #23605817, Bug #23306695)
- Table indexes were listed in the output of ndb_desc in a nondeterministic order that could vary between platforms. Now these indexes are ordered by ID in the output. (Bug #81763, Bug #23547742)
- Following a restart of the cluster, the first attempt to read from any of the ndbinfo cpustat, cpustat_50ms, cpustat_1sec, or cpustat_20sec tables generated a warning to the effect that columns were missing from the table. Subsequently, the thread_sleeping and spin_time columns were found to be missing from each of these tables. (Bug #81681, Bug #23514557)

References: See also: Bug #23305078.

- Using a ThreadConfig parameter value with a trailing comma led to an assertion. (Bug #81588, Bug #23344374)
- NDB Cluster APIs: The scan lock takeover issued by NdbScanOperation::lockCurrentTuple() did not set the operation type for the takeover operation. (Bug #23314028)

Changes in MySQL NDB Cluster 7.5.2 (5.7.12-ndb-7.5.2) (2016-06-01, Development Milestone)

MySQL Cluster NDB 7.5.2 is a new release of MySQL Cluster NDB 7.5, based on MySQL Server 5.7 and including features in version 7.5 of the NDB storage engine, as well as fixing recently discovered bugs in previous MySQL Cluster releases.

Obtaining MySQL Cluster NDB 7.5. MySQL Cluster NDB 7.5 source code and binaries can be obtained from http://dev.mysql.com/downloads/cluster/.

For an overview of changes made in MySQL Cluster NDB 7.5, see What is New in MySQL NDB Cluster 7.5.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.7 through MySQL 5.7.12 (see Changes in MySQL 5.7.12 (2016-04-11, General Availability)).

- Bugs Fixed

Functionality Added or Changed

• **Performance:** A deficiency in event buffer memory allocation was identified as inefficient and possibly leading to undesirable results. This could happen when additional memory was allocated from the operating system to buffer received event data even when memory had already been allocated but remained unused. This is fixed by allocating the event buffer memory directly from the page allocation memory manager (mmap()), where such functionality is offered by the operating system, allowing for direct control over the memory such that it is in fact returned to the system when released.

This remimplementation avoids the tendencies of the existing one to approach worst-case memory usage, maintainence of data structures for a worst-case event buffer event count, and useless caching of free memory in unusable positions. This work should also help minimize the runtime costs of buffering events, minimize heap fragmentation, and avoid OS-specific problems due to excessive numbers of distinct memory mappings.

In addition, the relationship between epochs and internal EventData objects is now preserved throughout the event lifecycle, reception to consumption, thus removing the need for iterating, and keeping in synch, two different lists representing the epochs and their EventData objects.

As part of this work, better reporting on the relevant event buffer metrics is now provided in the cluster logs.

References: See also: Bug #21651536, Bug #21660947, Bug #21661297, Bug #21673318, Bug #21689380, Bug #21809959.

• Important Change; NDB Replication: The ndb_binlog_index table now uses the InnoDB storage engine. When upgrading previous versions to the current release or to a later one, use mysql_upgrade with --force --upgrade-system-tables to have it perform ALTER TABLE ... ENGINE=INNODB on this table. Use of the MyISAM storage engine for this table continues to be supported for backward compatibility.

One benefit of this change is that it is now possible to depend on transactional behavior and lock-free reads for this table, which should help alleviate concurrency issues during purge operations and log rotation, and improve the availability of this table.

Due to differences in storage requirements for MyISAM and InnoDB tables, users should be aware that ndb_binlog_index may now take up more disk space than was previously required.

For more information, see NDB Cluster Replication Schema and Tables.

- ndb restore now performs output logging for specific stages of its operation. (Bug #21097957)
- An improvement in the hash index implementation used by MySQL Cluster data nodes means that partitions may now contain more than 16 GB of data for fixed columns, and the maximum partition size for fixed column data is now increased to 128 TB. The previous limitation originated with the DBACC block in the NDB kernel using only 32-bit references to the fixed-size part of a row handled in the DBTUP block, even though 45-bit references were already in use elsewhere in the kernel outside the DBACC block; all such references in DBACC now use 45-bit pointers instead.

As part of this work, error messages returned by the DBACC kernel block that were overly generic have now been improved by making them more specific. (Bug #17465232)

- The NDB storage engine supports the MySQL JSON data type and MySQL JSON functions implemented in MySQL 5.7.8 and later. This support is subject to the limitation that a single NDB table can have at most 3 JSON columns.
- A number of changes and improvements were made to the handling of send threads by NDB. The changes are summarized with brief descriptions in the following list:

- Decreased resource requirements for send threads, making sure that a given configuration using send threads outperforms the same configuration without send threads.
- Made use of otherwise idle threads (other than receiver threads) as send threads without incurring extra CPU resources in low-load situations.
- · Improved response time for write transactions.
- Provided for handling of bad configuration data in a more graceful manner.
- Made it possible to measure CPU usage with improved real-time reporting from data nodes on their resource usage.

As part of implementing the last item of those just listed, a number of new tables providing information about CPU and thread activity by node, thread ID, and thread type have been added to the ndbinfo information database. These tables are listed here:

- cpustat: Provides per-second, per-thread CPU statistics
- cpustat_50ms: Shows raw per-thread CPU statistics data, gathered every 50ms
- cpustat_1sec: Provides raw per-thread CPU statistics data, gathered each second
- cpustat_20sec: Displays raw per-thread CPU statistics data, gathered every 20 seconds
- threads: Shows names and descriptions of thread types

For more information, see The ndbinfo NDB Cluster Information Database.

- Rewrote the implementation of the NDB storage engine's global schema lock functionality to make use of the metadata lock hooks implemented in the MySQL Server in MySQL 5.7.11.
- A number of improvements provide additional read scalability for NDB by making it possible to read tables locally. It is now possible to enable reads from any replica, rather than from the primary replica only. This is disabled by default to remain compatible with previous behavior, but can be enabled for a given SQL node using the ndb_read_backup system variable added in this release.

It also becomes possible to be more flexible about the assignment of partitions by setting a fragment count type. Possible count types are one per node, one per node group, one per Local Data Manager (LDM) per node (this is the previous assignment scheme and still the default), and one per LDM per node group. This setting can be controlled for individual tables by means of a FRAGMENT_COUNT_TYPE option embedded in an NDB TABLE comment in CREATE TABLE or ALTER TABLE.

Tables using one of the two per-node-group settings for the fragment count type can also be fully replicated. This requires that the table's fragment count type is <code>ONE_PER_NODE_GROUP</code> or <code>ONE_PER_LDM_PER_NODE_GROUP</code>, and can be enabled using the option <code>FULLY_REPLICATED=1</code> within in an <code>NDB_TABLE</code> comment. The option can be enabled by default for all new <code>NDB</code> tables using the <code>ndb_fully_replicated</code> system variable added in this release.

Settings for table-level READ_BACKUP are also supported using the COMMENT="NDB_TABLE=..." syntax. It is also possible (and often preferable) to set multiple options in one comment within a single CREATE TABLE or ALTER TABLE statement. For more information and examples, see Setting NDB_TABLE Options in Table Comments.

This release also introduces the ndb_data_node_neighbour system variable, which is intended to be employed with transaction hinting (and fully-replicated tables), and to provide the current SQL node with

the ID of a "nearby" data node to use. See the description of this variable in the documentation for more information.

References: See also: Bug #18435416.

- Made the following enhancements and additions to the ThreadConfig multithreaded data node (ndbmtd) configuration parameter:
 - Added support for non-exclusive CPU locking on FreeBSD and Windows using cpubind and cpuset.
 - Added support for exclusive CPU locking on Solaris, using cpubind_exclusive and cpuset exclusive, which are added in this release.
 - Added thread prioritization using thread_prio, which is added in this release. thread_prio is supported on Linux, FreeBSD, Windows, and Solaris, but the exact effects of this setting are platformspecific; see the documentation for details.
 - Added support for setting realtime on Windows platforms.

For more information, see the description of the ThreadConfig parameter in the online documentation.

- NDB Cluster APIs: Added the Ndb::setEventBufferQueueEmptyEpoch() method, which makes it possible to enable queuing of empty events (event type TE_EMPTY). (Bug #22157845)
- NDB Cluster APIs: Ndb_free_list_t is a template used in the implementation of the NDB API to create a list keeping released API objects such as NdbTransaction, NdbOperation, and NdbRecAttr. One drawback to this template is that released API objects are kept in the list for the lifetime of the owning Ndb object, such that a transient peak in the demand for any object causes an effective leak in memory that persists until this Ndb object itself has been released.

This work adds statistics to each Ndb_free_list instance which samples the usage of objects maintained by the list; now, when objects are released, they can be released into the free list, or deallocated, based on the collected usage statistics.

• MySQL NDB ClusterJ: To make it easier for ClusterJ to handle fatal errors that require the SessionFactory to be closed, a new public method in the SessionFactory interface, getConnectionPoolSessionCounts(), has been created. When it returns zeros for all pooled connections, it means all sessions have been closed, at which point the SessionFactory can be closed and reopened. See Reconnecting to an NDB Cluster for more detail. (Bug #22353594)

Bugs Fixed

• **Performance:** A performance problem was found in an internal polling method do_poll() where the polling client did not check whether it had itself been woken up before completing the poll. Subsequent analysis showed that it is sufficient that only some clients in the polling queue receive data. do_poll() can then signal these clients and give up its polling rights, even if the maximum specified wait time (10 ms) has not expired.

This change allows do_poll() to continue polling until either the maximum specified wait time has expired, or the polling client itself has been woken up (by receiving what it was waiting for). This avoids unnecessary thread switches between client threads and thus reduces the associated overhead by as much as 10% in the API client, resulting in a significant performance improvement when client threads perform their own polling. (Bug #81229, Bug #23202735)

• **Incompatible Change:** When the data nodes are only partially connected to the API nodes, a node used for a pushdown join may get its request from a transaction coordinator on a different node, without

(yet) being connected to the API node itself. In such cases, the NodeInfo object for the requesting API node contained no valid info about the software version of the API node, which caused the DBSPJ block to assume (incorrectly) when aborting to assume that the API node used NDB version 7.2.4 or earlier, requiring the use of a backward compatability mode to be used during query abort which sent a node failure error instead of the real error causing the abort.

Now, whenever this situation occurs, it is assumed that, if the NDB software version is not yet available, the API node version is greater than 7.2.4. (Bug #23049170)

- Important Change: When started with the --initialize option, mysqld no longer enables the NDBCLUSTER storage engine plugin. This change was needed to prevent attempted initialization of system databases as distributed (rather than as specific to individual SQL nodes), which could result in a metadata lock deadlock. This fix also brings the behavior of --initialize in this regard into line with that of the discontinued --bootstrap option, which started a minimal mysqld instance without enabling NDB. (Bug #22758238)
- Microsoft Windows: ndb_mgmd failed to start on 32-bit Windows platforms, due to an issue with calling dynamically loaded functions; such issues were also likely to occur with other NDB programs using ndb_init(). It was found that all of the functions used are already supported in targeted versions of Windows, so this problem is fixed by removing the dynamic loading of these functions and using the versions provided by the Windows header files instead. (Bug #80876, Bug #23014820)
- **Microsoft Windows:** When building MySQL Cluster on Windows using more than one parallel build job it was sometimes possible for the build to fail because host_info.exe could not be be installed. To fix this problem, the install_mcc target is now always built prior to the host_info target. (Bug #80051, Bug #22566368)
- Microsoft Windows: Performing ANALYZE TABLE on a table having one or more indexes caused ndbmtd to fail with an *InvalidAttrInfo* error due to signal corruption. This issue occurred consistently on Windows, but could also be encountered on other platforms. (Bug #77716, Bug #21441297)
- Reserved send buffer for the loopback transporter, introduced in MySQL Cluster NDB 7.4.8 and used by API and management nodes for administrative signals, was calculated incorrectly. (Bug #23093656, Bug #22016081)

References: This issue is a regression of: Bug #21664515.

 During a node restart, re-creation of internal triggers used for verifying the referential integrity of foreign keys was not reliable, because it was possible that not all distributed TC and LDM instances agreed on all trigger identities. To fix this problem, an extra step is added to the node restart sequence, during which the trigger identities are determined by querying the current master node. (Bug #23068914)

References: See also: Bug #23221573.

- Following the forced shutdown of one of the 2 data nodes in a cluster where NoOfReplicas=2, the other data node shut down as well, due to arbitration failure. (Bug #23006431)
- Aborting a CREATE LOGFILE GROUP statement which had failed due to lack of shared global memory
 was not performed correctly, causing node failure. In addition, the transaction in which this occurred
 was not rolled back correctly, also causing any subsequent CREATE LOGFILE GROUP to fail. (Bug
 #22982618)
- The ndbinfo.tc_time_track_stats table uses histogram buckets to give a sense of the distribution
 of latencies. The sizes of these buckets were also reported as HISTOGRAM BOUNDARY INFO messages
 during data node startup; this printout was redundant and so has been removed. (Bug #22819868)

- Online upgrades from previous versions of MySQL Cluster to MySQL Cluster NDB 7.5 were not
 possible due to missing entries in the matrix used to test upgrade compatibility between versions. (Bug
 #22024947)
- A failure occurred in DBTUP in debug builds when variable-sized pages for a fragment totalled more than 4 GB. (Bug #21313546)
- Restoration of metadata with ndb_restore -m occasionally failed with the error message Failed to create index... when creating a unique index. While disgnosing this problem, it was found that the internal error prepare_seize_error (a temporary error) was reported as an unknown error. Now in such cases, ndb_restore retries the creation of the unique index, and prepare_seize_error is reported as NDB Error 748 Busy during read of event table. (Bug #21178339)

References: See also: Bug #22989944.

mysqld did not shut down cleanly when executing ndb_index_stat. (Bug #21098142)

References: See also: Bug #23343739.

- The following improvements were made to the data node error logging mechanism:
 - Increased the message slot size 499 bytes to 999 bytes to prevent log messages from overwriting one another or from being truncated.
 - Added a Trace file name field to the output. This field contains the trace file name (without any path) and trace file number for the thread causing the trace.
 - ndbmtd trace files are also now shown in the error log.

(Bug #21082710)

- DBDICT and GETTABINFOREQ queue debugging were enhanced as follows:
 - Monitoring by a data node of the progress of GETTABINFOREQ signals can be enabled by setting DictTrace >= 2.
 - Added the ApiVerbose configuration parameter, which enables NDB API debug logging for an API node where it is set greater than or equal to 2.
 - Added DUMP code 1229 which shows the current state of the GETTABINFOREQ queue. (See DUMP 1229.)

See also The DBDICT Block. (Bug #20368450)

References: See also: Bug #20368354.

- When a write to the ndb_binlog_index table failed during a MySQL Server shutdown, mysqld killed the NDB binary logging thread. (Bug #81166, Bug #23142945)
- Memory associated with table descriptions was not freed by the internal table information method NdbDictInterface::parseTableInfo(). (Bug #81141, Bug #23130084)
- Improved memory usage by the internal TransporterFacade constructor when performing mutex array initialization. (Bug #81134, Bug #23127824)
- Fixed a memory leak that occurred when an error was raised in ha_ndbcluster::get_metadata()
 or one of the functions which this method calls. (Bug #81045, Bug #23089566)

- An internal function used to validate connections failed to update the connection count when creating a new Ndb object. This had the potential to create a new Ndb object for every operation validating the connection, which could have an impact on performance, particularly when performing schema operations. (Bug #80750, Bug #22932982)
- A table scan on an NDB table using neither an ordered index nor any Disk Data columns normally uses an ACC scan. If this happened while scanning an unique but unordered index which shrank (due to rows being deleted) after the scan started and then grew again (rows inserted), a single row that had been neither deleted nor inserted could be scanned twice. (Bug #80733, Bug #22926938)
- On OS X, ndb_config failed when an empty string was used for the --host option. (Bug #80689, Bug #22908696)
- Starting a backup in the ndb_mgm client after creating a large number of tables caused a forced shutdown of the cluster. (Bug #80640, Bug #228849958)
- When an SQL node was started, and joined the schema distribution protocol, another SQL node, already
 waiting for a schema change to be distributed, timed out during that wait. This was because the code
 incorrectly assumed that the new SQL node would also acknowledge the schema distribution even
 though the new node joined too late to be a participant in it.

As part of this fix, printouts of schema distribution progress now always print the more significant part of a bitmask before the less significant; formatting of bitmasks in such printouts has also been improved. (Bug #80554, Bug #22842538)

- The ndb_print_file utility failed consistently on Solaris 9 for SPARC. (Bug #80096, Bug #22579581)
- The MySQL Cluster Auto-Installer failed to work in various ways on different platforms. (Bug #79853, Bug #22502247)
- The internal function ndbrequire(), which, like assert(), evaluates a given expression and terminates the process if the expression does not evaluate as true, now includes the failed expression in its output to the error logs. (Bug #77021, Bug #21128318)
- Trying to drop a table during an ongoing backup failed with the error message Unknown table; now, it fails with Unable to alter table as backup is in progress. (Bug #47301, Bug #11755512)

References: See also: Bug #44695, Bug #11753280.

- NDB Disk Data: The following improvements were made to logging during restarts by data nodes using MySQL Cluster Disk Data:
 - The total amount of undo log to be applied by the data node is now provided as the total number of pages present in the log. This is a worst case estimate.
 - Progress information is now provided at regular intervals (once for each 30000 records) as the undo
 log is applied. This information is supplied as the number of records and number of undo log pages
 applied so far during the current restart.

(Bug #22513381)

- NDB Cluster APIs: Deletion of Ndb objects used a dispoportionately high amount of CPU. (Bug #22986823)
- NDB Cluster APIs: Executing a transaction with an NdbIndexOperation based on an obsolete unique index caused the data node process to fail. Now the index is checked in such cases, and if it cannot be used the transaction fails with an appropriate error. (Bug #79494, Bug #22299443)

 mysql_upgrade failed to upgrade the sys schema if a sys database directory existed but was empty. (Bug #81352, Bug #23249846, Bug #22875519)

Changes in MySQL NDB Cluster 7.5.1 (5.7.11-ndb-7.5.1) (2016-03-18, Development Milestone)

MySQL Cluster NDB 7.5.1 is a new release of MySQL Cluster NDB 7.5, based on MySQL Server 5.7 and including features in version 7.5 of the NDB storage engine, as well as fixing recently discovered bugs in previous MySQL Cluster releases.

Obtaining MySQL Cluster NDB 7.5. MySQL Cluster NDB 7.5 source code and binaries can be obtained from http://dev.mysql.com/downloads/cluster/.

For an overview of changes made in MySQL Cluster NDB 7.5, see What is New in MySQL NDB Cluster 7.5.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.7 through MySQL 5.7.11 (see Changes in MySQL 5.7.11 (2016-02-05, General Availability)).

- · Functionality Added or Changed
- · Bugs Fixed

Functionality Added or Changed

• Important Change: When creating or adding columns to NDB tables, the default value used for both the COLUMN_FORMAT and ROW_FORMAT options is now DYNAMIC rather than FIXED.

This change does not affect the row format or column format used by existing tables. New columns added to such tables use the new defaults, and existing columns are changed to use these as well, provided that the ALTER TABLE statement in question uses ALGORITHM=COPY. Note that this cannot be done implicitly if mysqld is run with --ndb-allow-copying-alter-table=FALSE (the default is TRUE).

A new MySQL server option --ndb-default-column-format is added for backwards compatibility; set this to FIXED to force the old defaults to be used for COLUMN_FORMAT and ROW_FORMAT.

Note

This behavior change is superseded in MySQL Cluster NDB 7.5.4.

• Scans have been improved by replacing the DIH_SCAN_GET_NODES_REQ signal, formerly used for communication between the DBTC and DBDIH kernel blocks in NDB, with the DIGETNODESREQ signal, which supports direct execution and allows for the elimination of DIH_SCAN_GET_NODES_REF and DIH_SCAN_GET_NODES_CONF, as well as for DIH_SCAN_TAB_REQ and DIH_SCAN_TAB_COMPLETE_REP signals to EXECUTE_DIRECT. This enables enable higher scalability of data nodes when used for scan operations by decreasing the use of CPU resources for scan operations by an estimated five percent in some cases. This should also improve response times, which could help prevent issues with overload of the main threads.

As part of these changes, scans made in the BACKUP kernel block have also been improved and made more efficient.

References: See also: Bug #80640, Bug #22884995.

- The following improvements have been made to event buffer reporting in the cluster log:
 - Each report now identifies the API node that sent it.
 - The fields shown in the report have been improved and expanded. Percentages are now better specified and used only when appropriate. For improved clarity, the apply_epoch and latest_epoch fields have been renamed to latest_consumed_epoch and latest_buffered_epoch, respectively. The ID of the Ndb object serving as the source of the report is now shown, as is the reason for making the report (as the report reason field).
 - The frequency of unnecessary reporting has been reduced by limiting reports to those showing only significant changes in event buffer usage.
 - The MGM API adds a new NDB_LE_EventBufferStatus2 event type to handle the additional information provided by the new event buffer reporting. The NDB_LE_EventBufferStatus event type used in older versions of MySQL Cluster is now deprecated, and will eventually be removed.

For more information, see Event Buffer Reporting in the Cluster Log, as well as The ndb_logevent Structure.

Bugs Fixed

- Important Change: The minimum value for the BackupDataBufferSize data node configuration parameter has been lowered from 2 MB to 512 KB. The default and maximum values for this parameter remain unchanged. (Bug #22749509)
- During node failure handling, the request structure used to drive the cleanup operation was not
 maintained correctly when the request was executed. This led to inconsistencies that were harmless
 during normal operation, but these could lead to assertion failures during node failure handling, with
 subsequent failure of additional nodes. (Bug #22643129)
- The previous fix for a lack of mutex protection for the internal TransporterFacade::deliver_signal() function was found to be incomplete in some cases. (Bug #22615274)

References: This issue is a regression of: Bug #77225, Bug #21185585.

- Compilation of MySQL with Visual Studio 2015 failed in ConfigInfo.cpp, due to a change in Visual Studio's handling of spaces and concatenation. (Bug #22558836, Bug #80024)
- When setup of the binary log as an atomic operation on one SQL node failed, this could trigger a state in other SQL nodes in which they appeared to detect the SQL node participating in schema change distribution, whereas it had not yet completed binary log setup. This could in turn cause a deadlock on the global metadata lock when the SQL node still retrying binary log setup needed this lock, while another mysqld had taken the lock for itself as part of a schema change operation. In such cases, the second SQL node waited for the first one to act on its schema distribution changes, which it was not yet able to do. (Bug #22494024)
- Duplicate key errors could occur when ndb_restore was run on a backup containing a unique index.
 This was due to the fact that, during restoration of data, the database can pass through one or more inconsistent states prior to completion, such an inconsistent state possibly having duplicate values for a column which has a unique index. (If the restoration of data is preceded by a run with --disable-indexes and followed by one with --rebuild-indexes, these errors are avoided.)

Added a check for unique indexes in the backup which is performed only when restoring data, and which does not process tables that have explicitly been excluded. For each unique index found, a warning is now printed. (Bug #22329365)

- When setting up event logging for ndb_mgmd on Windows, MySQL Cluster tries to add a registry key to HKEY_LOCAL_MACHINE, which fails if the user does not have access to the registry. In such cases ndb_mgmd logged the error Could neither create or open key, which is not accurate and which can cause confusion for users who may not realize that file logging is available and being used. Now in such cases, ndb_mgmd logs a warning Could not create or access the registry key needed for the application to log to the Windows EventLog. Run the application with sufficient privileges once to create the key, or add the key manually, or turn off logging for that application. An error (as opposed to a warning) is now reported in such cases only if there is no available output at all for ndb_mgmd event logging. (Bug #20960839)
- NdbDictionary metadata operations had a hard-coded 7-day timeout, which proved to be excessive
 for short-lived operations such as retrieval of table definitions. This could lead to unnecessary hangs in
 user applications which were difficult to detect and handle correctly. To help address this issue, timeout
 behaviour is modified so that read-only or short-duration dictionary interactions have a 2-minute timeout,
 while schema transactions of potentially long duration retain the existing 7-day timeout.

Such timeouts are intended as a safety net: In the event of problems, these return control to users, who can then take corrective action. Any reproducible issue with NdbDictionary timeouts should be reported as a bug. (Bug #20368354)

- Optimization of signal sending by buffering and sending them periodically, or when the buffer became
 full, could cause SUB_GCP_COMPLETE_ACK signals to be excessively delayed. Such signals are sent
 for each node and epoch, with a minimum interval of TimeBetweenEpochs; if they are not received
 in time, the SUMA buffers can overflow as a result. The overflow caused API nodes to be disconnected,
 leading to current transactions being aborted due to node failure. This condition made it difficult for long
 transactions (such as altering a very large table), to be completed. Now in such cases, the ACK signal is
 sent without being delayed. (Bug #18753341)
- MySQL Cluster did not compile correctly with Microsoft Visual Studio 2015, due to a change from previous versions in the VS implementation of the _vsnprintf() function. (Bug #80276, Bug #22670525)
- When setting CPU spin time, the value was needlessly cast to a boolean internally, so that setting it to
 any nonzero value yielded an effective value of 1. This issue, as well as the fix for it, apply both to setting
 the SchedulerSpinTimer parameter and to setting spintime as part of a ThreadConfig parameter
 value. (Bug #80237, Bug #22647476)
- Processing of local checkpoints was not handled correctly on Mac OS X, due to an uninitialized variable. (Bug #80236, Bug #22647462)
- A logic error in an if statement in storage/ndb/src/kernel/blocks/dbacc/DbaccMain.cpp rendered useless a check for determining whether ZREAD_ERROR should be returned when comparing operations. This was detected when compiling with gcc using -Werror=logical-op. (Bug #80155, Bug #22601798)

References: This issue is a regression of: Bug #21285604.

- Suppressed a CMake warning that was caused by use of an incorrectly quoted variable name. (Bug #80066, Bug #22572632)
- When using CREATE INDEX to add an index on either of two NDB tables sharing circular foreign keys, the query succeeded but a temporary table was left on disk, breaking the foreign key constraints. This issue was also observed when attempting to create an index on a table in the middle of a chain of foreign keys—that is, a table having both parent and child keys, but on different tables. The problem did not occur when using ALTER TABLE to perform the same index creation operation; and subsequent

analysis revealed unintended differences in the way such operations were performed by CREATE INDEX.

To fix this problem, we now make sure that operations performed by a CREATE INDEX statement are always handled internally in the same way and at the same time that the same operations are handled when performed by ALTER TABLE or DROP INDEX. (Bug #79156, Bug #22173891)

• The PortNumber SCI, SHM, and TCP configuration parameters, which were deprecated in MySQL 5.1.3, have now been removed and are no longer accepted in configuration files.

This change does not affect the PortNumber management node configuration parameter, whose behavior remains unaltered. (Bug #77405, Bug #21280456)

• For busy servers, client connection or communication failure could occur if an I/O-related system call was interrupted. The mysql_options() C API function now has a MYSQL_OPT_RETRY_COUNT option to control the number of retries for interrupted system calls. (Bug #22336527)

References: See also: Bug #22389653.

Changes in MySQL NDB Cluster 7.5.0 (5.7.10-ndb-7.5.0) (2016-02-05, Development Milestone)

MySQL Cluster NDB 7.5.0 is a new release of MySQL Cluster NDB 7.5, based on MySQL Server 5.7 and including features in version 7.5 of the NDB storage engine, as well as fixing recently discovered bugs in previous MySQL Cluster releases.

Obtaining MySQL Cluster NDB 7.5. MySQL Cluster NDB 7.5 source code and binaries can be obtained from http://dev.mysql.com/downloads/cluster/.

For an overview of changes made in MySQL Cluster NDB 7.5, see What is New in MySQL NDB Cluster 7.5.

This release also incorporates all bugfixes and changes made in previous MySQL Cluster releases, as well as all bugfixes and feature changes which were added in mainline MySQL 5.7 through MySQL 5.7.10 (see Changes in MySQL 5.7.10 (2015-12-07, General Availability)).

- · Functionality Added or Changed
- Bugs Fixed

Functionality Added or Changed

- Important Change: Previously, the ndbinfo information database included lookup tables that used the MyISAM storage engine. This dependency on MyISAM has now been removed. (Bug #20075747)
- Important Change: Previously, the NDB scheduler always optimized for speed against throughput in a predetermined manner (this was hard coded); this balance can now be set using the SchedulerResponsiveness data node configuration parameter. This parameter accepts an integer in the range of 0-10 inclusive, with 5 as the default. Higher values provide better response times relative to throughput. Lower values provide increased throughput, but impose longer response times. (Bug #78531, Bug #21889312)
- Important Change: A number of MySQL Cluster data node configuration parameters were deprecated in earlier versions of MySQL Cluster, and have been removed with this release. These parameters include Id, NoOfDiskPagesToDiskDuringRestartTUP, NoOfDiskPagesToDiskDuringRestartACC, NoOfDiskPagesToDiskAfterRestartACC,

NoOfDiskPagesToDiskAfterRestartTUP, ReservedSendBufferMemory, MaxNoOfIndexes, and Discless (use Diskless instead), as well as DiskCheckpointSpeed and DiskCheckpointSpeedInRestart. The archaic and unused ByteOrder computer configuration parameter has also been removed, as well as the unused MaxNoOfSavedEvents management node confugration parameter. These parameters are no longer supported; most of them already did not have (or no longer had) any effect. Trying to use any of these parameters in a MySQL Cluster configuration file now results in an error.

For more information, see What is New in MySQL NDB Cluster 7.5. (Bug #77404, Bug #21280428)

• Important Change: The ExecuteOnComputer configuration parameter for management, data, and API nodes is now deprecated, and is subject to removal in a future MySQL Cluster release. For all types of MySQL Cluster nodes, you should now use the HostName parameter exclusively for identifying hosts in the cluster configuration file.

This information is also now displayed in the output of ndb_config --configinfo --xml. (Bug #53052, Bug #11760628)

- Important Change: The ndbinfo database can now provide default and current information about MySQL Cluster node configuration parameters as a result of the following changes:
 - 1. The config_params table has been enhanced with additional columns providing information about each configuration parameter, including its type, default, and maximum and minimum values (where applicable).
 - 2. A new config_values table has been added. A row in this table shows the current value of a parameter on a given node.

You can obtain values of MySQL Cluster configuration parameters by name using a join on these two tables such as the one shown here:

- Deprecated MySQL Cluster node configuration parameters are now indicated as such by ndb_config
 --configinfo --xml. For each parameter currently deprecated, the corresponding <param/> tag in
 the XML output now includes the attribute deprecated="true". (Bug #21127135)
- Added the --ndb-cluster-connection-pool-nodeids option for mysqld, which can be used to specify a list of nodes by node ID for connection pooling. The number of node IDs in the list must equal the value set for --ndb-cluster-connection-pool. (Bug #19521789)
- Added the PROMPT command in the ndb_mgm client. This command has the syntax PROMPT string,
 which sets the client's prompt to string. Issuing the command without an argument causes the prompt
 to be reset to the default (ndb_mgm>). See Commands in the NDB Cluster Management Client, for more
 information. (Bug #18421338)
- When the --database option has not been specified for ndb_show_tables, and no tables are
 found in the TEST_DB database, an appropriate warning message is now issued. (Bug #50633, Bug
 #11758430)

- The NDB storage engine now uses the improved records-per-key interface for index statistics introduced for the optimizer in MySQL 5.7. Some improvements due to this change are listed here:
 - The optimizer can now choose better execution plans for queries on NDB tables in many cases where a less optimal join index or table join order would previously have been chosen.
 - EXPLAIN now provides more accurate row estimates than previously.
 - Improved cardinality estimates can be obtained from SHOW INDEX.
- NDB Replication: Normally, RESET SLAVE causes all entries to be deleted from the mysql.ndb_apply_status table. This release adds the ndb_clear_apply_status system variable, which makes it possible to override this behavior. This variable is ON by default; setting it to OFF keeps RESET SLAVE from purging the ndb_apply_status table. (Bug #12630403)

Bugs Fixed

- Incompatible Change; NDB Cluster APIs: The pollEvents2() method now returns -1, indicating an error, whenever a negative value is used for the time argument. (Bug #20762291)
- **Important Change:** The options controlling behavior of NDB programs with regard to the number and timing of successive attempts to connect to a management server have changed as listed here:
 - The minimum value for the --connect-retry-delay option common to all NDB programs has been changed from 0 to 1; this means that all NDB programs now wait at least 1 second between successive connection attempts, and it is no longer possible to set a waiting time equal to 0.
 - The semantics for the --connect-retries option have changed slightly, such that the value of this option now sets the number of times an NDB program tries to connect to a management server. Setting this option to 0 now causes the program to attempt the connection indefinitely, until it either succeeds or is terminated by other means (such as kill).
 - In addition, the default for the --connect-retries option for the ndb_mgm client has been changed from 3 to 12, so that the minimum, maximum, and default values for this option when used with ndb mgm are now exactly the same as for all other NDB programs.

The ndb_mgm --try-reconnect option, although deprecated in MySQL Cluster NDB 7.4, continues to be supported as a synonym for ndb_mgm --connect-retries to provide backwards compatibility. The default value for --try-reconnect has also been changed from 3 to 12, respectively, so that this option continues to behave in the exactly in the same way as --connect-retries.

(Bug #22116937)

- Important Change: In previous versions of MySQL Cluster, other DDL operations could not be part of ALTER ONLINE TABLE ... RENAME (This was disallowed by the fix for BUG#16021021.) MySQL Cluster NDB 7.5 makes the following changes:
 - Support for the ONLINE and OFFLINE keywords, which was deprecated in MySQL Cluster NDB 7.3, is now removed, and use of these now causes a syntax error; the NDB storage engine now accepts *only* ALGORITHM = DEFAULT, ALGORITHM = COPY, and ALGORITHM = INPLACE to specify whether the ALTER operation is copying or in-place, just as in the standard MySQL Server.
 - NDB now allows ALTER TABLE ... ALGORITHM=COPYING RENAME. (Bug #20804269, Bug #76543, Bug #20479917, Bug #75797)

References: See also: Bug #16021021.

- Important Change; NDB Cluster APIs: Ndb::pollEvents() is now compatible with the TE_EMPTY, TE_INCONSISTENT, and TE_OUT_OF_MEMORY event types introduced in MySQL Cluster NDB 7.4.3. For detailed information about this change, see the description of this method in the MySQL Cluster API Developer Guide. (Bug #20646496)
- Important Change; NDB Cluster APIs: Added the method Ndb::isExpectingHigherQueuedEpochs() to the NDB API to detect when additional, newer event epochs were detected by pollEvents2().

The behavior of Ndb::pollEvents() has also been modified such that it now returns NDB_FAILURE_GCI (equal to ~(Uint64) 0) when a cluster failure has been detected. (Bug #18753887)

• Important Change; NDB Cluster APIs: To release the memory used for dropped event operations, the event API formerly depended on pollEvents() and nextEvent() to consume all events possibly referring to the dropped events. This dependency between dropEventOperation() and the first two methods required the entire event buffer to be read before attempting to release event operation memory (that is, until successive calls to pollEvents() and nextEvent() returned no more events).

A related cleanup issue arose following the reset of the event buffer (when all event operations had previously been dropped), and the event buffer was truncated by the first <code>createEventOperation()</code> call subsequent to the reset.

To fix these problems, the event buffer is now cleared when the last event operation is dropped, rather than waiting for a subsequent create operation which might or might not occur. Memory taken up by dropped event operations is also now released when the event queue has been cleared, which removes the hidden requirement for consuming all events to free up memory. In addition, event operation memory is now released as soon as all events referring to the operation have been consumed, rather than waiting for the entire event buffer to be consumed. (Bug #78145, Bug #21661297)

- Important Change; NDB Cluster APIs: The MGM API error-handling functions ndb_mgm_get_latest_error(), ndb_mgm_get_latest_error_msg(), and ndb_mgm_get_latest_error_desc() each failed when used with a NULL handle. You should note that, although these functions are now null-safe, values returned in this case are arbitrary and not meaningful. (Bug #78130, Bug #21651706)
- Important Change; NDB Cluster APIs: The following NDB API methods were not actually implemented and have been removed from the sources:
 - Datafile methods: getNode(), setNode(), and getFileNo()
 - Undofile methods: getNode(), setNode(), and getFileNo()
 - Table methods: getObjectType() and setObjectType()
- A serious regression was inadvertently introduced in MySQL Cluster NDB 7.4.8 whereby local
 checkpoints and thus restarts often took much longer than expected. This occurred due to the fact
 that the setting for MaxDiskWriteSpeedOwnRestart was ignored during restarts and the value
 of MaxDiskWriteSpeedOtherNodeRestart, which is much lower by default than the default
 for MaxDiskWriteSpeedOwnRestart, was used instead. This issue affected restart times and
 performance only and did not have any impact on normal operations. (Bug #22582233)
- The epoch for the latest restorable checkpoint provided in the cluster log as part of its reporting for EventBufferStatus events (see NDB Cluster: Messages in the Cluster Log) was not well defined and thus unreliable; depending on various factors, the reported epoch could be the one currently being consumed, the one most recently consumed, or the next one queued for consumption.

This fix ensures that the latest restorable global checkpoint is always regarded as the one that was most recently completely consumed by the user, and thus that it was the latest restorable global checkpoint that existed at the time the report was generated. (Bug #22378288)

Added the --ndb-allow-copying-alter-table option for mysqld. Setting this option (or the
equivalent system variable ndb_allow_copying_alter_table) to OFF keeps ALTER TABLE
statements from performing copying operations. The default value is ON. (Bug #22187649)

References: See also: Bug #17400320.

- Attempting to create an NDB table having greater than the maximum supported combined width for all BIT columns (4096) caused data node failure when these columns were defined with COLUMN_FORMAT DYNAMIC. (Bug #21889267)
- Creating a table with the maxmimum supported number of columns (512) all using COLUMN_FORMAT DYNAMIC led to data node failures. (Bug #21863798)
- In a MySQL Cluster with multiple LDM instances, all instances wrote to the node log, even inactive
 instances on other nodes. During restarts, this caused the log to be filled with messages from other
 nodes, such as the messages shown here:

```
2015-06-24 00:20:16 [ndbd] INFO -- We are adjusting Max Disk Write Speed, a restart is ongoing now ...
2015-06-24 01:08:02 [ndbd] INFO -- We are adjusting Max Disk Write Speed, no restarts ongoing anymore
```

Now this logging is performed only by the active LDM instance. (Bug #21362380)

Backup block states were reported incorrectly during backups. (Bug #21360188)

References: See also: Bug #20204854, Bug #21372136.

• For a timeout in GET_TABINFOREQ while executing a CREATE INDEX statement, mysqld returned Error 4243 (Index not found) instead of the expected Error 4008 (Receive from NDB failed).

The fix for this bug also fixes similar timeout issues for a number of other signals that are sent the DBDICT kernel block as part of DDL operations, including ALTER_TAB_REQ, CREATE_INDX_REQ, DROP_FK_REQ, DROP_INDX_REQ, INDEX_STAT_REQ, DROP_FILE_REQ, CREATE_FILEGROUP_REQ, DROP_FILEGROUP_REQ, CREATE_EVENT, WAIT_GCP_REQ, DROP_TAB_REQ, and LIST_TABLES_REQ, as well as several internal functions used in handling NDB schema operations. (Bug #21277472)

References: See also: Bug #20617891, Bug #20368354, Bug #19821115.

 Previously, multiple send threads could be invoked for handling sends to the same node; these threads then competed for the same send lock. While the send lock blocked the additional send threads, work threads could be passed to other nodes.

This issue is fixed by ensuring that new send threads are not activated while there is already an active send thread assigned to the same node. In addition, a node already having an active send thread assigned to it is no longer visible to other, already active, send threads; that is, such a node is longer added to the node list when a send thread is currently assigned to it. (Bug #20954804, Bug #76821)

Queueing of pending operations when the redo log was overloaded
 (DefaultOperationRedoProblemAction API node configuration parameter) could lead to timeouts
 when data nodes ran out of redo log space (P_TAIL_PROBLEM errors). Now when the redo log is full,
 the node aborts requests instead of queuing them. (Bug #20782580)

References: See also: Bug #20481140.

 An NDB event buffer can be used with an Ndb object to subscribe to table-level row change event streams. Users subscribe to an existing event; this causes the data nodes to start sending event data signals (SUB_TABLE_DATA) and epoch completion signals (SUB_GCP_COMPLETE) to the Ndb object. SUB_GCP_COMPLETE_REP signals can arrive for execution in concurrent receiver thread before completion of the internal method call used to start a subscription.

Execution of SUB_GCP_COMPLETE_REP signals depends on the total number of SUMA buckets (sub data streams), but this may not yet have been set, leading to the present issue, when the counter used for tracking the SUB_GCP_COMPLETE_REP signals (TOTAL_BUCKETS_INIT) was found to be set to erroneous values. Now TOTAL_BUCKETS_INIT is tested to be sure it has been set correctly before it is used. (Bug #20575424, Bug #76255)

References: See also: Bug #20561446, Bug #21616263.

NDB statistics queries could be delayed by the error delay set for ndb_index_stat_option (default
60 seconds) when the index that was queried had been marked with internal error. The same underlying
issue could also cause ANALYZE TABLE to hang when executed against an NDB table having multiple
indexes where an internal error occurred on one or more but not all indexes.

Now in such cases, any existing statistics are returned immediately, without waiting for any additional statistics to be discovered. (Bug #20553313, Bug #20707694, Bug #76325)

 Memory allocated when obtaining a list of tables or databases was not freed afterward. (Bug #20234681, Bug #74510)

References: See also: Bug #18592390, Bug #72322.

Added the BackupDiskWriteSpeedPct data node parameter. Setting this parameter causes the data node to reserve a percentage of its maximum write speed (as determined by the value of MaxDiskWriteSpeed) for use in local checkpoints while performing a backup.
 BackupDiskWriteSpeedPct is interpreted as a percentage which can be set between 0 and 90 inclusive, with a default value of 50. (Bug #20204854)

References: See also: Bug #21372136.

• After restoring the database schema from backup using ndb_restore, auto-discovery of restored tables in transactions having multiple statements did not work correctly, resulting in Deadlock found when trying to get lock; try restarting transaction errors.

This issue was encountered both in the mysql client, as well as when such transactions were executed by application programs using Connector/J and possibly other MySQL APIs.

Prior to upgrading, this issue can be worked around by executing SELECT TABLE_NAME, TABLE_SCHEMA FROM INFORMATION_SCHEMA.TABLES WHERE ENGINE = 'NDBCLUSTER' on all SQL nodes following the restore operation, before executing any other statements. (Bug #18075170)

- Using ndb_mgm STOP -f to force a node shutdown even when it triggered a complete shutdown of the cluster, it was possible to lose data when a sufficient number of nodes were shut down, triggering a cluster shutdown, and the timing was such that SUMA handovers had been made to nodes already in the process of shutting down. (Bug #17772138)
- When using a sufficiently large value for TransactionDeadlockDetectionTimeout and the default value for sort_buffer_size, executing SELECT * FROM ndbinfo.cluster_operations ORDER BY transid with multiple concurrent conflicting or deadlocked transactions, each transaction

having several pending operations, caused the SQL node where the query was run to fail. (Bug #16731538, Bug #67596)

- The ndbinfo.config_params table is now read-only. (Bug #11762750, Bug #55383)
- NDB failed during a node restart due to the status of the current local checkpoint being set but not as
 active, even though it could have other states under such conditions. (Bug #78780, Bug #21973758)
- ndbmtd checked for signals being sent only after a full cycle in run_job_buffers, which is performed
 for all job buffer inputs. Now this is done as part of run_job_buffers itself, which avoids executing
 for extended periods of time without sending to other nodes or flushing signals to other threads. (Bug
 #78530, Bug #21889088)
- When attempting to enable index statistics, creation of the required system tables, events and event subscriptions often fails when multiple mysqld processes using index statistics are started concurrently in conjunction with starting, restarting, or stopping the cluster, or with node failure handling. This is normally recoverable, since the affected mysqld process or processes can (and do) retry these operations shortly thereafter. For this reason, such failures are no longer logged as warnings, but merely as informational events. (Bug #77760, Bug #21462846)
- It was possible to end up with a lock on the send buffer mutex when send buffers became a limiting resource, due either to insufficient send buffer resource configuration, problems with slow or failing communications such that all send buffers became exhausted, or slow receivers failing to consume what was sent. In this situation worker threads failed to allocate send buffer memory for signals, and attempted to force a send in order to free up space, while at the same time the send thread was busy trying to send to the same node or nodes. All of these threads competed for taking the send buffer mutex, which resulted in the lock already described, reported by the watchdog as Stuck in Send. This fix is made in two parts, listed here:
 - 1. The send thread no longer holds the global send thread mutex while getting the send buffer mutex; it now releases the global mutex prior to locking the send buffer mutex. This keeps worker threads from getting stuck in send in such cases.
 - 2. Locking of the send buffer mutex done by the send threads now uses a try-lock. If the try-lock fails, the node to make the send to is reinserted at the end of the list of send nodes in order to be retried later. This removes the Stuck in Send condition for the send threads.

(Bug #77081, Bug #21109605)

- NDB Disk Data: A unique index on a column of an NDB table is implemented with an associated internal ordered index, used for scanning. While dropping an index, this ordered index was dropped first, followed by the drop of the unique index itself. This meant that, when the drop was rejected due to (for example) a constraint violation, the statement was rejected but the associated ordered index remained deleted, so that any subsequent operation using a scan on this table failed. We fix this problem by causing the unique index to be removed first, before removing the ordered index; removal of the related ordered index is no longer performed when removal of a unique index fails. (Bug #78306, Bug #21777589)
- NDB Replication: While the binary log injector thread was handling failure events, it was possible for all NDB tables to be left indefinitely in read-only mode. This was due to a race condition between the binary log injector thread and the utility thread handling events on the ndb_schema table, and to the fact that, when handling failure events, the binary log injector thread places all NDB tables in read-only mode until all such events are handled and the thread restarts itself.

When the binary log inject thread receives a group of one or more failure events, it drops all other existing event operations and expects no more events from the utility thread until it has handled all of the failure events and then restarted itself. However, it was possible for the utility thread to continue

attempting binary log setup while the injector thread was handling failures and thus attempting to create the schema distribution tables as well as event subscriptions on these tables. If the creation of these tables and event subscriptions occurred during this time, the binary log injector thread's expectation that there were no further event operations was never met; thus, the injector thread never restarted, and NDB tables remained in read-only as described previously.

To fix this problem, the Ndb object that handles schema events is now definitely dropped once the ndb_schema table drop event is handled, so that the utility thread cannot create any new events until after the injector thread has restarted, at which time, a new Ndb object for handling schema events is created. (Bug #17674771, Bug #19537961, Bug #22204186, Bug #22361695)

NDB Cluster APIs: The binary log injector did not work correctly with TE_INCONSISTENT event type
handling by Ndb::nextEvent(). (Bug #22135541)

References: See also: Bug #20646496.

• NDB Cluster APIs: While executing <code>dropEvent()</code>, if the coordinator <code>DBDICT</code> failed after the subscription manager (<code>SUMA</code> block) had removed all subscriptions but before the coordinator had deleted the event from the system table, the dropped event remained in the table, causing any subsequent drop or create event with the same name to fail with <code>NDB</code> error 1419 <code>Subscription</code> already <code>dropped</code> or error 746 <code>Event</code> <code>name</code> already <code>exists</code>. This occurred even when calling <code>dropEvent()</code> with a nonzero force argument.

Now in such cases, error 1419 is ignored, and DBDICT deletes the event from the table. (Bug #21554676)

- NDB Cluster APIs: Creation and destruction of Ndb_cluster_connection objects by multiple threads could make use of the same application lock, which in some cases led to failures in the global dictionary cache. To alleviate this problem, the creation and destruction of several internal NDB API objects have been serialized. (Bug #20636124)
- NDB Cluster APIs: When an Ndb object created prior to a failure of the cluster was reused, the event queue of this object could still contain data node events originating from before the failure. These events could reference "old" epochs (from before the failure occurred), which in turn could violate the assumption made by the nextEvent() method that epoch numbers always increase. This issue is addressed by explicitly clearing the event queue in such cases. (Bug #18411034)

References: See also: Bug #20888668.

• NDB Cluster APIs: Ndb::pollEvents() and pollEvents2() were slow to receive events, being dependent on other client threads or blocks to perform polling of transporters on their behalf. This fix allows a client thread to perform its own transporter polling when it has to wait in either of these methods.

Introduction of transporter polling also revealed a problem with missing mutex protection in the ndbcluster_binlog handler, which has been added as part of this fix. (Bug #79311, Bug #20957068, Bug #22224571)

• NDB Cluster APIs: After the initial restart of a node following a cluster failure, the cluster failure event added as part of the restart process was deleted when an event that existed prior to the restart was later deleted. This meant that, in such cases, an Event API client had no way of knowing that failure handling was needed. In addition, the GCI used for the final cleanup of deleted event operations, performed by pollEvents() and nextEvent() when these methods have consumed all available events, was lost. (Bug #78143, Bug #21660947)

Release Series Changelogs: MySQL Cluster NDB 7.5

This section contains unified changelog information for the MySQL Cluster NDB 7.5 release series.

For changelogs covering individual MySQL Cluster NDB 7.5 releases, see NDB Cluster Release Notes.

For general information about features added in MySQL Cluster NDB 7.5, see What is New in MySQL NDB Cluster 7.5.

For an overview of features added in MySQL 5.7 that are not specific to MySQL Cluster, see What Is New in MySQL 5.7. For a complete list of all bugfixes and feature changes made in MySQL 5.7 that are not specific to MySQL Cluster, see the MySQL 5.7 Release Notes.

- Changes in MySQL NDB Cluster 7.5.4 (5.7.16-ndb-7.5.4)
- Changes in MySQL NDB Cluster 7.5.3 (5.7.13-ndb-7.5.3)
- Changes in MySQL NDB Cluster 7.5.2 (5.7.12-ndb-7.5.2)
- Changes in MySQL NDB Cluster 7.5.1 (5.7.11-ndb-7.5.1)
- Changes in MySQL NDB Cluster 7.5.0 (5.7.10-ndb-7.5.0)

Changes in MySQL NDB Cluster 7.5.4 (5.7.16-ndb-7.5.4)

Functionality Added or Changed

• Important Change; Packaging: Naming and organization of the RPMs provided for MySQL Cluster have been changed to align with those released for the MySQL server. All MySQL Cluster RPM package names are now prefixed with mysql-cluster. Data nodes are now installed using the data-node package; management nodes are now installed from the management-server package; and SQL nodes require the server and common packages. Important: SQL nodes must use the mysql-cluster version of these RPMs; the versions released for the standard MySQL server do not provide support for the NDB storage engine. All client programs, including both the mysql client and the ndb_mgm management client, are now included in the client RPM.

For more information, see Installing NDB Cluster from RPM.

• Added the --print-sql-log option for the ndb_restore program included with the MySQL Cluster distribution. This option causes the program to log SQL statements to stdout.

Note that each table being restored in this fashion must have an explicitly defined primary key; the hidden primary key implemented by the NDB storage engine is *not* sufficient for this purpose. (Bug #13511949)

- For fully replicated tables, ndb_desc shows only nodes holding main fragment replicas for partitions; nodes with copy fragment replicas only are ignored. To make this information available in the mysql client, several new tables have been introduced in the ndbinfo information database. These tables are listed here, with brief descriptions:
 - dict_obj_info provides the names and types of database (DICT) objects in NDB, such as tables and indexes, as well as information about parent objects where applicable
 - table_distribution_status provides NDB table distribution status information
 - table_fragments provides information about the distribution of NDB table fragments
 - table_info provides information about logging, checkpointing, storage, and other options in force for each NDB table

• table_replicas provides information about fragment replicas

For more information, see The ndbinfo NDB Cluster Information Database. (Bug #81762, Bug #23547643)

Bugs Fixed

- Important Change: The default value of the --ndb-default-column-format server option has been changed from DYNAMIC to FIXED. This has been done for backwards compatibility. Only the default has been changed; setting this option to DYNAMIC continues to cause DYNAMIC to be used for ROW FORMAT and COLUMN FORMAT unless overridden. (Bug #24487363)
- Important Change: Event buffer status reporting has been improved by altering the semantics for calculating lag or slippage. Rather than defining this lag as the number of epochs behind, lag is now taken as the number of epochs completely buffered in the event buffer, but not yet consumed by the binlog injector thread. As part of this work, the default value for the ndb_report_thresh_binlog_epoch_slip system variable has been increased from 3 to 10. For more information, see the description of this variable in the documentation, as well as Event Buffer Reporting in the Cluster Log. (Bug #22916457)

References: See also: Bug #22901309.

• NDB Cluster APIs: The term "fragment count type" has been superceded by "partition balance". This change affects NDB_TABLE options for NDB tables as well as in the NDB API. In NDB_TABLE table option syntax, the FRAGMENT_COUNT_TYPE keyword is replaced with PARTITION_BALANCE. In the NDB API, the Table methods getFragmentCountType() and setFragmentCountType() have been renamed to getPartitionBalance() and setPartitionBalance(), respectively; getFragmentCountTypeString() is renamed to getPartitionBalanceString(). In addition, Object::FragmentCountType has been renamed to PartitionBalance, and the names of its enumerated values have been updated to be consistent with the new nomenclature.

For more information on how these changes affect NDB API applications, see the indicated Table and Object member descriptions. For more information on the SQL-level changes made as part of this fix, Setting NDB_TABLE Options in Table Comments. (Bug #81761, Bug #23547525)

References: See also: Bug #83147, Bug #24733331.

- If more than 4096 seconds elapsed while calculating an internal NdbDuration::microSec() value,
 this could cause an assert warning that the calculation would overflow. We fix this to avoid any overflow
 or precision loss when converting from the internal "tick" format to microseconds and nanoseconds,
 by performing the calculation in two parts corresponding to seconds and fractions of a second. (Bug
 #24695026)
- The serial commit protocol—which commits each operation at each replica individually and serially, and
 is used by the DBTC kernel block (see The DBTC Block) for takeover and when a transaction is judged
 to have timed out during the COMMIT or COMPLETE phase—had no support for LATE_COMMIT, which is
 required for the READ BACKUP and FULLY REPLICATED protocols. (Bug #24681305)
- In some cases, ALTER TABLE ... REORGANIZE PARTITION could lead to an unplanned shutdown of the cluster. This was due to the fact that, for fully replicated tables. the log part ID was assumed to be the same as the partition ID. This worked when FOR_RA_BY_LDM was used, but not necessarily for the other partition balancing types. (Bug #24610551)
- Using ALGORITHM=INPLACE when changing any of a table's NDB_TABLE properties (see Setting NDB_TABLE Options in Table Comments) caused the server to fail. (Bug #24584741)

- Following successive ALTER TABLE statements updating NDB_TABLE properties (see Setting NDB_TABLE Options in Table Comments), the current values were not always shown by SHOW CREATE TABLE or ndb_desc. (Bug #24584690)
- Case-insensitivity of keywords such as FULLY_REPLICATED in NDB_TABLE comments was not honored. (Bug #24577931)
- An ALTER TABLE statement attempting to set both FULLY_REPLICATED and PARTITION_BALANCE (see Setting NDB_TABLE Options in Table Comments) failed with a garbled error message. (Bug #24577894)
- A number of dependencies between the binlog injector thread and the NDB utility thread—a recurring source of synchronization and other problems—were removed. The principal changes are listed here:
 - Moved the setup of binlog injector structures from the utility thread to the injector thread itself.
 - Removed sharing of some utility and injector thread structures between these threads.
 - Moved stopping of the utility thread from the injector thread into a common block in which other such threads are stopped.
 - Removed a number of hacks required by the previous design.
 - Removed some injector mutex locking and injector condition signaling which were made obsolete by the changes already listed.

(Bug #24496910)

References: See also: Bug #22204186.

 A late commit ACK signal used for FULLY_REPLICATED or READ_BACKUP tables caused the associated ApiConnectionRecord to have an invalid state. (Bug #24459817)

References: See also: Bug #24444861.

- Added missing error information for a failure occurring when tables on disk became full. (Bug #24425373)
- When ndbmtd crashed, the resulting error log incorrectly specified the name of the trace for thread 0, appending the nonexistent suffix _t0 to the file name. (Bug #24353408)
- Passing a nonexistent node ID to CREATE NODEGROUP led to random data node failures. (Bug #23748958)
- DROP TABLE followed by a node shutdown and subesequent master takeover—and with the containing local checkpoint not yet complete prior to the takeover—caused the LCP to be ignored, and in some cases, the data node to fail. (Bug #23735996)

References: See also: Bug #23288252.

- Removed an invalid assertion to the effect that all cascading child scans are closed at the time API connection records are released following an abort of the main transaction. The assertion was invalid because closing of scans in such cases is by design asynchronous with respect to the main transaction, which means that subscans may well take some time to close after the main transaction is closed. (Bug #23709284)
- Although arguments to the DUMP command are 32-bit integers, ndb_mgmd used a buffer of only 10 bytes when processing them. (Bug #23708039)

- The READ_BACKUP setting was not honored when performing scans on BLOB tables. (Bug #23703536)
- Setting FULLY_REPLICATED=1 (see Setting NDB_TABLE Options in Table Comments) did not propagate to the internal BLOB part tables used for BLOB and TEXT columns. (Bug #23703343)
- The READ_BACKUP setting was not applied to unique indexes. (Bug #23702848)
- In ReadCommitted mode, DBSPJ read primary fragment replicas for tables with READ_BACKUP (see Setting NDB_TABLE Options in Table Comments), even when a local fragment was available. (Bug #23633848)
- ALL REPORT MemoryUsage produced incorrect output when fully replicated tables were in use. (Bug #23539805)
- Ordered indexes did not inherit READ_BACKUP (see Setting NDB_TABLE Options in Table Comments) from an indexed table, which meant that ordered index scans continued to be routed to only to primary fragment replicas and never to backup fragment replicas.

Now DBDICT sets this property on ordered indexes from the table property when it distributes this information to instances of DBTC and DBSPJ. (Bug #23522027)

- Updates to a table containing a virtual column could cause the binary logging thread to fail. (Bug #23514050)
- A number of potential buffer overflow issues were found and fixed in the NDB codebase. (Bug #23152979)
- During an online upgrade from a MySQL Cluster NDB 7.3 release to an NDB 7.4 (or later) release,
 the failures of several data nodes running the lower version during local checkpoints (LCPs), and just
 prior to upgrading these nodes, led to additional node failures following the upgrade. This was due to
 lingering elements of the EMPTY_LCP protocol initiated by the older nodes as part of an LCP-plus-restart
 sequence, and which is no longer used in NDB 7.4 and later due to LCP optimizations implemented in
 those versions. (Bug #23129433)
- A SIGNAL_DROPPED_REP handler invoked in response to long message buffer exhaustion was
 defined in the SPJ kernel block, but not actually used. This meant that the default handler from
 SimulatedBlock was used instead in such cases, which shut down the data node. (Bug #23048816)

References: See also: Bug #23251145, Bug #23251423.

• When a data node has insufficient redo buffer during a system restart, it does not participate in the restart until after the other nodes have started. After this, it performs a takeover of its fragments from the nodes in its node group that have already started; during this time, the cluster is already running and user activity is possible, including DML and DDL operations.

During a system restart, table creation is handled differently in the DIH kernel block than normally, as this creation actually consists of reloading table definition data from disk on the master node. Thus, DIH assumed that any table creation that occurred before all nodes had restarted must be related to the restart and thus always on the master node. However, during the takeover, table creation can occur on non-master nodes due to user activity; when this happened, the cluster underwent a forced shutdown.

Now an extra check is made during system restarts to detect in such cases whether the executing node is the master node, and use that information to determine whether the table creation is part of the restart proper, or is taking place during a subsequent takeover. (Bug #23028418)

 ndb_restore set the MAX_ROWS attribute for a table for which it had not been set prior to taking the backup. (Bug #22904640) • Whenever data nodes are added to or dropped from the cluster, the NDB kernel's Event API is notified of this using a SUB_GCP_COMPLETE_REP signal with either the ADD (add) flag or SUB (drop) flag set, as well as the number of nodes to add or drop; this allows NDB to maintain a correct count of SUB_GCP_COMPLETE_REP signals pending for every incomplete bucket. In addition to handling the bucket for the epoch associated with the addition or removal, it must also compensate for any later incomplete buckets associated with later epochs. Although it was possible to complete such buckets out of order, there was no handling of these, leading a stall in to event reception.

This fix adds detection and handling of such out of order bucket completion. (Bug #20402364)

References: See also: Bug #82424, Bug #24399450.

- When performing online reorganization of tables, unique indexes were not included in the reorganization. (Bug #13714258)
- Under very high loads, neither the receive thread nor any user thread had sufficient capacity to handle
 poll ownership properly. This meant that, as the load and the number of active thread increased, it
 became more difficult to sustain throughput. This fix attempts to increase the priority of the receive
 thread and retains poll ownership if successful.

This fix requires sufficient permissions to be enabled. On Linux systems, this means ensuring that either the data node binary or the user it runs as has permission to change the nice level. (Bug #83217, Bug #24761073)

- Local reads of unique index and blob tables did not work correctly for fully replicated tables using more than one node group. (Bug #83016, Bug #24675602)
- The effects of an ALTER TABLE statement changing a table to use READ_BACKUP were not preserved after a restart of the cluster. (Bug #82812, Bug #24570439)
- Using FOR_RP_BY_NODE or FOR_RP_BY_LDM for PARTITION_BALANCE did not work with fully replicated tables. (Bug #82801, Bug #24565265)
- Changes to READ_BACKUP settings were not propagated to internal blob tables. (Bug #82788, Bug #24558232)
- The count displayed by the c_exec column in the ndbinfo.threadstat table was incomplete. (Bug #82635, Bug #24482218)
- The default PARTITION_BALANCE setting for NDB tables created with READ_BACKUP=1 (see Setting NDB_TABLE Options in Table Comments) has been changed from FOR_RA_BY_LDM to FOR_RP_BY_LDM. (Bug #82634, Bug #24482114)
- The internal function ndbcluster_binlog_wait(), which provides a way to make sure that all events originating from a given thread arrive in the binary log, is used by SHOW BINLOG EVENTS as well as when resetting the binary log. This function waits on an injector condition while the latest global epoch handled by NDB is more recent than the epoch last committed in this session, which implies that this condition must be signalled whenever the binary log thread completes and updates a new latest global epoch. Inspection of the code revealed that this condition signalling was missing, and that, instead of being awakened whenever a new latest global epoch completes (~100ms), client threads waited for the maximum timeout (1 second).

This fix adds the missing injector condition signalling, while also changing it to a condition broadcast to make sure that all client threads are alerted. (Bug #82630, Bug #24481551)

• Fully replicated internal foreign key or unique index triggers could fire multiple times, which led to aborted transactions for an insert or a delete operation. This happened due to redundant deferred

constraint triggers firing during pre-commit. Now in such cases, we ensure that only triggers specific to unique indexes are fired in this stage. (Bug #82570, Bug #24454378)

 Backups potentially could fail when using fully replicated tables due to their high usage (and subsequent exhaustion) of internal trigger resources. To compensate for this, the amount of memory reserved in the NDB kernel for internal triggers has been increased, and is now based in part on the maximum number of tables. (Bug #82569, Bug #24454262)

References: See also: Bug #23539733.

• In the DBTC function executeFullyReplicatedTrigger() in the NDB kernel, an incorrect check of state led in some cases to failure handling when no failure had actually occurred. (Bug #82568, Bug #24454093)

References: See also: Bug #23539733.

When returning from LQHKEYREQ with failure in LQHKEYREF in an internal trigger operation, no check
was made as to whether the trigger was fully replicated, so that those triggers that were fully replicated
were never handled. (Bug #82566, Bug #24453949)

References: See also: Bug #23539733.

- When READ_BACKUP had not previously been set, then was set to 1 as part of an ALTER TABLE ...
 ALGORITHM=INPLACE statement, the change was not propagated to internal unique index tables or
 BLOB tables. (Bug #82491, Bug #24424459)
- Distribution of MySQL privileges was incomplete due to the failure of the mysql_cluster_move_privileges() procedure to convert the mysql.proxies_priv table to NDB. The root cause of this was an ALTER TABLE ... ENGINE NDB statement which sometimes failed when this table contained illegal TIMESTAMP values. (Bug #82464, Bug #24430209)
- The internal variable m_max_warning_level was not initialized in storage/ndb/src/kernel/blocks/thrman.cpp. This sometimes led to node failures during a restart when the uninitialized value was treated as 0. (Bug #82053, Bug #23717703)
- Usually, when performing a system restart, all nodes are restored from redo logs and local checkpoints (LCPs), but in some cases some node might require a copy phase before it is finished with the system restart. When this happens, the node in question waits for all other nodes to start up completely before performing the copy phase. Notwithstanding the fact that it is thus possible to begin a local checkpoint before reaching start phase 4 in the DBDIH block, LCP status was initialized to IDLE in all cases, which could lead to a node failure. Now, when performing this variant of a system restart, the LCP status is no longer initialized. (Bug #82050, Bug #23717479)
- After adding a new node group online and executing ALTER TABLE ... ALGORITHM=INPLACE REORGANIZE PARTITION, partition IDs were not set correctly for new fragments.

In a related change done as part of fixing this issue, ndb_desc -p now displays rows relating to partitions in order of partition ID. (Bug #82037, Bug #23710999)

- When executing STOP BACKUP it is possible sometimes that a few bytes are written to the backup data
 file before the backup process actually terminates. When using ODIRECT, this resulted in the wrong error
 code being returned. Now in such cases, nothing is written to O_DIRECT files unless the alignment is
 correct. (Bug #82017, Bug #23701911)
- When transaction coordinator (TC) connection records were used up, it was possible to handle scans
 only for local checkpoints and backups, so that operations coming from the DBUTIL block—used for
 ALTER TABLE ... REORGANIZE PARTITION and other operations that reorganize metadata—were
 unnecessarily blocked. In addition, such operations were not always retried when TC records were

exhausted. To fix this issue, a number of operation records are now earmarked for DBUTIL usage, as well as for LCP and backup usage so that these operations are also not negatively impacted by operations coming from DBUTIL.

For more information, see The DBUTIL Block. (Bug #81992, Bug #23642198)

- Operations performing multiple updates of the same row within the same transaction could sometimes lead to corruption of lengths of page entries. (Bug #81938, Bug #23619031)
- During a node restart, a fragment can be restored using information obtained from local checkpoints (LCPs); up to 2 restorable LCPs are retained at any given time. When an LCP is reported to the DIH kernel block as completed, but the node fails before the last global checkpoint index written into this LCP has actually completed, the latest LCP is not restorable. Although it should be possible to use the older LCP, it was instead assumed that no LCP existed for the fragment, which slowed the restart process. Now in such cases, the older, restorable LCP is used, which should help decrease long node restart times. (Bug #81894, Bug #23602217)
- Optimized node selection (ndb_optimized_node_selection setting) was not respected by ndb_data_node_neighbour when this was enabled. (Bug #81778, Bug #23555834)
- NDB no longer retries a global schema lock if this has failed due to a timeout (default 3000ms) and there
 is the potential for this lock request to participate in a metadata lock-global schema lock deadlock. Now
 in such cases it selects itself as a "victim", and returns the decision to the requestor of the metadata lock,
 which then handles the request as a failed lock request (preferable to remaining deadlocked indefinitely),
 or, where a deadlock handler exists, retries the metadata lock-global schema lock. (Bug #81775, Bug
 #23553267)
- Two issues were found in the implementation of hash maps—used by NDB for mapping a table row's hash value to a partition—for fully replicated tables:
 - 1. Hash maps were selected based on the number of fragments rather than the number of partitions. This was previously undetected due to the fact that, for other kinds of tables, these values are always the same.
 - 2. The hash map was employed as a partition-to-partition map, using the table row's hash value modulus the partition count as input.

This fix addresses both of the problems just described. (Bug #81757, Bug #23544220)

References: See also: Bug #81761, Bug #23547525, Bug #23553996.

• Using mysqld together with --initialize and --ndbcluster led to problems later when attempting to use mysql_upgrade. When running with --initialize, the server does not require NDB support, and having it enabled can lead to issues with ndbinfo tables. To prevent this from happening, using the --initialize option now causes mysqld to ignore the --ndbcluster option if the latter is also specified.

This issue affects upgrades from MySQL Cluster NDB 7.5.2 or 7.5.3 only. In cases where such upgrades fail for the reasons outlined previously, you can work around the issue by deleting all .frm files in the data/ndbinfo directory following a rolling restart of the entire cluster, then running mysql_upgrade. (Bug #81689, Bug #23518923)

References: See also: Bug #82724, Bug #24521927.

• While a mysqld was waiting to connect to the management server during initialization of the NDB handler, it was not possible to shut down the mysqld. If the mysqld was not able to make the connection, it could become stuck at this point. This was due to an internal wait condition in the utility

and index statistics threads that could go unmet indefinitely. This condition has been augmented with a maximum timeout of 1 second, which makes it more likely that these threads terminate themselves properly in such cases.

In addition, the connection thread waiting for the management server connection performed 2 sleeps in the case just described, instead of 1 sleep, as intended. (Bug #81585, Bug #23343673)

- ALTER TABLE ... ALGORITHM=INPLACE on a fully replicated table did not copy the associated trigger ID, leading to a failure in the DBDICT kernel block. (Bug #81544, Bug #23330359)
- The list of deferred tree node lookup requests created when preparing to abort a DBSPJ request were not cleared when this was complete, which could lead to deferred operations being started even after the DBSPJ request aborted. (Bug #81355, Bug #23251423)

References: See also: Bug #23048816.

Error and abort handling in Dbspj::execTRANSID_AI() was implemented such that its abort()
method was called before processing of the incoming signal was complete. Since this method sends
signals to the LDM, this partly overwrote the contents of the signal which was later required by
execTRANSID_AI(). This could result in aborted DBSPJ requests cleaning up their allocated resources
too early, or not at all. (Bug #81353, Bug #23251145)

References: See also: Bug #23048816.

- The read backup feature added in MySQL Cluster NDB 7.5.2 that makes it possible to read from backup replicas was not used for reads with lock, or for reads of BLOB tables or unique key tables where locks were upgraded to reads with lock. Now the TCKEYREQ and SCAN_TABREQ signals use a flag to convey information about such locks making it possible to read from a backup replica when a read lock was upgraded due to being the read of the base table for a BLOB table, or due to being the read for a unique key. (Bug #80861, Bug #23001841)
- Primary replicas of partitioned tables were not distributed evenly among node groups and local data managers.

As part of the fix for this issue, the maximum number of node groups supported for a single MySQL Cluster, which was previously not determined, is now set at 48 (MAX_NDB_NODE_GROUPS). (Bug #80845, Bug #22996305)

- Several object constructors and similar functions in the NDB codebase did not always perform sanity checks when creating new instances. These checks are now performed under such circumstances. (Bug #77408, Bug #21286722)
- An internal call to malloc() was not checked for NULL. The function call was replaced with a direct write. (Bug #77375, Bug #21271194)
- NDB Cluster APIs: Reuse of transaction IDs could occur when Ndb objects were created and deleted concurrently. As part of this fix, the NDB API methods lock_ndb_objects() and unlock_ndb_objects are now declared as const. (Bug #23709232)
- NDB Cluster APIs: When the management server was restarted while running an MGM API application that continuously monitored events, subsequent events were not reported to the application, with timeouts being returned indefinitely instead of an error.

This occurred because sockets for event listeners were not closed when restarting mgmd. This is fixed by ensuring that event listener sockets are closed when the management server shuts down, causing applications using functions such as ndb_logevent_get_next() to receive a read error following the restart. (Bug #19474782)

NDB Cluster APIs: To process incoming signals, a thread which wants to act as a receiver must acquire
polling rights from the transporter layer. This can be requested and assigned to a separate receiver
thread, or each client thread can take the receiver role when it is waiting for a result.

When the thread acting as poll owner receives a sufficient amount of data, it releases locks on any other clients taken while delivering signals to them. This could make them runnable again, and the operating system scheduler could decide that it was time to wake them up, which happened at the expense of the poll owner threads, which were in turn excluded from the CPU while still holding polling rights on it. After this fix, polling rights are released by a thread before unlocking and signalling other threads. This makes polling rights available for other threads that are actively executing on this CPU.

This change increases concurrency when polling receiver data, which should also reduce latency for clients waiting to be woken up. (Bug #83129, Bug #24716756)

NDB Cluster APIs: libndbclient and libmysqlclient exported conflicting symbols, resulting
in a segmentation fault in debug builds on Linux. To fix this issue, the conflicting symbols in
libndbclient.so are no longer publicly visible. Due to this change, the version number for
libndbclient.so has been raised from 6.0.0 to 6.1.0. (Bug #83093, Bug #24707521)

References: See also: Bug #80352, Bug #22722555.

• NDB Cluster APIs: When NDB schema object ownership checks are enabled by a given NdbTransaction, objects used by this transaction are checked to make sure that they belong to the NdbDictionary owned by this connection. An attempt to create a NdbOperation, NdbScanOperation, or NdbIndexScanOperation on a table or index not belonging to the same connection fails.

This fix corrects a resource leak which occurred when the operation object to be created was allocated before checking schema object ownership and subsequently not released when the object creation failed. (Bug #81949, Bug #23623978)

References: See also: Bug #81945, Bug #23623251.

• NDB Cluster APIs: NDB API objects are allocated in the context of an Ndb object, or of an NdbTransaction object which is itself owned by an Ndb object. When a given Ndb object is destroyed, all remaining NdbTransaction objects are terminated, and all NDB API objects related to this Ndb object should be released at this time as well. It was found, when there remained unclosed NdbTransaction objects when their parent Ndb object was destroyed, leaks of objects allocated from the NdbTransaction objects could occur. (However, the NdbTransaction objects themselves did not leak.)

While it is advisable (and, indeed, recommended) to close an NdbTransaction explicitly as soon as its lifetime ends, the destruction of the parent Ndb object should be sufficient to release whatever objects are dependent on it. Now in cases such as described previously, the Ndb destructor checks to ensure that all objects derived from a given Ndb instance are truly released. (Bug #81945, Bug #23623251)

• NDB Cluster APIs: In some of the NDB API example programs included with the MySQL Cluster distribution, ndb_end() was called prior to calling the Ndb_cluster_connection destructor. This caused a segmentation fault in debug builds on all platforms. The example programs affected have also been extensively revised and refactored. See NDB API Examples, for more information. (Bug #80352, Bug #22722555)

References: See also: Bug #83093, Bug #24707521.

Changes in MySQL NDB Cluster 7.5.3 (5.7.13-ndb-7.5.3)

Functionality Added or Changed

Important Change: It is now possible to set READ_BACKUP for an existing table
 online using an SQL statement such as ALTER TABLE ... ALGORITHM=INPLACE,
 COMMENT="NDB_TABLE=READ_BACKUP=1". See Setting NDB_TABLE Options in Table Comments, for
 further information about the READ_BACKUP option. (Bug #80858, Bug #23001617)

References: See also: Bug #18435416.

- Added three new tables to the ndbinfo information database to provide running information about locks and lock attempts in an active MySQL Cluster. These tables, with brief descriptions, are listed here:
 - cluster_locks: Current lock requests which are waiting for or holding locks; this information can be useful when investigating stalls and deadlocks. Analogous to cluster operations.
 - locks_per_fragment: Counts of lock claim requests, and their outcomes per fragment, as well as total time spent waiting for locks successfully and unsuccessfully. Analogous to operations_per_fragment and memory_per_fragment.
 - server_locks: Subset of cluster transactions—those running on the local mysqld, showing a connection ID per transaction. Analogous to server_operations.

For more information, see The ndbinfo NDB Cluster Information Database.

 The NDB storage engine now supports generated columns (see CREATE TABLE and Generated Columns) as well as indexes on stored generated columns.

Indexes on virtual generated columns of NDB tables are not supported.

ALTER TABLE statements that add stored generated columns to NDB tables cannot be performed online.

Bugs Fixed

- The ndbinfo cpustat_1sec and cpustat_20sec tables did not provide any history information. (Bug #23520271)
- During shutdown, the mysqld process could sometimes hang after logging NDB Util: Stop ... NDB Util: Wakeup. (Bug #23343739)

References: See also: Bug #21098142.

During expansion or reduction of a hash table, allocating a new overflow page in the DBACC kernel block
caused the data node to fail when it was out of index memory. This could sometimes occur after a large
table had increased or decreased very rapidly in size. (Bug #23304519)

References: This issue is a regression of: Bug #13436216.

- When tracking time elapsed from sending a SCAN_FRAGREQ signal to receiving a corresponding SCAN_FRAGCONF, the assumption was made in the DBTC kernel block that a SCAN_FRAGCONF can occur only after sending a SCAN_FRAGREQ or SCAN_NEXTREQ signal, which is not always the case: It it is actually possible that a local query handler can, immediately after sending a SCAN_FRAGCONF, send an additional SCAN_FRAGCONF signal upon reporting that the scan is closed. This problem is fixed by ensuring that the timer value is initialized each time before use. (Bug #81907, Bug #23605817, Bug #23306695)
- Table indexes were listed in the output of ndb_desc in a nondeterministic order that could vary between platforms. Now these indexes are ordered by ID in the output. (Bug #81763, Bug #23547742)
- Following a restart of the cluster, the first attempt to read from any of the ndbinfo cpustat, cpustat_50ms, cpustat_1sec, or cpustat_20sec tables generated a warning to the effect that

columns were missing from the table. Subsequently, the thread_sleeping and spin_time columns were found to be missing from each of these tables. (Bug #81681, Bug #23514557)

References: See also: Bug #23305078.

- Using a ThreadConfig parameter value with a trailing comma led to an assertion. (Bug #81588, Bug #23344374)
- NDB Cluster APIs: The scan lock takeover issued by NdbScanOperation::lockCurrentTuple() did not set the operation type for the takeover operation. (Bug #23314028)

Changes in MySQL NDB Cluster 7.5.2 (5.7.12-ndb-7.5.2)

Functionality Added or Changed

• **Performance:** A deficiency in event buffer memory allocation was identified as inefficient and possibly leading to undesirable results. This could happen when additional memory was allocated from the operating system to buffer received event data even when memory had already been allocated but remained unused. This is fixed by allocating the event buffer memory directly from the page allocation memory manager (mmap()), where such functionality is offered by the operating system, allowing for direct control over the memory such that it is in fact returned to the system when released.

This remimplementation avoids the tendencies of the existing one to approach worst-case memory usage, maintainence of data structures for a worst-case event buffer event count, and useless caching of free memory in unusable positions. This work should also help minimize the runtime costs of buffering events, minimize heap fragmentation, and avoid OS-specific problems due to excessive numbers of distinct memory mappings.

In addition, the relationship between epochs and internal EventData objects is now preserved throughout the event lifecycle, reception to consumption, thus removing the need for iterating, and keeping in synch, two different lists representing the epochs and their EventData objects.

As part of this work, better reporting on the relevant event buffer metrics is now provided in the cluster logs.

References: See also: Bug #21651536, Bug #21660947, Bug #21661297, Bug #21673318, Bug #21689380, Bug #21809959.

- ndb_restore now performs output logging for specific stages of its operation. (Bug #21097957)
- An improvement in the hash index implementation used by MySQL Cluster data nodes means that partitions may now contain more than 16 GB of data for fixed columns, and the maximum partition size for fixed column data is now increased to 128 TB. The previous limitation originated with the DBACC block in the NDB kernel using only 32-bit references to the fixed-size part of a row handled in the DBTUP block, even though 45-bit references were already in use elsewhere in the kernel outside the DBACC block; all such references in DBACC now use 45-bit pointers instead.

As part of this work, error messages returned by the DBACC kernel block that were overly generic have now been improved by making them more specific. (Bug #17465232)

- The NDB storage engine supports the MySQL JSON data type and MySQL JSON functions implemented in MySQL 5.7.8 and later. This support is subject to the limitation that a single NDB table can have at most 3 JSON columns.
- A number of changes and improvements were made to the handling of send threads by NDB. The changes are summarized with brief descriptions in the following list:

- Decreased resource requirements for send threads, making sure that a given configuration using send threads outperforms the same configuration without send threads.
- Made use of otherwise idle threads (other than receiver threads) as send threads without incurring extra CPU resources in low-load situations.
- Improved response time for write transactions.
- Provided for handling of bad configuration data in a more graceful manner.
- Made it possible to measure CPU usage with improved real-time reporting from data nodes on their resource usage.

As part of implementing the last item of those just listed, a number of new tables providing information about CPU and thread activity by node, thread ID, and thread type have been added to the ndbinfo information database. These tables are listed here:

- cpustat: Provides per-second, per-thread CPU statistics
- cpustat_50ms: Shows raw per-thread CPU statistics data, gathered every 50ms
- cpustat_1sec: Provides raw per-thread CPU statistics data, gathered each second
- cpustat_20sec: Displays raw per-thread CPU statistics data, gathered every 20 seconds
- threads: Shows names and descriptions of thread types

For more information, see The ndbinfo NDB Cluster Information Database.

- Rewrote the implementation of the NDB storage engine's global schema lock functionality to make use of the metadata lock hooks implemented in the MySQL Server in MySQL 5.7.11.
- A number of improvements provide additional read scalability for NDB by making it possible to read
 tables locally. It is now possible to enable reads from any replica, rather than from the primary replica
 only. This is disabled by default to remain compatible with previous behavior, but can be enabled for a
 given SQL node using the ndb_read_backup system variable added in this release.

It also becomes possible to be more flexible about the assignment of partitions by setting a fragment count type. Possible count types are one per node, one per node group, one per Local Data Manager (LDM) per node (this is the previous assignment scheme and still the default), and one per LDM per node group. This setting can be controlled for individual tables by means of a FRAGMENT_COUNT_TYPE option embedded in an NDB TABLE comment in CREATE TABLE or ALTER TABLE.

Tables using one of the two per-node-group settings for the fragment count type can also be fully replicated. This requires that the table's fragment count type is <code>ONE_PER_NODE_GROUP</code> or <code>ONE_PER_LDM_PER_NODE_GROUP</code>, and can be enabled using the option <code>FULLY_REPLICATED=1</code> within in an <code>NDB_TABLE</code> comment. The option can be enabled by default for all new <code>NDB</code> tables using the <code>ndb_fully_replicated</code> system variable added in this release.

Settings for table-level READ_BACKUP are also supported using the COMMENT="NDB_TABLE=..." syntax. It is also possible (and often preferable) to set multiple options in one comment within a single CREATE TABLE or ALTER TABLE statement. For more information and examples, see Setting NDB_TABLE Options in Table Comments.

This release also introduces the ndb_data_node_neighbour system variable, which is intended to be employed with transaction hinting (and fully-replicated tables), and to provide the current SQL node with

the ID of a "nearby" data node to use. See the description of this variable in the documentation for more information.

References: See also: Bug #18435416.

- Made the following enhancements and additions to the ThreadConfig multithreaded data node (ndbmtd) configuration parameter:
 - Added support for non-exclusive CPU locking on FreeBSD and Windows using cpubind and cpuset.
 - Added support for exclusive CPU locking on Solaris, using cpubind_exclusive and cpuset_exclusive, which are added in this release.
 - Added thread prioritization using thread_prio, which is added in this release. thread_prio is supported on Linux, FreeBSD, Windows, and Solaris, but the exact effects of this setting are platform-specific; see the documentation for details.
 - Added support for setting realtime on Windows platforms.

For more information, see the description of the ThreadConfig parameter in the online documentation.

- NDB Cluster APIs: Added the Ndb::setEventBufferQueueEmptyEpoch() method, which makes it possible to enable queuing of empty events (event type TE_EMPTY). (Bug #22157845)
- NDB Cluster APIs: Ndb_free_list_t is a template used in the implementation of the NDB API to create a list keeping released API objects such as NdbTransaction, NdbOperation, and NdbRecAttr. One drawback to this template is that released API objects are kept in the list for the lifetime of the owning Ndb object, such that a transient peak in the demand for any object causes an effective leak in memory that persists until this Ndb object itself has been released.

This work adds statistics to each Ndb_free_list instance which samples the usage of objects maintained by the list; now, when objects are released, they can be released into the free list, or deallocated, based on the collected usage statistics.

Bugs Fixed

• **Performance:** A performance problem was found in an internal polling method do_poll() where the polling client did not check whether it had itself been woken up before completing the poll. Subsequent analysis showed that it is sufficient that only some clients in the polling queue receive data. do_poll() can then signal these clients and give up its polling rights, even if the maximum specified wait time (10 ms) has not expired.

This change allows do_poll() to continue polling until either the maximum specified wait time has expired, or the polling client itself has been woken up (by receiving what it was waiting for). This avoids unnecessary thread switches between client threads and thus reduces the associated overhead by as much as 10% in the API client, resulting in a significant performance improvement when client threads perform their own polling. (Bug #81229, Bug #23202735)

Incompatible Change: When the data nodes are only partially connected to the API nodes, a node
used for a pushdown join may get its request from a transaction coordinator on a different node, without
(yet) being connected to the API node itself. In such cases, the NodeInfo object for the requesting API
node contained no valid info about the software version of the API node, which caused the DBSPJ block
to assume (incorrectly) when aborting to assume that the API node used NDB version 7.2.4 or earlier,
requiring the use of a backward compatability mode to be used during query abort which sent a node
failure error instead of the real error causing the abort.

Now, whenever this situation occurs, it is assumed that, if the NDB software version is not yet available, the API node version is greater than 7.2.4. (Bug #23049170)

- Important Change: When started with the --initialize option, mysqld no longer enables the NDBCLUSTER storage engine plugin. This change was needed to prevent attempted initialization of system databases as distributed (rather than as specific to individual SQL nodes), which could result in a metadata lock deadlock. This fix also brings the behavior of --initialize in this regard into line with that of the discontinued --bootstrap option, which started a minimal mysqld instance without enabling NDB. (Bug #22758238)
- **Microsoft Windows:** ndb_mgmd failed to start on 32-bit Windows platforms, due to an issue with calling dynamically loaded functions; such issues were also likely to occur with other NDB programs using ndb_init(). It was found that all of the functions used are already supported in targeted versions of Windows, so this problem is fixed by removing the dynamic loading of these functions and using the versions provided by the Windows header files instead. (Bug #80876, Bug #23014820)
- Microsoft Windows: When building MySQL Cluster on Windows using more than one parallel build job it was sometimes possible for the build to fail because host_info.exe could not be be installed. To fix this problem, the install_mcc target is now always built prior to the host_info target. (Bug #80051, Bug #22566368)
- **Microsoft Windows:** Performing ANALYZE TABLE on a table having one or more indexes caused ndbmtd to fail with an *InvalidAttrInfo* error due to signal corruption. This issue occurred consistently on Windows, but could also be encountered on other platforms. (Bug #77716, Bug #21441297)
- Reserved send buffer for the loopback transporter, introduced in MySQL Cluster NDB 7.4.8 and used by API and management nodes for administrative signals, was calculated incorrectly. (Bug #23093656, Bug #22016081)

References: This issue is a regression of: Bug #21664515.

• During a node restart, re-creation of internal triggers used for verifying the referential integrity of foreign keys was not reliable, because it was possible that not all distributed TC and LDM instances agreed on all trigger identities. To fix this problem, an extra step is added to the node restart sequence, during which the trigger identities are determined by guerying the current master node. (Bug #23068914)

References: See also: Bug #23221573.

- Following the forced shutdown of one of the 2 data nodes in a cluster where NoOfReplicas=2, the other data node shut down as well, due to arbitration failure. (Bug #23006431)
- Aborting a CREATE LOGFILE GROUP statement which had failed due to lack of shared global memory
 was not performed correctly, causing node failure. In addition, the transaction in which this occurred
 was not rolled back correctly, also causing any subsequent CREATE LOGFILE GROUP to fail. (Bug
 #22982618)
- The ndbinfo.tc_time_track_stats table uses histogram buckets to give a sense of the distribution of latencies. The sizes of these buckets were also reported as HISTOGRAM BOUNDARY INFO messages during data node startup; this printout was redundant and so has been removed. (Bug #22819868)
- Online upgrades from previous versions of MySQL Cluster to MySQL Cluster NDB 7.5 were not
 possible due to missing entries in the matrix used to test upgrade compatibility between versions. (Bug
 #22024947)
- A failure occurred in DBTUP in debug builds when variable-sized pages for a fragment totalled more than 4 GB. (Bug #21313546)

• Restoration of metadata with ndb_restore -m occasionally failed with the error message Failed to create index... when creating a unique index. While disgnosing this problem, it was found that the internal error PREPARE_SEIZE_ERROR (a temporary error) was reported as an unknown error. Now in such cases, ndb_restore retries the creation of the unique index, and PREPARE_SEIZE_ERROR is reported as NDB Error 748 Busy during read of event table. (Bug #21178339)

References: See also: Bug #22989944.

mysqld did not shut down cleanly when executing ndb_index_stat. (Bug #21098142)

References: See also: Bug #23343739.

- The following improvements were made to the data node error logging mechanism:
 - Increased the message slot size 499 bytes to 999 bytes to prevent log messages from overwriting one another or from being truncated.
 - Added a Trace file name field to the output. This field contains the trace file name (without any path) and trace file number for the thread causing the trace.
 - ndbmtd trace files are also now shown in the error log.

(Bug #21082710)

- DBDICT and GETTABINFOREQ queue debugging were enhanced as follows:
 - Monitoring by a data node of the progress of GETTABINFOREQ signals can be enabled by setting DictTrace >= 2.
 - Added the ApiVerbose configuration parameter, which enables NDB API debug logging for an API node where it is set greater than or equal to 2.
 - Added DUMP code 1229 which shows the current state of the GETTABINFOREQ queue. (See DUMP 1229.)

See also The DBDICT Block. (Bug #20368450)

References: See also: Bug #20368354.

- When a write to the ndb_binlog_index table failed during a MySQL Server shutdown, mysqld killed the NDB binary logging thread. (Bug #81166, Bug #23142945)
- Memory associated with table descriptions was not freed by the internal table information method NdbDictInterface::parseTableInfo(). (Bug #81141, Bug #23130084)
- Improved memory usage by the internal TransporterFacade constructor when performing mutex array initialization. (Bug #81134, Bug #23127824)
- Fixed a memory leak that occurred when an error was raised in ha_ndbcluster::get_metadata() or one of the functions which this method calls. (Bug #81045, Bug #23089566)
- An internal function used to validate connections failed to update the connection count when creating a new Ndb object. This had the potential to create a new Ndb object for every operation validating the connection, which could have an impact on performance, particularly when performing schema operations. (Bug #80750, Bug #22932982)
- A table scan on an NDB table using neither an ordered index nor any Disk Data columns normally uses an ACC scan. If this happened while scanning an unique but unordered index which shrank (due to rows

being deleted) after the scan started and then grew again (rows inserted), a single row that had been neither deleted nor inserted could be scanned twice. (Bug #80733, Bug #22926938)

- On OS X, ndb_config failed when an empty string was used for the --host option. (Bug #80689, Bug #22908696)
- Starting a backup in the ndb_mgm client after creating a large number of tables caused a forced shutdown of the cluster. (Bug #80640, Bug #228849958)
- When an SQL node was started, and joined the schema distribution protocol, another SQL node, already
 waiting for a schema change to be distributed, timed out during that wait. This was because the code
 incorrectly assumed that the new SQL node would also acknowledge the schema distribution even
 though the new node joined too late to be a participant in it.

As part of this fix, printouts of schema distribution progress now always print the more significant part of a bitmask before the less significant; formatting of bitmasks in such printouts has also been improved. (Bug #80554, Bug #22842538)

- The ndb_print_file utility failed consistently on Solaris 9 for SPARC. (Bug #80096, Bug #22579581)
- The MySQL Cluster Auto-Installer failed to work in various ways on different platforms. (Bug #79853, Bug #22502247)
- The internal function ndbrequire(), which, like assert(), evaluates a given expression and terminates the process if the expression does not evaluate as true, now includes the failed expression in its output to the error logs. (Bug #77021, Bug #21128318)
- Trying to drop a table during an ongoing backup failed with the error message Unknown table; now, it fails with Unable to alter table as backup is in progress. (Bug #47301, Bug #11755512)

References: See also: Bug #44695, Bug #11753280.

- NDB Disk Data: The following improvements were made to logging during restarts by data nodes using MySQL Cluster Disk Data:
 - The total amount of undo log to be applied by the data node is now provided as the total number of pages present in the log. This is a worst case estimate.
 - Progress information is now provided at regular intervals (once for each 30000 records) as the undo
 log is applied. This information is supplied as the number of records and number of undo log pages
 applied so far during the current restart.

(Bug #22513381)

- NDB Cluster APIs: Deletion of Ndb objects used a dispoportionately high amount of CPU. (Bug #22986823)
- NDB Cluster APIs: Executing a transaction with an NdbIndexOperation based on an obsolete unique index caused the data node process to fail. Now the index is checked in such cases, and if it cannot be used the transaction fails with an appropriate error. (Bug #79494, Bug #22299443)

Changes in MySQL NDB Cluster 7.5.1 (5.7.11-ndb-7.5.1)

Functionality Added or Changed

• Important Change: When creating or adding columns to NDB tables, the default value used for both the COLUMN_FORMAT and ROW_FORMAT options is now DYNAMIC rather than FIXED.

This change does not affect the row format or column format used by existing tables. New columns added to such tables use the new defaults, and existing columns are changed to use these as well, provided that the ALTER TABLE statement in question uses ALGORITHM=COPY. Note that this cannot be done implicitly if mysqld is run with --ndb-allow-copying-alter-table=FALSE (the default is TRUE).

A new MySQL server option --ndb-default-column-format is added for backwards compatibility; set this to FIXED to force the old defaults to be used for COLUMN_FORMAT and ROW_FORMAT.

Note

This behavior change is superseded in MySQL Cluster NDB 7.5.4.

• Scans have been improved by replacing the DIH_SCAN_GET_NODES_REQ signal, formerly used for communication between the DBTC and DBDIH kernel blocks in NDB, with the DIGETNODESREQ signal, which supports direct execution and allows for the elimination of DIH_SCAN_GET_NODES_REF and DIH_SCAN_GET_NODES_CONF, as well as for DIH_SCAN_TAB_REQ and DIH_SCAN_TAB_COMPLETE_REP signals to EXECUTE_DIRECT. This enables enable higher scalability of data nodes when used for scan operations by decreasing the use of CPU resources for scan operations by an estimated five percent in some cases. This should also improve response times, which could help prevent issues with overload of the main threads.

As part of these changes, scans made in the BACKUP kernel block have also been improved and made more efficient.

References: See also: Bug #80640, Bug #22884995.

- The following improvements have been made to event buffer reporting in the cluster log:
 - Each report now identifies the API node that sent it.
 - The fields shown in the report have been improved and expanded. Percentages are now better specified and used only when appropriate. For improved clarity, the apply_epoch and latest_epoch fields have been renamed to latest_consumed_epoch and latest_buffered_epoch, respectively. The ID of the Ndb object serving as the source of the report is now shown, as is the reason for making the report (as the report_reason field).
 - The frequency of unnecessary reporting has been reduced by limiting reports to those showing only significant changes in event buffer usage.
 - The MGM API adds a new NDB_LE_EventBufferStatus2 event type to handle the additional information provided by the new event buffer reporting. The NDB_LE_EventBufferStatus event type used in older versions of MySQL Cluster is now deprecated, and will eventually be removed.

For more information, see Event Buffer Reporting in the Cluster Log, as well as The ndb_logevent Structure.

Bugs Fixed

- Important Change: The minimum value for the BackupDataBufferSize data node configuration parameter has been lowered from 2 MB to 512 KB. The default and maximum values for this parameter remain unchanged. (Bug #22749509)
- During node failure handling, the request structure used to drive the cleanup operation was not maintained correctly when the request was executed. This led to inconsistencies that were harmless

during normal operation, but these could lead to assertion failures during node failure handling, with subsequent failure of additional nodes. (Bug #22643129)

• The previous fix for a lack of mutex protection for the internal TransporterFacade::deliver_signal() function was found to be incomplete in some cases. (Bug #22615274)

References: This issue is a regression of: Bug #77225, Bug #21185585.

- Compilation of MySQL with Visual Studio 2015 failed in ConfigInfo.cpp, due to a change in Visual Studio's handling of spaces and concatenation. (Bug #22558836, Bug #80024)
- When setup of the binary log as an atomic operation on one SQL node failed, this could trigger a state in other SQL nodes in which they appeared to detect the SQL node participating in schema change distribution, whereas it had not yet completed binary log setup. This could in turn cause a deadlock on the global metadata lock when the SQL node still retrying binary log setup needed this lock, while another mysqld had taken the lock for itself as part of a schema change operation. In such cases, the second SQL node waited for the first one to act on its schema distribution changes, which it was not yet able to do. (Bug #22494024)
- Duplicate key errors could occur when ndb_restore was run on a backup containing a unique index. This was due to the fact that, during restoration of data, the database can pass through one or more inconsistent states prior to completion, such an inconsistent state possibly having duplicate values for a column which has a unique index. (If the restoration of data is preceded by a run with --disable-indexes and followed by one with --rebuild-indexes, these errors are avoided.)

Added a check for unique indexes in the backup which is performed only when restoring data, and which does not process tables that have explicitly been excluded. For each unique index found, a warning is now printed. (Bug #22329365)

- When setting up event logging for ndb_mgmd on Windows, MySQL Cluster tries to add a registry key to HKEY_LOCAL_MACHINE, which fails if the user does not have access to the registry. In such cases ndb_mgmd logged the error Could neither create or open key, which is not accurate and which can cause confusion for users who may not realize that file logging is available and being used. Now in such cases, ndb_mgmd logs a warning Could not create or access the registry key needed for the application to log to the Windows EventLog. Run the application with sufficient privileges once to create the key, or add the key manually, or turn off logging for that application. An error (as opposed to a warning) is now reported in such cases only if there is no available output at all for ndb_mgmd event logging. (Bug #20960839)
- NdbDictionary metadata operations had a hard-coded 7-day timeout, which proved to be excessive
 for short-lived operations such as retrieval of table definitions. This could lead to unnecessary hangs in
 user applications which were difficult to detect and handle correctly. To help address this issue, timeout
 behaviour is modified so that read-only or short-duration dictionary interactions have a 2-minute timeout,
 while schema transactions of potentially long duration retain the existing 7-day timeout.

Such timeouts are intended as a safety net: In the event of problems, these return control to users, who can then take corrective action. Any reproducible issue with NdbDictionary timeouts should be reported as a bug. (Bug #20368354)

• Optimization of signal sending by buffering and sending them periodically, or when the buffer became full, could cause SUB_GCP_COMPLETE_ACK signals to be excessively delayed. Such signals are sent for each node and epoch, with a minimum interval of TimeBetweenEpochs; if they are not received in time, the SUMA buffers can overflow as a result. The overflow caused API nodes to be disconnected, leading to current transactions being aborted due to node failure. This condition made it difficult for long

transactions (such as altering a very large table), to be completed. Now in such cases, the ACK signal is sent without being delayed. (Bug #18753341)

- MySQL Cluster did not compile correctly with Microsoft Visual Studio 2015, due to a change from previous versions in the VS implementation of the _vsnprintf() function. (Bug #80276, Bug #22670525)
- When setting CPU spin time, the value was needlessly cast to a boolean internally, so that setting it to
 any nonzero value yielded an effective value of 1. This issue, as well as the fix for it, apply both to setting
 the SchedulerSpinTimer parameter and to setting spintime as part of a ThreadConfig parameter
 value. (Bug #80237, Bug #22647476)
- Processing of local checkpoints was not handled correctly on Mac OS X, due to an uninitialized variable. (Bug #80236, Bug #22647462)
- A logic error in an if statement in storage/ndb/src/kernel/blocks/dbacc/DbaccMain.cpp rendered useless a check for determining whether ZREAD_ERROR should be returned when comparing operations. This was detected when compiling with gcc using -Werror=logical-op. (Bug #80155, Bug #22601798)

References: This issue is a regression of: Bug #21285604.

- Suppressed a CMake warning that was caused by use of an incorrectly quoted variable name. (Bug #80066, Bug #22572632)
- When using CREATE INDEX to add an index on either of two NDB tables sharing circular foreign keys, the query succeeded but a temporary table was left on disk, breaking the foreign key constraints. This issue was also observed when attempting to create an index on a table in the middle of a chain of foreign keys—that is, a table having both parent and child keys, but on different tables. The problem did not occur when using ALTER TABLE to perform the same index creation operation; and subsequent analysis revealed unintended differences in the way such operations were performed by CREATE INDEX.

To fix this problem, we now make sure that operations performed by a CREATE INDEX statement are always handled internally in the same way and at the same time that the same operations are handled when performed by ALTER TABLE or DROP INDEX. (Bug #79156, Bug #22173891)

• The PortNumber SCI, SHM, and TCP configuration parameters, which were deprecated in MySQL 5.1.3, have now been removed and are no longer accepted in configuration files.

This change does not affect the PortNumber management node configuration parameter, whose behavior remains unaltered. (Bug #77405, Bug #21280456)

Changes in MySQL NDB Cluster 7.5.0 (5.7.10-ndb-7.5.0)

Functionality Added or Changed

- Important Change: Previously, the ndbinfo information database included lookup tables that used the MyISAM storage engine. This dependency on MyISAM has now been removed. (Bug #20075747)
- Important Change: Previously, the NDB scheduler always optimized for speed against throughput in a predetermined manner (this was hard coded); this balance can now be set using the SchedulerResponsiveness data node configuration parameter. This parameter accepts an integer in the range of 0-10 inclusive, with 5 as the default. Higher values provide better response times relative to throughput. Lower values provide increased throughput, but impose longer response times. (Bug #78531, Bug #21889312)

• Important Change: A number of MySQL Cluster data node configuration parameters were deprecated in earlier versions of MySQL Cluster, and have been removed with this release. These parameters include Id, NoOfDiskPagesToDiskDuringRestartTUP, NoOfDiskPagesToDiskDuringRestartACC, NoOfDiskPagesToDiskAfterRestartACC, NoOfDiskPagesToDiskAfterRestartTUP, ReservedSendBufferMemory, MaxNoOfIndexes, and Discless (use Diskless instead), as well as DiskCheckpointSpeed and DiskCheckpointSpeedInRestart. The archaic and unused ByteOrder computer configuration parameter has also been removed, as well as the unused MaxNoOfSavedEvents management node confugration parameter. These parameters are no longer supported; most of them already did not have (or no longer had) any effect. Trying to use any of these parameters in a MySQL Cluster configuration file now results in an error.

For more information, see What is New in MySQL NDB Cluster 7.5. (Bug #77404, Bug #21280428)

Important Change: The ExecuteOnComputer configuration parameter for management, data, and API nodes is now deprecated, and is subject to removal in a future MySQL Cluster release. For all types of MySQL Cluster nodes, you should now use the HostName parameter exclusively for identifying hosts in the cluster configuration file.

This information is also now displayed in the output of ndb_config --configinfo --xml. (Bug #53052, Bug #11760628)

- Important Change: The ndbinfo database can now provide default and current information about MySQL Cluster node configuration parameters as a result of the following changes:
 - 1. The config_params table has been enhanced with additional columns providing information about each configuration parameter, including its type, default, and maximum and minimum values (where applicable).
 - A new config_values table has been added. A row in this table shows the current value of a parameter on a given node.

You can obtain values of MySQL Cluster configuration parameters by name using a join on these two tables such as the one shown here:

- Deprecated MySQL Cluster node configuration parameters are now indicated as such by ndb_config
 --configinfo --xml. For each parameter currently deprecated, the corresponding <param/> tag in
 the XML output now includes the attribute deprecated="true". (Bug #21127135)
- Added the --ndb-cluster-connection-pool-nodeids option for mysqld, which can be used to specify a list of nodes by node ID for connection pooling. The number of node IDs in the list must equal the value set for --ndb-cluster-connection-pool. (Bug #19521789)
- Added the PROMPT command in the ndb_mgm client. This command has the syntax PROMPT string, which sets the client's prompt to string. Issuing the command without an argument causes the prompt to be reset to the default (ndb_mgm>). See Commands in the NDB Cluster Management Client, for more information. (Bug #18421338)

- When the --database option has not been specified for ndb_show_tables, and no tables are
 found in the TEST_DB database, an appropriate warning message is now issued. (Bug #50633, Bug
 #11758430)
- The NDB storage engine now uses the improved records-per-key interface for index statistics introduced for the optimizer in MySQL 5.7. Some improvements due to this change are listed here:
 - The optimizer can now choose better execution plans for queries on NDB tables in many cases where a less optimal join index or table join order would previously have been chosen.
 - EXPLAIN now provides more accurate row estimates than previously.
 - Improved cardinality estimates can be obtained from SHOW INDEX.

Bugs Fixed

- Incompatible Change; NDB Cluster APIs: The pollEvents2() method now returns -1, indicating an error, whenever a negative value is used for the time argument. (Bug #20762291)
- **Important Change:** The options controlling behavior of NDB programs with regard to the number and timing of successive attempts to connect to a management server have changed as listed here:
 - The minimum value for the --connect-retry-delay option common to all NDB programs has been changed from 0 to 1; this means that all NDB programs now wait at least 1 second between successive connection attempts, and it is no longer possible to set a waiting time equal to 0.
 - The semantics for the --connect-retries option have changed slightly, such that the value of this option now sets the number of times an NDB program tries to connect to a management server. Setting this option to 0 now causes the program to attempt the connection indefinitely, until it either succeeds or is terminated by other means (such as kill).
 - In addition, the default for the --connect-retries option for the ndb_mgm client has been changed from 3 to 12, so that the minimum, maximum, and default values for this option when used with ndb_mgm are now exactly the same as for all other NDB programs.

The ndb_mgm --try-reconnect option, although deprecated in MySQL Cluster NDB 7.4, continues to be supported as a synonym for ndb_mgm --connect-retries to provide backwards compatibility. The default value for --try-reconnect has also been changed from 3 to 12, respectively, so that this option continues to behave in the exactly in the same way as --connect-retries.

(Bug #22116937)

- Important Change: In previous versions of MySQL Cluster, other DDL operations could not be part
 of ALTER ONLINE TABLE ... RENAME (This was disallowed by the fix for BUG#16021021.)
 MySQL Cluster NDB 7.5 makes the following changes:
 - Support for the ONLINE and OFFLINE keywords, which was deprecated in MySQL Cluster NDB 7.3, is now removed, and use of these now causes a syntax error; the NDB storage engine now accepts *only* ALGORITHM = DEFAULT, ALGORITHM = COPY, and ALGORITHM = INPLACE to specify whether the ALTER operation is copying or in-place, just as in the standard MySQL Server.
 - NDB now allows ALTER TABLE ... ALGORITHM=COPYING RENAME. (Bug #20804269, Bug #76543, Bug #20479917, Bug #75797)

References: See also: Bug #16021021.

- Important Change; NDB Cluster APIs: Ndb::pollEvents() is now compatible with the TE_EMPTY, TE_INCONSISTENT, and TE_OUT_OF_MEMORY event types introduced in MySQL Cluster NDB 7.4.3. For detailed information about this change, see the description of this method in the MySQL Cluster API Developer Guide. (Bug #20646496)
- Important Change; NDB Cluster APIs: Added the method Ndb::isExpectingHigherQueuedEpochs() to the NDB API to detect when additional, newer event epochs were detected by pollEvents2().

The behavior of Ndb::pollEvents() has also been modified such that it now returns NDB_FAILURE_GCI (equal to ~(Uint64) 0) when a cluster failure has been detected. (Bug #18753887)

• Important Change; NDB Cluster APIs: To release the memory used for dropped event operations, the event API formerly depended on pollEvents() and nextEvent() to consume all events possibly referring to the dropped events. This dependency between dropEventOperation() and the first two methods required the entire event buffer to be read before attempting to release event operation memory (that is, until successive calls to pollEvents() and nextEvent() returned no more events).

A related cleanup issue arose following the reset of the event buffer (when all event operations had previously been dropped), and the event buffer was truncated by the first <code>createEventOperation()</code> call subsequent to the reset.

To fix these problems, the event buffer is now cleared when the last event operation is dropped, rather than waiting for a subsequent create operation which might or might not occur. Memory taken up by dropped event operations is also now released when the event queue has been cleared, which removes the hidden requirement for consuming all events to free up memory. In addition, event operation memory is now released as soon as all events referring to the operation have been consumed, rather than waiting for the entire event buffer to be consumed. (Bug #78145, Bug #21661297)

- Important Change; NDB Cluster APIs: The MGM API error-handling functions ndb_mgm_get_latest_error(), ndb_mgm_get_latest_error_msg(), and ndb_mgm_get_latest_error_desc() each failed when used with a NULL handle. You should note that, although these functions are now null-safe, values returned in this case are arbitrary and not meaningful. (Bug #78130, Bug #21651706)
- Important Change; NDB Cluster APIs: The following NDB API methods were not actually implemented and have been removed from the sources:
 - Datafile methods: getNode(), setNode(), and getFileNo()
 - Undofile methods: getNode(), setNode(), and getFileNo()
 - Table methods: getObjectType() and setObjectType()
- A serious regression was inadvertently introduced in MySQL Cluster NDB 7.4.8 whereby local
 checkpoints and thus restarts often took much longer than expected. This occurred due to the fact
 that the setting for MaxDiskWriteSpeedOwnRestart was ignored during restarts and the value
 of MaxDiskWriteSpeedOtherNodeRestart, which is much lower by default than the default
 for MaxDiskWriteSpeedOwnRestart, was used instead. This issue affected restart times and
 performance only and did not have any impact on normal operations. (Bug #22582233)
- The epoch for the latest restorable checkpoint provided in the cluster log as part of its reporting for EventBufferStatus events (see NDB Cluster: Messages in the Cluster Log) was not well defined and thus unreliable; depending on various factors, the reported epoch could be the one currently being consumed, the one most recently consumed, or the next one queued for consumption.

This fix ensures that the latest restorable global checkpoint is always regarded as the one that was most recently completely consumed by the user, and thus that it was the latest restorable global checkpoint that existed at the time the report was generated. (Bug #22378288)

Added the --ndb-allow-copying-alter-table option for mysqld. Setting this option (or the
equivalent system variable ndb_allow_copying_alter_table) to OFF keeps ALTER TABLE
statements from performing copying operations. The default value is ON. (Bug #22187649)

References: See also: Bug #17400320.

- Attempting to create an NDB table having greater than the maximum supported combined width for all BIT columns (4096) caused data node failure when these columns were defined with COLUMN_FORMAT DYNAMIC. (Bug #21889267)
- Creating a table with the maxmimum supported number of columns (512) all using COLUMN_FORMAT DYNAMIC led to data node failures. (Bug #21863798)
- In a MySQL Cluster with multiple LDM instances, all instances wrote to the node log, even inactive
 instances on other nodes. During restarts, this caused the log to be filled with messages from other
 nodes, such as the messages shown here:

```
2015-06-24 00:20:16 [ndbd] INFO -- We are adjusting Max Disk Write Speed, a restart is ongoing now ...
2015-06-24 01:08:02 [ndbd] INFO -- We are adjusting Max Disk Write Speed, no restarts ongoing anymore
```

Now this logging is performed only by the active LDM instance. (Bug #21362380)

Backup block states were reported incorrectly during backups. (Bug #21360188)

References: See also: Bug #20204854, Bug #21372136.

• For a timeout in GET_TABINFOREQ while executing a CREATE INDEX statement, mysqld returned Error 4243 (Index not found) instead of the expected Error 4008 (Receive from NDB failed).

The fix for this bug also fixes similar timeout issues for a number of other signals that are sent the DBDICT kernel block as part of DDL operations, including ALTER_TAB_REQ, CREATE_INDX_REQ, DROP_FK_REQ, DROP_INDX_REQ, INDEX_STAT_REQ, DROP_FILE_REQ, CREATE_FILEGROUP_REQ, DROP_FILEGROUP_REQ, CREATE_EVENT, WAIT_GCP_REQ, DROP_TAB_REQ, and LIST_TABLES_REQ, as well as several internal functions used in handling NDB schema operations. (Bug #21277472)

References: See also: Bug #20617891, Bug #20368354, Bug #19821115.

 Previously, multiple send threads could be invoked for handling sends to the same node; these threads then competed for the same send lock. While the send lock blocked the additional send threads, work threads could be passed to other nodes.

This issue is fixed by ensuring that new send threads are not activated while there is already an active send thread assigned to the same node. In addition, a node already having an active send thread assigned to it is no longer visible to other, already active, send threads; that is, such a node is longer added to the node list when a send thread is currently assigned to it. (Bug #20954804, Bug #76821)

Queueing of pending operations when the redo log was overloaded
 (DefaultOperationRedoProblemAction API node configuration parameter) could lead to timeouts
 when data nodes ran out of redo log space (P_TAIL_PROBLEM errors). Now when the redo log is full,
 the node aborts requests instead of queuing them. (Bug #20782580)

References: See also: Bug #20481140.

 An NDB event buffer can be used with an Ndb object to subscribe to table-level row change event streams. Users subscribe to an existing event; this causes the data nodes to start sending event data signals (SUB_TABLE_DATA) and epoch completion signals (SUB_GCP_COMPLETE) to the Ndb object. SUB_GCP_COMPLETE_REP signals can arrive for execution in concurrent receiver thread before completion of the internal method call used to start a subscription.

Execution of SUB_GCP_COMPLETE_REP signals depends on the total number of SUMA buckets (sub data streams), but this may not yet have been set, leading to the present issue, when the counter used for tracking the SUB_GCP_COMPLETE_REP signals (TOTAL_BUCKETS_INIT) was found to be set to erroneous values. Now TOTAL_BUCKETS_INIT is tested to be sure it has been set correctly before it is used. (Bug #20575424, Bug #76255)

References: See also: Bug #20561446, Bug #21616263.

NDB statistics queries could be delayed by the error delay set for ndb_index_stat_option (default
60 seconds) when the index that was queried had been marked with internal error. The same underlying
issue could also cause ANALYZE TABLE to hang when executed against an NDB table having multiple
indexes where an internal error occurred on one or more but not all indexes.

Now in such cases, any existing statistics are returned immediately, without waiting for any additional statistics to be discovered. (Bug #20553313, Bug #20707694, Bug #76325)

 Memory allocated when obtaining a list of tables or databases was not freed afterward. (Bug #20234681, Bug #74510)

References: See also: Bug #18592390, Bug #72322.

• Added the BackupDiskWriteSpeedPct data node parameter. Setting this parameter causes the data node to reserve a percentage of its maximum write speed (as determined by the value of MaxDiskWriteSpeed) for use in local checkpoints while performing a backup.

BackupDiskWriteSpeedPct is interpreted as a percentage which can be set between 0 and 90 inclusive, with a default value of 50. (Bug #20204854)

References: See also: Bug #21372136.

• After restoring the database schema from backup using ndb_restore, auto-discovery of restored tables in transactions having multiple statements did not work correctly, resulting in Deadlock found when trying to get lock; try restarting transaction errors.

This issue was encountered both in the mysql client, as well as when such transactions were executed by application programs using Connector/J and possibly other MySQL APIs.

Prior to upgrading, this issue can be worked around by executing SELECT TABLE_NAME, TABLE_SCHEMA FROM INFORMATION_SCHEMA.TABLES WHERE ENGINE = 'NDBCLUSTER' on all SQL nodes following the restore operation, before executing any other statements. (Bug #18075170)

- Using ndb_mgm STOP -f to force a node shutdown even when it triggered a complete shutdown of the cluster, it was possible to lose data when a sufficient number of nodes were shut down, triggering a cluster shutdown, and the timing was such that SUMA handovers had been made to nodes already in the process of shutting down. (Bug #17772138)
- When using a sufficiently large value for TransactionDeadlockDetectionTimeout and the default value for sort_buffer_size, executing SELECT * FROM ndbinfo.cluster_operations ORDER BY transid with multiple concurrent conflicting or deadlocked transactions, each transaction

having several pending operations, caused the SQL node where the query was run to fail. (Bug #16731538, Bug #67596)

- The ndbinfo.config_params table is now read-only. (Bug #11762750, Bug #55383)
- NDB failed during a node restart due to the status of the current local checkpoint being set but not as
 active, even though it could have other states under such conditions. (Bug #78780, Bug #21973758)
- ndbmtd checked for signals being sent only after a full cycle in run_job_buffers, which is performed
 for all job buffer inputs. Now this is done as part of run_job_buffers itself, which avoids executing
 for extended periods of time without sending to other nodes or flushing signals to other threads. (Bug
 #78530, Bug #21889088)
- When attempting to enable index statistics, creation of the required system tables, events and event subscriptions often fails when multiple mysqld processes using index statistics are started concurrently in conjunction with starting, restarting, or stopping the cluster, or with node failure handling. This is normally recoverable, since the affected mysqld process or processes can (and do) retry these operations shortly thereafter. For this reason, such failures are no longer logged as warnings, but merely as informational events. (Bug #77760, Bug #21462846)
- It was possible to end up with a lock on the send buffer mutex when send buffers became a limiting resource, due either to insufficient send buffer resource configuration, problems with slow or failing communications such that all send buffers became exhausted, or slow receivers failing to consume what was sent. In this situation worker threads failed to allocate send buffer memory for signals, and attempted to force a send in order to free up space, while at the same time the send thread was busy trying to send to the same node or nodes. All of these threads competed for taking the send buffer mutex, which resulted in the lock already described, reported by the watchdog as Stuck in Send. This fix is made in two parts, listed here:
 - 1. The send thread no longer holds the global send thread mutex while getting the send buffer mutex; it now releases the global mutex prior to locking the send buffer mutex. This keeps worker threads from getting stuck in send in such cases.
 - 2. Locking of the send buffer mutex done by the send threads now uses a try-lock. If the try-lock fails, the node to make the send to is reinserted at the end of the list of send nodes in order to be retried later. This removes the Stuck in Send condition for the send threads.

(Bug #77081, Bug #21109605)

- NDB Disk Data: A unique index on a column of an NDB table is implemented with an associated internal ordered index, used for scanning. While dropping an index, this ordered index was dropped first, followed by the drop of the unique index itself. This meant that, when the drop was rejected due to (for example) a constraint violation, the statement was rejected but the associated ordered index remained deleted, so that any subsequent operation using a scan on this table failed. We fix this problem by causing the unique index to be removed first, before removing the ordered index; removal of the related ordered index is no longer performed when removal of a unique index fails. (Bug #78306, Bug #21777589)
- NDB Cluster APIs: The binary log injector did not work correctly with TE_INCONSISTENT event type handling by Ndb::nextEvent(). (Bug #22135541)

References: See also: Bug #20646496.

NDB Cluster APIs: While executing dropEvent(), if the coordinator DBDICT failed after the
subscription manager (SUMA block) had removed all subscriptions but before the coordinator had deleted
the event from the system table, the dropped event remained in the table, causing any subsequent drop

or create event with the same name to fail with NDB error 1419 Subscription already dropped or error 746 Event name already exists. This occurred even when calling dropEvent() with a nonzero force argument.

Now in such cases, error 1419 is ignored, and DBDICT deletes the event from the table. (Bug #21554676)

- NDB Cluster APIs: Creation and destruction of Ndb_cluster_connection objects by multiple threads could make use of the same application lock, which in some cases led to failures in the global dictionary cache. To alleviate this problem, the creation and destruction of several internal NDB API objects have been serialized. (Bug #20636124)
- NDB Cluster APIs: When an Ndb object created prior to a failure of the cluster was reused, the event queue of this object could still contain data node events originating from before the failure. These events could reference "old" epochs (from before the failure occurred), which in turn could violate the assumption made by the nextEvent() method that epoch numbers always increase. This issue is addressed by explicitly clearing the event queue in such cases. (Bug #18411034)

References: See also: Bug #20888668.

• NDB Cluster APIs: Ndb::pollEvents() and pollEvents2() were slow to receive events, being dependent on other client threads or blocks to perform polling of transporters on their behalf. This fix allows a client thread to perform its own transporter polling when it has to wait in either of these methods.

Introduction of transporter polling also revealed a problem with missing mutex protection in the ndbcluster_binlog handler, which has been added as part of this fix. (Bug #79311, Bug #20957068, Bug #22224571)

NDB Cluster APIs: After the initial restart of a node following a cluster failure, the cluster failure event
added as part of the restart process was deleted when an event that existed prior to the restart was later
deleted. This meant that, in such cases, an Event API client had no way of knowing that failure handling
was needed. In addition, the GCI used for the final cleanup of deleted event operations, performed by
pollEvents() and nextEvent() when these methods have consumed all available events, was lost.
(Bug #78143, Bug #21660947)
