Chapter 1 Installing MySQL from Source

Building MySQL from the source code enables you to customize build parameters, compiler optimizations, and installation location. For a list of systems on which MySQL is known to run, see http://www.mysql.com/support/supportedplatforms/database.html.

Before you proceed with an installation from source, check whether Oracle produces a precompiled binary distribution for your platform and whether it works for you. We put a great deal of effort into ensuring that our binaries are built with the best possible options for optimal performance. Instructions for installing binary distributions are available in Installing MySQL on Unix/Linux Using Generic Binaries.

Source Installation Methods

There are two methods for installing MySQL from source:

 Use a standard MySQL source distribution. To obtain a standard distribution, see How to Get MySQL. For instructions on building from a standard distribution, see Chapter 2, *Installing MySQL Using a Standard Source Distribution*.

Standard distributions are available as compressed tar files, Zip archives, or RPM packages. Distribution files have names of the form <code>mysql-VERSION.tar.gz</code>, <code>mysql-VERSION.zip</code>, or <code>mysql-VERSION.rpm</code>, where <code>VERSION</code> is a number like 5.7.16. File names for source distributions can be distinguished from those for precompiled binary distributions in that source distribution names are generic and include no platform name, whereas binary distribution names include a platform name indicating the type of system for which the distribution is intended (for example, <code>pc-linux-i686</code> or <code>winx64</code>).

• Use a MySQL development tree. For information on building from one of the development trees, see Chapter 3, *Installing MySQL Using a Development Source Tree*.

Source Installation System Requirements

Installation of MySQL from source requires several development tools. Some of these tools are needed no matter whether you use a standard source distribution or a development source tree. Other tool requirements depend on which installation method you use.

To install MySQL from source, the following system requirements must be satisfied, regardless of installation method:

- CMake, which is used as the build framework on all platforms. CMake can be downloaded from http://www.cmake.org.
- A good make program. Although some platforms come with their own make implementations, it is
 highly recommended that you use GNU make 3.75 or higher. It may already be available on your
 system as qmake. GNU make is available from http://www.gnu.org/software/make/.
- A working ANSI C++ compiler. GCC 4.4.6 or later, Clang 3.3 or later (FreeBSD and OS X), Visual Studio 2013 or later, and many current vendor-supplied compilers are known to work.
- The Boost C++ libraries are required to build MySQL (but not to use it). Boost 1.59.0 must be installed. To obtain Boost and its installation instructions, visit the official site. After Boost is installed, tell the build system where the Boost files are located by defining the WITH_BOOST option when you invoke CMake. For example:

```
shell> cmake . -DWITH_BOOST=/usr/local/boost_1_59_0
```

Adjust the path as necessary to match your installation.

- Sufficient free memory. If you encounter problems such as "internal compiler error" when compiling large source files, it may be that you have too little memory. If compiling on a virtual machine, try increasing the memory allocation.
- Perl is needed if you intend to run test scripts. Most Unix-like systems include Perl. On Windows, you
 can use a version such as ActiveState Perl.

To install MySQL from a standard source distribution, one of the following tools is required to unpack the distribution file:

• For a .tar.gz compressed tar file: GNU gunzip to uncompress the distribution and a reasonable tar to unpack it. If your tar program supports the z option, it can both uncompress and unpack the file

GNU tar is known to work. The standard tar provided with some operating systems is not able to unpack the long file names in the MySQL distribution. You should download and install GNU tar, or if available, use a preinstalled version of GNU tar. Usually this is available as gnutar, gtar, or as tar within a GNU or Free Software directory, such as /usr/sfw/bin or /usr/local/bin. GNU tar is available from http://www.gnu.org/software/tar/.

- For a .zip Zip archive: WinZip or another tool that can read .zip files.
- For an .rpm RPM package: The rpmbuild program used to build the distribution unpacks it.

To install MySQL from a development source tree, the following additional tools are required:

- The Git revision control system is required to obtain the development source code. The GitHub
 Help provides instructions for downloading and installing Git on different platforms. MySQL officially
 joined GitHub in September, 2014. For more information about MySQL's move to GitHub, refer to the
 announcement on the MySQL Release Engineering blog: MySQL on GitHub
- bison 2.1 or higher, available from http://www.gnu.org/software/bison/. (Version 1 is no longer supported.) Use the latest version of bison where possible; if you experience problems, upgrade to a later version, rather than revert to an earlier one.

bison is available from http://www.gnu.org/software/bison/. bison for Windows can be downloaded from http://gnuwin32.sourceforge.net/packages/bison.htm. Download the package labeled "Complete package, excluding sources". On Windows, the default location for bison is the C:\Program Files\GnuWin32 directory. Some utilities may fail to find bison because of the space in the directory name. Also, Visual Studio may simply hang if there are spaces in the path. You can resolve these problems by installing into a directory that does not contain a space; for example C:\GnuWin32.

• On OpenSolaris and Solaris Express, m4 must be installed in addition to bison. m4 is available from http://www.gnu.org/software/m4/.

Note

If you have to install any programs, modify your PATH environment variable to include any directories in which the programs are located. See Setting Environment Variables.

If you run into problems and need to file a bug report, please use the instructions in How to Report Bugs or Problems.

Chapter 2 Installing MySQL Using a Standard Source Distribution

To install MySQL from a standard source distribution:

- 1. Verify that your system satisfies the tool requirements listed at Chapter 1, *Installing MySQL from Source*.
- 2. Obtain a distribution file using the instructions in How to Get MySQL.
- 3. Configure, build, and install the distribution using the instructions in this section.
- 4. Perform postinstallation procedures using the instructions in Postinstallation Setup and Testing.

In MySQL 5.7, CMake is used as the build framework on all platforms. The instructions given here should enable you to produce a working installation. For additional information on using CMake to build MySQL, see How to Build MySQL Server with CMake.

If you start from a source RPM, use the following command to make a binary RPM that you can install. If you do not have rpmbuild, use rpm instead.

```
shell> rpmbuild --rebuild --clean MySQL-VERSION.src.rpm
```

The result is one or more binary RPM packages that you install as indicated in Installing MySQL on Linux Using RPM Packages from Oracle.

The sequence for installation from a compressed tar file or Zip archive source distribution is similar to the process for installing from a generic binary distribution (see Installing MySQL on Unix/Linux Using Generic Binaries), except that it is used on all platforms and includes steps to configure and compile the distribution. For example, with a compressed tar file source distribution on Unix, the basic installation command sequence looks like this:

```
# Preconfiguration setup
shell> groupadd mysql
shell> useradd -r -g mysql -s /bin/false mysql
# Beginning of source-build specific instructions
shell> tar zxvf mysql-VERSION.tar.gz
shell> cd mysql-VERSION
shell> cmake
shell> make
shell> make install
# End of source-build specific instructions
# Postinstallation setup
shell> cd /usr/local/mysql
shell> chown -R mysql .
shell> chgrp -R mysql
shell> bin/mysql install db --user=mysql  # Before MySOL 5.7.6
shell> bin/mysqld --initialize --user=mysql # MySQL 5.7.6 and up
shell> bin/mysql_ssl_rsa_setup
                                            # MySQL 5.7.6 and up
shell> chown -R root
shell> chown -R mysql data
shell> bin/mysqld safe --user=mysql &
# Next command is optional
shell> cp support-files/mysql.server /etc/init.d/mysql.server
```

Before MySQL 5.7.5, mysql_install_db creates a default option file named my.cnf in the base installation directory. This file is created from a template included in the distribution package named my-default.cnf. For more information, see Server Configuration Defaults.

A more detailed version of the source-build specific instructions is shown following.

Note

The procedure shown here does not set up any passwords for MySQL accounts. After following the procedure, proceed to Postinstallation Setup and Testing, for postinstallation setup and testing.

Perform Preconfiguration Setup

On Unix, set up the mysql user and group that will be used to run and execute the MySQL server and own the database directory. For details, see Creating a mysql System User and Group, in Installing MySQL on Unix/Linux Using Generic Binaries. Then perform the following steps as the mysql user, except as noted.

Obtain and Unpack the Distribution

Pick the directory under which you want to unpack the distribution and change location into it.

Obtain a distribution file using the instructions in How to Get MySQL.

Unpack the distribution into the current directory:

• To unpack a compressed tar file, tar can uncompress and unpack the distribution if it has z option support:

```
shell> tar zxvf mysql-VERSION.tar.gz
```

If your tar does not have z option support, use gunzip to unpack the distribution and tar to unpack it:

```
shell> gunzip < mysql-VERSION.tar.gz | tar xvf -
```

Alternatively, CMake can uncompress and unpack the distribution:

```
shell> cmake -E tar zxvf mysql-VERSION.tar.gz
```

To unpack a Zip archive, use WinZip or another tool that can read .zip files.

Unpacking the distribution file creates a directory named mysql-VERSION.

Configure the Distribution

Change location into the top-level directory of the unpacked distribution:

```
shell> cd mysql-VERSION
```

Configure the source directory. The minimum configuration command includes no options to override configuration defaults:

```
shell> cmake .
```

On Windows, specify the development environment. For example, the following commands configure MySQL for 32-bit or 64-bit builds, respectively:

```
shell> cmake . -G "Visual Studio 10 2010"
shell> cmake . -G "Visual Studio 10 2010 Win64"
```

On OS X, to use the Xcode IDE:

```
shell> cmake . -G Xcode
```

When you run cmake, you might want to add options to the command line. Here are some examples:

- -DBUILD_CONFIG=mysql_release: Configure the source with the same build options used by Oracle to produce binary distributions for official MySQL releases.
- -DCMAKE_INSTALL_PREFIX=dir_name: Configure the distribution for installation under a particular location.
- -DCPACK_MONOLITHIC_INSTALL=1: Cause make package to generate a single installation file rather than multiple files.
- -DWITH_DEBUG=1: Build the distribution with debugging support.

For a more extensive list of options, see Chapter 4, MySQL Source-Configuration Options.

To list the configuration options, use one of the following commands:

```
shell> cmake . -L  # overview
shell> cmake . -LH  # overview with help text
shell> cmake . -LAH  # all params with help text
shell> ccmake .  # interactive display
```

If CMake fails, you might need to reconfigure by running it again with different options. If you do reconfigure, take note of the following:

- If CMake is run after it has previously been run, it may use information that was gathered during its
 previous invocation. This information is stored in CMakeCache.txt. When CMake starts up, it looks
 for that file and reads its contents if it exists, on the assumption that the information is still correct.
 That assumption is invalid when you reconfigure.
- Each time you run CMake, you must run make again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old object files or configuration information from being used, run these commands on Unix before re-running CMake:

```
shell> make clean
shell> rm CMakeCache.txt
```

Or, on Windows:

```
shell> devenv MySQL.sln /clean shell> del CMakeCache.txt
```

If you build out of the source tree (as described later), the CMakeCache.txt file and all built files are in the build directory, so you can remove that directory to object files and cached configuration information.

If you are going to send mail to a MySQL mailing list to ask for configuration assistance, first check the files in the CMakeFiles directory for useful information about the failure. To file a bug report, please use the instructions in How to Report Bugs or Problems.

Build the Distribution

On Unix:

```
shell> make
shell> make VERBOSE=1
```

The second command sets VERBOSE to show the commands for each compiled source.

Use gmake instead on systems where you are using GNU make and it has been installed as gmake.

On Windows:

```
shell> devenv MySQL.sln /build RelWithDebInfo
```

It is possible to build out of the source tree to keep the tree clean. If the top-level source directory is named mysql-src under your current working directory, you can build in a directory named bld at the same level like this:

```
shell> mkdir bld
shell> cd bld
shell> cmake ../mysql-src
```

The build directory need not actually be outside the source tree. For example, to build in a directory, you can build in a directory named bld under the top-level source tree, do this, starting with mysql-src as your current working directory:

```
shell> mkdir bld
shell> cd bld
shell> cmake ..
```

If you have multiple source trees at the same level (for example, to build multiple versions of MySQL), the second strategy can be advantageous. The first strategy places all build directories at the same level, which requires that you choose a unique name for each. With the second strategy, you can use the same name for the build directory within each source tree.

If you have gotten to the compilation stage, but the distribution does not build, see Chapter 5, *Dealing with Problems Compiling MySQL*, for help. If that does not solve the problem, please enter it into our bugs database using the instructions given in How to Report Bugs or Problems. If you have installed the latest versions of the required tools, and they crash trying to process our configuration files, please report that also. However, if you get a command not found error or a similar problem for required tools, do not report it. Instead, make sure that all the required tools are installed and that your PATH variable is set correctly so that your shell can find them.

Install the Distribution

On Unix:

```
shell> make install
```

This installs the files under the configured installation directory (by default, /usr/local/mysql). You might need to run the command as root.

To install in a specific directory, add a DESTDIR parameter to the command line:

```
shell> make install DESTDIR="/opt/mysql"
```

Alternatively, generate installation package files that you can install where you like:

```
shell> make package
```

This operation produces one or more .tar.gz files that can be installed like generic binary distribution packages. See Installing MySQL on Unix/Linux Using Generic Binaries. If you run CMake with -

DCPACK_MONOLITHIC_INSTALL=1, the operation produces a single file. Otherwise, it produces multiple files.

On Windows, generate the data directory, then create a .zip archive installation package:

```
shell> devenv MySQL.sln /build RelWithDebInfo /project initial_database shell> devenv MySQL.sln /build RelWithDebInfo /project package
```

You can install the resulting <code>.zip</code> archive where you like. See Installing MySQL on Microsoft Windows Using a noinstall Zip Archive.

Perform Postinstallation Setup

The remainder of the installation process involves setting up the configuration file, creating the core databases, and starting the MySQL server. For instructions, see Postinstallation Setup and Testing.

Note

The accounts that are listed in the MySQL grant tables initially have no passwords. After starting the server, you should set up passwords for them using the instructions in Postinstallation Setup and Testing.

Chapter 3 Installing MySQL Using a Development Source Tree

This section describes how to install MySQL from the latest development source code, which is currently hosted on GitHub. To obtain the MySQL Server source code from this repository hosting service, you can set up a local MySQL Git repository.

On GitHub, MySQL Server and other MySQL projects are found on the MySQL page. The MySQL Server project is a single repository that contains branches for several MySQL series, such as 5.5, 5.6, and 5.7.

MySQL officially joined GitHub in September, 2014. For more information about MySQL's move to GitHub, refer to the announcement on the MySQL Release Engineering blog: MySQL on GitHub

Prerequisites for Installing from Development Source

To install MySQL from a development source tree, your system must satisfy the tool requirements outlined in Chapter 1, *Installing MySQL from Source*.

Setting Up a MySQL Git Repository

To set up a MySQL Git repository on your machine, use this procedure:

1. Clone the MySQL Git repository to your machine. The following command clones the MySQL Git repository to a directory named mysql-server. The download size is approximately 437 MB. The initial download will take some time to complete, depending on the speed of your connection.

```
~$ git clone https://github.com/mysql/mysql-server.git
Cloning into 'mysql-server'...
remote: Counting objects: 1035465, done.
remote: Total 1035465 (delta 0), reused 0 (delta 0)
Receiving objects: 100% (1035465/1035465), 437.48 MiB | 5.10 MiB/s, done.
Resolving deltas: 100% (855607/855607), done.
Checking connectivity... done.
Checking out files: 100% (21902/21902), done.
```

2. When the clone operation completes, the contents of your local MySQL Git repository appear similar to the following:

```
~$ cd mysql-server$ ls

BUILD COPYING libmysqld regex unittest

BUILD-CMAKE dbug libservices scripts VERSION

client Docs man sql vio

cmake extra mysql-test sql-common win

CMakeLists.txt include mysys storage zlib

cmd-line-utils INSTALL-SOURCE packaging strings

config.h.cmake INSTALL-WIN-SOURCE plugin support-files

configure.cmake libmysql README tests
```

3. Use the git branch -r command to view the remote tracking branches for the MySQL repository.

```
~/mysql-server$ git branch -r
  origin/5.5
  origin/5.6
  origin/5.7
  origin/HEAD -> origin/5.7
  origin/cluster-7.2
  origin/cluster-7.3
  origin/cluster-7.4
```

4. To view the branches that are checked out in your local repository, issue the git branch command. When you cloned the MySQL Git repository, the MySQL 5.7 branch was checked out automatically. The asterisk identifies the 5.7 branch as the active branch.

```
~/mysql-server$ git branch
* 5.7
```

5. To check out a different MySQL branch, run the git checkout command, specifying the branch name. For example, to checkout the MySQL 5.5 branch:

```
~/mysql-server$ git checkout 5.5
Branch 5.5 set up to track remote branch 5.5 from origin.
Switched to a new branch '5.5'
```

6. Run git branch to verify that the MySQL 5.5 branch is present. MySQL 5.5, which is the last branch you checked out, is marked by an asterisk indicating that it is the active branch.

```
~/mysql-server$ git branch
* 5.5
5.7
```

7. Use the git checkout command to switch back to the MySQL 5.7 branch:

```
~/mysql-server$ git checkout 5.7
```

8. To obtain changes made after your initial setup of the MySQL Git repository, switch to the branch you want to update and issue the git pull command:

```
~/mysql-server$ git checkout 5.7 
~/mysql-server$ git pull
```

To examine the commit history, use the git log option:

```
~/mysql-server$ git log
```

You can also browse commit history and source code on the GitHub MySQL site.

If you see changes or code that you have a question about, send an email to the MySQL internals mailing list. See MySQL Mailing Lists. For information about contributing a patch, see Contributing to MySQL Server.

 After you have cloned the MySQL Git repository and have checked out the branch you want to build, you can build MySQL Server from the source code. Instructions are provided in Chapter 2, Installing MySQL Using a Standard Source Distribution, except that you skip the part about obtaining and unpacking the distribution.

Be careful about installing a build from a distribution source tree on a production machine. The installation command may overwrite your live release installation. If you already have MySQL installed and do not want to overwrite it, run CMake with values for the CMAKE_INSTALL_PREFIX, MYSQL_TCP_PORT, and MYSQL_UNIX_ADDR options different from those used by your production server. For additional information about preventing multiple servers from interfering with each other, see Running Multiple MySQL Instances on One Machine.

Play hard with your new installation. For example, try to make new features crash. Start by running make test. See The MySQL Test Suite.

Chapter 4 MySQL Source-Configuration Options

The CMake program provides a great deal of control over how you configure a MySQL source distribution. Typically, you do this using options on the CMake command line. For information about options supported by CMake, run either of these commands in the top-level source directory:

```
shell> cmake . -LH shell> ccmake .
```

You can also affect CMake using certain environment variables. See Environment Variables.

The following table shows the available CMake options. In the Default column, PREFIX stands for the value of the CMAKE_INSTALL_PREFIX option, which specifies the installation base directory. This value is used as the parent location for several of the installation subdirectories.

- · CMake Options for Compiling MySQL Cluster

For boolean options, the value may be specified as 1 or $online{N}$ to enable the option, or as 0 or off to disable the option.

Many options configure compile-time defaults that can be overridden at server startup. For example, the CMAKE_INSTALL_PREFIX, MYSQL_TCP_PORT, and MYSQL_UNIX_ADDR options that configure the default installation base directory location, TCP/IP port number, and Unix socket file can be changed at server startup with the --basedir, --port, and --socket options for mysqld. Where applicable, configuration option descriptions indicate the corresponding mysqld startup option.

General Options

-DBUILD_CONFIG=mysql_release

This option configures a source distribution with the same build options used by Oracle to produce binary distributions for official MySQL releases.

• -DCMAKE_BUILD_TYPE=type

The type of build to produce:

- RelWithDebInfo: Enable optimizations and generate debugging information. This is the default MySQL build type.
- Debug: Disable optimizations and generate debugging information. This build type is also used if the WITH_DEBUG option is enabled. That is, -DWITH_DEBUG=1 has the same effect as -DCMAKE_BUILD_TYPE=Debug.

• -DCPACK_MONOLITHIC_INSTALL=bool

This option affects whether the make package operation produces multiple installation package files or a single file. If disabled, the operation produces multiple installation package files, which may be useful if you want to install only a subset of a full MySQL installation. If enabled, it produces a single file for installing everything.

Installation Layout Options

The CMAKE_INSTALL_PREFIX option indicates the base installation directory. Other options with names of the form INSTALL_xxx that indicate component locations are interpreted relative to the prefix and their values are relative pathnames. Their values should not include the prefix.

• -DCMAKE_INSTALL_PREFIX=dir_name

The installation base directory.

This value can be set at server startup with the --basedir option.

• -DINSTALL_BINDIR=dir_name

Where to install user programs.

• -DINSTALL_DOCDIR=dir_name

Where to install documentation.

• -DINSTALL_DOCREADMEDIR=dir_name

Where to install README files.

• -DINSTALL_INCLUDEDIR=dir_name

Where to install header files.

• -DINSTALL INFODIR=dir name

Where to install Info files.

• -DINSTALL_LAYOUT=name

Select a predefined installation layout:

- STANDALONE: Same layout as used for .tar.gz and .zip packages. This is the default.
- RPM: Layout similar to RPM packages.
- SVR4: Solaris package layout.
- DEB: DEB package layout (experimental).

You can select a predefined layout but modify individual component installation locations by specifying other options. For example:

```
shell> cmake . -DINSTALL_LAYOUT=SVR4 -DMYSQL_DATADIR=/var/mysql/data
```

As of MySQL 5.7.6, the INSTALL_LAYOUT value determines the default value of the secure_file_priv system and keyring_file_data system variables; see the descriptions of those variables in Server System Variables.

-DINSTALL_LIBDIR=dir_name

Where to install library files.

• -DINSTALL_MANDIR=dir_name

Where to install manual pages.

-DINSTALL_MYSQLKEYRINGDIR=dir_path

The default directory to use as the location of the keyring_file plugin data file. The default value is platform specific and depends on the value of the INSTALL_LAYOUT CMake option; see the description of the keyring file data system variable in Server System Variables.

This option was added in MySQL 5.7.11.

• -DINSTALL_MYSQLSHAREDIR=dir_name

Where to install shared data files.

• -DINSTALL_MYSQLTESTDIR=dir_name

Where to install the mysql-test directory. As of MySQL 5.7.2, to suppress installation of this directory, explicitly set the option to the empty value (-DINSTALL_MYSQLTESTDIR=).

• -DINSTALL_PKGCONFIGDIR=dir_name

The directory in which to install the <code>mysqlclient.pc</code> file for use by <code>pkg-config</code>. The default value is <code>INSTALL_LIBDIR/pkgconfig</code>, unless <code>INSTALL_LIBDIR</code> ends with <code>/mysql</code>, in which case that is removed first.

This option was added in MySQL 5.7.9.

-DINSTALL_PLUGINDIR=dir_name

The location of the plugin directory.

This value can be set at server startup with the --plugin_dir option.

• -DINSTALL_SBINDIR=dir_name

Where to install the mysqld server.

• -DINSTALL SCRIPTDIR=dir name

Where to install mysql_install_db.

-DINSTALL_SECURE_FILE_PRIVDIR=dir_name

The default value for the <code>secure_file_priv</code> system variable. The default value is platform specific and depends on the value of the <code>INSTALL_LAYOUT</code> CMake option; see the description of the <code>secure_file_priv</code> system variable in Server System Variables.

This option was added in MySQL 5.7.6. To set the value for the libmysqld embedded server, use INSTALL_SECURE_FILE_PRIV_EMBEDDEDDIR.

• -DINSTALL_SECURE_FILE_PRIV_EMBEDDEDDIR=dir_name

The default value for the secure_file_priv system variable, for the libmysqld embedded server. This option was added in MySQL 5.7.8.

• -DINSTALL SHAREDIR=dir name

Where to install aclocal/mysql.m4.

-DINSTALL SQLBENCHDIR=dir name

Where to install the sql-bench directory. To suppress installation of this directory, explicitly set the option to the empty value (-DINSTALL_SQLBENCHDIR=).

As of MySQL 5.7.8, the sql-bench directory is no longer included in MYSQL distributions, so the INSTALL_SQLBENCHDIR= option is removed as well.

• -DINSTALL_SUPPORTFILESDIR=dir_name

Where to install extra support files.

• -DMYSQL_DATADIR=dir_name

The location of the MySQL data directory.

This value can be set at server startup with the --datadir option.

• -DODBC_INCLUDES=dir_name

The location of the ODBC includes directory, and may be used while configuring Connector/ODBC.

• -DODBC_LIB_DIR=dir_name

The location of the ODBC library directory, and may be used while configuring Connector/ODBC.

• -DSYSCONFDIR=dir name

The default my.cnf option file directory.

This location cannot be set at server startup, but you can start the server with a given option file using the --defaults-file=file_name option, where file_name is the full path name to the file.

• -DSYSTEMD_PID_DIR=dir_name

The name of the directory in which to create the PID file when MySQL is managed by systemd. The default is /var/run/mysqld; this might be changed implicitly according to the INSTALL_LAYOUT value.

This option is ignored unless WITH SYSTEMD is enabled. It was added in MySQL 5.7.6.

• -DSYSTEMD_SERVICE_NAME=name

The name of the MySQL service to use when MySQL is managed by systemd. The default is mysqld; this might be changed implicitly according to the INSTALL LAYOUT value.

This option is ignored unless WITH_SYSTEMD is enabled. It was added in MySQL 5.7.6.

• -DTMPDIR=dir name

The default location to use for the tmpdir system variable. If unspecified, the value defaults to P_tmpdir in stdio.h. This option was added in MySQL 5.7.4.

Storage Engine Options

Storage engines are built as plugins. You can build a plugin as a static module (compiled into the server) or a dynamic module (built as a dynamic library that must be installed into the server using the INSTALL PLUGIN statement or the --plugin-load option before it can be used). Some plugins might not support static or dynamic building.

The MyISAM, MERGE, MEMORY, and CSV engines are mandatory (always compiled into the server) and need not be installed explicitly.

To compile a storage engine statically into the server, use <code>-DWITH_engine_STORAGE_ENGINE=1</code>. Some permissible <code>engine</code> values are <code>ARCHIVE</code>, <code>BLACKHOLE</code>, <code>EXAMPLE</code>, <code>FEDERATED</code>, <code>INNOBASE</code> (<code>InnobB</code>), <code>NDB</code> or <code>NDBCLUSTER</code> (<code>NDB</code>), <code>PARTITION</code> (partitioning support), and <code>PERFSCHEMA</code> (Performance Schema). Examples:

```
-DWITH_INNOBASE_STORAGE_ENGINE=1
-DWITH_ARCHIVE_STORAGE_ENGINE=1
-DWITH_BLACKHOLE_STORAGE_ENGINE=1
-DWITH_PERFSCHEMA_STORAGE_ENGINE=1
```

Note

WITH_NDBCLUSTER_STORAGE_ENGINE is supported only when building MySQL Cluster using the MySQL Cluster sources. It cannot be used to enable clustering support in other MySQL source trees or distributions. In MySQL Cluster source distributions, it is enabled by default. See Building MySQL Cluster from Source on Linux, and Compiling and Installing MySQL Cluster from Source on Windows, for more information.

Note

As of MySQL 5.7.9, it is not possible to compile without Performance Schema support. If it is desired to compile without particular types of instrumentation, that can be done with the following CMake options:

```
DISABLE_PSI_COND
DISABLE PSI FILE
DISABLE_PSI_IDLE
DISABLE_PSI_MEMORY
DISABLE_PSI_METADATA
DISABLE PSI MUTEX
DISABLE_PSI_PS
DISABLE_PSI_RWLOCK
DISABLE_PSI_SOCKET
DISABLE_PSI_SP
DISABLE_PSI_STAGE
DISABLE_PSI_STATEMENT
DISABLE_PSI_STATEMENT_DIGEST
DISABLE_PSI_TABLE
DISABLE_PSI_THREAD
DISABLE_PSI_TRANSACTION
```

For example, to compile without mutex instrumentation, configure MySQL using the <code>-DDISABLE_PSI_MUTEX=1</code> option.

As of MySQL 5.7.4, to exclude a storage engine from the build, use -DWITH_engine_STORAGE_ENGINE=0. Examples:

```
-DWITH_EXAMPLE_STORAGE_ENGINE=0
-DWITH_FEDERATED_STORAGE_ENGINE=0
-DWITH_PARTITION_STORAGE_ENGINE=0
```

Before MySQL 5.7.4, to exclude a storage engine from the build, use – DWITHOUT_engine_STORAGE_ENGINE=1. (That syntax also works in 5.7.4 or later, but – DWITH_engine_STORAGE_ENGINE=0 is preferred.) Examples:

```
-DWITHOUT_EXAMPLE_STORAGE_ENGINE=1
-DWITHOUT_FEDERATED_STORAGE_ENGINE=1
-DWITHOUT_PARTITION_STORAGE_ENGINE=1
```

If neither -DWITH_engine_STORAGE_ENGINE nor -DWITHOUT_engine_STORAGE_ENGINE are specified for a given storage engine, the engine is built as a shared module, or excluded if it cannot be built as a shared module.

Feature Options

• -DCOMPILATION_COMMENT=string

A descriptive comment about the compilation environment.

• -DDEFAULT_CHARSET=charset_name

The server character set. By default, MySQL uses the latin1 (cp1252 West European) character set.

charset_name may be one of binary, armscii8, ascii, big5, cp1250, cp1251, cp1256, cp1257, cp850, cp852, cp866, cp932, dec8, eucjpms, euckr, gb2312, gbk, geostd8, greek, hebrew, hp8, keybcs2, koi8r, koi8u, latin1, latin2, latin5, latin7, macce, macroman, sjis, swe7, tis620, ucs2, ujis, utf8, utf8mb4, utf16, utf161e, utf32. The permissible character sets are listed in the cmake/character_sets.cmake file as the value of CHARSETS_AVAILABLE.

This value can be set at server startup with the --character_set_server option.

• -DDEFAULT_COLLATION=collation_name

The server collation. By default, MySQL uses latin1_swedish_ci. Use the SHOW COLLATION statement to determine which collations are available for each character set.

This value can be set at server startup with the --collation_server option.

• -DDISABLE_PSI_COND=bool

Whether to exclude the Performance Schema condition instrumentation. The default is OFF (include). This option was added in MySQL 5.7.3.

• -DDISABLE_PSI_FILE=bool

Whether to exclude the Performance Schema file instrumentation. The default is OFF (include). This option was added in MySQL 5.7.3.

• -DDISABLE_PSI_IDLE=bool

Whether to exclude the Performance Schema idle instrumentation. The default is OFF (include). This option was added in MySQL 5.7.3.

• -DDISABLE_PSI_MEMORY=bool

Whether to exclude the Performance Schema memory instrumentation. The default is OFF (include). This option was added in MySQL 5.7.3.

• -DDISABLE_PSI_METADATA=bool

Whether to exclude the Performance Schema metadata instrumentation. The default is OFF (include). This option was added in MySQL 5.7.3.

• -DDISABLE_PSI_MUTEX=bool

Whether to exclude the Performance Schema mutex instrumentation. The default is OFF (include). This option was added in MySQL 5.7.3.

• -DDISABLE_PSI_RWLOCK=bool

Whether to exclude the Performance Schema rwlock instrumentation. The default is OFF (include). This option was added in MySQL 5.7.3.

-DDISABLE_PSI_SOCKET=bool

Whether to exclude the Performance Schema socket instrumentation. The default is OFF (include). This option was added in MySQL 5.7.3.

• -DDISABLE_PSI_SP=bool

Whether to exclude the Performance Schema stored program instrumentation. The default is OFF (include). This option was added in MySQL 5.7.3.

• -DDISABLE PSI STAGE=bool

Whether to exclude the Performance Schema stage instrumentation. The default is OFF (include). This option was added in MySQL 5.7.3.

• -DDISABLE PSI STATEMENT=bool

Whether to exclude the Performance Schema statement instrumentation. The default is OFF (include). This option was added in MySQL 5.7.3.

• -DDISABLE_PSI_STATEMENT_DIGEST=bool

Whether to exclude the Performance Schema statement_digest instrumentation. The default is OFF (include). This option was added in MySQL 5.7.3.

• -DDISABLE PSI TABLE=bool

Whether to exclude the Performance Schema table instrumentation. The default is OFF (include). This option was added in MySQL 5.7.3.

• -DDOWNLOAD BOOST=bool

Whether to download the Boost library. The default is OFF. This option was added in MySQL 5.7.5.

See the WITH_BOOST option for additional discussion about using Boost.

• -DDOWNLOAD_BOOST_TIMEOUT=seconds

The timeout in seconds for downloading the Boost library. The default is 600 seconds. This option was added in MySQL 5.7.6.

See the WITH_BOOST option for additional discussion about using Boost.

• -DENABLE_DEBUG_SYNC=bool

Whether to compile the Debug Sync facility into the server. This facility is used for testing and debugging. This option is enabled by default, but has no effect unless MySQL is configured with debugging enabled. If debugging is enabled and you want to disable Debug Sync, use – DENABLE_DEBUG_SYNC=0.

When compiled in, Debug Sync is disabled by default at runtime. To enable it, start mysqld with the --debug-sync-timeout=N option, where N is a timeout value greater than 0. (The default value is 0, which disables Debug Sync.) N becomes the default timeout for individual synchronization points.

As of MySQL 5.7.8, sync debug checking for the InnoDB storage engine is available when debugging support is compiled in using the WITH_DEBUG option.

For a description of the Debug Sync facility and how to use synchronization points, see MySQL Internals: Test Synchronization.

• -DENABLE DOWNLOADS=bool

Whether to download optional files. For example, with this option enabled, CMake downloads the Google Test distribution that is used by the test suite to run unit tests.

• -DENABLE_DTRACE=bool

Whether to include support for DTrace probes. For information about DTrace, wee Tracing mysqld Using DTrace

• -DENABLE_GCOV=bool

Whether to include gcov support (Linux only).

• -DENABLE GPROF=bool

Whether to enable gprof (optimized Linux builds only).

• -DENABLED_LOCAL_INFILE=boo1

Whether to enable LOCAL capability in the client library for LOAD DATA INFILE.

This option controls client-side LOCAL capability, but the capability can be set on the server side at server startup with the --local-infile option. See Security Issues with LOAD DATA LOCAL.

• -DENABLED_PROFILING=bool

Whether to enable query profiling code (for the SHOW PROFILE and SHOW PROFILES statements).

• -DFORCE UNSUPPORTED COMPILER=bool

By default, CMake checks for minimum versions of supported compilers: gcc 4.4 (Linux, Solaris); Sun Studio 12u2 (Solaris client library); Clang 3.3 (OS X, FreeBSD). To disable this check, use - DFORCE_UNSUPPORTED_COMPILER=ON. This option was added in MySQL 5.7.5.

• -DIGNORE_AIO_CHECK=bool

If the <code>-DBUILD_CONFIG=mysql_release</code> option is given on Linux, the <code>libaio</code> library must be linked in by default. If you do not have <code>libaio</code> or do not want to install it, you can suppress the check for it by <code>specifying -DIGNORE_AIO_CHECK=1</code>.

-DINNODB_PAGE_ATOMIC_REF_COUNT=bool

Whether to enable or disable atomic page reference counting. Fetching and releasing pages from the buffer pool and tracking the page state are expensive and complex operations. Using a page mutex to track these operations does not scale well. With INNODB_PAGE_ATOMIC_REF_COUNT=ON
(default), fetch and release is tracked using atomics where available. For platforms that do not support atomics, set INNODB_PAGE_ATOMIC_REF_COUNT=OFF
to disable atomic page reference counting.

When atomic page reference counting is enabled (default), "[Note] InnoDB: Using atomics to ref count buffer pool pages" is printed to the error log at server startup. If atomic page reference counting is disabled, "[Note] InnoDB: Using mutexes to ref count buffer pool pages" is printed instead.

INNODB_PAGE_ATOMIC_REF_COUNT was introduced with the fix for MySQL Bug #68079. The option is removed in MySQL 5.7.5. Support for atomics is required to build MySQL as of MySQL 5.7.5, which makes the option obsolete.

• -DMAX_INDEXES=num

The maximum number of indexes per table. The default is 64. The maximum is 255. Values smaller than 64 are ignored and the default of 64 is used.

• -DMYSQL_MAINTAINER_MODE=bool

Whether to enable a MySQL maintainer-specific development environment. If enabled, this option causes compiler warnings to become errors.

-DMUTEX_TYPE=type

The mutex type used by InnoDB. Options include:

- event: Use event mutexes. This is the default value and the original InnoDB mutex implementation.
- sys: Use POSIX mutexes on UNIX systems. Use CRITICAL_SECTION onjects on Windows, if available.
- futex: Use Linux futexes instead of condition variables to schedule waiting threads.
- -DMYSQL_PROJECT_NAME=name

For Windows or OS X, the project name to incorporate into the project file name.

• -DMYSQL_TCP_PORT=port_num

The port number on which the server listens for TCP/IP connections. The default is 3306.

This value can be set at server startup with the --port option.

• -DMYSQL_UNIX_ADDR=file_name

The Unix socket file path on which the server listens for socket connections. This must be an absolute path name. The default is /tmp/mysql.sock.

This value can be set at server startup with the --socket option.

• -DOPTIMIZER_TRACE=bool

Whether to support optimizer tracing. See MySQL Internals: Tracing the Optimizer.

• -DWIN_DEBUG_NO_INLINE=bool

Whether to disable function inlining on Windows. The default is off (inlining enabled). This option was added in MySQL 5.7.6.

-DWITH_ASAN=bool

Whether to enable the AddressSanitizer, for compilers that support it. The default is off. This option was added in MySQL 5.7.3.

• -DWITH_AUTHENTICATION_PAM=bool

Whether to build the PAM authentication plugin, for source trees that include this plugin. (See The PAM Authentication Plugin.) Beginning with MySQL 5.7.2, if this option is specified and the plugin cannot be compiled, the build fails.

-DWITH_BOOST=path_name

As of MySQL 5.7.5, the Boost library is required to build MySQL. These CMake options enable control over the library source location, and whether to download it automatically:

• -DWITH_BOOST=path_name specifies the Boost library directory location. It is also possible to specify the Boost location by setting the BOOST_ROOT or WITH_BOOST environment variable.

As of MySQL 5.7.11, -DWITH_BOOST=system is permitted and indicates that the correct version of Boost is installed on the compilation host in the standard location. In this case, the installed version of Boost is used rather than any version included with a MySQL source distribution.

• -DDOWNLOAD_BOOST=boo1 specifies whether to download the Boost source if it is not present in the specified location. The default is OFF.

• -DDOWNLOAD_BOOST_TIMEOUT=seconds the timeout in seconds for downloading the Boost library. The default is 600 seconds.

For example, if you normally build MySQL placing the object output in the bld subdirectory of your MySQL source tree, you can build with Boost like this:

```
mkdir bld
cd bld
cmake .. -DDOWNLOAD_BOOST=ON -DWITH_BOOST=$HOME/my_boost
```

This causes Boost to be downloaded into the my_boost directory under your home directory. If the required Boost version is already there, no download is done. If the required Boost version changes, the newer version is downloaded.

If Boost is already installed locally and your compiler finds the Boost header files on its own, it may not be necessary to specify the preceding CMake options. However, if the version of Boost required by MySQL changes and the locally installed version has not been upgraded, you may have build problems. Using the CMake options should give you a successful build.

• -DWITH_CLIENT_PROTOCOL_TRACING=bool

Whether to build the client-side protocol tracing framework into the client library. By default, this option is enabled. This option was added in MySQL 5.7.2.

For information about writing protocol trace client plugins, see Writing Protocol Trace Plugins.

See also the WITH_TEST_TRACE_PLUGIN option.

• -DWITH DEBUG=bool

Whether to include debugging support.

Configuring MySQL with debugging support enables you to use the <code>--debug="d,parser_debug"</code> option when you start the server. This causes the Bison parser that is used to process SQL statements to dump a parser trace to the server's standard error output. Typically, this output is written to the error log.

As of MySQL 5.7.8, sync debug checking for the InnoDB storage engine is defined under UNIV_DEBUG and is available when debugging support is compiled in using the WITH_DEBUG option. When debugging support is compiled in, the innodb_sync_debug configuration option can be used to enable or disable InnoDB sync debug checking.

• -DWITH_DEFAULT_FEATURE_SET=bool

Whether to use the flags from cmake/build configurations/feature set.cmake.

• -DWITH EDITLINE=value

Which libedit/editline library to use. The permitted values are bundled (the default) and system.

WITH EDITLINE was added in MySQL 5.7.2. It replaces WITH LIBEDIT, which has been removed.

• -DWITH_EMBEDDED_SERVER=bool

Whether to build the libmysqld embedded server library.

 $\bullet \quad \text{-DWITH_EMBEDDED_SHARED_LIBRARY} = bool$

Whether to build a shared libmysqld embedded server library. This option was added in MySQL 5.7.4.

-DWITH_EXTRA_CHARSETS=name

Which extra character sets to include:

- · all: All character sets. This is the default.
- complex: Complex character sets.
- none: No extra character sets.
- -DWITH INNODB EXTRA DEBUG=bool

Whether to include extra InnoDB debugging support.

Enabling with_INNODB_EXTRA_DEBUG turns on extra InnoDB debug checks. This option can only be enabled when with DEBUG is enabled.

• -DWITH_INNODB_MEMCACHED=bool

Whether to generate memcached shared libraries (libmemcached.so and innodb_engine.so).

• -DWITH_KEYRING_TEST=bool

Whether to build the test program that accompanies the keyring_file plugin. The default is OFF. Test file source code is located in the plugin/keyring/keyring-test directory.

This option was added in MySQL 5.7.11.

-DWITH_LIBEVENT=string

Which libevent library to use. Permitted values are bundled (default), system, and yes. If you specify system or yes, the system library is used if present. If the system library is not found, the bundled libevent library is used. The libevent library is required by InnoDB memcached.

• -DWITH_LIBWRAP=bool

Whether to include libwrap (TCP wrappers) support.

-DWITH_MSAN=bool

Whether to enable MemorySanitizer, for compilers that support it. The default is off.

For this option to have an effect if enabled, all libraries linked to MySQL must also have been compiled with the option enabled.

This option was added in MySQL 5.7.4.

• -DWITH_MECAB={disabled|system|path_name}

Use this option to compile the MeCab parser. If you have installed MeCab to its default installation directory, set -DWITH_MECAB=system. The system option applies to MeCab installations performed from source or from binaries using a native package management utility. If you installed MeCab to a custom installation directory, specify the path to the MeCab installation. For example, -DWITH_MECAB=/opt/mecab. If the system option does not work, specifying the MeCab installation path should work in all cases.

For related information, see MeCab Full-Text Parser Plugin.

• -DWITH_MSCRT_DEBUG=bool

Whether to enable Visual Studio CRT memory leak tracing. The default is OFF. This option was added in MySQL 5.7.6.

-DWITH_PROTOBUF=protobuf_type

Which Protocol Buffers package to use. protobuf_type can be one of the following values:

- bundled: Use the package bundled with the distribution. This is the default.
- system: Use the package installed on the system.

Other values are ignored, with a fallback to bundled.

This option was added in MySQL 5.7.12.

• -DWITH RAPID=bool

Whether to build the rapid development cycle plugins. When enabled, a rapid directory is created in the build tree containing these plugins. When disabled, no rapid directory is created in the build tree. The default is ON, unless the rapid directory is removed from the source tree, in which case the default becomes OFF. This option was added in MySQL 5.7.12.

• -DWITH_SSL={ssl_type|path_name}

The type of SSL support to include or the path name to the OpenSSL installation to use.

- ssl_type can be one of the following values:
 - yes: Use the system SSL library if present, else the library bundled with the distribution.
 - bundled: Use the SSL library bundled with the distribution. This is the default.
 - system: Use the system SSL library.
- path_name is the path name to the OpenSSL installation to use. Using this can be preferable to using the ssl_type value of system, for it can prevent CMake from detecting and using an older or incorrect OpenSSL version installed on the system. (Another permitted way to do the same thing is to set the CMAKE_PREFIX_PATH option to path_name.)

For information about using SSL support, see Using Secure Connections.

• -DWITH SYSTEMD=bool

Whether to enable installation of systemd support files. By default, this option is disabled. When enabled, systemd support files are installed, and scripts such as mysqld_safe and the System V initialization script are not installed. On platforms where systemd is not available, enabling WITH_SYSTEMD results in an error from CMake.

For more information about using systemd, see Managing MySQL Server with systemd. That section also includes information about specifying options previously specified in $[mysqld_safe]$ option groups. Because $mysqld_safe$ is not installed when systemd is used, such options must be specified another way.

This option was added in MySQL 5.7.6.

-DWITH_TEST_TRACE_PLUGIN=bool

Whether to build the test protocol trace client plugin (see Using the Test Protocol Trace Plugin). By default, this option is disabled. Enabling this option has no effect unless the WITH_CLIENT_PROTOCOL_TRACING option is enabled. If MySQL is configured with both options enabled, the libmysqlclient client library is built with the test protocol trace plugin built in, and all the standard MySQL clients load the plugin. However, even when the test plugin is enabled, it has no effect by default. Control over the plugin is afforded using environment variables; see Using the Test Protocol Trace Plugin.

This option was added in MySQL 5.7.2.

Note

Do *not* enable the WITH_TEST_TRACE_PLUGIN option if you want to use your own protocol trace plugins because only one such plugin can be loaded at a time and an error occurs for attempts to load a second one. If you have already built MySQL with the test protocol trace plugin enabled to see how it works, you must rebuild MySQL without it before you can use your own plugins.

For information about writing trace plugins, see Writing Protocol Trace Plugins.

• -DWITH_UBSAN=bool

Whether to enable the Undefined Behavior Sanitizer, for compilers that support it. The default is off. This option was added in MySQL 5.7.6.

• -DWITH_UNIXODBC=1

Enables unixODBC support, for Connector/ODBC.

• -DWITH_VALGRIND=bool

Whether to compile in the Valgrind header files, which exposes the Valgrind API to MySQL code. The default is OFF.

To generate a Valgrind-aware debug build, -DWITH_VALGRIND=1 normally is combined with -DWITH_DEBUG=1. See Building Debug Configurations.

• -DWITH_ZLIB=zlib_type

Some features require that the server be built with compression library support, such as the ${\tt COMPRESS}()$ and ${\tt UNCOMPRESS}()$ functions, and compression of the client/server protocol. The ${\tt WITH_ZLIB}$ indicates the source of ${\tt zlib}$ support:

- bundled: Use the zlib library bundled with the distribution. This is the default.
- system: Use the system zlib library.
- -DWITHOUT SERVER=bool

Whether to build without the MySQL server. The default is OFF, which does build the server.

Compiler Flags

• -DCMAKE_C_FLAGS="flags"

Flags for the C Compiler.

• -DCMAKE_CXX_FLAGS="flags"

Flags for the C++ Compiler.

• -DWITH_DEFAULT_COMPILER_OPTIONS=bool

Whether to use the flags from cmake/build_configurations/compiler_options.cmake.

Note

All optimization flags were carefully chosen and tested by the MySQL build team. Overriding them can lead to unexpected results and is done at your own risk.

• -DSUNPRO_CXX_LIBRARY="lib_name"

Enable linking against libCstd instead of stlport4 on Solaris 10 or later. This works only for client code because the server depends on C++98. Example usage:

```
cmake -DWITHOUT_SERVER=1 -DSUNPRO_CXX_LIBRARY=Cstd
```

This option was added in MySQL 5.7.5.

To specify your own C and C++ compiler flags, for flags that do not affect optimization, use the CMAKE_C_FLAGS and CMAKE_CXX_FLAGS CMake options.

When providing your own compiler flags, you might want to specify CMAKE_BUILD_TYPE as well.

For example, to create a 32-bit release build on a 64-bit Linux machine, do this:

If you set flags that affect optimization (-Onumber), you must set the CMAKE_C_FLAGS_build_type and/or CMAKE_CXX_FLAGS_build_type options, where build_type corresponds to the CMAKE_BUILD_TYPE value. To specify a different optimization for the default build type (RelWithDebInfo) set the CMAKE_C_FLAGS_RELWITHDEBINFO and CMAKE_CXX_FLAGS_RELWITHDEBINFO options. For example, to compile on Linux with -O3 and with debug symbols, do this:

```
shell> cmake .. -DCMAKE_C_FLAGS_RELWITHDEBINFO="-03 -g" \
-DCMAKE_CXX_FLAGS_RELWITHDEBINFO="-03 -g"
```

CMake Options for Compiling MySQL Cluster

The following options are for use when building MySQL Cluster with the MySQL Cluster sources; they are not currently supported when using sources from the MySQL 5.6 Server tree.

• -DMEMCACHED_HOME=dir_name

Perform the build using the memcached (version 1.6 or later) installed in the system directory indicated by dir_name . Files from this installation that are used in the build include the memcached binary, header files, and libraries, as well as the memcached_utilities library and the header file engine_testapp.h.

You must leave this option unset when building ndbmemcache using the bundled memcached sources (WITH_BUNDLED_MEMCACHED option); in other words, the bundled sources are used by default).

While additional CMake options—such as for SASL authorization and for providing dtrace support—are available for use when compiling memcached from external sources, these options are currently not enabled for the memcached sources bundled with MySQL Cluster.

• -DWITH BUNDLED LIBEVENT={ON|OFF}

Use the libevent included in the MySQL Cluster sources when building MySQL Cluster with ndbmemcached support. Enabled by default. OFF causes the system's libevent to be used instead.

• -DWITH_BUNDLED_MEMCACHED={ON | OFF}

Build the memcached sources included in the MySQL Cluster source tree, then use the resulting memcached server when building the ndbmemcache engine. In this case, make install places the memcached binary in the installation bin directory, and the ndbmemcache engine shared library file ndb_engine.so in the installation lib directory.

This option is ON by default.

• -DWITH CLASSPATH=path

Sets the classpath for building MySQL Cluster Connector for Java. The default is empty. This option is ignored if <code>-DWITH_NDB_JAVA=OFF</code> is used.

• -DWITH_ERROR_INSERT={ON|OFF}

Enables error injection in the NDB kernel. For testing only; not intended for use in building production binaries. The default is OFF.

• -DWITH_NDBCLUSTER_STORAGE_ENGINE={ON|OFF}

Build and link in support for the NDB (NDBCLUSTER) storage engine in mysqld. The default is ON.

• -DWITH_NDBCLUSTER={ON|OFF}

This is an alias for with_ndbcluster_storage_engine.

• -DWITH_NDBMTD={ON|OFF}

Build the multi-threaded data node executable ndbmtd. The default is ON.

• -DWITH_NDB_BINLOG={ON|OFF}

Enable binary logging by default in the mysqld built using this option. ON by default.

-DWITH NDB DEBUG={ON | OFF}

Enable building the debug versions of the MySQL Cluster binaries. OFF by default.

-DWITH_NDB_JAVA={ON|OFF}

Enable building MySQL Cluster with Java support, including ClusterJ.

This option is ON by default. If you do not wish to compile MySQL Cluster with Java support, you must disable it explicitly by specifying <code>-DWITH_NDB_JAVA=OFF</code> when running <code>CMake</code>. Otherwise, if Java cannot be found, configuration of the build fails.

• -DWITH_NDB_PORT=port

Causes the MySQL Cluster management server (ndb_mgmd) that is built to use this port by default. If this option is unset, the resulting management server tries to use port 1186 by default.

-DWITH_NDB_TEST={ON|OFF}

If enabled, include a set of NDB API test programs. The default is OFF.

Chapter 5 Dealing with Problems Compiling MySQL

The solution to many problems involves reconfiguring. If you do reconfigure, take note of the following:

- If CMake is run after it has previously been run, it may use information that was gathered during its previous invocation. This information is stored in CMakeCache.txt. When CMake starts up, it looks for that file and reads its contents if it exists, on the assumption that the information is still correct. That assumption is invalid when you reconfigure.
- Each time you run CMake, you must run make again to recompile. However, you may want to remove old object files from previous builds first because they were compiled using different configuration options.

To prevent old object files or configuration information from being used, run the following commands before re-running CMake:

On Unix:

```
shell> make clean
shell> rm CMakeCache.txt
```

On Windows:

```
shell> devenv MySQL.sln /clean shell> del CMakeCache.txt
```

If you build outside of the source tree, remove and recreate your build directory before re-running CMake. For instructions on building outside of the source tree, see How to Build MySQL Server with CMake.

On some systems, warnings may occur due to differences in system include files. The following list describes other problems that have been found to occur most often when compiling MySQL:

• To define which C and C++ compilers to use, you can define the CC and CXX environment variables. For example:

```
shell> CC=gcc
shell> CXX=g++
shell> export CC CXX
```

To specify your own C and C++ compiler flags, use the CMAKE_C_FLAGS and CMAKE_CXX_FLAGS CMake options. See Compiler Flags.

To see what flags you might need to specify, invoke mysql_config with the --cflags and --cxxflags options.

- To see what commands are executed during the compile stage, after using CMake to configure MySQL, run make VERBOSE=1 rather than just make.
- If compilation fails, check whether the MYSQL_MAINTAINER_MODE option is enabled. This mode causes compiler warnings to become errors, so disabling it may enable compilation to proceed.
- If your compile fails with errors such as any of the following, you must upgrade your version of make to GNU make:

```
make: Fatal error in reader: Makefile, line 18:
Badly formed macro assignment
```

Or:

```
make: file `Makefile' line 18: Must be a separator (:
```

Or:

```
pthread.h: No such file or directory
```

Solaris and FreeBSD are known to have troublesome make programs.

GNU make 3.75 is known to work.

• The sql_yacc.cc file is generated from sql_yacc.yy. Normally, the build process does not need to create sql_yacc.cc because MySQL comes with a pregenerated copy. However, if you do need to re-create it, you might encounter this error:

```
"sql_yacc.yy", line xxx fatal: default action causes potential...
```

This is a sign that your version of yacc is deficient. You probably need to install a recent version of bison (the GNU version of yacc) and use that instead.

Versions of bison older than 1.75 may report this error:

```
sql_yacc.yy:#####: fatal error: maximum table size (32767) exceeded
```

The maximum table size is not actually exceeded; the error is caused by bugs in older versions of bison.

For information about acquiring or updating tools, see the system requirements in Chapter 1, *Installing MySQL from Source*.
