mysql> SELECT IS_IPV4_MAPPED(INET6_ATON('::ffff:10.0.5.9'));
-> 1
```

As with `IS_IPV4_COMPAT()` the IPv4 part of an IPv4-mapped address can also be represented using hexadecimal notation:

```
mysql> SELECT
-> IS_IPV4_MAPPED(INET6_ATON('::ffff:192.168.0.1')),
-> IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:0001')),
-> IS_IPV4_MAPPED(INET6_ATON('::ffff:c0a8:1'));
-> 1, 1, 1
```

- `IS_IPV6(expr)`

Returns 1 if the argument is a valid IPv6 address specified as a string, 0 otherwise. This function does not consider IPv4 addresses to be valid IPv6 addresses.

```
mysql> SELECT IS_IPV6('10.0.5.9'), IS_IPV6('::1');
-> 0, 1
```

For a given argument, if `IS_IPV6()` returns 1, `INET6_ATON()` will return non-NULL.

- `IS_USED_LOCK(str)`

Checks whether the lock named `str` is in use (that is, locked). If so, it returns the connection identifier of the client session that holds the lock. Otherwise, it returns NULL.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `IS_UUID(string_uuid)`

Returns 1 if the argument is a valid string-format UUID, 0 if the argument is not a valid UUID, and `NULL` if the argument is `NULL`.

“Valid” means that the value is in a format that can be parsed. That is, it has the correct length and contains only the permitted characters (hexadecimal digits in any lettercase and, optionally, dashes and curly braces). This format is most common:

```
aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee
```

These other formats are also permitted:

```
aaaaaaaaabbbbccccddddeeeeeeeeeeee
{aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee}
```

For the meanings of fields within the value, see the `UUID()` function description.

```
mysql> SELECT IS_UUID('6ccd780c-baba-1026-9564-5b8c656024db');
+-----+
| IS_UUID('6ccd780c-baba-1026-9564-5b8c656024db') |
+-----+
|                                     1 |
+-----+
mysql> SELECT IS_UUID('6CCD780C-BABA-1026-9564-5B8C656024DB');
+-----+
| IS_UUID('6CCD780C-BABA-1026-9564-5B8C656024DB') |
+-----+
|                                     1 |
+-----+
mysql> SELECT IS_UUID('6ccd780cbaba102695645b8c656024db');
+-----+
| IS_UUID('6ccd780cbaba102695645b8c656024db') |
+-----+
|                                     1 |
+-----+
mysql> SELECT IS_UUID('{6ccd780c-baba-1026-9564-5b8c656024db}');
+-----+
| IS_UUID('{6ccd780c-baba-1026-9564-5b8c656024db}') |
+-----+
|                                     1 |
+-----+
mysql> SELECT IS_UUID('6ccd780c-baba-1026-9564-5b8c6560');
+-----+
| IS_UUID('6ccd780c-baba-1026-9564-5b8c6560') |
+-----+
|                                     0 |
+-----+
mysql> SELECT IS_UUID(RAND());
+-----+
| IS_UUID(RAND()) |
+-----+
|                 0 |
+-----+
```

- `MASTER_POS_WAIT(log_name, log_pos [, timeout] [, channel_name])`

This function is useful for control of master/slave synchronization. It blocks until the slave has read and applied all updates up to the specified position in the master log. The return value is the number of log events the slave had to wait for to advance to the specified position. The function returns `NULL` if the slave SQL thread is not started, the slave's master information is not initialized, the arguments

are incorrect, or an error occurs. It returns `-1` if the timeout has been exceeded. If the slave SQL thread stops while `MASTER_POS_WAIT()` is waiting, the function returns `NULL`. If the slave is past the specified position, the function returns immediately.

If a `timeout` value is specified, `MASTER_POS_WAIT()` stops waiting when `timeout` seconds have elapsed. `timeout` must be greater than 0; a zero or negative `timeout` means no timeout.

The optional `channel` enables you to choose which replication channel the function applies to. See [Section 18.2.3, “Replication Channels”](#) for more information.

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `NAME_CONST(name, value)`

Returns the given value. When used to produce a result set column, `NAME_CONST()` causes the column to have the given name. The arguments should be constants.

```
mysql> SELECT NAME_CONST('myname', 14);
+-----+
| myname |
+-----+
|      14 |
+-----+
```

This function is for internal use only. The server uses it when writing statements from stored programs that contain references to local program variables, as described in [Section 23.7, “Binary Logging of Stored Programs”](#). You might see this function in the output from `mysqlbinlog`.

For your applications, you can obtain exactly the same result as in the example just shown by using simple aliasing, like this:

```
mysql> SELECT 14 AS myname;
+-----+
| myname |
+-----+
|      14 |
+-----+
1 row in set (0.00 sec)
```

See [Section 13.2.10, “SELECT Syntax”](#), for more information about column aliases.

- `RELEASE_ALL_LOCKS()`

Releases all named locks held by the current session and returns the number of locks released (0 if there were none)

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `RELEASE_LOCK(str)`

Releases the lock named by the string `str` that was obtained with `GET_LOCK()`. Returns `1` if the lock was released, `0` if the lock was not established by this thread (in which case the lock is not released), and `NULL` if the named lock did not exist. The lock does not exist if it was never obtained by a call to `GET_LOCK()` or if it has previously been released.

The `DO` statement is convenient to use with `RELEASE_LOCK()`. See [Section 13.2.3, “DO Syntax”](#).

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `SLEEP(duration)`

Sleeps (pauses) for the number of seconds given by the *duration* argument, then returns 0. The duration may have a fractional part. If the argument is `NULL` or negative, `SLEEP()` produces a warning, or an error in strict SQL mode.

When sleep returns normally (without interruption), it returns 0:

```
mysql> SELECT SLEEP(1000);
+-----+
| SLEEP(1000) |
+-----+
|           0 |
+-----+
```

When `SLEEP()` is the only thing invoked by a query that is interrupted, it returns 1 and the query itself returns no error. This is true whether the query is killed or times out:

- This statement is interrupted using `KILL QUERY` from another session:

```
mysql> SELECT SLEEP(1000);
+-----+
| SLEEP(1000) |
+-----+
|           1 |
+-----+
```

- This statement is interrupted by timing out:

```
mysql> SELECT /*+ MAX_EXECUTION_TIME(1) */ SLEEP(1000);
+-----+
| SLEEP(1000) |
+-----+
|           1 |
+-----+
```

When `SLEEP()` is only part of a query that is interrupted, the query returns an error:

- This statement is interrupted using `KILL QUERY` from another session:

```
mysql> SELECT 1 FROM t1 WHERE SLEEP(1000);
ERROR 1317 (70100): Query execution was interrupted
```

- This statement is interrupted by timing out:

```
mysql> SELECT /*+ MAX_EXECUTION_TIME(1000) */ 1 FROM t1 WHERE SLEEP(1000);
ERROR 3024 (HY000): Query execution was interrupted, maximum statement
execution time exceeded
```

This function is unsafe for statement-based replication. A warning is logged if you use this function when `binlog_format` is set to `STATEMENT`.

- `UUID()`

Returns a Universal Unique Identifier (UUID) generated according to RFC 4122, “A Universally Unique Identifier (UUID) URN Namespace” (<http://www.ietf.org/rfc/rfc4122.txt>).

A UUID is designed as a number that is globally unique in space and time. Two calls to `UUID()` are expected to generate two different values, even if these calls are performed on two separate devices not connected to each other.

**Warning**

Although `UUID()` values are intended to be unique, they are not necessarily unguessable or unpredictable. If unpredictability is required, UUID values should be generated some other way.

`UUID()` returns a value that conforms to UUID version 1 as described in RFC 4122. The value is a 128-bit number represented as a `utf8` string of five hexadecimal numbers in `aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee` format:

- The first three numbers are generated from the low, middle, and high parts of a timestamp. The high part also includes the UUID version number.
- The fourth number preserves temporal uniqueness in case the timestamp value loses monotonicity (for example, due to daylight saving time).
- The fifth number is an IEEE 802 node number that provides spatial uniqueness. A random number is substituted if the latter is not available (for example, because the host device has no Ethernet card, or it is unknown how to find the hardware address of an interface on the host operating system). In this case, spatial uniqueness cannot be guaranteed. Nevertheless, a collision should have very low probability.

The MAC address of an interface is taken into account only on FreeBSD and Linux. On other operating systems, MySQL uses a randomly generated 48-bit number.

```
mysql> SELECT UUID();
-> '6ccd780c-baba-1026-9564-5b8c656024db'
```

To convert between string and binary UUID values, use the `UUID_TO_BIN()` and `BIN_TO_UUID()` functions. To check whether a string is a valid UUID value, use the `IS_UUID()` function.

**Note**

`UUID()` does not work with statement-based replication.

- `UUID_SHORT()`

Returns a “short” universal identifier as a 64-bit unsigned integer. Values returned by `UUID_SHORT()` differ from the string-format 128-bit identifiers returned by the `UUID()` function and have different uniqueness properties. The value of `UUID_SHORT()` is guaranteed to be unique if the following conditions hold:

- The `server_id` value of the current server is between 0 and 255 and is unique among your set of master and slave servers
- You do not set back the system time for your server host between `mysqld` restarts
- You invoke `UUID_SHORT()` on average fewer than 16 million times per second between `mysqld` restarts

The `UUID_SHORT()` return value is constructed this way:

```
(server_id & 255) << 56
+ (server_startup_time_in_seconds << 24)
+ incremented_variable++;
```

```
mysql> SELECT UUID_SHORT();
-> 92395783831158784
```

**Note**

`UUID_SHORT()` does not work with statement-based replication.

- `UUID_TO_BIN(string_uuid)`, `UUID_TO_BIN(string_uuid, swap_flag)`

Converts a string UUID to a binary UUID and returns the result. (The `IS_UUID()` function description lists the permitted string UUID formats.) The return binary UUID is a `VARBINARY(16)` value. If the UUID argument is `NULL`, the return value is `NULL`. If any argument is invalid, an error occurs.

`UUID_TO_BIN()` takes one or two arguments:

- The one-argument form takes a string UUID value. The binary result is in the same order as the string argument.
- The two-argument form takes a string UUID value and a flag value:
 - If `swap_flag` is 0, the two-argument form is equivalent to the one-argument form. The binary result is in the same order as the string argument.
 - If `swap_flag` is 1, the format of the return value differs: The time-low and time-high parts (the first and third groups of hexadecimal digits, respectively) are swapped. This moves the more rapidly varying part to the right and can improve indexing efficiency if the result is stored in an indexed column.

Time-part swapping assumes the use of UUID version 1 values, such as are generated by the `UUID()` function. For UUID values produced by other means that do not follow version 1 format, time-part swapping provides no benefit. For details about version 1 format, see the `UUID()` function description.

Suppose that you have the following string UUID value:

```
mysql> SET @uuid = '6ccd780c-baba-1026-9564-5b8c656024db';
```

To convert the string UUID to binary with or without time-part swapping, use `UUID_TO_BIN()`:

```
mysql> SELECT HEX(UUID_TO_BIN(@uuid));
+-----+
| HEX(UUID_TO_BIN(@uuid)) |
+-----+
| 6CCD780CBABA102695645B8C656024DB |
+-----+
mysql> SELECT HEX(UUID_TO_BIN(@uuid, 0));
+-----+
| HEX(UUID_TO_BIN(@uuid, 0)) |
+-----+
| 6CCD780CBABA102695645B8C656024DB |
+-----+
mysql> SELECT HEX(UUID_TO_BIN(@uuid, 1));
+-----+
| HEX(UUID_TO_BIN(@uuid, 1)) |
+-----+
| 1026BABA6CCD780C95645B8C656024DB |
+-----+
```

To convert a binary UUID returned by `UUID_TO_BIN()` to a string UUID, use `BIN_TO_UUID()`. If you produce a binary UUID by calling `UUID_TO_BIN()` with a second argument of 1 to swap time parts, you should also pass a second argument of 1 to `BIN_TO_UUID()` to unswap the time parts when converting the binary UUID back to a string UUID:

```
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid));
+-----+
| BIN_TO_UUID(UUID_TO_BIN(@uuid)) |
+-----+
| 6ccd780c-baba-1026-9564-5b8c656024db |
+-----+
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid,0),0);
+-----+
| BIN_TO_UUID(UUID_TO_BIN(@uuid,0),0) |
+-----+
| 6ccd780c-baba-1026-9564-5b8c656024db |
+-----+
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid,1),1);
+-----+
| BIN_TO_UUID(UUID_TO_BIN(@uuid,1),1) |
+-----+
| 6ccd780c-baba-1026-9564-5b8c656024db |
+-----+
```

If the use of time-part swapping is not the same for the conversion in both directions, the original UUID will not be recovered properly:

```
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid,0),1);
+-----+
| BIN_TO_UUID(UUID_TO_BIN(@uuid,0),1) |
+-----+
| baba1026-780c-6ccd-9564-5b8c656024db |
+-----+
mysql> SELECT BIN_TO_UUID(UUID_TO_BIN(@uuid,1),0);
+-----+
| BIN_TO_UUID(UUID_TO_BIN(@uuid,1),0) |
+-----+
| 1026baba-6ccd-780c-9564-5b8c656024db |
+-----+
```

- `VALUES(col_name)`

In an `INSERT ... ON DUPLICATE KEY UPDATE` statement, you can use the `VALUES(col_name)` function in the `UPDATE` clause to refer to column values from the `INSERT` portion of the statement. In other words, `VALUES(col_name)` in the `UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in the `ON DUPLICATE KEY UPDATE` clause of `INSERT` statements and returns `NULL` otherwise. See [Section 13.2.6.3, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).

```
mysql> INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
-> ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

12.22 Precision Math

MySQL provides support for precision math: numeric value handling that results in extremely accurate results and a high degree control over invalid values. Precision math is based on these two features:

- SQL modes that control how strict the server is about accepting or rejecting invalid data.
- The MySQL library for fixed-point arithmetic.

These features have several implications for numeric operations and provide a high degree of compliance with standard SQL:

- **Precise calculations:** For exact-value numbers, calculations do not introduce floating-point errors. Instead, exact precision is used. For example, MySQL treats a number such as `.0001` as an exact

value rather than as an approximation, and summing it 10,000 times produces a result of exactly 1, not a value that is merely “close” to 1.

- **Well-defined rounding behavior:** For exact-value numbers, the result of `ROUND()` depends on its argument, not on environmental factors such as how the underlying C library works.
- **Platform independence:** Operations on exact numeric values are the same across different platforms such as Windows and Unix.
- **Control over handling of invalid values:** Overflow and division by zero are detectable and can be treated as errors. For example, you can treat a value that is too large for a column as an error rather than having the value truncated to lie within the range of the column's data type. Similarly, you can treat division by zero as an error rather than as an operation that produces a result of `NULL`. The choice of which approach to take is determined by the setting of the server SQL mode.

The following discussion covers several aspects of how precision math works, including possible incompatibilities with older applications. At the end, some examples are given that demonstrate how MySQL handles numeric operations precisely. For information about controlling the SQL mode, see [Section 5.1.8, “Server SQL Modes”](#).

12.22.1 Types of Numeric Values

The scope of precision math for exact-value operations includes the exact-value data types (integer and `DECIMAL` types) and exact-value numeric literals. Approximate-value data types and numeric literals are handled as floating-point numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: `1`, `.2`, `3.4`, `-5`, `-6.78`, `+9.10`.

Approximate-value numeric literals are represented in scientific notation with a mantissa and exponent. Either or both parts may be signed. Examples: `1.2E3`, `1.2E-3`, `-1.2E3`, `-1.2E-3`.

Two numbers that look similar may be treated differently. For example, `2.34` is an exact-value (fixed-point) number, whereas `2.34E0` is an approximate-value (floating-point) number.

The `DECIMAL` data type is a fixed-point type and calculations are exact. In MySQL, the `DECIMAL` type has several synonyms: `NUMERIC`, `DEC`, `FIXED`. The integer types also are exact-value types.

The `FLOAT` and `DOUBLE` data types are floating-point types and calculations are approximate. In MySQL, types that are synonymous with `FLOAT` or `DOUBLE` are `DOUBLE PRECISION` and `REAL`.

12.22.2 DECIMAL Data Type Characteristics

This section discusses the characteristics of the `DECIMAL` data type (and its synonyms), with particular regard to the following topics:

- Maximum number of digits
- Storage format
- Storage requirements
- The nonstandard MySQL extension to the upper range of `DECIMAL` columns

The declaration syntax for a `DECIMAL` column is `DECIMAL(M,D)`. The ranges of values for the arguments are as follows:

- `M` is the maximum number of digits (the precision). It has a range of 1 to 65.
- `D` is the number of digits to the right of the decimal point (the scale). It has a range of 0 to 30 and must be no larger than `M`.

The maximum value of 65 for *M* means that calculations on `DECIMAL` values are accurate up to 65 digits. This limit of 65 digits of precision also applies to exact-value numeric literals, so the maximum range of such literals differs from before.

Values for `DECIMAL` columns are stored using a binary format that packs nine decimal digits into 4 bytes. The storage requirements for the integer and fractional parts of each value are determined separately. Each multiple of nine digits requires 4 bytes, and any remaining digits left over require some fraction of 4 bytes. The storage required for remaining digits is given by the following table.

Leftover Digits	Number of Bytes
0	0
1–2	1
3–4	2
5–6	3
7–9	4

For example, a `DECIMAL(18,9)` column has nine digits on either side of the decimal point, so the integer part and the fractional part each require 4 bytes. A `DECIMAL(20,6)` column has fourteen integer digits and six fractional digits. The integer digits require four bytes for nine of the digits and 3 bytes for the remaining five digits. The six fractional digits require 3 bytes.

`DECIMAL` columns do not store a leading `+` character or `-` character or leading `0` digits. If you insert `+0003.1` into a `DECIMAL(5,1)` column, it is stored as `3.1`. For negative numbers, a literal `-` character is not stored.

`DECIMAL` columns do not permit values larger than the range implied by the column definition. For example, a `DECIMAL(3,0)` column supports a range of `-999` to `999`. A `DECIMAL(M,D)` column permits at most $M - D$ digits to the left of the decimal point.

The SQL standard requires that the precision of `NUMERIC(M,D)` be *exactly* *M* digits. For `DECIMAL(M,D)`, the standard requires a precision of at least *M* digits but permits more. In MySQL, `DECIMAL(M,D)` and `NUMERIC(M,D)` are the same, and both have a precision of exactly *M* digits.

For a full explanation of the internal format of `DECIMAL` values, see the file `strings/decimal.c` in a MySQL source distribution. The format is explained (with an example) in the `decimal2bin()` function.

12.22.3 Expression Handling

With precision math, exact-value numbers are used as given whenever possible. For example, numbers in comparisons are used exactly as given without a change in value. In strict SQL mode, for `INSERT` into a column with an exact data type (`DECIMAL` or integer), a number is inserted with its exact value if it is within the column range. When retrieved, the value should be the same as what was inserted. (If strict SQL mode is not enabled, truncation for `INSERT` is permissible.)

Handling of a numeric expression depends on what kind of values the expression contains:

- If any approximate values are present, the expression is approximate and is evaluated using floating-point arithmetic.
- If no approximate values are present, the expression contains only exact values. If any exact value contains a fractional part (a value following the decimal point), the expression is evaluated using `DECIMAL` exact arithmetic and has a precision of 65 digits. The term “exact” is subject to the limits of what can be represented in binary. For example, `1.0/3.0` can be approximated in decimal notation as `.333...`, but not written as an exact number, so `(1.0/3.0)*3.0` does not evaluate to exactly `1.0`.
- Otherwise, the expression contains only integer values. The expression is exact and is evaluated using integer arithmetic and has a precision the same as `BIGINT` (64 bits).

If a numeric expression contains any strings, they are converted to double-precision floating-point values and the expression is approximate.

Inserts into numeric columns are affected by the SQL mode, which is controlled by the `sql_mode` system variable. (See [Section 5.1.8, “Server SQL Modes”](#).) The following discussion mentions strict mode (selected by the `STRICT_ALL_TABLES` or `STRICT_TRANS_TABLES` mode values) and `ERROR_FOR_DIVISION_BY_ZERO`. To turn on all restrictions, you can simply use `TRADITIONAL` mode, which includes both strict mode values and `ERROR_FOR_DIVISION_BY_ZERO`:

```
mysql> SET sql_mode='TRADITIONAL';
```

If a number is inserted into an exact type column (`DECIMAL` or integer), it is inserted with its exact value if it is within the column range.

If the value has too many digits in the fractional part, rounding occurs and a warning is generated. Rounding is done as described in [Section 12.22.4, “Rounding Behavior”](#).

If the value has too many digits in the integer part, it is too large and is handled as follows:

- If strict mode is not enabled, the value is truncated to the nearest legal value and a warning is generated.
- If strict mode is enabled, an overflow error occurs.

Underflow is not detected, so underflow handling is undefined.

For inserts of strings into numeric columns, conversion from string to number is handled as follows if the string has nonnumeric contents:

- A string that does not begin with a number cannot be used as a number and produces an error in strict mode, or a warning otherwise. This includes the empty string.
- A string that begins with a number can be converted, but the trailing nonnumeric portion is truncated. If the truncated portion contains anything other than spaces, this produces an error in strict mode, or a warning otherwise.

By default, division by zero produces a result of `NULL` and no warning. By setting the SQL mode appropriately, division by zero can be restricted.

With the `ERROR_FOR_DIVISION_BY_ZERO` SQL mode enabled, MySQL handles division by zero differently:

- If strict mode is not enabled, a warning occurs.
- If strict mode is enabled, inserts and updates involving division by zero are prohibited, and an error occurs.

In other words, inserts and updates involving expressions that perform division by zero can be treated as errors, but this requires `ERROR_FOR_DIVISION_BY_ZERO` in addition to strict mode.

Suppose that we have this statement:

```
INSERT INTO t SET i = 1/0;
```

This is what happens for combinations of strict and `ERROR_FOR_DIVISION_BY_ZERO` modes.

<code>sql_mode</code> Value	Result
' ' (Default)	No warning, no error; <code>i</code> is set to <code>NULL</code> .
strict	No warning, no error; <code>i</code> is set to <code>NULL</code> .
<code>ERROR_FOR_DIVISION_BY_ZERO</code>	Warning, no error; <code>i</code> is set to <code>NULL</code> .

sql_mode Value	Result
strict,ERROR_FOR_DIVISION_BY_ZERO	Error condition; no row is inserted.

12.22.4 Rounding Behavior

This section discusses precision math rounding for the `ROUND()` function and for inserts into columns with exact-value types (`DECIMAL` and integer).

The `ROUND()` function rounds differently depending on whether its argument is exact or approximate:

- For exact-value numbers, `ROUND()` uses the “round half up” rule: A value with a fractional part of .5 or greater is rounded up to the next integer if positive or down to the next integer if negative. (In other words, it is rounded away from zero.) A value with a fractional part less than .5 is rounded down to the next integer if positive or up to the next integer if negative.
- For approximate-value numbers, the result depends on the C library. On many systems, this means that `ROUND()` uses the “round to nearest even” rule: A value with any fractional part is rounded to the nearest even integer.

The following example shows how rounding differs for exact and approximate values:

```
mysql> SELECT ROUND(2.5), ROUND(25E-1);
+-----+-----+
| ROUND(2.5) | ROUND(25E-1) |
+-----+-----+
| 3          | 2            |
+-----+-----+
```

For inserts into a `DECIMAL` or integer column, the target is an exact data type, so rounding uses “round half away from zero,” regardless of whether the value to be inserted is exact or approximate:

```
mysql> CREATE TABLE t (d DECIMAL(10,0));
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t VALUES(2.5),(2.5E0);
Query OK, 2 rows affected, 2 warnings (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 2

mysql> SELECT d FROM t;
+-----+
| d     |
+-----+
| 3     |
| 3     |
+-----+
```

12.22.5 Precision Math Examples

This section provides some examples that show precision math query results in MySQL. These examples demonstrate the principles described in [Section 12.22.3, “Expression Handling”](#), and [Section 12.22.4, “Rounding Behavior”](#).

Example 1. Numbers are used with their exact value as given when possible:

```
mysql> SELECT (.1 + .2) = .3;
+-----+
| (.1 + .2) = .3 |
+-----+
| 1              |
+-----+
```

For floating-point values, results are inexact:

```
mysql> SELECT (.1E0 + .2E0) = .3E0;
+-----+
| (.1E0 + .2E0) = .3E0 |
+-----+
| 0 |
+-----+
```

Another way to see the difference in exact and approximate value handling is to add a small number to a sum many times. Consider the following stored procedure, which adds `.0001` to a variable 1,000 times.

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 0;
  DECLARE d DECIMAL(10,4) DEFAULT 0;
  DECLARE f FLOAT DEFAULT 0;
  WHILE i < 10000 DO
    SET d = d + .0001;
    SET f = f + .0001E0;
    SET i = i + 1;
  END WHILE;
  SELECT d, f;
END;
```

The sum for both `d` and `f` logically should be 1, but that is true only for the decimal calculation. The floating-point calculation introduces small errors:

```
+-----+-----+
| d      | f      |
+-----+-----+
| 1.0000 | 0.999999999999991 |
+-----+-----+
```

Example 2. Multiplication is performed with the scale required by standard SQL. That is, for two numbers `X1` and `X2` that have scale `S1` and `S2`, the scale of the result is `S1 + S2`:

```
mysql> SELECT .01 * .01;
+-----+
| .01 * .01 |
+-----+
| 0.0001    |
+-----+
```

Example 3. Rounding behavior for exact-value numbers is well-defined:

Rounding behavior (for example, with the `ROUND()` function) is independent of the implementation of the underlying C library, which means that results are consistent from platform to platform.

- Rounding for exact-value columns (`DECIMAL` and integer) and exact-valued numbers uses the “round half away from zero” rule. Values with a fractional part of `.5` or greater are rounded away from zero to the nearest integer, as shown here:

```
mysql> SELECT ROUND(2.5), ROUND(-2.5);
+-----+-----+
| ROUND(2.5) | ROUND(-2.5) |
+-----+-----+
| 3          | -3          |
+-----+-----+
```

- Rounding for floating-point values uses the C library, which on many systems uses the “round to nearest even” rule. Values with any fractional part on such systems are rounded to the nearest even integer:

```
mysql> SELECT ROUND(2.5E0), ROUND(-2.5E0);
+-----+-----+
| ROUND(2.5E0) | ROUND(-2.5E0) |
+-----+-----+
|          2 |          -2 |
+-----+-----+
```

Example 4. In strict mode, inserting a value that is out of range for a column causes an error, rather than truncation to a legal value.

When MySQL is not running in strict mode, truncation to a legal value occurs:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO t SET i = 128;
Query OK, 1 row affected, 1 warning (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i |
+-----+
| 127 |
+-----+
1 row in set (0.00 sec)
```

However, an error occurs if strict mode is in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 128;
ERROR 1264 (22003): Out of range value adjusted for column 'i' at row 1

mysql> SELECT i FROM t;
Empty set (0.00 sec)
```

Example 5: In strict mode and with `ERROR_FOR_DIVISION_BY_ZERO` set, division by zero causes an error, not a result of `NULL`.

In nonstrict mode, division by zero has a result of `NULL`:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT i FROM t;
+-----+
| i |
+-----+
| NULL |
+-----+
1 row in set (0.03 sec)
```

However, division by zero is an error if the proper SQL modes are in effect:

```
mysql> SET sql_mode='STRICT_ALL_TABLES,ERROR_FOR_DIVISION_BY_ZERO';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t (i TINYINT);
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t SET i = 1 / 0;
ERROR 1365 (22012): Division by 0

mysql> SELECT i FROM t;
Empty set (0.01 sec)
```

Example 6. Exact-value literals are evaluated as exact values.

Approximate-value literals are evaluated using floating point, but exact-value literals are handled as `DECIMAL`:

```
mysql> CREATE TABLE t SELECT 2.5 AS a, 25E-1 AS b;
Query OK, 1 row affected (0.01 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> DESCRIBE t;
+-----+-----+-----+-----+-----+-----+
| Field | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| a     | decimal(2,1) unsigned | NO   |     | 0.0     |       |
| b     | double               | NO   |     | 0       |       |
+-----+-----+-----+-----+-----+-----+
2 rows in set (0.01 sec)
```

Example 7. If the argument to an aggregate function is an exact numeric type, the result is also an exact numeric type, with a scale at least that of the argument.

Consider these statements:

```
mysql> CREATE TABLE t (i INT, d DECIMAL, f FLOAT);
mysql> INSERT INTO t VALUES(1,1,1);
mysql> CREATE TABLE y SELECT AVG(i), AVG(d), AVG(f) FROM t;
```

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type:

```
mysql> DESCRIBE y;
+-----+-----+-----+-----+-----+-----+
| Field | Type                | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| AVG(i) | decimal(14,4)      | YES  |     | NULL    |       |
| AVG(d) | decimal(14,4)      | YES  |     | NULL    |       |
| AVG(f) | double              | YES  |     | NULL    |       |
+-----+-----+-----+-----+-----+-----+
```

The result is a double only for the floating-point argument. For exact type arguments, the result is also an exact type.

Chapter 13 SQL Statement Syntax

Table of Contents

13.1 Data Definition Statements	1598
13.1.1 ALTER DATABASE Syntax	1598
13.1.2 ALTER EVENT Syntax	1599

13.1.28 DROP VIEW Syntax	1685
13.1.29 RENAME TABLE Syntax	1685
13.1.30 TRUNCATE TABLE Syntax	1686
13.2 Data Manipulation Statements	1688
13.2.1 CALL Syntax	1688
13.2.2 DELETE Syntax	1689
13.2.3 DO Syntax	1693
13.2.4 HANDLER Syntax	1694
13.2.5 IMPORT TABLE Syntax	1695
13.2.6 INSERT Syntax	1698
13.2.7 LOAD DATA INFILE Syntax	1704
13.2.8 LOAD XML Syntax	1714
13.2.9 REPLACE Syntax	1721
13.2.10 SELECT Syntax	1723
13.2.11 Subquery Syntax	1740
13.2.12 UPDATE Syntax	1763
13.3 Transactional and Locking Statements	1765
13.3.1 START TRANSACTION, COMMIT, and ROLLBACK Syntax	1765
13.3.2 Statements That Cannot Be Rolled Back	1768
13.3.3 Statements That Cause an Implicit Commit	1768
13.3.4 SAVEPOINT, ROLLBACK TO SAVEPOINT, and RELEASE SAVEPOINT Syntax	1769
13.3.5 LOCK TABLES and UNLOCK TABLES Syntax	1770
13.3.6 SET TRANSACTION Syntax	1776
13.3.7 XA Transactions	1777

13.4 Replication Statements	1781
13.4.1 SQL Statements for Controlling Master Servers	1781
13.4.2 SQL Statements for Controlling Slave Servers	1784
13.4.3 SQL Statements for Controlling Group Replication	1798
13.5 Prepared SQL Statement Syntax	1798
13.5.1 PREPARE Syntax	1802
13.5.2 EXECUTE Syntax	1802
13.5.3 DEALLOCATE PREPARE Syntax	1803
13.6 Compound-Statement Syntax	1803
13.6.1 BEGIN ... END Compound-Statement Syntax	1803
13.6.2 Statement Label Syntax	1803
13.6.3 DECLARE Syntax	1804
13.6.4 Variables in Stored Programs	1804
13.6.5 Flow Control Statements	1806
13.6.6 Cursors	1810
13.6.7 Condition Handling	1812
13.7 Database Administration Statements	1839
13.7.1 Account Management Statements	1839
13.7.2 Table Maintenance Statements	1871
13.7.3 Component, Plugin, and User-Defined Function Statements	1882
13.7.4 SET Syntax	1886
13.7.5 SHOW Syntax	1891
13.7.6 Other Administrative Statements	1937
13.8 Utility Statements	1946
13.8.1 DESCRIBE Syntax	1946
13.8.2 EXPLAIN Syntax	1947
13.8.3 HELP Syntax	1949
13.8.4 USE Syntax	1951

This chapter describes the syntax for the [SQL](#) statements supported by MySQL.

13.1 Data Definition Statements

13.1.1 ALTER DATABASE Syntax

```
ALTER {DATABASE | SCHEMA} [db_name]
    alter_specification ...

alter_specification:
    [DEFAULT] CHARACTER SET [=] charset_name
    | [DEFAULT] COLLATE [=] collation_name
```

[ALTER DATABASE](#) enables you to change the overall characteristics of a database. These characteristics are stored in the data dictionary. To use [ALTER DATABASE](#), you need the [ALTER](#) privilege on the database. [ALTER SCHEMA](#) is a synonym for [ALTER DATABASE](#).

The database name can be omitted from the first syntax, in which case the statement applies to the default database.

National Language Characteristics

The [CHARACTER SET](#) clause changes the default database character set. The [COLLATE](#) clause changes the default database collation. [Section 10.1, “Character Set Support”](#), discusses character set and collation names.

You can see what character sets and collations are available using, respectively, the [SHOW CHARACTER SET](#) and [SHOW COLLATION](#) statements. See [Section 13.7.5.3, “SHOW CHARACTER SET Syntax”](#), and [Section 13.7.5.4, “SHOW COLLATION Syntax”](#), for more information.

If you change the default character set or collation for a database, stored routines that use the database defaults must be dropped and recreated so that they use the new defaults. (In a stored routine, variables with character data types use the database defaults if the character set or collation are not specified explicitly. See [Section 13.1.13, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).)

13.1.2 ALTER EVENT Syntax

```
ALTER
  [DEFINER = { user | CURRENT_USER }]
  EVENT event_name
  [ON SCHEDULE schedule]
  [ON COMPLETION [NOT] PRESERVE]
  [RENAME TO new_event_name]
  [ENABLE | DISABLE | DISABLE ON SLAVE]
  [COMMENT 'comment']
  [DO event_body]
```

The `ALTER EVENT` statement changes one or more of the characteristics of an existing event without the need to drop and recreate it. The syntax for each of the `DEFINER`, `ON SCHEDULE`, `ON COMPLETION`, `COMMENT`, `ENABLE / DISABLE`, and `DO` clauses is exactly the same as when used with `CREATE EVENT`. (See [Section 13.1.10, “CREATE EVENT Syntax”](#).)

Any user can alter an event defined on a database for which that user has the `EVENT` privilege. When a user executes a successful `ALTER EVENT` statement, that user becomes the definer for the affected event.

`ALTER EVENT` works only with an existing event:

```
mysql> ALTER EVENT no_such_event
> ON SCHEDULE
> EVERY '2:3' DAY_HOUR;
ERROR 1517 (HY000): Unknown event 'no_such_event'
```

In each of the following examples, assume that the event named `myevent` is defined as shown here:

```
CREATE EVENT myevent
  ON SCHEDULE
  EVERY 6 HOUR
  COMMENT 'A sample comment.'
  DO
  UPDATE myschema.mytable SET mycol = mycol + 1;
```

The following statement changes the schedule for `myevent` from once every six hours starting immediately to once every twelve hours, starting four hours from the time the statement is run:

```
ALTER EVENT myevent
  ON SCHEDULE
  EVERY 12 HOUR
  STARTS CURRENT_TIMESTAMP + INTERVAL 4 HOUR;
```

It is possible to change multiple characteristics of an event in a single statement. This example changes the SQL statement executed by `myevent` to one that deletes all records from `mytable`; it also changes the schedule for the event such that it executes once, one day after this `ALTER EVENT` statement is run.

```
ALTER EVENT myevent
  ON SCHEDULE
  AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
  DO
```

```
TRUNCATE TABLE myschema.mytable;
```

Specify the options in an `ALTER EVENT` statement only for those characteristics that you want to change; omitted options keep their existing values. This includes any default values for `CREATE EVENT` such as `ENABLE`.

To disable `myevent`, use this `ALTER EVENT` statement:

```
ALTER EVENT myevent
  DISABLE;
```

The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the `timestamp` or `interval` values which it contains. You cannot use stored routines or user-defined functions in such expressions, and you cannot use any table references; however, you can use `SELECT FROM DUAL`. This is true for both `ALTER EVENT` and `CREATE EVENT` statements. References to stored routines, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Although an `ALTER EVENT` statement that contains another `ALTER EVENT` statement in its `DO` clause appears to succeed, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

To rename an event, use the `ALTER EVENT` statement's `RENAME TO` clause. This statement renames the event `myevent` to `yourevent`:

```
ALTER EVENT myevent
  RENAME TO yourevent;
```

You can also move an event to a different database using `ALTER EVENT ... RENAME TO ...` and `db_name.event_name` notation, as shown here:

```
ALTER EVENT olddb.myevent
  RENAME TO newdb.myevent;
```

To execute the previous statement, the user executing it must have the `EVENT` privilege on both the `olddb` and `newdb` databases.

Note

There is no `RENAME EVENT` statement.

The value `DISABLE ON SLAVE` is used on a replication slave instead of `ENABLE` or `DISABLE` to indicate an event that was created on the master and replicated to the slave, but that is not executed on the slave. Normally, `DISABLE ON SLAVE` is set automatically as required; however, there are some circumstances under which you may want or need to change it manually. See [Section 18.4.1.12, “Replication of Invoked Features”](#), for more information.

13.1.3 ALTER FUNCTION Syntax

```
ALTER FUNCTION func_name [characteristic ...]

characteristic:
  COMMENT 'string'
  | LANGUAGE SQL
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
```

This statement can be used to change the characteristics of a stored function. More than one change may be specified in an `ALTER FUNCTION` statement. However, you cannot change the parameters or

body of a stored function using this statement; to make such changes, you must drop and re-create the function using [DROP FUNCTION](#) and [CREATE FUNCTION](#).

You must have the [ALTER ROUTINE](#) privilege for the function. (That privilege is granted automatically to the function creator.) If binary logging is enabled, the [ALTER FUNCTION](#) statement might also require the [SUPER](#) privilege, as described in [Section 23.7, “Binary Logging of Stored Programs”](#).

13.1.4 ALTER INSTANCE Syntax

```
ALTER INSTANCE ROTATE INNODB MASTER KEY
```

[ALTER INSTANCE](#) defines actions applicable to a MySQL server instance.

The [ALTER INSTANCE ROTATE INNODB MASTER KEY](#) statement is used to rotate the master encryption key used for [InnoDB](#) tablespace encryption. A keyring plugin must be loaded to use this statement. By default, the MySQL server loads the [keyring_file](#) plugin. Key rotation requires the [ENCRYPTION_KEY_ADMIN](#) or [SUPER](#) privilege.

[ALTER INSTANCE ROTATE INNODB MASTER KEY](#) supports concurrent DML. However, it cannot be run concurrently with [CREATE TABLE ... ENCRYPTION](#) or [ALTER TABLE ... ENCRYPTION](#) operations, and locks are taken to prevent conflicts that could arise from concurrent execution of these statements. If one of the conflicting statements is running, it must complete before another can proceed.

[ALTER INSTANCE](#) actions are written to the binary log so that they can be executed on replicated servers.

For additional [ALTER INSTANCE ROTATE INNODB MASTER KEY](#) usage information, see [Section 15.7.10, “InnoDB Tablespace Encryption”](#). For information about the [keyring_file](#) plugin, see [Section 6.5.4, “The MySQL Keyring”](#).

13.1.5 ALTER PROCEDURE Syntax

```
ALTER PROCEDURE proc_name [characteristic ...]

characteristic:
  COMMENT 'string'
  | LANGUAGE SQL
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
```

This statement can be used to change the characteristics of a stored procedure. More than one change may be specified in an [ALTER PROCEDURE](#) statement. However, you cannot change the parameters or body of a stored procedure using this statement; to make such changes, you must drop and re-create the procedure using [DROP PROCEDURE](#) and [CREATE PROCEDURE](#).

You must have the [ALTER ROUTINE](#) privilege for the procedure. By default, that privilege is granted automatically to the procedure creator. This behavior can be changed by disabling the [automatic_sp_privileges](#) system variable. See [Section 23.2.2, “Stored Routines and MySQL Privileges”](#).

13.1.6 ALTER SERVER Syntax

```
ALTER SERVER server_name
  OPTIONS (option [, option] ...)
```

Alters the server information for *server_name*, adjusting any of the options permitted in the [CREATE SERVER](#) statement. The corresponding fields in the [mysql.servers](#) table are updated accordingly. This statement requires the [SUPER](#) privilege.

For example, to update the [USER](#) option:

```
ALTER SERVER s OPTIONS (USER 'sally');
```

`ALTER SERVER` does not cause an automatic commit.

In MySQL 8.0, `ALTER SERVER` is not written to the binary log, regardless of the logging format that is in use.

13.1.7 ALTER TABLE Syntax

```
ALTER TABLE tbl_name
  [alter_specification [, alter_specification] ...]
  [partition_options]

alter_specification:
  table_options
| ADD [COLUMN] col_name column_definition
  [FIRST | AFTER col_name ]
| ADD [COLUMN] (col_name column_definition,...)
| ADD {INDEX|KEY} [index_name]
  [index_type] (index_col_name,...) [index_option] ...
| ADD [CONSTRAINT [symbol]] PRIMARY KEY
  [index_type] (index_col_name,...) [index_option] ...
| ADD [CONSTRAINT [symbol]]
  UNIQUE [INDEX|KEY] [index_name]
  [index_type] (index_col_name,...) [index_option] ...
| ADD FULLTEXT [INDEX|KEY] [index_name]
  (index_col_name,...) [index_option] ...
| ADD SPATIAL [INDEX|KEY] [index_name]
  (index_col_name,...) [index_option] ...
| ADD [CONSTRAINT [symbol]]
  FOREIGN KEY [index_name] (index_col_name,...)
  reference_definition
| ALGORITHM [=] {DEFAULT|INPLACE|COPY}
| ALTER [COLUMN] col_name {SET DEFAULT literal | DROP DEFAULT}
| CHANGE [COLUMN] old_col_name new_col_name column_definition
  [FIRST|AFTER col_name]
| LOCK [=] {DEFAULT|NONE|SHARED|EXCLUSIVE}
| MODIFY [COLUMN] col_name column_definition
  [FIRST | AFTER col_name]
| DROP [COLUMN] col_name
| DROP PRIMARY KEY
| DROP {INDEX|KEY} index_name
| DROP FOREIGN KEY fk_symbol
| ALTER INDEX index_name {VISIBLE | INVISIBLE}
| DISABLE KEYS
| ENABLE KEYS
| RENAME [TO|AS] new_tbl_name
| RENAME {INDEX|KEY} old_index_name TO new_index_name
| ORDER BY col_name [, col_name] ...
| CONVERT TO CHARACTER SET charset_name [COLLATE collation_name]
| [DEFAULT] CHARACTER SET [=] charset_name [COLLATE [=] collation_name]
| DISCARD TABLESPACE
| IMPORT TABLESPACE
| FORCE
| {WITHOUT|WITH} VALIDATION
| ADD PARTITION (partition_definition)
| DROP PARTITION partition_names
| DISCARD PARTITION {partition_names | ALL} TABLESPACE
| IMPORT PARTITION {partition_names | ALL} TABLESPACE
| TRUNCATE PARTITION {partition_names | ALL}
| COALESCE PARTITION number
| REORGANIZE PARTITION partition_names INTO (partition_definitions)
| EXCHANGE PARTITION partition_name WITH TABLE tbl_name [{WITH|WITHOUT} VALIDATION]
| ANALYZE PARTITION {partition_names | ALL}
| CHECK PARTITION {partition_names | ALL}
| OPTIMIZE PARTITION {partition_names | ALL}
| REBUILD PARTITION {partition_names | ALL}
| REPAIR PARTITION {partition_names | ALL}
| REMOVE PARTITIONING
| UPGRADE PARTITIONING
```

```

index_col_name:
    col_name [(length)] [ASC | DESC]

index_type:
    USING {BTREE | HASH}

index_option:
    KEY_BLOCK_SIZE [=] value
    | index_type
    | WITH PARSER parser_name
    | COMMENT 'string'
    | {VISIBLE | INVISIBLE}

table_options:
    table_option [, table_option] ...

table_option:
    ENGINE [=] engine_name
    | AUTO_INCREMENT [=] value
    | AVG_ROW_LENGTH [=] value
    | [DEFAULT] CHARACTER SET [=] charset_name
    | CHECKSUM [=] {0 | 1}
    | [DEFAULT] COLLATE [=] collation_name
    | COMMENT [=] 'string'
    | COMPRESSION [=] {'ZLIB' | 'LZ4' | 'NONE'}
    | CONNECTION [=] 'connect_string'
    | DATA DIRECTORY [=] 'absolute path to directory'
    | DELAY_KEY_WRITE [=] {0 | 1}
    | ENCRYPTION [=] {'Y' | 'N'}
    | INDEX DIRECTORY [=] 'absolute path to directory'
    | INSERT_METHOD [=] { NO | FIRST | LAST }
    | KEY_BLOCK_SIZE [=] value
    | MAX_ROWS [=] value
    | MIN_ROWS [=] value
    | PACK_KEYS [=] {0 | 1 | DEFAULT}
    | PASSWORD [=] 'string'

    | STATS_AUTO_RECALC [=] {DEFAULT | 0 | 1}
    | STATS_PERSISTENT [=] {DEFAULT | 0 | 1}
    | STATS_SAMPLE_PAGES [=] value
    | TABLESPACE tablespace_name
    | UNION [=] (tbl_name[, tbl_name]...)

partition_options:
    (see CREATE TABLE options)

```

ALTER TABLE changes the structure of a table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change characteristics such as the storage engine used for the table or the table comment.

- To use **ALTER TABLE**, you need **ALTER**, **CREATE**, and **INSERT** privileges for the table. Renaming a table requires **ALTER** and **DROP** on the old table, **ALTER**, **CREATE**, and **INSERT** on the new table.
- Following the table name, specify the alterations to be made. If none are given, **ALTER TABLE** does nothing.
- The syntax for many of the permissible alterations is similar to clauses of the **CREATE TABLE** statement. *column_definition* clauses use the same syntax for **ADD** and **CHANGE** as for **CREATE TABLE**. See [Section 13.1.15, “CREATE TABLE Syntax”](#), for more information.
- The word **COLUMN** is optional and can be omitted.
- You can issue multiple **ADD**, **ALTER**, **DROP**, and **CHANGE** clauses in a single **ALTER TABLE** statement, separated by commas. This is a MySQL extension to standard SQL, which permits only one of each clause per **ALTER TABLE** statement. For example, to drop multiple columns in a single statement, do this:

```
ALTER TABLE t2 DROP COLUMN c, DROP COLUMN d;
```

- Some operations may result in warnings if attempted on a table for which the storage engine does not support the operation. These warnings can be displayed with `SHOW WARNINGS`. See [Section 13.7.5.40, “SHOW WARNINGS Syntax”](#). For information on troubleshooting `ALTER TABLE`, see [Section B.5.6.1, “Problems with ALTER TABLE”](#).
- For usage examples, see [Section 13.1.7.3, “ALTER TABLE Examples”](#).
- For information about generated columns, see [Section 13.1.7.2, “ALTER TABLE and Generated Columns”](#).
- With the `mysql_info()` C API function, you can find out how many rows were copied by `ALTER TABLE`. See [Section 27.7.7.36, “mysql_info\(\)”](#).

There are several additional aspects to the `ALTER TABLE` statement, described under the following topics in this section:

- [Table Options](#)
- [Performance and Storage Considerations](#)
- [Using the LOCK Clause to Control Concurrency](#)
- [Column Attributes](#)
- [Primary Keys and Indexes](#)
- [Foreign Keys](#)
- [Dropping Columns](#)
- [Changing the Character Set](#)
- [Discarding and Importing InnoDB Tablespaces](#)
- [Row Order for MyISAM Tables](#)
- [Partitioning Options](#)

Table Options

table_options signifies table options of the kind that can be used in the `CREATE TABLE` statement, such as `ENGINE`, `AUTO_INCREMENT`, `AVG_ROW_LENGTH`, `MAX_ROWS`, `ROW_FORMAT`, or `TABLESPACE`.

For descriptions of all table options, see [Section 13.1.15, “CREATE TABLE Syntax”](#). However, `ALTER TABLE` ignores `DATA DIRECTORY` and `INDEX DIRECTORY` when given as table options. `ALTER TABLE` permits them only as partitioning options, and requires that you have the `FILE` privilege.

Use of table options with `ALTER TABLE` provides a convenient way of altering single table characteristics. For example:

- If `t1` is currently not an `InnoDB` table, this statement changes its storage engine to `InnoDB`:

```
ALTER TABLE t1 ENGINE = InnoDB;
```

- See [Section 15.8.1.4, “Converting Tables from MyISAM to InnoDB”](#) for considerations when switching tables to the `InnoDB` storage engine.
- When you specify an `ENGINE` clause, `ALTER TABLE` rebuilds the table. This is true even if the table already has the specified storage engine.
- Running `ALTER TABLE tbl_name ENGINE=INNODB` on an existing `InnoDB` table performs a “null” `ALTER TABLE` operation, which can be used to defragment an `InnoDB` table, as described

in [Section 15.11.4, “Defragmenting a Table”](#). Running `ALTER TABLE tbl_name FORCE` on an InnoDB table performs the same function.

- `ALTER TABLE tbl_name ENGINE=INNODB` and `ALTER TABLE tbl_name FORCE` use [online DDL](#). For more information, see [Section 15.12.1, “Online DDL Overview”](#).
- The outcome of attempting to change the storage engine of a table is affected by whether the desired storage engine is available and the setting of the `NO_ENGINE_SUBSTITUTION` SQL mode, as described in [Section 5.1.8, “Server SQL Modes”](#).
- To prevent inadvertent loss of data, `ALTER TABLE` cannot be used to change the storage engine of a table to `MERGE` or `BLACKHOLE`.
- To change the InnoDB table to use compressed row-storage format:

```
ALTER TABLE t1 ROW_FORMAT = COMPRESSED;
```

- If the InnoDB tablespace encryption feature is enabled (see [Section 15.7.10, “InnoDB Tablespace Encryption”](#)), encryption for `t1` can be enabled or disabled like this:

```
ALTER TABLE t1 ENCRYPTION='Y';
ALTER TABLE t1 ENCRYPTION='N';
```

- To reset the current auto-increment value:

```
ALTER TABLE t1 AUTO_INCREMENT = 13;
```

You cannot reset the counter to a value less than or equal to the value that is currently in use. For both InnoDB and MyISAM, if the value is less than or equal to the maximum value currently in the `AUTO_INCREMENT` column, the value is reset to the current maximum `AUTO_INCREMENT` column value plus one.

- To change the default table character set:

```
ALTER TABLE t1 CHARACTER SET = utf8;
```

- To add (or change) a table comment:

```
ALTER TABLE t1 COMMENT = 'New table comment';
```

- You can use `ALTER TABLE` with the `TABLESPACE` option to move non-partitioned InnoDB tables between existing [general tablespaces](#), [file-per-table tablespaces](#), and the [system tablespace](#). See [Moving Non-Partitioned Tables Between Tablespaces Using ALTER TABLE](#).
- For partitioned tables, `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` only modifies the default tablespace. It does not move partitions from one tablespace to another. To move table partitions, you must move each partition using `ALTER TABLE tbl_name REORGANIZE PARTITION`. See [Moving Table Partitions Between Tablespaces Using ALTER TABLE](#).
- `ALTER TABLE ... TABLESPACE` operations always cause a full table rebuild, even if the `TABLESPACE` attribute has not changed from its previous value.
- `ALTER TABLE ... TABLESPACE` syntax does not support moving a table from a temporary tablespace to a persistent tablespace.
- The `DATA DIRECTORY` clause, which is supported with `CREATE TABLE ... TABLESPACE`, is not supported with `ALTER TABLE ... TABLESPACE`, and is ignored if specified.

- For more information about the capabilities and limitations of the [TABLESPACE](#) option, see [CREATE TABLE](#).

To verify that the table options were changed as intended, use [SHOW CREATE TABLE](#), or query [INFORMATION_SCHEMA.TABLES](#).

Performance and Storage Considerations

[ALTER TABLE](#) operations that are **not** performed in place make a temporary copy of the original table. MySQL waits for other operations that are modifying the table, then proceeds. It incorporates the alteration into the copy, deletes the original table, and renames the new one. While [ALTER TABLE](#) is executing, the original table is readable by other sessions (with the exception noted shortly). Updates and writes to the table that begin after the [ALTER TABLE](#) operation begins are stalled until the new table is ready, then are automatically redirected to the new table without any failed updates. The temporary copy of the original table is created in the database directory of the new table. This can differ from the database directory of the original table for [ALTER TABLE](#) operations that rename the table to a different database.

The exception referred to earlier is that [ALTER TABLE](#) blocks reads (not just writes) at the point where it is ready to clear outdated table structures from the table and table definition caches. At this point, it must acquire an exclusive lock. To do so, it waits for current readers to finish, and blocks new reads (and writes).

For [MyISAM](#) tables, you can speed up index re-creation (the slowest part of the alteration process) by setting the [mysam_sort_buffer_size](#) system variable to a high value.

For [InnoDB](#) tables, a table-copying [ALTER TABLE](#) operation on table that resides in a shared tablespace such as a [general tablespace](#) or the [system tablespace](#) can increase the amount of space used by the tablespace. Such operations require as much additional space as the data in the table plus indexes. For a table that resides in a shared tablespace, the additional space used during a table-copying [ALTER TABLE](#) operation is not released back to the operating system as it is for a table that resides in a [file-per-table](#) tablespace.

[ALTER TABLE](#) operations that are performed in place do not require creating a temporary copy of the original table. These operations include:

- [ALTER TABLE](#) operations on [InnoDB](#) tables that are supported by the [InnoDB online DDL](#) feature. For an overview of supported operations, see [Section 15.12.1, “Online DDL Overview”](#). For information about performance and concurrency of online DDL operations, see [Section 15.12.2, “Online DDL Performance, Concurrency, and Space Requirements”](#).
- [ALTER TABLE *tbl_name* RENAME TO *new_tbl_name*](#). When run without other options, MySQL renames files that correspond to the table *tbl_name* without making a copy. (You can also use the [RENAME TABLE](#) statement to rename tables. See [Section 13.1.29, “RENAME TABLE Syntax”](#).) Privileges granted specifically for the renamed table are not migrated to the new name. They must be changed manually.
- Alterations that modify only table metadata and not table data are immediate because the server only needs to alter table metadata, not touch table contents. The following changes are made in this way:
 - Renaming a column.
 - Changing the default value of a column.
 - Changing the definition of an [ENUM](#) or [SET](#) column by adding new enumeration or set members to the *end* of the list of valid member values, as long as the storage size of the data type does not change. For example, adding a member to a [SET](#) column that has 8 members changes the required storage per value from 1 byte to 2 bytes; this will require a table copy. Adding members in the middle of the list causes renumbering of existing members, which requires a table copy.

- Renaming an index.
- Adding or dropping an index, for `InnoDB`. See [Section 15.12.1, “Online DDL Overview”](#).
- Modifying index visibility with an `ALTER INDEX` operation.
- Column modifications of tables containing generated columns that depend on columns with a `DEFAULT` value if the modified columns are not involved in the generated column expressions. For example, changing the `NULL` property of a separate column can be done in place without a table rebuild.

Specifying `ALGORITHM=INPLACE` makes the operation use the in-place technique for clauses and storage engines that support it, and fail with an error otherwise, thus avoiding a lengthy table copy if you try altering a table that uses a different storage engine than you expect.

You can force an `ALTER TABLE` operation that would otherwise not use the table copy method by setting the `old_alter_table` system variable to `ON`, or specifying `ALGORITHM=COPY` as one of the `alter_specification` clauses. If there is a conflict between the `old_alter_table` setting and an `ALGORITHM` clause with a value other than `DEFAULT`, the `ALGORITHM` clause takes precedence.

Specifying `ALGORITHM=DEFAULT` is the same as specifying no `ALGORITHM` clause at all, in which case `ALGORITHM=INPLACE` is used if supported by the storage engine. Otherwise, `ALGORITHM=COPY` is used.

An `ALTER TABLE` operation run with the `ALGORITHM=COPY` clause prevents concurrent DML operations. Concurrent queries are still allowed. That is, a table-copying operation always includes at least the concurrency restrictions of `LOCK=SHARED` (allow queries but not DML). You can further restrict concurrency for such operations by specifying `LOCK=EXCLUSIVE`, which prevents DML and queries.

As of MySQL 5.7.4, `ALTER TABLE` upgrades MySQL 5.5 temporal columns to 5.6 format for `ADD COLUMN`, `CHANGE COLUMN`, `MODIFY COLUMN`, `ADD INDEX`, and `FORCE` operations. This conversion cannot be done using the `INPLACE` algorithm because the table must be rebuilt, so specifying `ALGORITHM=INPLACE` in these cases results in an error. Specify `ALGORITHM=COPY` if necessary.

If an `ALTER TABLE` operation on a multicolumn index used to partition a table by `KEY` changes the order of the columns, it can only be performed using `ALGORITHM=COPY`.

The `WITHOUT VALIDATION` and `WITH VALIDATION` clauses affect whether `ALTER TABLE` performs an in-place operation for `virtual generated column` modifications. See [Section 13.1.7.2, “ALTER TABLE and Generated Columns”](#).

`ALTER TABLE` with `DISCARD ... PARTITION ... TABLESPACE` or `IMPORT ... PARTITION ... TABLESPACE` does not create any temporary tables or temporary partition files.

`ALTER TABLE` with `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REBUILD PARTITION`, or `REORGANIZE PARTITION` does not create temporary tables (except when used with `NDB` tables); however, these operations can and do create temporary partition files.

`ADD` or `DROP` operations for `RANGE` or `LIST` partitions are immediate operations or nearly so. `ADD` or `COALESCE` operations for `HASH` or `KEY` partitions copy data between all partitions, unless `LINEAR HASH` or `LINEAR KEY` was used; this is effectively the same as creating a new table, although the `ADD` or `COALESCE` operation is performed partition by partition. `REORGANIZE` operations copy only changed partitions and do not touch unchanged ones.

Using the LOCK Clause to Control Concurrency

You can control the level of concurrent reading and writing of the table while it is being altered, using the `LOCK` clause. Specifying a non-default value for this clause lets you require a certain amount of

concurrent access or exclusivity during the alter operation, and halts the operation if the requested degree of locking is not available. The parameters for the `LOCK` clause are:

- `LOCK = DEFAULT`

Maximum level of concurrency for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation: Permit concurrent reads and writes if supported. If not, permit concurrent reads if supported. If not, enforce exclusive access.

- `LOCK = NONE`

If supported, permit concurrent reads and writes. Otherwise, return an error message.

- `LOCK = SHARED`

If supported, permit concurrent reads but block writes. Note that writes will be blocked even if concurrent writes are supported by the storage engine for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation. If concurrent reads are not supported, return an error message.

- `LOCK = EXCLUSIVE`

Enforce exclusive access. This will be done even if concurrent reads/writes are supported by the storage engine for the given `ALGORITHM` clause (if any) and `ALTER TABLE` operation.

Column Attributes

- You can rename a column using a `CHANGE old_col_name new_col_name column_definition` clause. To do so, specify the old and new column names and the definition that the column currently has. For example, to rename an `INTEGER` column from `a` to `b`, you can do this:

```
ALTER TABLE t1 CHANGE a b INTEGER;
```

- To change a column's type but not the name, `CHANGE` syntax still requires an old and new column name, even if they are the same. For example:

```
ALTER TABLE t1 CHANGE b b BIGINT NOT NULL;
```

- You can also use `MODIFY` to change a column's type without renaming it:

```
ALTER TABLE t1 MODIFY b BIGINT NOT NULL;
```

`MODIFY` is an extension to `ALTER TABLE` for Oracle compatibility.

- When you use `CHANGE` or `MODIFY`, `column_definition` must include the data type and all attributes that should apply to the new column, other than index attributes such as `PRIMARY KEY` or `UNIQUE`. Attributes present in the original definition but not specified for the new definition are not carried forward. Suppose that a column `col1` is defined as `INT UNSIGNED DEFAULT 1 COMMENT 'my column'` and you modify the column as follows:

```
ALTER TABLE t1 MODIFY col1 BIGINT;
```

The resulting column will be defined as `BIGINT`, but will not include the attributes `UNSIGNED DEFAULT 1 COMMENT 'my column'`. To retain them, the statement should be:

```
ALTER TABLE t1 MODIFY col1 BIGINT UNSIGNED DEFAULT 1 COMMENT 'my column';
```

- When you change a data type using [CHANGE](#) or [MODIFY](#), MySQL tries to convert existing column values to the new type as well as possible.

Warning

This conversion may result in alteration of data. For example, if you shorten a string column, values may be truncated. To prevent the operation from succeeding if conversions to the new data type would result in loss of data, enable strict SQL mode before using [ALTER TABLE](#) (see [Section 5.1.8, “Server SQL Modes”](#)).

- To add a column at a specific position within a table row, use [FIRST](#) or [AFTER col_name](#). The default is to add the column last. You can also use [FIRST](#) and [AFTER](#) in [CHANGE](#) or [MODIFY](#) operations to reorder columns within a table.
- If you use [CHANGE](#) or [MODIFY](#) to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.
- [CHANGE col_name](#) is a MySQL extension to standard SQL.
- [ALTER ... SET DEFAULT](#) or [ALTER ... DROP DEFAULT](#) specify a new default value for a column or remove the old default value, respectively. If the old default is removed and the column can be [NULL](#), the new default is [NULL](#). If the column cannot be [NULL](#), MySQL assigns a default value as described in [Section 11.7, “Data Type Default Values”](#).

Primary Keys and Indexes

- [DROP PRIMARY KEY](#) drops the [primary key](#). If there is no primary key, an error occurs. For information about the performance characteristics of primary keys, especially for [InnoDB](#) tables, see [Section 8.3.2, “Using Primary Keys”](#).
- If you add a [UNIQUE INDEX](#) or [PRIMARY KEY](#) to a table, MySQL stores it before any nonunique index to permit detection of duplicate keys as early as possible.
- [DROP INDEX](#) removes an index. This is a MySQL extension to standard SQL. See [Section 13.1.22, “DROP INDEX Syntax”](#). If you are unsure of the index name, use [SHOW INDEX FROM tbl_name](#).
- Some storage engines permit you to specify an index type when creating an index. The syntax for the [index_type](#) specifier is [USING type_name](#). For details about [USING](#), see [Section 13.1.12, “CREATE INDEX Syntax”](#). The preferred position is after the column list. Support for use of the option before the column list will be removed in a future MySQL release.
- [index_option](#) values specify additional options for an index. [USING](#) is one such option. For details about permissible [index_option](#) values, see [Section 13.1.12, “CREATE INDEX Syntax”](#).
- [RENAME INDEX old_index_name TO new_index_name](#) renames an index. This is a MySQL extension to standard SQL. The content of the table remains unchanged. [old_index_name](#) must be the name of an existing index in the table that is not dropped by the same [ALTER TABLE](#) statement. [new_index_name](#) is the new index name, which cannot duplicate the name of an index in the resulting table after changes have been applied. Neither index name can be [PRIMARY](#).
- If you use [ALTER TABLE](#) on a [MyISAM](#) table, all nonunique indexes are created in a separate batch (as for [REPAIR TABLE](#)). This should make [ALTER TABLE](#) much faster when you have many indexes.
- For [MyISAM](#) tables, key updating can be controlled explicitly. Use [ALTER TABLE ... DISABLE KEYS](#) to tell MySQL to stop updating nonunique indexes. Then use [ALTER TABLE ... ENABLE KEYS](#) to re-create missing indexes. [MyISAM](#) does this with a special algorithm that is much faster

than inserting keys one by one, so disabling keys before performing bulk insert operations should give a considerable speedup. Using `ALTER TABLE ... DISABLE KEYS` requires the `INDEX` privilege in addition to the privileges mentioned earlier.

While the nonunique indexes are disabled, they are ignored for statements such as `SELECT` and `EXPLAIN` that otherwise would use them.

- After an `ALTER TABLE` statement, it may be necessary to run `ANALYZE TABLE` to update index cardinality information. See [Section 13.7.5.22, “SHOW INDEX Syntax”](#).
- The `ALTER INDEX` operation permits an index to be made visible or invisible. An invisible index is not used by the optimizer. Modification of index visibility applies to indexes other than primary keys (either explicit or implicit). This feature is storage engine neutral (supported for any engine). For more information, see [Section 8.3.11, “Invisible Indexes”](#).

Foreign Keys

- The `FOREIGN KEY` and `REFERENCES` clauses are supported by the `InnoDB` storage engine, which implements `ADD [CONSTRAINT symbol] FOREIGN KEY [index_name] (...) REFERENCES ... (...)`. See [Section 15.8.1.6, “InnoDB and FOREIGN KEY Constraints”](#). For other storage engines, the clauses are parsed but ignored. The `CHECK` clause is parsed but ignored by all storage engines. See [Section 13.1.15, “CREATE TABLE Syntax”](#). The reason for accepting but ignoring syntax clauses is for compatibility, to make it easier to port code from other SQL servers, and to run applications that create tables with references. See [Section 1.8.2, “MySQL Differences from Standard SQL”](#).

For `ALTER TABLE`, unlike `CREATE TABLE, ADD FOREIGN KEY` ignores *index_name* if given and uses an automatically generated foreign key name. As a workaround, include the `CONSTRAINT` clause to specify the foreign key name:

```
ADD CONSTRAINT name FOREIGN KEY (...)
```

Important

The inline `REFERENCES` specifications where the references are defined as part of the column specification are silently ignored. MySQL only accepts `REFERENCES` clauses defined as part of a separate `FOREIGN KEY` specification.

Note

Partitioned `InnoDB` tables do not support foreign keys. See [Section 22.6.2, “Partitioning Limitations Relating to Storage Engines”](#), for more information.

- MySQL supports the use of `ALTER TABLE` to drop foreign keys:

```
ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;
```

- Adding and dropping a foreign key in the same `ALTER TABLE` statement is supported for `ALTER TABLE ... ALGORITHM=INPLACE` but is unsupported for `ALTER TABLE ... ALGORITHM=COPY`.
- The server prohibits changes to foreign key columns that have the potential to cause loss of referential integrity. It also prohibits changes to the data type of such columns that may be unsafe. For example, changing `VARCHAR(20)` to `VARCHAR(30)` is permitted, but changing it to `VARCHAR(1024)` is not because that alters the number of length bytes required to store individual values. A workaround is to use `ALTER TABLE ... DROP FOREIGN KEY` before changing the column definition and `ALTER TABLE ... ADD FOREIGN KEY` afterward.
- `ALTER TABLE tbl_name RENAME new_tbl_name` changes internally generated foreign key constraint names and user-defined foreign key constraint names that contain the string

“*tbl_name_ibfk_*” to reflect the new table name. InnoDB interprets foreign key constraint names that contain the string “*tbl_name_ibfk_*” as internally generated names.

Dropping Columns

- If a table contains only one column, the column cannot be dropped. If what you intend is to remove the table, use `DROP TABLE` instead.
- If columns are dropped from a table, the columns are also removed from any index of which they are a part. If all columns that make up an index are dropped, the index is dropped as well. If you use `CHANGE` or `MODIFY` to shorten a column for which an index exists on the column, and the resulting column length is less than the index length, MySQL shortens the index automatically.
- `DROP col_name` is a MySQL extension to standard SQL.

Changing the Character Set

To change the table default character set and all character columns (`CHAR`, `VARCHAR`, `TEXT`) to a new character set, use a statement like this:

```
ALTER TABLE tbl_name CONVERT TO CHARACTER SET charset_name;
```

The statement also changes the collation of all character columns. If you specify no `COLLATE` clause to indicate which collation to use, the statement uses default collation for the character set. If this collation is inappropriate for the intended table use (for example, if it would change from a case-sensitive collation to a case-insensitive collation), specify a collation explicitly.

For a column that has a data type of `VARCHAR` or one of the `TEXT` types, `CONVERT TO CHARACTER SET` will change the data type as necessary to ensure that the new column is long enough to store as many characters as the original column. For example, a `TEXT` column has two length bytes, which store the byte-length of values in the column, up to a maximum of 65,535. For a `latin1 TEXT` column, each character requires a single byte, so the column can store up to 65,535 characters. If the column is converted to `utf8`, each character might require up to three bytes, for a maximum possible length of $3 \times 65,535 = 196,605$ bytes. That length will not fit in a `TEXT` column's length bytes, so MySQL will convert the data type to `MEDIUMTEXT`, which is the smallest string type for which the length bytes can record a value of 196,605. Similarly, a `VARCHAR` column might be converted to `MEDIUMTEXT`.

To avoid data type changes of the type just described, do not use `CONVERT TO CHARACTER SET`. Instead, use `MODIFY` to change individual columns. For example:

```
ALTER TABLE t MODIFY latin1_text_col TEXT CHARACTER SET utf8;
ALTER TABLE t MODIFY latin1_varchar_col VARCHAR(M) CHARACTER SET utf8;
```

If you specify `CONVERT TO CHARACTER SET binary`, the `CHAR`, `VARCHAR`, and `TEXT` columns are converted to their corresponding binary string types (`BINARY`, `VARBINARY`, `BLOB`). This means that the columns no longer will have a character set and a subsequent `CONVERT TO` operation will not apply to them.

If *charset_name* is `DEFAULT`, the database character set is used.

Warning

The `CONVERT TO` operation converts column values between the character sets. This is *not* what you want if you have a column in one character set (like `latin1`) but the stored values actually use some other, incompatible character set (like `utf8`). In this case, you have to do the following for each such column:

```
ALTER TABLE t1 CHANGE c1 c1 BLOB;
ALTER TABLE t1 CHANGE c1 c1 TEXT CHARACTER SET utf8;
```

The reason this works is that there is no conversion when you convert to or from `BLOB` columns.

To change only the *default* character set for a table, use this statement:

```
ALTER TABLE tbl_name DEFAULT CHARACTER SET charset_name;
```

The word `DEFAULT` is optional. The default character set is the character set that is used if you do not specify the character set for columns that you add to a table later (for example, with `ALTER TABLE ... ADD column`).

When `foreign_key_checks` is enabled, which is the default setting, character set conversion is not permitted on tables that include a character string column used in a foreign key constraint. The workaround is to disable `foreign_key_checks` before performing the character set conversion. You must perform the conversion on both tables involved in the foreign key constraint before re-enabling `foreign_key_checks`. If you re-enable `foreign_key_checks` after converting only one of the tables, an `ON DELETE CASCADE` or `ON UPDATE CASCADE` operation could corrupt data in the referencing table due to implicit conversion that occurs during these operations (Bug #45290, Bug #74816).

Discarding and Importing InnoDB Tablespaces

An InnoDB table created in its own `file-per-table` tablespace can be discarded and imported using the `DISCARD TABLESPACE` and `IMPORT TABLESPACE` options. These options can be used to import a file-per-table tablespace from a backup or to copy a file-per-table tablespace from one database server to another. See [Section 15.7.6, “Copying File-Per-Table Tablespaces to Another Instance”](#).

Row Order for MyISAM Tables

`ORDER BY` enables you to create the new table with the rows in a specific order. This option is useful primarily when you know that you query the rows in a certain order most of the time. By using this option after major changes to the table, you might be able to get higher performance. In some cases, it might make sorting easier for MySQL if the table is in order by the column that you want to order it by later.

Note

The table does not remain in the specified order after inserts and deletes.

`ORDER BY` syntax permits one or more column names to be specified for sorting, each of which optionally can be followed by `ASC` or `DESC` to indicate ascending or descending sort order, respectively. The default is ascending order. Only column names are permitted as sort criteria; arbitrary expressions are not permitted. This clause should be given last after any other clauses.

`ORDER BY` does not make sense for InnoDB tables because InnoDB always orders table rows according to the `clustered index`.

When used on a partitioned table, `ALTER TABLE ... ORDER BY` orders rows within each partition only.

Partitioning Options

`partition_options` signifies options that can be used with partitioned tables for repartitioning, for adding, dropping, discarding, importing, merging, and splitting partitions, and for performing partitioning maintenance.

It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITIONING` clause in an addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITIONING` clause must be specified last after any other specifications. The `ADD PARTITION`, `DROP PARTITION`,

`DISCARD PARTITION`, `IMPORT PARTITION`, `COALESCE PARTITION`, `REORGANIZE PARTITION`, `EXCHANGE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, and `REPAIR PARTITION` options cannot be combined with other alter specifications in a single `ALTER TABLE`, since the options just listed act on individual partitions.

For more information about partition options, see [Section 13.1.15, “CREATE TABLE Syntax”](#), and [Section 13.1.7.1, “ALTER TABLE Partition Operations”](#). For information about and examples of `ALTER TABLE ... EXCHANGE PARTITION` statements, see [Section 22.3.3, “Exchanging Partitions and Subpartitions with Tables”](#).

Prior to MySQL 5.7.6, partitioned `InnoDB` tables used the generic `ha_partition` partitioning handler employed by `MyISAM` and other storage engines not supplying their own partitioning handlers; in MySQL 5.7.6 and later, such tables are created using the `InnoDB` storage engine's own (or “native”) partitioning handler. Beginning with MySQL 5.7.9, you can upgrade an `InnoDB` table that was created in MySQL 5.7.6 or earlier (that is, created using `ha_partition`) to the `InnoDB` native partition handler using `ALTER TABLE ... UPGRADE PARTITIONING`. (Bug #76734, Bug #20727344) This version of `ALTER TABLE` does not accept any other options and can be used only on a single table at a time. You can also use `mysql_upgrade` to upgrade older partitioned `InnoDB` tables to the native partitioning handler.

13.1.7.1 ALTER TABLE Partition Operations

Partitioning-related clauses for `ALTER TABLE` can be used with partitioned tables for repartitioning, for adding, dropping, discarding, importing, merging, and splitting partitions, and for performing partitioning maintenance.

- Simply using a `partition_options` clause with `ALTER TABLE` on a partitioned table repartitions the table according to the partitioning scheme defined by the `partition_options`. This clause always begins with `PARTITION BY`, and follows the same syntax and other rules as apply to the `partition_options` clause for `CREATE TABLE` (see [Section 13.1.15, “CREATE TABLE Syntax”](#), for more detailed information), and can also be used to partition an existing table that is not already partitioned. For example, consider a (nonpartitioned) table defined as shown here:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
);
```

This table can be partitioned by `HASH`, using the `id` column as the partitioning key, into 8 partitions by means of this statement:

```
ALTER TABLE t1
  PARTITION BY HASH(id)
  PARTITIONS 8;
```

MySQL supports an `ALGORITHM` option with `[SUB]PARTITION BY [LINEAR] KEY`. `ALGORITHM=1` causes the server to use the same key-hashing functions as MySQL 5.1 when computing the placement of rows in partitions; `ALGORITHM=2` means that the server employs the key-hashing functions implemented and used by default for new `KEY` partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using `ALGORITHM=2`. This option is intended for use chiefly when upgrading or downgrading `[LINEAR] KEY` partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by `KEY` or `LINEAR KEY` on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server.

To upgrade a `KEY` partitioned table that was created in MySQL 5.1, first execute `SHOW CREATE TABLE` and note the exact columns and number of partitions shown. Now execute an `ALTER TABLE` statement using exactly the same column list and number of partitions as in the `CREATE TABLE` statement, while adding `ALGORITHM=2` immediately following the `PARTITION BY` keywords. (You

should also include the `LINEAR` keyword if it was used for the original table definition.) An example from a session in the `mysql` client is shown here:

```
mysql> SHOW CREATE TABLE p\G
***** 1. row *****
      Table: p
Create Table: CREATE TABLE `p` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `cd` datetime NOT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY LINEAR KEY (id)
PARTITIONS 32 */
1 row in set (0.00 sec)

mysql> ALTER TABLE p PARTITION BY LINEAR KEY ALGORITHM=2 (id) PARTITIONS 32;
Query OK, 0 rows affected (5.34 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW CREATE TABLE p\G
***** 1. row *****
      Table: p
Create Table: CREATE TABLE `p` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `cd` datetime NOT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY LINEAR KEY (id)
PARTITIONS 32 */
1 row in set (0.00 sec)
```

Downgrading a table created using the default key-hashing used in MySQL 5.5 and later to enable its use by a MySQL 5.1 server is similar, except in this case you should use `ALGORITHM=1` to force the table's partitions to be rebuilt using the MySQL 5.1 key-hashing functions. It is recommended that you not do this except when necessary for compatibility with a MySQL 5.1 server, as the improved `KEY` hashing functions used by default in MySQL 5.5 and later provide fixes for a number of issues found in the older implementation.

Note

A table upgraded by means of `ALTER TABLE ... PARTITION BY ALGORITHM=2 [LINEAR] KEY ...` can no longer be used by a MySQL 5.1 server. (Such a table would need to be downgraded with `ALTER TABLE ... PARTITION BY ALGORITHM=1 [LINEAR] KEY ...` before it could be used again by a MySQL 5.1 server.)

The table that results from using an `ALTER TABLE ... PARTITION BY` statement must follow the same rules as one created using `CREATE TABLE ... PARTITION BY`. This includes the rules governing the relationship between any unique keys (including any primary key) that the table might have, and the column or columns used in the partitioning expression, as discussed in [Section 22.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#). The `CREATE TABLE ... PARTITION BY` rules for specifying the number of partitions also apply to `ALTER TABLE ... PARTITION BY`.

The `partition_definition` clause for `ALTER TABLE ADD PARTITION` supports the same options as the clause of the same name for the `CREATE TABLE` statement. (See [Section 13.1.15, “CREATE TABLE Syntax”](#), for the syntax and description.) Suppose that you have the partitioned table created as shown here:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
```

```
PARTITION p1 VALUES LESS THAN (1995),
PARTITION p2 VALUES LESS THAN (1999)
);
```

You can add a new partition `p3` to this table for storing values less than `2002` as follows:

```
ALTER TABLE t1 ADD PARTITION (PARTITION p3 VALUES LESS THAN (2002));
```

`ADD PARTITION` can also be used with the `TABLESPACE` clause to add a new partition to an existing general tablespace, to a file-per-table tablespace, or to the system tablespace.

```
ALTER TABLE t1 ADD PARTITION (PARTITION p4 VALUES LESS THAN (2015) TABLESPACE = `ts1`);
ALTER TABLE t1 ADD PARTITION (PARTITION p4 VALUES LESS THAN (2015) TABLESPACE = `innodb_file_per_table`);
ALTER TABLE t1 ADD PARTITION (PARTITION p4 VALUES LESS THAN (2015) TABLESPACE = `innodb_system`);
```

Note

If the `TABLESPACE = tablespace_name` option is not defined, the `ALTER TABLE ... ADD PARTITION` operation adds the partition to the table's default tablespace, which can be specified at the table level during `CREATE TABLE` or `ALTER TABLE`.

`DROP PARTITION` can be used to drop one or more `RANGE` or `LIST` partitions. This statement cannot be used with `HASH` or `KEY` partitions; instead, use `COALESCE PARTITION` (see later in this section). Any data that was stored in the dropped partitions named in the `partition_names` list is discarded. For example, given the table `t1` defined previously, you can drop the partitions named `p0` and `p1` as shown here:

```
ALTER TABLE t1 DROP PARTITION p0, p1;
```

`ADD PARTITION` and `DROP PARTITION` do not currently support `IF [NOT] EXISTS`.

The `DISCARD PARTITION ... TABLESPACE` and `IMPORT PARTITION ... TABLESPACE` options extend the [Transportable Tablespace](#) feature to individual InnoDB table partitions. Each InnoDB table partition has its own tablespace file (`.idb` file). The [Transportable Tablespace](#) feature makes it easy to copy the tablespaces from a running MySQL server instance to another running instance, or to perform a restore on the same instance. Both options take a comma-separated list of one or more partition names. For example:

```
ALTER TABLE t1 DISCARD PARTITION p2, p3 TABLESPACE;
ALTER TABLE t1 IMPORT PARTITION p2, p3 TABLESPACE;
```

When running `DISCARD PARTITION ... TABLESPACE` and `IMPORT PARTITION ... TABLESPACE` on subpartitioned tables, both partition and subpartition names are allowed. When a partition name is specified, subpartitions of that partition are included.

The [Transportable Tablespace](#) feature also supports copying or restoring partitioned InnoDB tables (all partitions at once). For additional information, see [Section 15.7.6, “Copying File-Per-Table Tablespaces to Another Instance”](#), as well as, [Section 15.7.6.1, “Transportable Tablespace Examples”](#).

Renames of partitioned table are supported. You can rename individual partitions indirectly using `ALTER TABLE ... REORGANIZE PARTITION`; however, this operation copies the partition's data.

It is possible to delete rows from selected partitions using the `TRUNCATE PARTITION` option. This option takes a comma-separated list of one or more partition names. Consider the table `t1` created by this statement:

```
CREATE TABLE t1 (
  id INT,
  year_col INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999),
  PARTITION p3 VALUES LESS THAN (2003),
  PARTITION p4 VALUES LESS THAN (2007)
);
```

To delete all rows from partition `p0`, you can use the following statement:

```
ALTER TABLE t1 TRUNCATE PARTITION p0;
```

The statement just shown has the same effect as the following `DELETE` statement:

```
DELETE FROM t1 WHERE year_col < 1991;
```

When truncating multiple partitions, the partitions do not have to be contiguous: This can greatly simplify delete operations on partitioned tables that would otherwise require very complex `WHERE` conditions if done with `DELETE` statements. For example, this statement deletes all rows from partitions `p1` and `p3`:

```
ALTER TABLE t1 TRUNCATE PARTITION p1, p3;
```

An equivalent `DELETE` statement is shown here:

```
DELETE FROM t1 WHERE
  (year_col >= 1991 AND year_col < 1995)
  OR
  (year_col >= 2003 AND year_col < 2007);
```

You can use the `ALL` keyword in place of the list of partition names; in this case, the statement acts on all partitions in the table.

`TRUNCATE PARTITION` merely deletes rows; it does not alter the definition of the table itself, or of any of its partitions.

You can verify that the rows were dropped by checking the `INFORMATION_SCHEMA.PARTITIONS` table, using a query such as this one:

```
SELECT PARTITION_NAME, TABLE_ROWS
FROM INFORMATION_SCHEMA.PARTITIONS
WHERE TABLE_NAME = 't1';
```

`COALESCE PARTITION` can be used with a table that is partitioned by `HASH` or `KEY` to reduce the number of partitions by *number*. Suppose that you have created table `t2` as follows:

```
CREATE TABLE t2 (
  name VARCHAR (30),
  started DATE
)
PARTITION BY HASH( YEAR(started) )
```

```
PARTITIONS 6;
```

You can reduce the number of partitions used by `t2` from 6 to 4 using the following statement:

```
ALTER TABLE t2 COALESCE PARTITION 2;
```

The data contained in the last *number* partitions is merged into the remaining partitions. In this case, partitions 4 and 5 will be merged into the first 4 partitions (the partitions numbered 0, 1, 2, and 3).

To change some but not all the partitions used by a partitioned table, you can use `REORGANIZE PARTITION`. This statement can be used in several ways:

- To merge a set of partitions into a single partition. This can be done by naming several partitions in the *partition_names* list and supplying a single definition for *partition_definition*.
- To split an existing partition into several partitions. You can accomplish this by naming a single partition for *partition_names* and providing multiple *partition_definitions*.
- To change the ranges for a subset of partitions defined using `VALUES LESS THAN` or the value lists for a subset of partitions defined using `VALUES IN`.
- To move a partition from one tablespace to another. For an example, see [Moving Table Partitions Between Tablespaces Using ALTER TABLE](#).

Note

For partitions that have not been explicitly named, MySQL automatically provides the default names `p0`, `p1`, `p2`, and so on. The same is true with regard to subpartitions.

For more detailed information about and examples of `ALTER TABLE ... REORGANIZE PARTITION` statements, see [Section 22.3.1, “Management of RANGE and LIST Partitions”](#).

- It is possible to exchange a table partition or subpartition with a table using the `ALTER TABLE ... EXCHANGE PARTITION` statement—that is, to move any existing rows in the partition or subpartition to the nonpartitioned table, and any existing rows in the nonpartitioned table to the table partition or subpartition.

For usage information and examples, see [Section 22.3.3, “Exchanging Partitions and Subpartitions with Tables”](#).

- Several additional options provide partition maintenance and repair functionality analogous to that implemented for nonpartitioned tables by statements such as `CHECK TABLE` and `REPAIR TABLE` (which are also supported for partitioned tables; see [Section 13.7.2, “Table Maintenance Statements”](#) for more information). These include `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, and `REPAIR PARTITION`. Each of these options takes a *partition_names* clause consisting of one or more names of partitions, separated by commas. The partitions must already exist in the target table. You can also use the `ALL` keyword in place of *partition_names*, in which case the statement acts on all partitions in the table. For more information and examples, see [Section 22.3.4, “Maintenance of Partitions”](#).

InnoDB does not currently support per-partition optimization; `ALTER TABLE ... OPTIMIZE PARTITION` causes the entire table to be rebuilt and analyzed, and an appropriate warning to be issued. (Bug #11751825, Bug #42822) To work around this problem, use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead.

The `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, and `REPAIR PARTITION` options are not supported for tables which are not partitioned.

- `REMOVE PARTITIONING` enables you to remove a table's partitioning without otherwise affecting the table or its data. This option can be combined with other `ALTER TABLE` options such as those used to add, drop, or rename columns or indexes.
- Using the `ENGINE` option with `ALTER TABLE` changes the storage engine used by the table without affecting the partitioning. The target storage engine must provide its own partitioning handler. Only the `InnoDB` and `NDB` storage engines have native partitioning handlers; `NDB` is not currently supported in MySQL 8.0.

It is possible for an `ALTER TABLE` statement to contain a `PARTITION BY` or `REMOVE PARTITIONING` clause in an addition to other alter specifications, but the `PARTITION BY` or `REMOVE PARTITIONING` clause must be specified last after any other specifications.

The `ADD PARTITION`, `DROP PARTITION`, `COALESCE PARTITION`, `REORGANIZE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, and `REPAIR PARTITION` options cannot be combined with other alter specifications in a single `ALTER TABLE`, since the options just listed act on individual partitions. For more information, see [Section 13.1.7.1, “ALTER TABLE Partition Operations”](#).

Only a single instance of any one of the following options can be used in a given `ALTER TABLE` statement: `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `TRUNCATE PARTITION`, `EXCHANGE PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION`, `ANALYZE PARTITION`, `CHECK PARTITION`, `OPTIMIZE PARTITION`, `REBUILD PARTITION`, `REMOVE PARTITIONING`.

For example, the following two statements are invalid:

```
ALTER TABLE t1 ANALYZE PARTITION p1, ANALYZE PARTITION p2;
ALTER TABLE t1 ANALYZE PARTITION p1, CHECK PARTITION p2;
```

In the first case, you can analyze partitions `p1` and `p2` of table `t1` concurrently using a single statement with a single `ANALYZE PARTITION` option that lists both of the partitions to be analyzed, like this:

```
ALTER TABLE t1 ANALYZE PARTITION p1, p2;
```

In the second case, it is not possible to perform `ANALYZE` and `CHECK` operations on different partitions of the same table concurrently. Instead, you must issue two separate statements, like this:

```
ALTER TABLE t1 ANALYZE PARTITION p1;
ALTER TABLE t1 CHECK PARTITION p2;
```

`REBUILD` operations are currently unsupported for subpartitions. The `REBUILD` keyword is expressly disallowed with subpartitions, and causes `ALTER TABLE` to fail with an error if so used.

`CHECK PARTITION` and `REPAIR PARTITION` operations fail when the partition to be checked or repaired contains any duplicate key errors.

For more information about these statements, see [Section 22.3.4, “Maintenance of Partitions”](#).

13.1.7.2 ALTER TABLE and Generated Columns

`ALTER TABLE` operations permitted for generated columns are `ADD`, `MODIFY`, and `CHANGE`.

- Generated columns can be added.
- The data type and expression of generated columns can be modified.
- Generated columns can be renamed or dropped, if no other column refers to them.
- Virtual generated columns cannot be altered to stored generated columns, or vice versa. To work around this, drop the column, then add it with the new definition.
- Nongenerated columns can be altered to stored but not virtual generated columns.

- Stored but not virtual generated columns can be altered to nongenerated columns. The stored generated values become the values of the nongenerated column.
- `ADD COLUMN` is not an in-place operation for stored columns (done without using a temporary table) because the expression must be evaluated by the server. For stored columns, indexing changes are done in place, and expression changes are not done in place. Changes to column comments are done in place.
- For non-partitioned tables, `ADD COLUMN` and `DROP COLUMN` are in-place operations for virtual columns. However, adding or dropping a virtual column cannot be performed in place in combination with other `ALTER TABLE` operations.

For partitioned tables, `ADD COLUMN` and `DROP COLUMN` are not in-place operations for virtual columns.

- `InnoDB` supports secondary indexes on virtual generated columns. Adding or dropping a secondary index on a virtual generated column is an in-place operation. For more information, see [Section 13.1.15.9, “Secondary Indexes and Generated Columns”](#).
- When a `VIRTUAL` generated column is added to a table or modified, it is not ensured that data being calculated by the generated column expression will not be out of range for the column. This can lead to inconsistent data being returned and unexpectedly failed statements. To permit control over whether validation occurs for such columns, `ALTER TABLE` supports `WITHOUT VALIDATION` and `WITH VALIDATION` clauses:
 - With `WITHOUT VALIDATION` (the default if neither clause is specified), an in-place operation is performed (if possible), data integrity is not checked, and the statement finishes more quickly. However, later reads from the table might report warnings or errors for the column if values are out of range.
 - With `WITH VALIDATION`, `ALTER TABLE` copies the table. If an out-of-range or any other error occurs, the statement fails. Because a table copy is performed, the statement takes longer.

`WITHOUT VALIDATION` and `WITH VALIDATION` are permitted only with `ADD COLUMN`, `CHANGE COLUMN`, and `MODIFY COLUMN` operations. An `ER_WRONG_USAGE` error occurs otherwise.

- If expression evaluation causes truncation or provides incorrect input to a function, the `ALTER TABLE` statement terminates with an error and the DDL operation is rejected.
- An `ALTER TABLE` statement that changes the default value of a column `col_name` may also change the value of a generated column expression that refers to the column using `col_name`, which may change the value of a generated column expression that refers to the column using `DEFAULT(col_name)`. For this reason, `ALTER TABLE` operations that change the definition of a column now cause a table rebuild if any generated column expression uses `DEFAULT()`.

13.1.7.3 ALTER TABLE Examples

Begin with a table `t1` that is created as shown here:

```
CREATE TABLE t1 (a INTEGER,b CHAR(10));
```

To rename the table from `t1` to `t2`:

```
ALTER TABLE t1 RENAME t2;
```

To change column `a` from `INTEGER` to `TINYINT NOT NULL` (leaving the name the same), and to change column `b` from `CHAR(10)` to `CHAR(20)` as well as renaming it from `b` to `c`:

```
ALTER TABLE t2 MODIFY a TINYINT NOT NULL, CHANGE b c CHAR(20);
```

To add a new `TIMESTAMP` column named `d`:

```
ALTER TABLE t2 ADD d TIMESTAMP;
```

To add an index on column `d` and a `UNIQUE` index on column `a`:

```
ALTER TABLE t2 ADD INDEX (d), ADD UNIQUE (a);
```

To remove column `c`:

```
ALTER TABLE t2 DROP COLUMN c;
```

To add a new `AUTO_INCREMENT` integer column named `c`:

```
ALTER TABLE t2 ADD c INT UNSIGNED NOT NULL AUTO_INCREMENT,  
ADD PRIMARY KEY (c);
```

We indexed `c` (as a `PRIMARY KEY`) because `AUTO_INCREMENT` columns must be indexed, and we declare `c` as `NOT NULL` because primary key columns cannot be `NULL`.

When you add an `AUTO_INCREMENT` column, column values are filled in with sequence numbers automatically. For `MyISAM` tables, you can set the first sequence number by executing `SET INSERT_ID=value` before `ALTER TABLE` or by using the `AUTO_INCREMENT=value` table option. See [Section 5.1.5, “Server System Variables”](#).

With `MyISAM` tables, if you do not change the `AUTO_INCREMENT` column, the sequence number is not affected. If you drop an `AUTO_INCREMENT` column and then add another `AUTO_INCREMENT` column, the numbers are resequenced beginning with 1.

When replication is used, adding an `AUTO_INCREMENT` column to a table might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to the table `t1`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 (id INT AUTO_INCREMENT PRIMARY KEY)  
SELECT * FROM t1 ORDER BY col1, col2;
```

This assumes that the table `t1` has columns `col1` and `col2`.

This set of statements will also produce a new table `t2` identical to `t1`, with the addition of an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 LIKE t1;  
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;  
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

Important

To guarantee the same ordering on both master and slave, *all* columns of `t1` must be referenced in the `ORDER BY` clause.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP TABLE t1;  
ALTER TABLE t2 RENAME t1;
```

13.1.8 ALTER VIEW Syntax

```
ALTER
  [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
  [DEFINER = { user | CURRENT_USER }]
  [SQL SECURITY { DEFINER | INVOKER }]
  VIEW view_name [(column_list)]
  AS select_statement
  [WITH [CASCADED | LOCAL] CHECK OPTION]
```

This statement changes the definition of a view, which must exist. The syntax is similar to that for [CREATE VIEW](#) and the effect is the same as for [CREATE OR REPLACE VIEW](#). See [Section 13.1.18, “CREATE VIEW Syntax”](#). This statement requires the [CREATE VIEW](#) and [DROP](#) privileges for the view, and some privilege for each column referred to in the [SELECT](#) statement. [ALTER VIEW](#) is permitted only to the definer or users with the [SET_USER_ID](#) or [SUPER](#) privilege.

13.1.9 CREATE DATABASE Syntax

```
CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
  [create_specification] ...

create_specification:
  [DEFAULT] CHARACTER SET [=] charset_name
  | [DEFAULT] COLLATE [=] collation_name
```

[CREATE DATABASE](#) creates a database with the given name. To use this statement, you need the [CREATE](#) privilege for the database. [CREATE SCHEMA](#) is a synonym for [CREATE DATABASE](#).

An error occurs if the database exists and you did not specify [IF NOT EXISTS](#).

In MySQL 8.0, [CREATE DATABASE](#) is not permitted within a session that has an active [LOCK TABLES](#) statement.

[create_specification](#) options specify database characteristics. Database characteristics are stored in the data dictionary. The [CHARACTER SET](#) clause specifies the default database character set. The [COLLATE](#) clause specifies the default database collation. [Section 10.1, “Character Set Support”](#), discusses character set and collation names.

A database in MySQL is implemented as a directory containing files that correspond to tables in the database. Because there are no tables in a database when it is initially created, the [CREATE DATABASE](#) statement creates only a directory under the MySQL data directory. Rules for permissible database names are given in [Section 9.2, “Schema Object Names”](#). If a database name contains special characters, the name for the database directory contains encoded versions of those characters as described in [Section 9.2.3, “Mapping of Identifiers to File Names”](#).

Creating a database directory by manually creating a directory under the data directory (for example, with `mkdir`) is temporarily unsupported in MySQL 8.0.0.

You can also use the `mysqladmin` program to create databases. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

13.1.10 CREATE EVENT Syntax

```
CREATE
  [DEFINER = { user | CURRENT_USER }]
  EVENT
  [IF NOT EXISTS]
  event_name
  ON SCHEDULE schedule
  [ON COMPLETION [NOT] PRESERVE]
  [ENABLE | DISABLE | DISABLE ON SLAVE]
  [COMMENT 'comment']
  DO event_body;

schedule:
```

```

AT timestamp [+ INTERVAL interval] ...
| EVERY interval
[STARTS timestamp [+ INTERVAL interval] ...]
[ENDS timestamp [+ INTERVAL interval] ...]

interval:
  quantity {YEAR | QUARTER | MONTH | DAY | HOUR | MINUTE |
            WEEK | SECOND | YEAR_MONTH | DAY_HOUR | DAY_MINUTE |
            DAY_SECOND | HOUR_MINUTE | HOUR_SECOND | MINUTE_SECOND}

```

This statement creates and schedules a new event. The event will not run unless the Event Scheduler is enabled. For information about checking Event Scheduler status and enabling it if necessary, see [Section 23.4.2, “Event Scheduler Configuration”](#).

`CREATE EVENT` requires the `EVENT` privilege for the schema in which the event is to be created. It might also require the `SET_USER_ID` or `SUPER` privilege, depending on the `DEFINER` value, as described later in this section.

The minimum requirements for a valid `CREATE EVENT` statement are as follows:

- The keywords `CREATE EVENT` plus an event name, which uniquely identifies the event in a database schema.
- An `ON SCHEDULE` clause, which determines when and how often the event executes.
- A `DO` clause, which contains the SQL statement to be executed by an event.

This is an example of a minimal `CREATE EVENT` statement:

```

CREATE EVENT myevent
  ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
  DO
    UPDATE myschema.mytable SET mycol = mycol + 1;

```

The previous statement creates an event named `myevent`. This event executes once—one hour following its creation—by running an SQL statement that increments the value of the `myschema.mytable` table's `mycol` column by 1.

The `event_name` must be a valid MySQL identifier with a maximum length of 64 characters. Event names are not case sensitive, so you cannot have two events named `myevent` and `MyEvent` in the same schema. In general, the rules governing event names are the same as those for names of stored routines. See [Section 9.2, “Schema Object Names”](#).

An event is associated with a schema. If no schema is indicated as part of `event_name`, the default (current) schema is assumed. To create an event in a specific schema, qualify the event name with a schema using `schema_name.event_name` syntax.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at event execution time. If a `user` value is given, it should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE EVENT` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the valid `DEFINER` user values:

- If you do not have the `SET_USER_ID` or `SUPER` privilege, the only permitted `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SET_USER_ID` or `SUPER` privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.
- Although it is possible to create an event with a nonexistent `DEFINER` account, an error occurs at event execution time if the account does not exist.

For more information about event security, see [Section 23.6, “Access Control for Stored Programs and Views”](#).

Within an event, the `CURRENT_USER()` function returns the account used to check privileges at event execution time, which is the `DEFINER` user. For information about user auditing within events, see [Section 6.3.13, “SQL-Based MySQL Account Activity Auditing”](#).

`IF NOT EXISTS` has the same meaning for `CREATE EVENT` as for `CREATE TABLE`: If an event named `event_name` already exists in the same schema, no action is taken, and no error results. (However, a warning is generated in such cases.)

The `ON SCHEDULE` clause determines when, how often, and for how long the `event_body` defined for the event repeats. This clause takes one of two forms:

- `AT timestamp` is used for a one-time event. It specifies that the event executes one time only at the date and time given by `timestamp`, which must include both the date and time, or must be an expression that resolves to a datetime value. You may use a value of either the `DATETIME` or `TIMESTAMP` type for this purpose. If the date is in the past, a warning occurs, as shown here:

```
mysql> SELECT NOW();
+-----+
| NOW() |
+-----+
| 2006-02-10 23:59:01 |
+-----+
1 row in set (0.04 sec)

mysql> CREATE EVENT e_totals
  -> ON SCHEDULE AT '2006-02-10 23:59:00'
  -> DO INSERT INTO test.totals VALUES (NOW());
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 1588
Message: Event execution time is in the past and ON COMPLETION NOT
PRESERVE is set. The event was dropped immediately after
creation.
```

`CREATE EVENT` statements which are themselves invalid—for whatever reason—fail with an error.

You may use `CURRENT_TIMESTAMP` to specify the current date and time. In such a case, the event acts as soon as it is created.

To create an event which occurs at some point in the future relative to the current date and time—such as that expressed by the phrase “three weeks from now”—you can use the optional clause `+ INTERVAL interval`. The `interval` portion consists of two parts, a quantity and a unit of time, and follows the same syntax rules that govern intervals used in the `DATE_ADD()` function (see [Section 12.7, “Date and Time Functions”](#)). The units keywords are also the same, except that you cannot use any units involving microseconds when defining an event. With some interval types, complex time units may be used. For example, “two minutes and ten seconds” can be expressed as `+ INTERVAL '2:10' MINUTE_SECOND`.

You can also combine intervals. For example, `AT CURRENT_TIMESTAMP + INTERVAL 3 WEEK + INTERVAL 2 DAY` is equivalent to “three weeks and two days from now”. Each portion of such a clause must begin with `+ INTERVAL`.

- To repeat actions at a regular interval, use an `EVERY` clause. The `EVERY` keyword is followed by an `interval` as described in the previous discussion of the `AT` keyword. (`+ INTERVAL` is *not* used with `EVERY`.) For example, `EVERY 6 WEEK` means “every six weeks”.

Although `+ INTERVAL` clauses are not permitted in an `EVERY` clause, you can use the same complex time units permitted in a `+ INTERVAL`.

An `EVERY` clause may contain an optional `STARTS` clause. `STARTS` is followed by a *timestamp* value that indicates when the action should begin repeating, and may also use `+ INTERVAL interval` to specify an amount of time “from now”. For example, `EVERY 3 MONTH STARTS CURRENT_TIMESTAMP + INTERVAL 1 WEEK` means “every three months, beginning one week from now”. Similarly, you can express “every two weeks, beginning six hours and fifteen minutes from now” as `EVERY 2 WEEK STARTS CURRENT_TIMESTAMP + INTERVAL '6:15' HOUR_MINUTE`. Not specifying `STARTS` is the same as using `STARTS CURRENT_TIMESTAMP`—that is, the action specified for the event begins repeating immediately upon creation of the event.

An `EVERY` clause may contain an optional `ENDS` clause. The `ENDS` keyword is followed by a *timestamp* value that tells MySQL when the event should stop repeating. You may also use `+ INTERVAL interval` with `ENDS`; for instance, `EVERY 12 HOUR STARTS CURRENT_TIMESTAMP + INTERVAL 30 MINUTE ENDS CURRENT_TIMESTAMP + INTERVAL 4 WEEK` is equivalent to “every twelve hours, beginning thirty minutes from now, and ending four weeks from now”. Not using `ENDS` means that the event continues executing indefinitely.

`ENDS` supports the same syntax for complex time units as `STARTS` does.

You may use `STARTS`, `ENDS`, both, or neither in an `EVERY` clause.

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the `GET_LOCK()` function, or row or table locking.

The `ON SCHEDULE` clause may use expressions involving built-in MySQL functions and user variables to obtain any of the *timestamp* or *interval* values which it contains. You may not use stored functions or user-defined functions in such expressions, nor may you use any table references; however, you may use `SELECT FROM DUAL`. This is true for both `CREATE EVENT` and `ALTER EVENT` statements. References to stored functions, user-defined functions, and tables in such cases are specifically not permitted, and fail with an error (see Bug #22830).

Times in the `ON SCHEDULE` clause are interpreted using the current session `time_zone` value. This becomes the event time zone; that is, the time zone that is used for event scheduling and is in effect within the event as it executes. These times are converted to UTC and stored along with the event time zone in the `mysql.event` table. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. For additional information about representation of event times, see [Section 23.4.4, “Event Metadata”](#). See also [Section 13.7.5.18, “SHOW EVENTS Syntax”](#), and [Section 24.8, “The INFORMATION_SCHEMA EVENTS Table”](#).

Normally, once an event has expired, it is immediately dropped. You can override this behavior by specifying `ON COMPLETION PRESERVE`. Using `ON COMPLETION NOT PRESERVE` merely makes the default nonpersistent behavior explicit.

You can create an event but prevent it from being active using the `DISABLE` keyword. Alternatively, you can use `ENABLE` to make explicit the default status, which is active. This is most useful in conjunction with `ALTER EVENT` (see [Section 13.1.2, “ALTER EVENT Syntax”](#)).

A third value may also appear in place of `ENABLE` or `DISABLE`; `DISABLE ON SLAVE` is set for the status of an event on a replication slave to indicate that the event was created on the master and replicated to the slave, but is not executed on the slave. See [Section 18.4.1.12, “Replication of Invoked Features”](#).

You may supply a comment for an event using a `COMMENT` clause. *comment* may be any string of up to 64 characters that you wish to use for describing the event. The comment text, being a string literal, must be surrounded by quotation marks.

The `DO` clause specifies an action carried by the event, and consists of an SQL statement. Nearly any valid MySQL statement that can be used in a stored routine can also be used as the action

statement for a scheduled event. (See [Section C.1, “Restrictions on Stored Programs”](#).) For example, the following event `e_hourly` deletes all rows from the `sessions` table once per hour, where this table is part of the `site_activity` schema:

```
CREATE EVENT e_hourly
  ON SCHEDULE
    EVERY 1 HOUR
  COMMENT 'Clears out sessions table each hour.'
  DO
    DELETE FROM site_activity.sessions;
```

MySQL stores the `sql_mode` system variable setting in effect when an event is created or altered, and always executes the event with this setting in force, *regardless of the current server SQL mode when the event begins executing*.

A `CREATE EVENT` statement that contains an `ALTER EVENT` statement in its `DO` clause appears to succeed; however, when the server attempts to execute the resulting scheduled event, the execution fails with an error.

Note

Statements such as `SELECT` or `SHOW` that merely return a result set have no effect when used in an event; the output from these is not sent to the MySQL Monitor, nor is it stored anywhere. However, you can use statements such as `SELECT ... INTO` and `INSERT INTO ... SELECT` that store a result. (See the next example in this section for an instance of the latter.)

The schema to which an event belongs is the default schema for table references in the `DO` clause. Any references to tables in other schemas must be qualified with the proper schema name.

As with stored routines, you can use compound-statement syntax in the `DO` clause by using the `BEGIN` and `END` keywords, as shown here:

```
delimiter |

CREATE EVENT e_daily
  ON SCHEDULE
    EVERY 1 DAY
  COMMENT 'Saves total number of sessions then clears the table each day'
  DO
    BEGIN
      INSERT INTO site_activity.totals (time, total)
        SELECT CURRENT_TIMESTAMP, COUNT(*)
          FROM site_activity.sessions;
      DELETE FROM site_activity.sessions;
    END |

delimiter ;
```

This example uses the `delimiter` command to change the statement delimiter. See [Section 23.1, “Defining Stored Programs”](#).

More complex compound statements, such as those used in stored routines, are possible in an event. This example uses local variables, an error handler, and a flow control construct:

```
delimiter |

CREATE EVENT e
  ON SCHEDULE
    EVERY 5 SECOND
  DO
    BEGIN
      DECLARE v INTEGER;
      DECLARE CONTINUE HANDLER FOR SQLEXCEPTION BEGIN END;
```

```

SET v = 0;

WHILE v < 5 DO
  INSERT INTO t1 VALUES (0);
  UPDATE t2 SET s1 = s1 + 1;
  SET v = v + 1;
END WHILE;
END |
delimiter ;

```

There is no way to pass parameters directly to or from events; however, it is possible to invoke a stored routine with parameters within an event:

```

CREATE EVENT e_call_myproc
ON SCHEDULE
  AT CURRENT_TIMESTAMP + INTERVAL 1 DAY
DO CALL myproc(5, 27);

```

If an event's definer has the [SYSTEM_VARIABLES_ADMIN](#) or [SUPER](#) privilege, the event can read and write global variables. As granting this privilege entails a potential for abuse, extreme care must be taken in doing so.

Generally, any statements that are valid in stored routines may be used for action statements executed by events. For more information about statements permissible within stored routines, see [Section 23.2.1, "Stored Routine Syntax"](#). You can create an event as part of a stored routine, but an event cannot be created by another event.

13.1.11 CREATE FUNCTION Syntax

The [CREATE FUNCTION](#) statement is used to create stored functions and user-defined functions (UDFs):

- For information about creating stored functions, see [Section 13.1.13, "CREATE PROCEDURE and CREATE FUNCTION Syntax"](#).
- For information about creating user-defined functions, see [Section 13.7.3.1, "CREATE FUNCTION Syntax for User-Defined Functions"](#).

13.1.12 CREATE INDEX Syntax

```

CREATE [UNIQUE|FULLTEXT|SPATIAL] INDEX index_name
  [index_type]
  ON tbl_name (index_col_name,...)
  [index_option]
  [algorithm_option | lock_option] ...

index_col_name:
  col_name [(length)] [ASC | DESC]

index_option:
  KEY_BLOCK_SIZE [=] value
  | index_type
  | WITH PARSER parser_name
  | COMMENT 'string'
  | {VISIBLE | INVISIBLE}

index_type:
  USING {BTREE | HASH}

algorithm_option:
  ALGORITHM [=] {DEFAULT|INPLACE|COPY}

lock_option:
  LOCK [=] {DEFAULT|NONE|SHARED|EXCLUSIVE}

```

`CREATE INDEX` is mapped to an `ALTER TABLE` statement to create indexes. See [Section 13.1.7, “ALTER TABLE Syntax”](#). `CREATE INDEX` cannot be used to create a `PRIMARY KEY`; use `ALTER TABLE` instead. For more information about indexes, see [Section 8.3.1, “How MySQL Uses Indexes”](#).

Normally, you create all indexes on a table at the time the table itself is created with `CREATE TABLE`. See [Section 13.1.15, “CREATE TABLE Syntax”](#). This guideline is especially important for `InnoDB` tables, where the primary key determines the physical layout of rows in the data file. `CREATE INDEX` enables you to add indexes to existing tables.

A column list of the form `(col1, col2, ...)` creates a multiple-column index. Index key values are formed by concatenating the values of the given columns.

For string columns, indexes can be created that use only the leading part of column values, using `col_name(length)` syntax to specify an index prefix length:

- Prefixes can be specified for `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY` column indexes.
- Prefixes *must* be specified for `BLOB` and `TEXT` column indexes.
- Prefix limits are measured in bytes, whereas the prefix length in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements is interpreted as number of characters for nonbinary string types (`CHAR`, `VARCHAR`, `TEXT`) and number of bytes for binary string types (`BINARY`, `VARBINARY`, `BLOB`). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.
- For spatial columns, prefix values cannot be given, as described later in this section.

The statement shown here creates an index using the first 10 characters of the `name` column (assuming that `name` has a nonbinary string type):

```
CREATE INDEX part_of_name ON customer (name(10));
```

If names in the column usually differ in the first 10 characters, this index should not be much slower than an index created from the entire `name` column. Also, using column prefixes for indexes can make the index file much smaller, which could save a lot of disk space and might also speed up `INSERT` operations.

Prefix support and lengths of prefixes (where supported) are storage engine dependent. For example, a prefix can be up to 767 bytes long for `InnoDB` tables that use the `REDUNDANT` or `COMPACT` row format. The length limit is raised to 3072 bytes for `InnoDB` tables that use the `DYNAMIC` or `COMPRESSED` row format. For `MyISAM` tables, the prefix limit is 1000 bytes.

A `UNIQUE` index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a `UNIQUE` index permits multiple `NULL` values for columns that can contain `NULL`. If you specify a prefix value for a column in a `UNIQUE` index, the column values must be unique within the prefix.

`FULLTEXT` indexes are supported only for `InnoDB` and `MyISAM` tables and can include only `CHAR`, `VARCHAR`, and `TEXT` columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See [Section 12.9, “Full-Text Search Functions”](#), for details of operation.

The `MyISAM`, `InnoDB`, `NDB`, and `ARCHIVE` storage engines support spatial columns such as (`POINT` and `GEOMETRY`). ([Section 11.5, “Extensions for Spatial Data”](#), describes the spatial data types.) However, support for spatial column indexing varies among engines. Spatial and nonspatial indexes are available according to the following rules.

Spatial indexes (created using `SPATIAL INDEX`) have these characteristics:

- Available only for `InnoDB` and `MyISAM` tables. Specifying `SPATIAL INDEX` for other storage engines results in an error.
- Indexed columns must be `NOT NULL`.

- Column prefix lengths are prohibited. The full width of each column is indexed.

Characteristics of nonspatial indexes (created with `INDEX`, `UNIQUE`, or `PRIMARY KEY`):

- Permitted for any storage engine that supports spatial columns except `ARCHIVE`.
- Columns can be `NULL` unless the index is a primary key.
- For each spatial column in a non-`SPATIAL` index except `POINT` columns, a column prefix length must be specified. (This is the same requirement as for indexed `BLOB` columns.) The prefix length is given in bytes.
- The index type for a non-`SPATIAL` index depends on the storage engine. Currently, B-tree is used.
- You can add an index on a column that can have `NULL` values only for `InnoDB`, `MyISAM`, and `MEMORY` tables.
- You can add an index on a `BLOB` or `TEXT` column only for using the `InnoDB` and `MyISAM` tables.
- When the `innodb_stats_persistent` setting is enabled, run the `ANALYZE TABLE` statement for an `InnoDB` table after creating an index on that table.

`InnoDB` supports secondary indexes on virtual columns. For more information, see [Section 13.1.15.9, “Secondary Indexes and Generated Columns”](#).

An `index_col_name` specification can end with `ASC` or `DESC` to specify whether index values are stored in ascending or descending order. The default is ascending if no order specifier is given. `ASC` and `DESC` are not permitted for `HASH` indexes.

Following the index column list, index options can be given. An `index_option` value can be any of the following:

- `KEY_BLOCK_SIZE [=] value`

For `MyISAM` tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A `KEY_BLOCK_SIZE` value specified for an individual index definition overrides a table-level `KEY_BLOCK_SIZE` value.

`KEY_BLOCK_SIZE` is not supported at the index level for `InnoDB` tables. See [Section 13.1.15, “CREATE TABLE Syntax”](#).

- `index_type`

Some storage engines permit you to specify an index type when creating an index. For example:

```
CREATE TABLE lookup (id INT) ENGINE = MEMORY;
CREATE INDEX id_index ON lookup (id) USING BTREE;
```

[Table 13.1, “Index Types Per Storage Engine”](#) shows the permissible index type values supported by different storage engines. Where multiple index types are listed, the first one is the default when no index type specifier is given. Storage engines not listed in the table do not support an `index_type` clause in index definitions.

Table 13.1 Index Types Per Storage Engine

Storage Engine	Permissible Index Types
<code>InnoDB</code>	<code>BTREE</code>
<code>MyISAM</code>	<code>BTREE</code>
<code>MEMORY/HEAP</code>	<code>HASH</code> , <code>BTREE</code>
<code>NDB</code>	<code>HASH</code> , <code>BTREE</code> (see note in text)

The *index_type* clause cannot be used for `FULLTEXT INDEX` or `SPATIAL INDEX` specifications. Full-text index implementation is storage engine dependent. Spatial indexes are implemented as R-tree indexes.

If you specify an index type that is not valid for a given storage engine, but another index type is available that the engine can use without affecting query results, the engine uses the available type. The parser recognizes `RTREE` as a type name, but currently this cannot be specified for any storage engine.

Note

Use of the *index_type* option before the `ON tbl_name` clause is deprecated; support for use of the option in this position will be removed in a future MySQL release. If an *index_type* option is given in both the earlier and later positions, the final option applies.

`TYPE type_name` is recognized as a synonym for `USING type_name`. However, `USING` is the preferred form.

For the storage engines that support an *index_type* option, [Table 13.2, “Storage Engine Index Characteristics”](#) shows some characteristics of index use.

Table 13.2 Storage Engine Index Characteristics

Storage Engine	Index Type	Index Class	Stores NULL Values	Permits Multiple NULL Values	IS NULL Scan Type	IS NOT NULL Scan Type
InnoDB	BTREE	Primary key	No	No	N/A	N/A
		Unique	Yes	Yes	Index	Index
		Key	Yes	Yes	Index	Index
	Inapplicable	FULLTEXT	Yes	Yes	Table	Table
	Inapplicable	SPATIAL	No	No	N/A	N/A
MyISAM	BTREE	Primary key	No	No	N/A	N/A
		Unique	Yes	Yes	Index	Index
		Key	Yes	Yes	Index	Index
	Inapplicable	FULLTEXT	Yes	Yes	Table	Table
	Inapplicable	SPATIAL	No	No	N/A	N/A
MEMORY	HASH	Primary key	No	No	N/A	N/A
		Unique	Yes	Yes	Index	Index
		Key	Yes	Yes	Index	Index
	BTREE	Primary	No	No	N/A	N/A
		Unique	Yes	Yes	Index	Index
		Key	Yes	Yes	Index	Index

- `WITH PARSER parser_name`

This option can be used only with `FULLTEXT` indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. `InnoDB` and `MyISAM` support

full-text parser plugins. See [Full-Text Parser Plugins](#) and [Section 28.2.4.4, “Writing Full-Text Parser Plugins”](#) for more information.

- `COMMENT 'string'`

Index definitions can include an optional comment of up to 1024 characters.

The `MERGE_THRESHOLD` for index pages can be configured for individual indexes using the `index_option COMMENT` clause of the `CREATE INDEX` statement. For example:

```
CREATE TABLE t1 (id INT);
CREATE INDEX id_index ON t1 (id) COMMENT 'MERGE_THRESHOLD=40';
```

If the page-full percentage for an index page falls below the `MERGE_THRESHOLD` value when a row is deleted or when a row is shortened by an update operation, InnoDB attempts to merge the index page with a neighboring index page. The default `MERGE_THRESHOLD` value is 50, which is the previously hardcoded value.

`MERGE_THRESHOLD` can also be defined at the index level and table level using `CREATE TABLE` and `ALTER TABLE` statements. For more information, see [Section 15.6.12, “Configuring the Merge Threshold for Index Pages”](#).

- `VISIBLE, INVISIBLE`

Modify index visibility. Indexes are visible by default. An invisible index is not used by the optimizer. Modification of index visibility applies to indexes other than primary keys (either explicit or implicit). This feature is storage engine neutral (supported for any engine). For more information, see [Section 8.3.11, “Invisible Indexes”](#).

`ALGORITHM` and `LOCK` clauses may be given to influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the `ALTER TABLE` statement. For more information, see [Section 13.1.7, “ALTER TABLE Syntax”](#)

13.1.13 CREATE PROCEDURE and CREATE FUNCTION Syntax

```
CREATE
  [DEFINER = { user | CURRENT_USER }]
  PROCEDURE sp_name ([proc_parameter[,...]])
  [characteristic ...] routine_body

CREATE
  [DEFINER = { user | CURRENT_USER }]
  FUNCTION sp_name ([func_parameter[,...]])
  RETURNS type
  [characteristic ...] routine_body

proc_parameter:
  [ IN | OUT | INOUT ] param_name type

func_parameter:
  param_name type

type:
  Any valid MySQL data type

characteristic:
  COMMENT 'string'
  | LANGUAGE SQL
  | [NOT] DETERMINISTIC
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
```

Valid SQL routine statement

These statements create stored routines. By default, a routine is associated with the default database. To associate the routine explicitly with a given database, specify the name as `db_name.sp_name` when you create it.

The `CREATE FUNCTION` statement is also used in MySQL to support UDFs (user-defined functions). See [Section 28.4, “Adding New Functions to MySQL”](#). A UDF can be regarded as an external stored function. Stored functions share their namespace with UDFs. See [Section 9.2.4, “Function Name Parsing and Resolution”](#), for the rules describing how the server interprets references to different kinds of functions.

To invoke a stored procedure, use the `CALL` statement (see [Section 13.2.1, “CALL Syntax”](#)). To invoke a stored function, refer to it in an expression. The function returns a value during expression evaluation.

`CREATE PROCEDURE` and `CREATE FUNCTION` require the `CREATE ROUTINE` privilege. They might also require the `SET_USER_ID` or `SUPER` privilege, depending on the `DEFINER` value, as described later in this section. If binary logging is enabled, `CREATE FUNCTION` might require the `SUPER` privilege, as described in [Section 23.7, “Binary Logging of Stored Programs”](#).

By default, MySQL automatically grants the `ALTER ROUTINE` and `EXECUTE` privileges to the routine creator. This behavior can be changed by disabling the `automatic_sp_privileges` system variable. See [Section 23.2.2, “Stored Routines and MySQL Privileges”](#).

The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at routine execution time, as described later in this section.

If the routine name is the same as the name of a built-in SQL function, a syntax error occurs unless you use a space between the name and the following parenthesis when defining the routine or invoking it later. For this reason, avoid using the names of existing SQL functions for your own stored routines.

The `IGNORE_SPACE` SQL mode applies to built-in functions, not to stored routines. It is always permissible to have spaces after a stored routine name, regardless of whether `IGNORE_SPACE` is enabled.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of `()` should be used. Parameter names are not case sensitive.

Each parameter is an `IN` parameter by default. To specify otherwise for a parameter, use the keyword `OUT` or `INOUT` before the parameter name.

Note

Specifying a parameter as `IN`, `OUT`, or `INOUT` is valid only for a `PROCEDURE`. For a `FUNCTION`, parameters are always regarded as `IN` parameters.

An `IN` parameter passes a value into a procedure. The procedure might modify the value, but the modification is not visible to the caller when the procedure returns. An `OUT` parameter passes a value from the procedure back to the caller. Its initial value is `NULL` within the procedure, and its value is visible to the caller when the procedure returns. An `INOUT` parameter is initialized by the caller, can be modified by the procedure, and any change made by the procedure is visible to the caller when the procedure returns.

For each `OUT` or `INOUT` parameter, pass a user-defined variable in the `CALL` statement that invokes the procedure so that you can obtain its value when the procedure returns. If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `IN` or `INOUT` parameter.

Routine parameters cannot be referenced in statements prepared within the routine; see [Section C.1, “Restrictions on Stored Programs”](#).

The following example shows a simple stored procedure that uses an `OUT` parameter:

```
mysql> delimiter //

mysql> CREATE PROCEDURE simpleproc (OUT param1 INT)
-> BEGIN
->   SELECT COUNT(*) INTO param1 FROM t;
-> END//
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;

mysql> CALL simpleproc(@a);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @a;
+-----+
| @a    |
+-----+
| 3     |
+-----+
1 row in set (0.00 sec)
```

The example uses the `mysql` client `delimiter` command to change the statement delimiter from `;` to `//` while the procedure is being defined. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself. See [Section 23.1, “Defining Stored Programs”](#).

The `RETURNS` clause may be specified only for a `FUNCTION`, for which it is mandatory. It indicates the return type of the function, and the function body must contain a `RETURN value` statement. If the `RETURN` statement returns a value of a different type, the value is coerced to the proper type. For example, if a function specifies an `ENUM` or `SET` value in the `RETURNS` clause, but the `RETURN` statement returns an integer, the value returned from the function is the string for the corresponding `ENUM` member or set of `SET` members.

The following example function takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
-> RETURN CONCAT('Hello, ',s,'!');
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world!  |
+-----+
1 row in set (0.00 sec)
```

Parameter types and function return types can be declared to use any valid data type. The `COLLATE` attribute can be used if preceded by the `CHARACTER SET` attribute.

The `routine_body` consists of a valid SQL routine statement. This can be a simple statement such as `SELECT` or `INSERT`, or a compound statement written using `BEGIN` and `END`. Compound statements can contain declarations, loops, and other control structure statements. The syntax for these statements is described in [Section 13.6, “Compound-Statement Syntax”](#).

MySQL permits routines to contain DDL statements, such as `CREATE` and `DROP`. MySQL also permits stored procedures (but not stored functions) to contain SQL transaction statements such as `COMMIT`. Stored functions may not contain statements that perform explicit or implicit commit or rollback. Support for these statements is not required by the SQL standard, which states that each DBMS vendor may decide whether to permit them.

Statements that return a result set can be used within a stored procedure but not within a stored function. This prohibition includes `SELECT` statements that do not have an `INTO var_list` clause

and other statements such as `SHOW`, `EXPLAIN`, and `CHECK TABLE`. For statements that can be determined at function definition time to return a result set, a `Not allowed to return a result set from a function` error occurs (`ER_SP_NO_RETSET`). For statements that can be determined only at runtime to return a result set, a `PROCEDURE %s can't return a result set in the given context` error occurs (`ER_SP_BADSELECT`).

`USE` statements within stored routines are not permitted. When a routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). This causes the routine to have the given default database while it executes. References to objects in databases other than the routine default database should be qualified with the appropriate database name.

For additional information about statements that are not permitted in stored routines, see [Section C.1, “Restrictions on Stored Programs”](#).

For information about invoking stored procedures from within programs written in a language that has a MySQL interface, see [Section 13.2.1, “CALL Syntax”](#).

MySQL stores the `sql_mode` system variable setting in effect when a routine is created or altered, and always executes the routine with this setting in force, *regardless of the current server SQL mode when the routine begins executing*.

The switch from the SQL mode of the invoker to that of the routine occurs after evaluation of arguments and assignment of the resulting values to routine parameters. If you define a routine in strict SQL mode but invoke it in nonstrict mode, assignment of arguments to routine parameters does not take place in strict mode. If you require that expressions passed to a routine be assigned in strict SQL mode, you should invoke the routine with strict mode in effect.

The `COMMENT` characteristic is a MySQL extension, and may be used to describe the stored routine. This information is displayed by the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements.

The `LANGUAGE` characteristic indicates the language in which the routine is written. The server ignores this characteristic; only SQL routines are supported.

A routine is considered “deterministic” if it always produces the same result for the same input parameters, and “not deterministic” otherwise. If neither `DETERMINISTIC` nor `NOT DETERMINISTIC` is given in the routine definition, the default is `NOT DETERMINISTIC`. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.

Assessment of the nature of a routine is based on the “honesty” of the creator: MySQL does not check that a routine declared `DETERMINISTIC` is free of statements that produce nondeterministic results. However, misdeclaring a routine might affect results or affect performance. Declaring a nondeterministic routine as `DETERMINISTIC` might lead to unexpected results by causing the optimizer to make incorrect execution plan choices. Declaring a deterministic routine as `NONDETERMINISTIC` might diminish performance by causing available optimizations not to be used.

If binary logging is enabled, the `DETERMINISTIC` characteristic affects which routine definitions MySQL accepts. See [Section 23.7, “Binary Logging of Stored Programs”](#).

A routine that contains the `NOW()` function (or its synonyms) or `RAND()` is nondeterministic, but it might still be replication-safe. For `NOW()`, the binary log includes the timestamp and replicates correctly. `RAND()` also replicates correctly as long as it is called only a single time during the execution of a routine. (You can consider the routine execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

Several characteristics provide information about the nature of data use by the routine. In MySQL, these characteristics are advisory only. The server does not use them to constrain what kinds of statements a routine will be permitted to execute.

- `CONTAINS SQL` indicates that the routine does not contain statements that read or write data. This is the default if none of these characteristics is given explicitly. Examples of such statements are `SET @x = 1` or `DO RELEASE_LOCK('abc')`, which execute but neither read nor write data.

- `NO SQL` indicates that the routine contains no SQL statements.
- `READS SQL DATA` indicates that the routine contains statements that read data (for example, `SELECT`), but not statements that write data.
- `MODIFIES SQL DATA` indicates that the routine contains statements that may write data (for example, `INSERT` or `DELETE`).

The `SQL SECURITY` characteristic can be `DEFINER` or `INVOKER` to specify the security context; that is, whether the routine executes using the privileges of the account named in the routine `DEFINER` clause or the user who invokes it. This account must have permission to access the database with which the routine is associated. The default value is `DEFINER`. The user who invokes the routine must have the `EXECUTE` privilege for it, as must the `DEFINER` account if the routine executes in definer security context.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at routine execution time for routines that have the `SQL SECURITY DEFINER` characteristic.

If a `user` value is given for the `DEFINER` clause, it should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE PROCEDURE` or `CREATE FUNCTION` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the valid `DEFINER` user values:

- If you do not have the `SET_USER_ID` or `SUPER` privilege, the only permitted `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SET_USER_ID` or `SUPER` privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.
- Although it is possible to create a routine with a nonexistent `DEFINER` account, an error occurs at routine execution time if the `SQL SECURITY` value is `DEFINER` but the definer account does not exist.

For more information about stored routine security, see [Section 23.6, “Access Control for Stored Programs and Views”](#).

Within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER` returns the routine's `DEFINER` value. For information about user auditing within stored routines, see [Section 6.3.13, “SQL-Based MySQL Account Activity Auditing”](#).

Consider the following procedure, which displays a count of the number of MySQL accounts listed in the `mysql.user` table:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
BEGIN
  SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure is assigned a `DEFINER` account of `'admin'@'localhost'` no matter which user defines it. It executes with the privileges of that account no matter which user invokes it (because the default security characteristic is `DEFINER`). The procedure succeeds or fails depending on whether invoker has the `EXECUTE` privilege for it and `'admin'@'localhost'` has the `SELECT` privilege for the `mysql.user` table.

Now suppose that the procedure is defined with the `SQL SECURITY INVOKER` characteristic:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE account_count()
SQL SECURITY INVOKER
BEGIN
```

```
SELECT 'Number of accounts:', COUNT(*) FROM mysql.user;
END;
```

The procedure still has a `DEFINER` of `'admin'@'localhost'`, but in this case, it executes with the privileges of the invoking user. Thus, the procedure succeeds or fails depending on whether the invoker has the `EXECUTE` privilege for it and the `SELECT` privilege for the `mysql.user` table.

The server handles the data type of a routine parameter, local routine variable created with `DECLARE`, or function return value as follows:

- Assignments are checked for data type mismatches and overflow. Conversion and overflow problems result in warnings, or errors in strict SQL mode.
- Only scalar values can be assigned. For example, a statement such as `SET x = (SELECT 1, 2)` is invalid.
- For character data types, if there is a `CHARACTER SET` attribute in the declaration, the specified character set and its default collation is used. If the `COLLATE` attribute is also present, that collation is used rather than the default collation.

If `CHARACTER SET` and `COLLATE` attributes are not present, the database character set and collation in effect at routine creation time are used. To avoid having the server use the database character set and collation, provide explicit `CHARACTER SET` and `COLLATE` attributes for character data parameters.

If you change the database default character set or collation, stored routines that use the database defaults must be dropped and recreated so that they use the new defaults.

The database character set and collation are given by the value of the `character_set_database` and `collation_database` system variables. For more information, see [Section 10.1.3.3](#), “Database Character Set and Collation”.

13.1.14 CREATE SERVER Syntax

```
CREATE SERVER server_name
  FOREIGN DATA WRAPPER wrapper_name
  OPTIONS (option [, option] ...)
```

option:

```
{ HOST character-literal
  | DATABASE character-literal
  | USER character-literal
  | PASSWORD character-literal
  | SOCKET character-literal
  | OWNER character-literal
  | PORT numeric-literal }
```

This statement creates the definition of a server for use with the `FEDERATED` storage engine. The `CREATE SERVER` statement creates a new row in the `servers` table in the `mysql` database. This statement requires the `SUPER` privilege.

The `server_name` should be a unique reference to the server. Server definitions are global within the scope of the server, it is not possible to qualify the server definition to a specific database. `server_name` has a maximum length of 64 characters (names longer than 64 characters are silently truncated), and is case insensitive. You may specify the name as a quoted string.

The `wrapper_name` should be `mysql`, and may be quoted with single quotation marks. Other values for `wrapper_name` are not currently supported.

For each `option` you must specify either a character literal or numeric literal. Character literals are UTF-8, support a maximum length of 64 characters and default to a blank (empty) string. String literals are silently truncated to 64 characters. Numeric literals must be a number between 0 and 9999, default value is 0.

**Note**

The `OWNER` option is currently not applied, and has no effect on the ownership or operation of the server connection that is created.

The `CREATE SERVER` statement creates an entry in the `mysql.servers` table that can later be used with the `CREATE TABLE` statement when creating a `FEDERATED` table. The options that you specify will be used to populate the columns in the `mysql.servers` table. The table columns are `Server_name`, `Host`, `Db`, `Username`, `Password`, `Port` and `Socket`.

For example:

```
CREATE SERVER s
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'Remote', HOST '192.168.1.106', DATABASE 'test');
```

Be sure to specify all options necessary to establish a connection to the server. The user name, host name, and database name are mandatory. Other options might be required as well, such as password.

The data stored in the table can be used when creating a connection to a `FEDERATED` table:

```
CREATE TABLE t (s1 INT) ENGINE=FEDERATED CONNECTION='s';
```

For more information, see [Section 16.8, “The FEDERATED Storage Engine”](#).

`CREATE SERVER` causes an automatic commit.

In MySQL 8.0, `CREATE SERVER` is not written to the binary log, regardless of the logging format that is in use.

13.1.15 CREATE TABLE Syntax

```
CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
(create_definition,...)
[table_options]
[partition_options]

CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
[(create_definition,...)]
[table_options]
[partition_options]
[IGNORE | REPLACE]
[AS] query_expression

CREATE [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
{ LIKE old_tbl_name | (LIKE old_tbl_name) }

    SELECT ... (Some valid select or union statement)

```

CREATE TABLE creates a table with the given name. You must have the **CREATE** privilege for the table.

By default, tables are created in the default database, using the [InnoDB](#) storage engine. An error occurs if the table exists, if there is no default database, or if the database does not exist.

For information about the physical representation of a table, see [Section 13.1.15.2, “Files Created by CREATE TABLE”](#).

The original `CREATE TABLE` statement, including all specifications and table options are stored by MySQL when the table is created. For more information, see [Section 13.1.15.1, “CREATE TABLE Statement Retention”](#).

There are several aspects to the `CREATE TABLE` statement, described under the following topics in this section:

- [Table Name](#)
- [Temporary Tables](#)
- [Cloning or Copying a Table](#)
- [Column Data Types and Attributes](#)
- [Indexes and Foreign Keys](#)
- [Table Options](#)
- [Creating Partitioned Tables](#)

Table Name

- *tbl_name*

The table name can be specified as *db_name.tbl_name* to create the table in a specific database. This works regardless of whether there is a default database, assuming that the database exists. If you use quoted identifiers, quote the database and table names separately. For example, write ``mydb`.`mytbl``, not ``mydb.mytbl``.

Rules for permissible table names are given in [Section 9.2, “Schema Object Names”](#).

- `IF NOT EXISTS`

Prevents an error from occurring if the table exists. However, there is no verification that the existing table has a structure identical to that indicated by the `CREATE TABLE` statement.

Temporary Tables

You can use the `TEMPORARY` keyword when creating a table. A `TEMPORARY` table is visible only to the current session, and is dropped automatically when the session is closed. For more information, see [Section 13.1.15.3, “CREATE TEMPORARY TABLE Syntax”](#).

Cloning or Copying a Table

- `LIKE`

Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

For more information, see [Section 13.1.15.4, “CREATE TABLE ... LIKE Syntax”](#).

- `[AS] query_expression`

To create one table from another, add a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl AS SELECT * FROM orig_tbl;
```

For more information, see [Section 13.1.15.5, “CREATE TABLE ... SELECT Syntax”](#).

- [IGNORE | REPLACE](#)

The [IGNORE](#) and [REPLACE](#) options indicate how to handle rows that duplicate unique key values when copying a table using a [SELECT](#) statement.

For more information, see [Section 13.1.15.5, “CREATE TABLE ... SELECT Syntax”](#).

Column Data Types and Attributes

There is a hard limit of 4096 columns per table, but the effective maximum may be less for a given table and depends on the factors discussed in [Section C.10.4, “Limits on Table Column Count and Row Size”](#).

- [data_type](#)

[data_type](#) represents the data type in a column definition. [spatial_type](#) represents a spatial data type. The data type syntax shown is representative only. For a full description of the syntax available for specifying column data types, as well as information about the properties of each type, see [Chapter 11, Data Types](#), and [Section 11.5, “Extensions for Spatial Data”](#). A [JSON](#) data type is also supported for table columns; see [Section 11.6, “The JSON Data Type”](#), for more information.

- Some attributes do not apply to all data types. [AUTO_INCREMENT](#) applies only to integer and floating-point types. [DEFAULT](#) does not apply to the [BLOB](#), [TEXT](#), [GEOMETRY](#), and [JSON](#) types.
- Character data types ([CHAR](#), [VARCHAR](#), [TEXT](#)) can include [CHARACTER SET](#) and [COLLATE](#) attributes to specify the character set and collation for the column. For details, see [Section 10.1, “Character Set Support”](#). [CHARSET](#) is a synonym for [CHARACTER SET](#). Example:

```
CREATE TABLE t (c CHAR(20) CHARACTER SET utf8 COLLATE utf8_bin);
```

MySQL 8.0 interprets length specifications in character column definitions in characters. Lengths for [BINARY](#) and [VARBINARY](#) are in bytes.

- For [CHAR](#), [VARCHAR](#), [BINARY](#), and [VARBINARY](#) columns, indexes can be created that use only the leading part of column values, using [col_name\(length\)](#) syntax to specify an index prefix length. [BLOB](#) and [TEXT](#) columns also can be indexed, but a prefix length *must* be given. Prefix lengths are given in characters for nonbinary string types and in bytes for binary string types. That is, index entries consist of the first *length* characters of each column value for [CHAR](#), [VARCHAR](#), and [TEXT](#) columns, and the first *length* bytes of each column value for [BINARY](#), [VARBINARY](#), and [BLOB](#) columns. Indexing only a prefix of column values like this can make the index file much smaller. For additional information about index prefixes, see [Section 13.1.12, “CREATE INDEX Syntax”](#).

Only the [InnoDB](#) and [MyISAM](#) storage engines support indexing on [BLOB](#) and [TEXT](#) columns. For example:

```
CREATE TABLE test (blob_col BLOB, INDEX(blob_col(10)));
```

- [JSON](#) columns cannot be indexed. You can work around this restriction by creating an index on a generated column that extracts a scalar value from the [JSON](#) column. See [Indexing a Generated Column to Provide a JSON Column Index](#), for a detailed example.
- [NOT NULL | NULL](#)

If neither [NULL](#) nor [NOT NULL](#) is specified, the column is treated as though [NULL](#) had been specified.

In MySQL 8.0, only the [InnoDB](#), [MyISAM](#), and [MEMORY](#) storage engines support indexes on columns that can have [NULL](#) values. In other cases, you must declare indexed columns as [NOT NULL](#) or an error results.

- [DEFAULT](#)

Specifies a default value for a column. With one exception, the default value must be a constant; it cannot be a function or an expression. This means, for example, that you cannot set the default for a date column to be the value of a function such as [NOW\(\)](#) or [CURRENT_DATE](#). The exception is that you can specify [CURRENT_TIMESTAMP](#) as the default for a [TIMESTAMP](#) or [DATETIME](#) column. See [Section 11.3.5, “Automatic Initialization and Updating for TIMESTAMP and DATETIME”](#).

If a column definition includes no explicit [DEFAULT](#) value, MySQL determines the default value as described in [Section 11.7, “Data Type Default Values”](#).

[BLOB](#), [TEXT](#), and [JSON](#) columns cannot be assigned a default value.

If the [NO_ZERO_DATE](#) or [NO_ZERO_IN_DATE](#) SQL mode is enabled and a date-valued default is not correct according to that mode, [CREATE TABLE](#) produces a warning if strict SQL mode is not enabled and an error if strict mode is enabled. For example, with [NO_ZERO_IN_DATE](#) enabled, `c1 DATE DEFAULT '2010-00-00'` produces a warning.

- [AUTO_INCREMENT](#)

An integer or floating-point column can have the additional attribute [AUTO_INCREMENT](#). When you insert a value of [NULL](#) (recommended) or `0` into an indexed [AUTO_INCREMENT](#) column, the column is set to the next sequence value. Typically this is `value+1`, where `value` is the largest value for the column currently in the table. [AUTO_INCREMENT](#) sequences begin with `1`.

To retrieve an [AUTO_INCREMENT](#) value after inserting a row, use the [LAST_INSERT_ID\(\)](#) SQL function or the [mysql_insert_id\(\)](#) C API function. See [Section 12.14, “Information Functions”](#), and [Section 27.7.7.38, “mysql_insert_id\(\)”](#).

If the [NO_AUTO_VALUE_ON_ZERO](#) SQL mode is enabled, you can store `0` in [AUTO_INCREMENT](#) columns as `0` without generating a new sequence value. See [Section 5.1.8, “Server SQL Modes”](#).

There can be only one [AUTO_INCREMENT](#) column per table, it must be indexed, and it cannot have a [DEFAULT](#) value. An [AUTO_INCREMENT](#) column works properly only if it contains only positive values. Inserting a negative number is regarded as inserting a very large positive number. This is done to avoid precision problems when numbers “wrap” over from positive to negative and also to ensure that you do not accidentally get an [AUTO_INCREMENT](#) column that contains `0`.

For [MyISAM](#) tables, you can specify an [AUTO_INCREMENT](#) secondary column in a multiple-column key. See [Section 3.6.9, “Using AUTO_INCREMENT”](#).

To make MySQL compatible with some ODBC applications, you can find the [AUTO_INCREMENT](#) value for the last inserted row with the following query:

```
SELECT * FROM tbl_name WHERE auto_col IS NULL
```

This method requires that `sql_auto_is_null` variable is not set to `0`. See [Section 5.1.5, “Server System Variables”](#).

For information about [InnoDB](#) and [AUTO_INCREMENT](#), see [Section 15.8.1.5, “AUTO_INCREMENT Handling in InnoDB”](#). For information about [AUTO_INCREMENT](#) and MySQL Replication, see [Section 18.4.1.1, “Replication and AUTO_INCREMENT”](#).

- [COMMENT](#)

A comment for a column can be specified with the `COMMENT` option, up to 1024 characters long. The comment is displayed by the `SHOW CREATE TABLE` and `SHOW FULL COLUMNS` statements.

- `COLUMN_FORMAT`

Used by MySQL Cluster to determine a column's storage format. This option currently has no effect on columns of tables using storage engines other than `NDB`. In MySQL 8.0 and later, `COLUMN_FORMAT` is silently ignored.

- `GENERATED ALWAYS`

Used to specify a generated column expression. For information about [generated columns](#), see [Section 13.1.15.8, "CREATE TABLE and Generated Columns"](#).

[Stored generated columns](#) can be indexed. `InnoDB` supports secondary indexes on [virtual generated columns](#). See [Section 13.1.15.9, "Secondary Indexes and Generated Columns"](#).

Indexes and Foreign Keys

- `CONSTRAINT symbol`

If the `CONSTRAINT symbol` clause is given, the *symbol* value, if used, must be unique in the database. A duplicate *symbol* results in an error. If the clause is not given, or a *symbol* is not included following the `CONSTRAINT` keyword, a name for the constraint is created automatically.

- `PRIMARY KEY`

A unique index where all key columns must be defined as `NOT NULL`. If they are not explicitly declared as `NOT NULL`, MySQL declares them so implicitly (and silently). A table can have only one `PRIMARY KEY`. The name of a `PRIMARY KEY` is always `PRIMARY`, which thus cannot be used as the name for any other kind of index.

If you do not have a `PRIMARY KEY` and an application asks for the `PRIMARY KEY` in your tables, MySQL returns the first `UNIQUE` index that has no `NULL` columns as the `PRIMARY KEY`.

In `InnoDB` tables, keep the `PRIMARY KEY` short to minimize storage overhead for secondary indexes. Each secondary index entry contains a copy of the primary key columns for the corresponding row. (See [Section 15.8.2.1, "Clustered and Secondary Indexes"](#).)

In the created table, a `PRIMARY KEY` is placed first, followed by all `UNIQUE` indexes, and then the nonunique indexes. This helps the MySQL optimizer to prioritize which index to use and also more quickly to detect duplicated `UNIQUE` keys.

A `PRIMARY KEY` can be a multiple-column index. However, you cannot create a multiple-column index using the `PRIMARY KEY` key attribute in a column specification. Doing so only marks that single column as primary. You must use a separate `PRIMARY KEY(index_col_name, ...)` clause.

If a `PRIMARY KEY` consists of only one column that has an integer type, you can also refer to the column as `_rowid` in `SELECT` statements.

In MySQL, the name of a `PRIMARY KEY` is `PRIMARY`. For other indexes, if you do not assign a name, the index is assigned the same name as the first indexed column, with an optional suffix (`_2`, `_3`, ...) to make it unique. You can see index names for a table using `SHOW INDEX FROM tbl_name`. See [Section 13.7.5.22, "SHOW INDEX Syntax"](#).

- `KEY | INDEX`

`KEY` is normally a synonym for `INDEX`. The key attribute `PRIMARY KEY` can also be specified as just `KEY` when given in a column definition. This was implemented for compatibility with other database systems.

- **UNIQUE**

A **UNIQUE** index creates a constraint such that all values in the index must be distinct. An error occurs if you try to add a new row with a key value that matches an existing row. For all engines, a **UNIQUE** index permits multiple **NULL** values for columns that can contain **NULL**.

If a **UNIQUE** index consists of only one column that has an integer type, you can also refer to the column as `_rowid` in **SELECT** statements.

- **FULLTEXT**

A **FULLTEXT** index is a special type of index used for full-text searches. Only the **InnoDB** and **MyISAM** storage engines support **FULLTEXT** indexes. They can be created only from **CHAR**, **VARCHAR**, and **TEXT** columns. Indexing always happens over the entire column; column prefix indexing is not supported and any prefix length is ignored if specified. See [Section 12.9, “Full-Text Search Functions”](#), for details of operation. A **WITH PARSER** clause can be specified as an *index_option* value to associate a parser plugin with the index if full-text indexing and searching operations need special handling. This clause is valid only for **FULLTEXT** indexes. **InnoDB** and **MyISAM** support full-text parser plugins. See [Full-Text Parser Plugins](#) and [Section 28.2.4.4, “Writing Full-Text Parser Plugins”](#) for more information.

- **SPATIAL**

You can create **SPATIAL** indexes on spatial data types. Spatial types are supported only for **InnoDB** and **MyISAM** tables, and indexed columns must be declared as **NOT NULL**. See [Section 11.5, “Extensions for Spatial Data”](#).

- **FOREIGN KEY**

MySQL supports foreign keys, which let you cross-reference related data across tables, and foreign key constraints, which help keep this spread-out data consistent. For definition and option information, see *reference_definition*, and *reference_option*.

Partitioned tables employing the **InnoDB** storage engine do not support foreign keys. See [Section 22.6, “Restrictions and Limitations on Partitioning”](#), for more information.

- **CHECK**

The **CHECK** clause is parsed but ignored by all storage engines. See [Section 1.8.2.3, “Foreign Key Differences”](#).

- *index_col_name*

- An *index_col_name* specification can end with **ASC** or **DESC** to specify whether index values are stored in ascending or descending order. The default is ascending if no order specifier is given.
- Prefixes, defined by the *length* attribute, can be up to 767 bytes long for **InnoDB** tables that use the **REDUNDANT** or **COMPACT** row format. The length limit is raised to 3072 bytes for **InnoDB** tables that use the **DYNAMIC** or **COMPRESSED** row format. For **MyISAM** tables, the prefix limit is 1000 bytes.

Prefix limits are measured in bytes, whereas the prefix length in **CREATE TABLE**, **ALTER TABLE**, and **CREATE INDEX** statements is interpreted as number of characters for nonbinary string types (**CHAR**, **VARCHAR**, **TEXT**) and number of bytes for binary string types (**BINARY**, **VARBINARY**, **BLOB**). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

- *index_type*

Some storage engines permit you to specify an index type when creating an index. The syntax for the *index_type* specifier is **USING type_name**.

Example:

```
CREATE TABLE lookup
  (id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

The preferred position for `USING` is after the index column list. It can be given before the column list, but support for use of the option in that position is deprecated and will be removed in a future MySQL release.

- *index_option*

index_option values specify additional options for an index.

- `KEY_BLOCK_SIZE`

For `MyISAM` tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A `KEY_BLOCK_SIZE` value specified for an individual index definition overrides the table-level `KEY_BLOCK_SIZE` value.

For information about the table-level `KEY_BLOCK_SIZE` attribute, see [Table Options](#).

- `WITH PARSER`

The `WITH PARSER` option can only be used with `FULLTEXT` indexes. It associates a parser plugin with the index if full-text indexing and searching operations need special handling. `InnoDB` and `MyISAM` support full-text parser plugins. If you have a `MyISAM` table with an associated full-text parser plugin, you can convert the table to `InnoDB` using `ALTER TABLE`.

- `COMMENT`

In MySQL 8.0, index definitions can include an optional comment of up to 1024 characters.

You can set the `InnoDB MERGE_THRESHOLD` value for an individual index using the *index_option* `COMMENT` clause. See [Section 15.6.12, “Configuring the Merge Threshold for Index Pages”](#).

For more information about permissible *index_option* values, see [Section 13.1.12, “CREATE INDEX Syntax”](#). For more information about indexes, see [Section 8.3.1, “How MySQL Uses Indexes”](#).

- *reference_definition*

For *reference_definition* syntax details and examples, see [Section 13.1.15.6, “Using FOREIGN KEY Constraints”](#). For information specific to foreign keys in `InnoDB`, see [Section 15.8.1.6, “InnoDB and FOREIGN KEY Constraints”](#).

`InnoDB` tables support checking of foreign key constraints. The columns of the referenced table must always be explicitly named. Both `ON DELETE` and `ON UPDATE` actions on foreign keys. For more detailed information and examples, see [Section 13.1.15.6, “Using FOREIGN KEY Constraints”](#). For information specific to foreign keys in `InnoDB`, see [Section 15.8.1.6, “InnoDB and FOREIGN KEY Constraints”](#).

For other storage engines, MySQL Server parses and ignores the `FOREIGN KEY` and `REFERENCES` syntax in `CREATE TABLE` statements. See [Section 1.8.2.3, “Foreign Key Differences”](#).

Important

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including `InnoDB`, recognizes or enforces the `MATCH` clause used in referential integrity constraint definitions. Use of an explicit `MATCH` clause will not have the specified effect, and also causes `ON DELETE` and `ON UPDATE` clauses to be ignored. For these reasons, specifying `MATCH` should be avoided.

The `MATCH` clause in the SQL standard controls how `NULL` values in a composite (multiple-column) foreign key are handled when comparing to a primary key. `InnoDB` essentially implements the semantics defined by `MATCH SIMPLE`, which permit a foreign key to be all or partially `NULL`. In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL requires that the referenced columns be indexed for performance. However, `InnoDB` does not enforce any requirement that the referenced columns be declared `UNIQUE` or `NOT NULL`. The handling of foreign key references to nonunique keys or keys that contain `NULL` values is not well defined for operations such as `UPDATE` or `DELETE CASCADE`. You are advised to use foreign keys that reference only keys that are both `UNIQUE` (or `PRIMARY`) and `NOT NULL`.

MySQL parses but ignores “inline `REFERENCES` specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts `REFERENCES` clauses only when specified as part of a separate `FOREIGN KEY` specification.

- [reference_option](#)

For information about the `RESTRICT`, `CASCADE`, `SET NULL`, `NO ACTION`, and `SET DEFAULT` options, see [Section 13.1.15.6, “Using FOREIGN KEY Constraints”](#).

Table Options

Table options are used to optimize the behavior of the table. In most cases, you do not have to specify any of them. These options apply to all storage engines unless otherwise indicated. Options that do not apply to a given storage engine may be accepted and remembered as part of the table definition. Such options then apply if you later use `ALTER TABLE` to convert the table to use a different storage engine.

- `ENGINE`

Specifies the storage engine for the table, using one of the names shown in the following table. The engine name can be unquoted or quoted. The quoted name `'DEFAULT'` is recognized but ignored.

Storage Engine	Description
<code>InnoDB</code>	Transaction-safe tables with row locking and foreign keys. The default storage engine for new tables. See Chapter 15, The InnoDB Storage Engine , and in particular Section 15.1, “Introduction to InnoDB” if you have MySQL experience but are new to <code>InnoDB</code> .
<code>MyISAM</code>	The binary portable storage engine that is primarily used for read-only or read-mostly workloads. See Section 16.2, “The MyISAM Storage Engine” .
<code>MEMORY</code>	The data for this storage engine is stored only in memory. See Section 16.3, “The MEMORY Storage Engine” .

Storage Engine	Description
CSV	Tables that store rows in comma-separated values format. See Section 16.4, “The CSV Storage Engine” .
ARCHIVE	The archiving storage engine. See Section 16.5, “The ARCHIVE Storage Engine” .
EXAMPLE	An example engine. See Section 16.9, “The EXAMPLE Storage Engine” .
FEDERATED	Storage engine that accesses remote tables. See Section 16.8, “The FEDERATED Storage Engine” .
HEAP	This is a synonym for <code>MEMORY</code> .
MERGE	A collection of <code>MyISAM</code> tables used as one table. Also known as <code>MRG_MyISAM</code> . See Section 16.7, “The MERGE Storage Engine” .

By default, if a storage engine is specified that is not available, the statement fails with an error. You can override this behavior by removing `NO_ENGINE_SUBSTITUTION` from the server SQL mode (see [Section 5.1.8, “Server SQL Modes”](#)) so that MySQL allows substitution of the specified engine with the default storage engine instead. Normally in such cases, this is `InnoDB`, which is the default value for the `default_storage_engine` system variable. When `NO_ENGINE_SUBSTITUTION` is disabled, a warning occurs if the storage engine specification is not honored.

- `AUTO_INCREMENT`

The initial `AUTO_INCREMENT` value for the table. In MySQL 8.0, this works for `MyISAM`, `MEMORY`, `InnoDB`, and `ARCHIVE` tables. To set the first auto-increment value for engines that do not support the `AUTO_INCREMENT` table option, insert a “dummy” row with a value one less than the desired value after creating the table, and then delete the dummy row.

For engines that support the `AUTO_INCREMENT` table option in `CREATE TABLE` statements, you can also use `ALTER TABLE tbl_name AUTO_INCREMENT = N` to reset the `AUTO_INCREMENT` value. The value cannot be set lower than the maximum value currently in the column.

- `AVG_ROW_LENGTH`

An approximation of the average row length for your table. You need to set this only for large tables with variable-size rows.

When you create a `MyISAM` table, MySQL uses the product of the `MAX_ROWS` and `AVG_ROW_LENGTH` options to decide how big the resulting table is. If you don't specify either option, the maximum size for `MyISAM` data and index files is 256TB by default. (If your operating system does not support files that large, table sizes are constrained by the file size limit.) If you want to keep down the pointer sizes to make the index smaller and faster and you don't really need big files, you can decrease the default pointer size by setting the `myisam_data_pointer_size` system variable. (See [Section 5.1.5, “Server System Variables”](#).) If you want all your tables to be able to grow above the default limit and are willing to have your tables slightly slower and larger than necessary, you can increase the default pointer size by setting this variable. Setting the value to 7 permits table sizes up to 65,536TB.

- `[DEFAULT] CHARACTER SET`

Specifies a default character set for the table. `CHARSET` is a synonym for `CHARACTER SET`. If the character set name is `DEFAULT`, the database character set is used.

- `CHECKSUM`

Set this to 1 if you want MySQL to maintain a live checksum for all rows (that is, a checksum that MySQL updates automatically as the table changes). This makes the table a little slower to update, but also makes it easier to find corrupted tables. The `CHECKSUM TABLE` statement reports the checksum. (`MyISAM` only.)

- `[DEFAULT] COLLATE`

Specifies a default collation for the table.

- `COMMENT`

A comment for the table, up to 2048 characters long.

You can set the `InnoDB MERGE_THRESHOLD` value for a table using the `table_option COMMENT` clause. See [Section 15.6.12, “Configuring the Merge Threshold for Index Pages”](#).

- `COMPRESSION`

The compression algorithm used for page level compression for `InnoDB` tables. Supported values include `Zlib`, `LZ4`, and `None`. The `COMPRESSION` attribute was introduced with the transparent page compression feature. Page compression is only supported with `InnoDB` tables that reside in `file-per-table` tablespaces, and is only available on Linux and Windows platforms that support sparse files and hole punching. For more information, see [Section 15.9.2, “InnoDB Page Compression”](#).

- `CONNECTION`

The connection string for a `FEDERATED` table.

Note

Older versions of MySQL used a `COMMENT` option for the connection string.

- `DATA DIRECTORY, INDEX DIRECTORY`

For `InnoDB`, the `DATA DIRECTORY='directory'` option allows you to create `InnoDB` file-per-table tablespaces outside the MySQL data directory. Within the directory that you specify, MySQL creates a subdirectory corresponding to the database name, and within that a `.ibd` file for the table. The `innodb_file_per_table` configuration option must be enabled to use the `DATA DIRECTORY` option with `InnoDB`. The full directory path must be specified. See [Section 15.7.5, “Creating File-Per-Table Tablespaces Outside the Data Directory”](#) for more information.

When creating `MyISAM` tables, you can use the `DATA DIRECTORY='directory'` clause, the `INDEX DIRECTORY='directory'` clause, or both. They specify where to put a `MyISAM` table's data file and index file, respectively. Unlike `InnoDB` tables, MySQL does not create subdirectories that correspond to the database name when creating a `MyISAM` table with a `DATA DIRECTORY` or `INDEX DIRECTORY` option. Files are created in the directory that is specified.

You must have the `FILE` privilege to use the `DATA DIRECTORY` or `INDEX DIRECTORY` table option.

Important

Table-level `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored for partitioned tables. (Bug #32091)

These options work only when you are not using the `--skip-symbolic-links` option. Your operating system must also have a working, thread-safe `realpath()` call. See [Section 8.12.2.2, “Using Symbolic Links for MyISAM Tables on Unix”](#), for more complete information.

If a `MyISAM` table is created with no `DATA DIRECTORY` option, the `.MYD` file is created in the database directory. By default, if `MyISAM` finds an existing `.MYD` file in this case, it overwrites it. The same applies to `.MYI` files for tables created with no `INDEX DIRECTORY` option. To suppress this behavior, start the server with the `--keep_files_on_create` option, in which case `MyISAM` will not overwrite existing files and returns an error instead.

If a `MyISAM` table is created with a `DATA DIRECTORY` or `INDEX DIRECTORY` option and an existing `.MYD` or `.MYI` file is found, `MyISAM` always returns an error. It will not overwrite a file in the specified directory.

Important

You cannot use path names that contain the MySQL data directory with `DATA DIRECTORY` or `INDEX DIRECTORY`. This includes partitioned tables and individual table partitions. (See Bug #32167.)

- `DELAY_KEY_WRITE`

Set this to 1 if you want to delay key updates for the table until the table is closed. See the description of the `delay_key_write` system variable in [Section 5.1.5, “Server System Variables”](#). (`MyISAM` only.)

- `ENCRYPTION`

Set the `ENCRYPTION` option to `'Y'` to enable page-level data encryption for an `InnoDB` table created in a `file-per-table` tablespace. Option values are not case sensitive. The `ENCRYPTION` option was introduced with the `InnoDB` tablespace encryption feature; see [Section 15.7.10, “InnoDB Tablespace Encryption”](#). The `keyring_file` plugin must be loaded to use the `ENCRYPTION` option.

- `INSERT_METHOD`

If you want to insert data into a `MERGE` table, you must specify with `INSERT_METHOD` the table into which the row should be inserted. `INSERT_METHOD` is an option useful for `MERGE` tables only. Use a value of `FIRST` or `LAST` to have inserts go to the first or last table, or a value of `NO` to prevent inserts. See [Section 16.7, “The MERGE Storage Engine”](#).

- `KEY_BLOCK_SIZE`

For `MyISAM` tables, `KEY_BLOCK_SIZE` optionally specifies the size in bytes to use for index key blocks. The value is treated as a hint; a different size could be used if necessary. A `KEY_BLOCK_SIZE` value specified for an individual index definition overrides the table-level `KEY_BLOCK_SIZE` value.

For `InnoDB` tables, `KEY_BLOCK_SIZE` optionally specifies the `page` size (in kilobytes) to use for `compressed` `InnoDB` tables. The `KEY_BLOCK_SIZE` value is treated as a hint; a different size could be used by `InnoDB` if necessary. `KEY_BLOCK_SIZE` can only be less than or equal to the `innodb_page_size` value. A value of 0 represents the default compressed page size, which is half of the `innodb_page_size` value. Depending on `innodb_page_size`, possible `KEY_BLOCK_SIZE` values include 0, 1, 2, 4, 8, and 16. See [Section 15.9.1, “InnoDB Table Compression”](#) for more information.

Oracle recommends enabling `innodb_strict_mode` when specifying `KEY_BLOCK_SIZE` for `InnoDB` tables. When `innodb_strict_mode` is enabled, specifying an invalid `KEY_BLOCK_SIZE` value returns an error. If `innodb_strict_mode` is disabled, an invalid `KEY_BLOCK_SIZE` value results in a warning, and the `KEY_BLOCK_SIZE` option is ignored.

`InnoDB` only supports `KEY_BLOCK_SIZE` at the table level.

`KEY_BLOCK_SIZE` is not supported with 32k and 64k `innodb_page_size` values. `InnoDB` table compression does not support these pages sizes.

`InnoDB` does not support the `KEY_BLOCK_SIZE` option when creating temporary tables.

- `MAX_ROWS`

The maximum number of rows you plan to store in the table. This is not a hard limit, but rather a hint to the storage engine that the table must be able to store at least this many rows.

The maximum `MAX_ROWS` value is 4294967295; larger values are truncated to this limit.

- `MIN_ROWS`

The minimum number of rows you plan to store in the table. The `MEMORY` storage engine uses this option as a hint about memory use.

- `PACK_KEYS`

Takes effect only with `MyISAM` tables. Set this option to 1 if you want to have smaller indexes. This usually makes updates slower and reads faster. Setting the option to 0 disables all packing of keys. Setting it to `DEFAULT` tells the storage engine to pack only long `CHAR`, `VARCHAR`, `BINARY`, or `VARBINARY` columns.

If you do not use `PACK_KEYS`, the default is to pack strings, but not numbers. If you use `PACK_KEYS=1`, numbers are packed as well.

When packing binary number keys, MySQL uses prefix compression:

- Every key needs one extra byte to indicate how many bytes of the previous key are the same for the next key.
- The pointer to the row is stored in high-byte-first order directly after the key, to improve compression.

This means that if you have many equal keys on two consecutive rows, all following “same” keys usually only take two bytes (including the pointer to the row). Compare this to the ordinary case where the following keys takes `storage_size_for_key + pointer_size` (where the pointer size is usually 4). Conversely, you get a significant benefit from prefix compression only if you have many numbers that are the same. If all keys are totally different, you use one byte more per key, if the key is not a key that can have `NULL` values. (In this case, the packed key length is stored in the same byte that is used to mark if a key is `NULL`.)

- `PASSWORD`

This option is unused.

- `ROW_FORMAT`

Defines the physical format in which the rows are stored.

When executing a `CREATE TABLE` statement, if you specify a row format that is not supported by the storage engine that is used for the table, the table is created using that storage engine's default row format. The information reported in this column in response to `SHOW TABLE STATUS` is the actual row format used. This may differ from the value in the `Create_options` column because the original `CREATE TABLE` definition is retained during creation.

Row format choices differ depending on the storage engine used for the table.

For `InnoDB` tables:

- The default row format is defined by `innodb_default_row_format`, which has a default setting of `DYNAMIC`. The default row format is used when the `ROW_FORMAT` option is not defined or when `ROW_FORMAT=DEFAULT` is used.

If the `ROW_FORMAT` option is not defined, or if `ROW_FORMAT=DEFAULT` is used, operations that rebuild a table also silently change the row format of the table to the default defined by

`innodb_default_row_format`. For more information, see [Section 15.10.2, “Specifying the Row Format for a Table”](#).

- For more efficient `InnoDB` storage of data types, especially `BLOB` types, use the `DYNAMIC`. See [Section 15.10.3, “DYNAMIC and COMPRESSED Row Formats”](#) for requirements associated with the `DYNAMIC` row format.
- To enable compression for `InnoDB` tables, specify `ROW_FORMAT=COMPRESSED`. The `ROW_FORMAT=COMPRESSED` option is not supported when creating temporary tables. See [Section 15.9, “InnoDB Table and Page Compression”](#) for requirements associated with the `COMPRESSED` row format.
- The row format used in older versions of MySQL can still be requested by specifying the `REDUNDANT` row format.
- When you specify a non-default `ROW_FORMAT` clause, consider also enabling the `innodb_strict_mode` configuration option.
- `ROW_FORMAT=FIXED` is not supported. If `ROW_FORMAT=FIXED` is specified while `innodb_strict_mode` is disabled, `InnoDB` issues a warning and assumes `ROW_FORMAT=DYNAMIC`. If `ROW_FORMAT=FIXED` is specified while `innodb_strict_mode` is enabled, which is the default, `InnoDB` returns an error.
- For additional information about `InnoDB` row formats, see [Section 15.10, “InnoDB Row Storage and Row Formats”](#).

For `MyISAM` tables, the option value can be `FIXED` or `DYNAMIC` for static or variable-length row format. `myisampack` sets the type to `COMPRESSED`. See [Section 16.2.3, “MyISAM Table Storage Formats”](#).

- `STATS_AUTO_RECALC`

Specifies whether to automatically recalculate [persistent statistics](#) for an `InnoDB` table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_auto_recalc` configuration option. The value `1` causes statistics to be recalculated when 10% of the data in the table has changed. The value `0` prevents automatic recalculation for this table; with this setting, issue an `ANALYZE TABLE` statement to recalculate the statistics after making substantial changes to the table. For more information about the persistent statistics feature, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `STATS_PERSISTENT`

Specifies whether to enable [persistent statistics](#) for an `InnoDB` table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_persistent` configuration option. The value `1` enables persistent statistics for the table, while the value `0` turns off this feature. After enabling persistent statistics through a `CREATE TABLE` or `ALTER TABLE` statement, issue an `ANALYZE TABLE` statement to calculate the statistics, after loading representative data into the table. For more information about the persistent statistics feature, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `STATS_SAMPLE_PAGES`

The number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by `ANALYZE TABLE`. For more information, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `TABLESPACE`

The `TABLESPACE` option may be used to create a table in an existing general tablespace, a file-per-table tablespace, or the system tablespace.

```
CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name
```

For information about general tablespaces, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

The *tablespace_name* is a case-sensitive identifier. It may be quoted or unquoted. The forward slash character (“/”) is not permitted. Names beginning with “innodb_” are reserved for special use.

The `TABLESPACE` option may be used to assign InnoDB table partitions or subpartitions to a [general tablespace](#), a separate file-per-table tablespace, or the system tablespace. All partitions must belong to the same storage engine.

A tablespace specified at the table level becomes the default tablespace for new partitions and subpartitions. The default tablespace may be overridden by specifying a tablespace at the partition or subpartition level in a `CREATE TABLE` or `ALTER TABLE` statement. The following example shows tablespaces defined at the table level and partition level.

```
mysql> CREATE TABLE t1 ( a INT NOT NULL, PRIMARY KEY (a))
-> ENGINE=InnoDB TABLESPACE ts1
-> PARTITION BY RANGE (a) PARTITIONS 3 (
-> PARTITION P1 VALUES LESS THAN (2),
-> PARTITION P2 VALUES LESS THAN (4) TABLESPACE ts2,
-> PARTITION P3 VALUES LESS THAN (6) TABLESPACE ts3);
```

For more information about the `TABLESPACE` option and partitioning, see [Section 15.7.9, “InnoDB General Tablespaces”](#)

To create a table in the system tablespace, specify `innodb_system` as the tablespace name.

```
CREATE TABLE tbl_name ... TABLESPACE [=] innodb_system
```

Using the `TABLESPACE [=] innodb_system` option, you can place a table of any uncompressed row format in the system tablespace regardless of the `innodb_file_per_table` setting. For example, you can add a table with `ROW_FORMAT=DYNAMIC` to the system tablespace using the `TABLESPACE [=] innodb_system` option.

To create a table in a file-per-table tablespace, specify `innodb_file_per_table` as the tablespace name.

```
CREATE TABLE tbl_name ... TABLESPACE [=] innodb_file_per_table
```

Note

If `innodb_file_per_table` is enabled, you need not specify `TABLESPACE=innodb_file_per_table` to create an InnoDB file-per-table tablespace. InnoDB tables are created in file-per-table tablespaces by default when `innodb_file_per_table` is enabled.

The `DATA DIRECTORY` clause is permitted with `CREATE TABLE ... TABLESPACE=innodb_file_per_table` but is otherwise not supported for use in combination with the `TABLESPACE` option.

The `TABLESPACE` option is supported with `ALTER TABLE` and `ALTER TABLE ... REORGANIZE PARTITION` statements, which can be used to move tables and partitions from one tablespace to another, respectively. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

- `UNION`

Used to access a collection of identical MyISAM tables as one. This works only with `MERGE` tables. See [Section 16.7, “The MERGE Storage Engine”](#).

You must have `SELECT`, `UPDATE`, and `DELETE` privileges for the tables you map to a `MERGE` table.

**Note**

Formerly, all tables used had to be in the same database as the `MERGE` table itself. This restriction no longer applies.

Creating Partitioned Tables

`partition_options` can be used to control partitioning of the table created with `CREATE TABLE`.

Not all options shown in the syntax for `partition_options` at the beginning of this section are available for all partitioning types. Please see the listings for the following individual types for information specific to each type, and see [Chapter 22, Partitioning](#), for more complete information about the workings of and uses for partitioning in MySQL, as well as additional examples of table creation and other statements relating to MySQL partitioning.

Partitions can be modified, merged, added to tables, and dropped from tables. For basic information about the MySQL statements to accomplish these tasks, see [Section 13.1.7, “ALTER TABLE Syntax”](#). For more detailed descriptions and examples, see [Section 22.3, “Partition Management”](#).

- `PARTITION BY`

If used, a `partition_options` clause begins with `PARTITION BY`. This clause contains the function that is used to determine the partition; the function returns an integer value ranging from 1 to `num`, where `num` is the number of partitions. (The maximum number of user-defined partitions which a table may contain is 1024; the number of subpartitions—discussed later in this section—is included in this maximum.)

**Note**

The expression (`expr`) used in a `PARTITION BY` clause cannot refer to any columns not in the table being created; such references are specifically not permitted and cause the statement to fail with an error. (Bug #29444)

- `HASH(expr)`

Hashes one or more columns to create a key for placing and locating rows. `expr` is an expression using one or more table columns. This can be any valid MySQL expression (including MySQL functions) that yields a single integer value. For example, these are both valid `CREATE TABLE` statements using `PARTITION BY HASH`:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5))
  PARTITION BY HASH(col1);

CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATETIME)
  PARTITION BY HASH ( YEAR(col3) );
```

You may not use either `VALUES LESS THAN` or `VALUES IN` clauses with `PARTITION BY HASH`.

`PARTITION BY HASH` uses the remainder of `expr` divided by the number of partitions (that is, the modulus). For examples and additional information, see [Section 22.2.4, “HASH Partitioning”](#).

The `LINEAR` keyword entails a somewhat different algorithm. In this case, the number of the partition in which a row is stored is calculated as the result of one or more logical `AND` operations. For discussion and examples of linear hashing, see [Section 22.2.4.1, “LINEAR HASH Partitioning”](#).

- `KEY(column_list)`

This is similar to `HASH`, except that MySQL supplies the hashing function so as to guarantee an even data distribution. The `column_list` argument is simply a list of 1 or more table columns (maximum: 16). This example shows a simple table partitioned by key, with 4 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY KEY(col3)
PARTITIONS 4;
```

For tables that are partitioned by key, you can employ linear partitioning by using the `LINEAR` keyword. This has the same effect as with tables that are partitioned by `HASH`. That is, the partition number is found using the `&` operator rather than the modulus (see [Section 22.2.4.1, “LINEAR HASH Partitioning”](#), and [Section 22.2.5, “KEY Partitioning”](#), for details). This example uses linear partitioning by key to distribute data between 5 partitions:

```
CREATE TABLE tk (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY LINEAR KEY(col3)
PARTITIONS 5;
```

The `ALGORITHM={1|2}` option is supported with `[SUB]PARTITION BY [LINEAR] KEY`. `ALGORITHM=1` causes the server to use the same key-hashing functions as MySQL 5.1; `ALGORITHM=2` means that the server employs the key-hashing functions implemented and used by default for new `KEY` partitioned tables in MySQL 5.5 and later. (Partitioned tables created with the key-hashing functions employed in MySQL 5.5 and later cannot be used by a MySQL 5.1 server.) Not specifying the option has the same effect as using `ALGORITHM=2`. This option is intended for use chiefly when upgrading or downgrading `[LINEAR] KEY` partitioned tables between MySQL 5.1 and later MySQL versions, or for creating tables partitioned by `KEY` or `LINEAR KEY` on a MySQL 5.5 or later server which can be used on a MySQL 5.1 server. For more information, see [Section 13.1.7.1, “ALTER TABLE Partition Operations”](#).

`mysqldump` in MySQL 5.7 (and later) writes this option encased in versioned comments, like this:

```
CREATE TABLE t1 (a INT)
/*!50100 PARTITION BY KEY */ /*!50611 ALGORITHM = 1 */ /*!50100 ()
PARTITIONS 3 */
```

This causes MySQL 5.6.10 and earlier servers to ignore the option, which would otherwise cause a syntax error in those versions. If you plan to load a dump made on a MySQL 5.7 server where you use tables that are partitioned or subpartitioned by `KEY` into a MySQL 5.6 server previous to version 5.6.11, be sure to consult [Changes Affecting Upgrades to MySQL 5.6](#), before proceeding. (The information found there also applies if you are loading a dump containing `KEY` partitioned or subpartitioned tables made from a MySQL 5.7—actually 5.6.11 or later—server into a MySQL 5.5.30 or earlier server.)

Also in MySQL 5.6.11 and later, `ALGORITHM=1` is shown when necessary in the output of `SHOW CREATE TABLE` using versioned comments in the same manner as `mysqldump`. `ALGORITHM=2` is always omitted from `SHOW CREATE TABLE` output, even if this option was specified when creating the original table.

You may not use either `VALUES LESS THAN` or `VALUES IN` clauses with `PARTITION BY KEY`.

- `RANGE(expr)`

In this case, `expr` shows a range of values using a set of `VALUES LESS THAN` operators. When using range partitioning, you must define at least one partition using `VALUES LESS THAN`. You cannot use `VALUES IN` with range partitioning.

Note

For tables partitioned by `RANGE`, `VALUES LESS THAN` must be used with either an integer literal value or an expression that evaluates to a single integer value. In MySQL 8.0, you can overcome this limitation in a table that

is defined using `PARTITION BY RANGE COLUMNS`, as described later in this section.

Suppose that you have a table that you wish to partition on a column containing year values, according to the following scheme.

Partition Number:	Years Range:
0	1990 and earlier
1	1991 to 1994
2	1995 to 1998
3	1999 to 2002
4	2003 to 2005
5	2006 and later

A table implementing such a partitioning scheme can be realized by the `CREATE TABLE` statement shown here:

```
CREATE TABLE t1 (
  year_col INT,
  some_data INT
)
PARTITION BY RANGE (year_col) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1995),
  PARTITION p2 VALUES LESS THAN (1999),
  PARTITION p3 VALUES LESS THAN (2002),
  PARTITION p4 VALUES LESS THAN (2006),
  PARTITION p5 VALUES LESS THAN MAXVALUE
);
```

`PARTITION ... VALUES LESS THAN ...` statements work in a consecutive fashion. `VALUES LESS THAN MAXVALUE` works to specify “leftover” values that are greater than the maximum value otherwise specified.

`VALUES LESS THAN` clauses work sequentially in a manner similar to that of the `case` portions of a `switch ... case` block (as found in many programming languages such as C, Java, and PHP). That is, the clauses must be arranged in such a way that the upper limit specified in each successive `VALUES LESS THAN` is greater than that of the previous one, with the one referencing `MAXVALUE` coming last of all in the list.

- `RANGE COLUMNS(column_list)`

This variant on `RANGE` facilitates partition pruning for queries using range conditions on multiple columns (that is, having conditions such as `WHERE a = 1 AND b < 10` or `WHERE a = 1 AND b = 10 AND c < 10`). It enables you to specify value ranges in multiple columns by using a list of columns in the `COLUMNS` clause and a set of column values in each `PARTITION ... VALUES LESS THAN (value_list)` partition definition clause. (In the simplest case, this set consists of a single column.) The maximum number of columns that can be referenced in the `column_list` and `value_list` is 16.

The `column_list` used in the `COLUMNS` clause may contain only names of columns; each column in the list must be one of the following MySQL data types: the integer types; the string types; and time or date column types. Columns using `BLOB`, `TEXT`, `SET`, `ENUM`, `BIT`, or spatial data types are not permitted; columns that use floating-point number types are also not permitted. You also may not use functions or arithmetic expressions in the `COLUMNS` clause.

The `VALUES LESS THAN` clause used in a partition definition must specify a literal value for each column that appears in the `COLUMNS()` clause; that is, the list of values used for each `VALUES`

`LESS THAN` clause must contain the same number of values as there are columns listed in the `COLUMNS` clause. An attempt to use more or fewer values in a `VALUES LESS THAN` clause than there are in the `COLUMNS` clause causes the statement to fail with the error `Inconsistency in usage of column lists for partitioning...` You cannot use `NULL` for any value appearing in `VALUES LESS THAN`. It is possible to use `MAXVALUE` more than once for a given column other than the first, as shown in this example:

```
CREATE TABLE rc (
  a INT NOT NULL,
  b INT NOT NULL
)
PARTITION BY RANGE COLUMNS(a,b) (
  PARTITION p0 VALUES LESS THAN (10,5),
  PARTITION p1 VALUES LESS THAN (20,10),
  PARTITION p2 VALUES LESS THAN (50,MAXVALUE),
  PARTITION p3 VALUES LESS THAN (65,MAXVALUE),
  PARTITION p4 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);
```

Each value used in a `VALUES LESS THAN` value list must match the type of the corresponding column exactly; no conversion is made. For example, you cannot use the string `'1'` for a value that matches a column that uses an integer type (you must use the numeral `1` instead), nor can you use the numeral `1` for a value that matches a column that uses a string type (in such a case, you must use a quoted string: `'1'`).

For more information, see [Section 22.2.1, “RANGE Partitioning”](#), and [Section 22.4, “Partition Pruning”](#).

- `LIST(expr)`

This is useful when assigning partitions based on a table column with a restricted set of possible values, such as a state or country code. In such a case, all rows pertaining to a certain state or country can be assigned to a single partition, or a partition can be reserved for a certain set of states or countries. It is similar to `RANGE`, except that only `VALUES IN` may be used to specify permissible values for each partition.

`VALUES IN` is used with a list of values to be matched. For instance, you could create a partitioning scheme such as the following:

```
CREATE TABLE client_firms (
  id INT,
  name VARCHAR(35)
)
PARTITION BY LIST (id) (
  PARTITION r0 VALUES IN (1, 5, 9, 13, 17, 21),
  PARTITION r1 VALUES IN (2, 6, 10, 14, 18, 22),
  PARTITION r2 VALUES IN (3, 7, 11, 15, 19, 23),
  PARTITION r3 VALUES IN (4, 8, 12, 16, 20, 24)
);
```

When using list partitioning, you must define at least one partition using `VALUES IN`. You cannot use `VALUES LESS THAN` with `PARTITION BY LIST`.

Note

For tables partitioned by `LIST`, the value list used with `VALUES IN` must consist of integer values only. In MySQL 8.0, you can overcome this limitation using partitioning by `LIST COLUMNS`, which is described later in this section.

- `LIST COLUMNS(column_list)`

This variant on `LIST` facilitates partition pruning for queries using comparison conditions on multiple columns (that is, having conditions such as `WHERE a = 5 AND b = 5` or `WHERE a = 1 AND`

`b = 10 AND c = 5`). It enables you to specify values in multiple columns by using a list of columns in the `COLUMNS` clause and a set of column values in each `PARTITION ... VALUES IN (value_list)` partition definition clause.

The rules governing regarding data types for the column list used in `LIST COLUMNS(column_list)` and the value list used in `VALUES IN(value_list)` are the same as those for the column list used in `RANGE COLUMNS(column_list)` and the value list used in `VALUES LESS THAN(value_list)`, respectively, except that in the `VALUES IN` clause, `MAXVALUE` is not permitted, and you may use `NULL`.

There is one important difference between the list of values used for `VALUES IN` with `PARTITION BY LIST COLUMNS` as opposed to when it is used with `PARTITION BY LIST`. When used with `PARTITION BY LIST COLUMNS`, each element in the `VALUES IN` clause must be a set of column values; the number of values in each set must be the same as the number of columns used in the `COLUMNS` clause, and the data types of these values must match those of the columns (and occur in the same order). In the simplest case, the set consists of a single column. The maximum number of columns that can be used in the `column_list` and in the elements making up the `value_list` is 16.

The table defined by the following `CREATE TABLE` statement provides an example of a table using `LIST COLUMNS` partitioning:

```
CREATE TABLE lc (
  a INT NULL,
  b INT NULL
)
PARTITION BY LIST COLUMNS(a,b) (
  PARTITION p0 VALUES IN( (0,0), (NULL,NULL) ),
  PARTITION p1 VALUES IN( (0,1), (0,2), (0,3), (1,1), (1,2) ),
  PARTITION p2 VALUES IN( (1,0), (2,0), (2,1), (3,0), (3,1) ),
  PARTITION p3 VALUES IN( (1,3), (2,2), (2,3), (3,2), (3,3) )
);
```

- `PARTITIONS num`

The number of partitions may optionally be specified with a `PARTITIONS num` clause, where `num` is the number of partitions. If both this clause *and* any `PARTITION` clauses are used, `num` must be equal to the total number of any partitions that are declared using `PARTITION` clauses.

Note

Whether or not you use a `PARTITIONS` clause in creating a table that is partitioned by `RANGE` or `LIST`, you must still include at least one `PARTITION VALUES` clause in the table definition (see below).

- `SUBPARTITION BY`

A partition may optionally be divided into a number of subpartitions. This can be indicated by using the optional `SUBPARTITION BY` clause. Subpartitioning may be done by `HASH` or `KEY`. Either of these may be `LINEAR`. These work in the same way as previously described for the equivalent partitioning types. (It is not possible to subpartition by `LIST` or `RANGE`.)

The number of subpartitions can be indicated using the `SUBPARTITIONS` keyword followed by an integer value.

- Rigorous checking of the value used in `PARTITIONS` or `SUBPARTITIONS` clauses is applied and this value must adhere to the following rules:
 - The value must be a positive, nonzero integer.
 - No leading zeros are permitted.

- The value must be an integer literal, and cannot not be an expression. For example, `PARTITIONS 0.2E+01` is not permitted, even though `0.2E+01` evaluates to `2`. (Bug #15890)
- *partition_definition*

Each partition may be individually defined using a *partition_definition* clause. The individual parts making up this clause are as follows:

- `PARTITION partition_name`

Specifies a logical name for the partition.

- `VALUES`

For range partitioning, each partition must include a `VALUES LESS THAN` clause; for list partitioning, you must specify a `VALUES IN` clause for each partition. This is used to determine which rows are to be stored in this partition. See the discussions of partitioning types in [Chapter 22, Partitioning](#), for syntax examples.

- `[STORAGE] ENGINE`

MySQL accepts a `[STORAGE] ENGINE` option for both `PARTITION` and `SUBPARTITION`. Currently, the only way in which this option can be used is to set all partitions or all subpartitions to the same storage engine, and an attempt to set different storage engines for partitions or subpartitions in the same table will give rise to the error `ERROR 1469 (HY000): The mix of handlers in the partitions is not permitted in this version of MySQL`.

- `COMMENT`

An optional `COMMENT` clause may be used to specify a string that describes the partition. Example:

```
COMMENT = 'Data for the years previous to 1999'
```

The maximum length for a partition comment is 1024 characters.

- `DATA DIRECTORY` and `INDEX DIRECTORY`

`DATA DIRECTORY` and `INDEX DIRECTORY` may be used to indicate the directory where, respectively, the data and indexes for this partition are to be stored. Both the *data_dir* and the *index_dir* must be absolute system path names.

You must have the `FILE` privilege to use the `DATA DIRECTORY` or `INDEX DIRECTORY` partition option.

Example:

```
CREATE TABLE th (id INT, name VARCHAR(30), adate DATE)
PARTITION BY LIST(YEAR(adate))
(
  PARTITION p1999 VALUES IN (1995, 1999, 2003)
    DATA DIRECTORY = '/var/appdata/95/data'
    INDEX DIRECTORY = '/var/appdata/95/idx',
  PARTITION p2000 VALUES IN (1996, 2000, 2004)
    DATA DIRECTORY = '/var/appdata/96/data'
    INDEX DIRECTORY = '/var/appdata/96/idx',
  PARTITION p2001 VALUES IN (1997, 2001, 2005)
    DATA DIRECTORY = '/var/appdata/97/data'
    INDEX DIRECTORY = '/var/appdata/97/idx',
  PARTITION p2002 VALUES IN (1998, 2002, 2006)
    DATA DIRECTORY = '/var/appdata/98/data'
    INDEX DIRECTORY = '/var/appdata/98/idx'
);
```

`DATA DIRECTORY` and `INDEX DIRECTORY` behave in the same way as in the `CREATE TABLE` statement's `table_option` clause as used for `MyISAM` tables.

One data directory and one index directory may be specified per partition. If left unspecified, the data and indexes are stored by default in the table's database directory.

The `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored for creating partitioned tables if `NO_DIR_IN_CREATE` is in effect.

- `MAX_ROWS` and `MIN_ROWS`

May be used to specify, respectively, the maximum and minimum number of rows to be stored in the partition. The values for `max_number_of_rows` and `min_number_of_rows` must be positive integers. As with the table-level options with the same names, these act only as “suggestions” to the server and are not hard limits.

- `TABLESPACE`

May be used to assign `InnoDB` table partitions or subpartitions to a `general tablespace`, a separate file-per-table tablespace, or the system tablespace. All partitions must belong to the same storage engine. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

- `subpartition_definition`

The partition definition may optionally contain one or more `subpartition_definition` clauses. Each of these consists at a minimum of the `SUBPARTITION name`, where `name` is an identifier for the subpartition. Except for the replacement of the `PARTITION` keyword with `SUBPARTITION`, the syntax for a subpartition definition is identical to that for a partition definition.

Subpartitioning must be done by `HASH` or `KEY`, and can be done only on `RANGE` or `LIST` partitions. See [Section 22.2.6, “Subpartitioning”](#).

Partitioning by Generated Columns

Partitioning by generated columns is permitted. For example:

```
CREATE TABLE t1 (
  s1 INT,
  s2 INT AS (EXP(s1)) STORED
)
PARTITION BY LIST (s2) (
  PARTITION p1 VALUES IN (1)
);
```

Partitioning sees a generated column as a regular column, which enables workarounds for limitations on functions that are not permitted for partitioning (see [Section 22.6.3, “Partitioning Limitations Relating to Functions”](#)). The preceding example demonstrates this technique: `EXP()` cannot be used directly in the `PARTITION BY` clause, but a generated column defined using `EXP()` is permitted.

13.1.15.1 CREATE TABLE Statement Retention

The original `CREATE TABLE` statement, including all specifications and table options are stored by MySQL when the table is created. The information is retained so that if you change storage engines, collations or other settings using an `ALTER TABLE` statement, the original table options specified are retained. This enables you to change between `InnoDB` and `MyISAM` table types even though the row formats supported by the two engines are different.

Because the text of the original statement is retained, but due to the way that certain values and options may be silently reconfigured (such as the `ROW_FORMAT`), the active table definition (accessible through `DESCRIBE` or with `SHOW TABLE STATUS`) and the table creation string (accessible through `SHOW CREATE TABLE`) will report different values.

13.1.15.2 Files Created by CREATE TABLE

For an [InnoDB](#) table created in a file-per-table tablespace or general tablespace, table data and associated indexes are stored in an [ibd file](#) in the database directory. When an [InnoDB](#) table is created in the system tablespace, table data and indexes are stored in the [ibdata* files](#) that represent the system tablespace. The [innodb_file_per_table](#) option controls whether tables are created in file-per-table tablespaces or the system tablespace, by default. The [TABLESPACE](#) option can be used to place a table in a file-per-table tablespace, general tablespace, or the system tablespace, regardless of the [innodb_file_per_table](#) setting.

For [MyISAM](#) tables, the storage engine creates data and index files. Thus, for each [MyISAM](#) table *tbl_name*, there are two disk files.

File	Purpose
<i>tbl_name</i> .MYD	Data file
<i>tbl_name</i> .MYI	Index file

[Chapter 16, Alternative Storage Engines](#), describes what files each storage engine creates to represent tables. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in [Section 9.2.3, “Mapping of Identifiers to File Names”](#).

13.1.15.3 CREATE TEMPORARY TABLE Syntax

You can use the [TEMPORARY](#) keyword when creating a table. A [TEMPORARY](#) table is visible only to the current session, and is dropped automatically when the session is closed. This means that two different sessions can use the same temporary table name without conflicting with each other or with an existing non-[TEMPORARY](#) table of the same name. (The existing table is hidden until the temporary table is dropped.)

[InnoDB](#) does not support compressed temporary tables. When [innodb_strict_mode](#) is enabled (the default), [CREATE TEMPORARY TABLE](#) returns an error if [ROW_FORMAT=COMPRESSED](#) or [KEY_BLOCK_SIZE](#) is specified. If [innodb_strict_mode](#) is disabled, warnings are issued and the temporary table is created using a non-compressed row format. [InnoDB](#) temporary tables are created in the shared temporary tablespace, [ibtmp1](#). The [innodb_file_per-table](#) option does not affect the creation of [InnoDB](#) temporary tables.

[CREATE TABLE](#) does not automatically commit the current active transaction if you use the [TEMPORARY](#) keyword.

[TEMPORARY](#) tables have a very loose relationship with databases (schemas). Dropping a database does not automatically drop any [TEMPORARY](#) tables created within that database. Also, you can create a [TEMPORARY](#) table in a nonexistent database if you qualify the table name with the database name in the [CREATE TABLE](#) statement. In this case, all subsequent references to the table must be qualified with the database name.

To create a temporary table, you must have the [CREATE TEMPORARY TABLES](#) privilege. After a session has created a temporary table, the server performs no further privilege checks on the table. The creating session can perform any operation on the table, such as [DROP TABLE](#), [INSERT](#), [UPDATE](#), or [SELECT](#).

One implication of this behavior is that a session can manipulate its temporary tables even if the current user has no privilege to create them. Suppose that the current user does not have the [CREATE TEMPORARY TABLES](#) privilege but is able to execute a [DEFINER](#)-context stored procedure that executes with the privileges of a user who does have [CREATE TEMPORARY TABLES](#) and that creates a temporary table. While the procedure executes, the session uses the privileges of the defining user. After the procedure returns, the effective privileges revert to those of the current user, which can still see the temporary table and perform any operation on it.

As of MySQL 8.0.2, you cannot use `CREATE TEMPORARY TABLE ... LIKE` to create an empty table based on the definition of a table that resides in the `mysql` tablespace, `InnoDB` system tablespace (`innodb_system`), or a general tablespace. The tablespace definition for such a table includes a `TABLESPACE` attribute that defines the tablespace where the table resides, and the aforementioned tablespaces do not support temporary tables. To create a temporary table based on the definition of such a table, use this syntax instead:

```
CREATE TEMPORARY TABLE new_tbl SELECT * FROM orig_tbl LIMIT 0;
```

13.1.15.4 CREATE TABLE ... LIKE Syntax

Use `CREATE TABLE ... LIKE` to create an empty table based on the definition of another table, including any column attributes and indexes defined in the original table:

```
CREATE TABLE new_tbl LIKE orig_tbl;
```

The copy is created using the same version of the table storage format as the original table. The `SELECT` privilege is required on the original table.

`LIKE` works only for base tables, not for views.

Important

You cannot execute `CREATE TABLE` or `CREATE TABLE ... LIKE` while a `LOCK TABLES` statement is in effect.

`CREATE TABLE ... LIKE` makes the same checks as `CREATE TABLE`. This means that if the current SQL mode is different from the mode in effect when the original table was created, the table definition might be considered invalid for the new mode and the statement will fail.

For `CREATE TABLE ... LIKE`, the destination table preserves generated column information from the original table.

`CREATE TABLE ... LIKE` does not preserve any `DATA DIRECTORY` or `INDEX DIRECTORY` table options that were specified for the original table, or any foreign key definitions.

If the original table is a `TEMPORARY` table, `CREATE TABLE ... LIKE` does not preserve `TEMPORARY`. To create a `TEMPORARY` destination table, use `CREATE TEMPORARY TABLE ... LIKE`.

As of MySQL 8.0.2, tables created in the `mysql` tablespace, the `InnoDB` system tablespace (`innodb_system`), or general tablespaces include a `TABLESPACE` attribute in the table definition, which defines the tablespace where the table resides. Due to a temporary regression introduced by this change, `CREATE TABLE ... LIKE` preserves the `TABLESPACE` attribute and creates the table in the defined tablespace regardless of the `innodb_file_per_table` setting. To avoid the `TABLESPACE` attribute when creating an empty table based on the definition of such a table, use this syntax instead:

```
CREATE TABLE new_tbl SELECT * FROM orig_tbl LIMIT 0;
```

13.1.15.5 CREATE TABLE ... SELECT Syntax

You can create one table from another by adding a `SELECT` statement at the end of the `CREATE TABLE` statement:

```
CREATE TABLE new_tbl [AS] SELECT * FROM orig_tbl;
```

MySQL creates new columns for all elements in the `SELECT`. For example:

```
mysql> CREATE TABLE test (a INT NOT NULL AUTO_INCREMENT,
-> PRIMARY KEY (a), KEY(b))
-> ENGINE=MyISAM SELECT b,c FROM test2;
```

This creates a `MyISAM` table with three columns, `a`, `b`, and `c`. The `ENGINE` option is part of the `CREATE TABLE` statement, and should not be used following the `SELECT`; this would result in a syntax error. The same is true for other `CREATE TABLE` options such as `CHARSET`.

Notice that the columns from the `SELECT` statement are appended to the right side of the table, not overlapped onto it. Take the following example:

```
mysql> SELECT * FROM foo;
+----+
| n |
+----+
| 1 |
+----+

mysql> CREATE TABLE bar (m INT) SELECT n FROM foo;
Query OK, 1 row affected (0.02 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM bar;
+-----+-----+
| m      | n |
+-----+-----+
| NULL  | 1 |
+-----+-----+
1 row in set (0.00 sec)
```

For each row in table `foo`, a row is inserted in `bar` with the values from `foo` and default values for the new columns.

In a table resulting from `CREATE TABLE ... SELECT`, columns named only in the `CREATE TABLE` part come first. Columns named in both parts or only in the `SELECT` part come after that. The data type of `SELECT` columns can be overridden by also specifying the column in the `CREATE TABLE` part.

If any errors occur while copying the data to the table, it is automatically dropped and not created.

You can precede the `SELECT` by `IGNORE` or `REPLACE` to indicate how to handle rows that duplicate unique key values. With `IGNORE`, rows that duplicate an existing row on a unique key value are discarded. With `REPLACE`, new rows replace rows that have the same unique key value. If neither `IGNORE` nor `REPLACE` is specified, duplicate unique key values result in an error. For more information, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).

Because the ordering of the rows in the underlying `SELECT` statements cannot always be determined, `CREATE TABLE ... IGNORE SELECT` and `CREATE TABLE ... REPLACE SELECT` statements are flagged as unsafe for statement-based replication. With this change, such statements produce a warning in the log when using statement-based mode and are logged using the row-based format when using `MIXED` mode. See also [Section 18.2.1.1, "Advantages and Disadvantages of Statement-Based and Row-Based Replication"](#).

`CREATE TABLE ... SELECT` does not automatically create any indexes for you. This is done intentionally to make the statement as flexible as possible. If you want to have indexes in the created table, you should specify these before the `SELECT` statement:

```
mysql> CREATE TABLE bar (UNIQUE (n)) SELECT n FROM foo;
```

For `CREATE TABLE ... SELECT`, the destination table does not preserve information about whether columns in the selected-from table are generated columns. The `SELECT` part of the statement cannot assign values to generated columns in the destination table.

Some conversion of data types might occur. For example, the `AUTO_INCREMENT` attribute is not preserved, and `VARCHAR` columns can become `CHAR` columns. Retained attributes are `NULL` (or `NOT NULL`) and, for those columns that have them, `CHARACTER SET`, `COLLATION`, `COMMENT`, and the `DEFAULT` clause.

When creating a table with `CREATE TABLE ... SELECT`, make sure to alias any function calls or expressions in the query. If you do not, the `CREATE` statement might fail or result in undesirable column names.

```
CREATE TABLE artists_and_works
  SELECT artist.name, COUNT(work.artist_id) AS number_of_works
  FROM artist LEFT JOIN work ON artist.id = work.artist_id
  GROUP BY artist.id;
```

You can also explicitly specify the data type for a column in the created table:

```
CREATE TABLE foo (a TINYINT NOT NULL) SELECT b+1 AS a FROM bar;
```

For `CREATE TABLE ... SELECT`, if `IF NOT EXISTS` is given and the target table exists, nothing is inserted into the destination table, and the statement is not logged.

To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts during `CREATE TABLE ... SELECT`.

You cannot use `FOR UPDATE` as part of the `SELECT` in a statement such as `CREATE TABLE new_table SELECT ... FROM old_table ...`. If you attempt to do so, the statement fails.

13.1.15.6 Using FOREIGN KEY Constraints

MySQL supports foreign keys, which let you cross-reference related data across tables, and [foreign key constraints](#), which help keep this spread-out data consistent. The essential syntax for a foreign key constraint definition in a `CREATE TABLE` or `ALTER TABLE` statement looks like this:

```
[CONSTRAINT symbol] FOREIGN KEY
  [index_name] (index_col_name, ...)
  REFERENCES tbl_name (index_col_name,...)
  [ON DELETE reference_option]
  [ON UPDATE reference_option]

reference_option:
  RESTRICT | CASCADE | SET NULL | NO ACTION | SET DEFAULT
```

`index_name` represents a foreign key ID. The `index_name` value is ignored if there is already an explicitly defined index on the child table that can support the foreign key. Otherwise, MySQL implicitly creates a foreign key index that is named according to the following rules:

- If defined, the `CONSTRAINT symbol` value is used. Otherwise, the `FOREIGN KEY index_name` value is used.
- If neither a `CONSTRAINT symbol` or `FOREIGN KEY index_name` is defined, the foreign key index name is generated using the name of the referencing foreign key column.

Foreign keys definitions are subject to the following conditions:

- Foreign key relationships involve a [parent table](#) that holds the central data values, and a [child table](#) with identical values pointing back to its parent. The `FOREIGN KEY` clause is specified in the child table. The parent and child tables must use the same storage engine. They must not be `TEMPORARY` tables.

In MySQL 8.0, creation of a foreign key constraint requires the `REFERENCES` privilege for the parent table.

- Corresponding columns in the foreign key and the referenced key must have similar data types. *The size and sign of integer types must be the same.* The length of string types need not be the same. For nonbinary (character) string columns, the character set and collation must be the same.
- When `foreign_key_checks` is enabled, which is the default setting, character set conversion is not permitted on tables that include a character string column used in a foreign key constraint. The workaround is described in [Section 13.1.7, “ALTER TABLE Syntax”](#).
- MySQL requires indexes on foreign keys and referenced keys so that foreign key checks can be fast and not require a table scan. In the referencing table, there must be an index where the foreign key columns are listed as the *first* columns in the same order. Such an index is created on the referencing table automatically if it does not exist. This index might be silently dropped later, if you create another index that can be used to enforce the foreign key constraint. `index_name`, if given, is used as described previously.
- `InnoDB` permits a foreign key to reference any column or group of columns. However, in the referenced table, there must be an index where the referenced columns are listed as the *first* columns in the same order.
- Index prefixes on foreign key columns are not supported. One consequence of this is that `BLOB` and `TEXT` columns cannot be included in a foreign key because indexes on those columns must always include a prefix length.
- If the `CONSTRAINT symbol` clause is given, the `symbol` value, if used, must be unique in the database. A duplicate `symbol` will result in an error similar to: `ERROR 1022 (2300): Can't write; duplicate key in table '#sql- 464_1'`. If the clause is not given, or a `symbol` is not included following the `CONSTRAINT` keyword, a name for the constraint is created automatically.
- `InnoDB` does not currently support foreign keys for tables with user-defined partitioning. This includes both parent and child tables.

Referential Actions

This section describes how foreign keys help guarantee [referential integrity](#).

For storage engines supporting foreign keys, MySQL rejects any `INSERT` or `UPDATE` operation that attempts to create a foreign key value in a child table if there is no a matching candidate key value in the parent table.

When an `UPDATE` or `DELETE` operation affects a key value in the parent table that has matching rows in the child table, the result depends on the *referential action* specified using `ON UPDATE` and `ON DELETE` subclauses of the `FOREIGN KEY` clause. MySQL supports five options regarding the action to be taken, listed here:

- `CASCADE`: Delete or update the row from the parent table, and automatically delete or update the matching rows in the child table. Both `ON DELETE CASCADE` and `ON UPDATE CASCADE` are supported. Between two tables, do not define several `ON UPDATE CASCADE` clauses that act on the same column in the parent table or in the child table.

Note

Cascaded foreign key actions do not activate triggers.

- `SET NULL`: Delete or update the row from the parent table, and set the foreign key column or columns in the child table to `NULL`. Both `ON DELETE SET NULL` and `ON UPDATE SET NULL` clauses are supported.

If you specify a `SET NULL` action, *make sure that you have not declared the columns in the child table as `NOT NULL`*.

- `RESTRICT`: Rejects the delete or update operation for the parent table. Specifying `RESTRICT` (or `NO ACTION`) is the same as omitting the `ON DELETE` or `ON UPDATE` clause.

- **NO ACTION:** A keyword from standard SQL. In MySQL, equivalent to **RESTRICT**. The MySQL Server rejects the delete or update operation for the parent table if there is a related foreign key value in the referenced table. Some database systems have deferred checks, and **NO ACTION** is a deferred check. In MySQL, foreign key constraints are checked immediately, so **NO ACTION** is the same as **RESTRICT**.
- **SET DEFAULT:** This action is recognized by the MySQL parser, but **InnoDB** rejects table definitions containing **ON DELETE SET DEFAULT** or **ON UPDATE SET DEFAULT** clauses.

For an **ON DELETE** or **ON UPDATE** that is not specified, the default action is always **RESTRICT**.

MySQL supports foreign key references between one column and another within a table. (A column cannot have a foreign key reference to itself.) In these cases, “child table records” really refers to dependent records within the same table.

A foreign key constraint on a stored generated column cannot use **ON UPDATE CASCADE**, **ON DELETE SET NULL**, **ON UPDATE SET NULL**, **ON DELETE SET DEFAULT**, or **ON UPDATE SET DEFAULT**.

A foreign key constraint cannot reference a virtual generated column.

For **InnoDB** restrictions related to foreign keys and generated columns, see [Section 15.8.1.6, “InnoDB and FOREIGN KEY Constraints”](#).

Examples of Foreign Key Clauses

Here is a simple example that relates **parent** and **child** tables through a single-column foreign key:

```
CREATE TABLE parent (
  id INT NOT NULL,
  PRIMARY KEY (id)
) ENGINE=INNODB;

CREATE TABLE child (
  id INT,
  parent_id INT,
  INDEX par_ind (parent_id),
  FOREIGN KEY (parent_id)
    REFERENCES parent(id)
    ON DELETE CASCADE
) ENGINE=INNODB;
```

A more complex example in which a **product_order** table has foreign keys for two other tables. One foreign key references a two-column index in the **product** table. The other references a single-column index in the **customer** table:

```
CREATE TABLE product (
  category INT NOT NULL, id INT NOT NULL,
  price DECIMAL,
  PRIMARY KEY(category, id)
) ENGINE=INNODB;

CREATE TABLE customer (
  id INT NOT NULL,
  PRIMARY KEY (id)
) ENGINE=INNODB;

CREATE TABLE product_order (
  no INT NOT NULL AUTO_INCREMENT,
  product_category INT NOT NULL,
  product_id INT NOT NULL,
  customer_id INT NOT NULL,

  PRIMARY KEY(no),
  INDEX (product_category, product_id),
```

```

INDEX (customer_id),

FOREIGN KEY (product_category, product_id)
  REFERENCES product(category, id)
  ON UPDATE CASCADE ON DELETE RESTRICT,

FOREIGN KEY (customer_id)
  REFERENCES customer(id)
) ENGINE=INNODB;

```

Adding foreign keys

You can add a new foreign key constraint to an existing table by using `ALTER TABLE`. The syntax relating to foreign keys for this statement is shown here:

```

ALTER TABLE tbl_name
  ADD [CONSTRAINT [symbol]] FOREIGN KEY
  [index_name] (index_col_name, ...)
  REFERENCES tbl_name (index_col_name,...)
  [ON DELETE reference_option]
  [ON UPDATE reference_option]

```

The foreign key can be self referential (referring to the same table). When you add a foreign key constraint to a table using `ALTER TABLE`, *remember to create the required indexes first*.

Dropping Foreign Keys

You can also use `ALTER TABLE` to drop foreign keys, using the syntax shown here:

```

ALTER TABLE tbl_name DROP FOREIGN KEY fk_symbol;

```

If the `FOREIGN KEY` clause included a `CONSTRAINT` name when you created the foreign key, you can refer to that name to drop the foreign key. Otherwise, the `fk_symbol` value is generated internally when the foreign key is created. To find out the symbol value when you want to drop a foreign key, use a `SHOW CREATE TABLE` statement, as shown here:

```

mysql> SHOW CREATE TABLE ibtest11c\G
***** 1. row *****
      Table: ibtest11c
Create Table: CREATE TABLE `ibtest11c` (
  `A` int(11) NOT NULL auto_increment,
  `D` int(11) NOT NULL default '0',
  `B` varchar(200) NOT NULL default '',
  `C` varchar(175) default NULL,
  PRIMARY KEY (`A`,`D`,`B`),
  KEY `B` (`B`,`C`),
  KEY `C` (`C`),
  CONSTRAINT `0_38775` FOREIGN KEY (`A`, `D`)
REFERENCES `ibtest11a` (`A`, `D`)
ON DELETE CASCADE ON UPDATE CASCADE,
  CONSTRAINT `0_38776` FOREIGN KEY (`B`, `C`)
REFERENCES `ibtest11a` (`B`, `C`)
ON DELETE CASCADE ON UPDATE CASCADE
) ENGINE=INNODB CHARSET=utf8mb4
1 row in set (0.01 sec)

mysql> ALTER TABLE ibtest11c DROP FOREIGN KEY `0_38775`;

```

Adding and dropping a foreign key in the same `ALTER TABLE` statement is supported for `ALTER TABLE ... ALGORITHM=INPLACE` but is unsupported for `ALTER TABLE ... ALGORITHM=COPY`.

In MySQL 8.0, the server prohibits changes to foreign key columns with the potential to cause loss of referential integrity. A workaround is to use `ALTER TABLE ... DROP FOREIGN KEY` before changing the column definition and `ALTER TABLE ... ADD FOREIGN KEY` afterward.

Foreign Keys and Other MySQL Statements

Table and column identifiers in a `FOREIGN KEY ... REFERENCES ...` clause can be quoted within backticks (```). Alternatively, double quotation marks (`"`) can be used if the `ANSI_QUOTES` SQL mode is enabled. The setting of the `lower_case_table_names` system variable is also taken into account.

You can view a child table's foreign key definitions as part of the output of the `SHOW CREATE TABLE` statement:

```
SHOW CREATE TABLE tbl_name;
```

You can also obtain information about foreign keys by querying the `INFORMATION_SCHEMA.KEY_COLUMN_USAGE` table.

You can find information about foreign keys used by `InnoDB` tables in the `INNODB_SYS_FOREIGN` and `INNODB_SYS_FOREIGN_COLS` tables, also in the `INFORMATION_SCHEMA` database.

`mysqldump` produces correct definitions of tables in the dump file, including the foreign keys for child tables.

To make it easier to reload dump files for tables that have foreign key relationships, `mysqldump` automatically includes a statement in the dump output to set `foreign_key_checks` to 0. This avoids problems with tables having to be reloaded in a particular order when the dump is reloaded. It is also possible to set this variable manually:

```
mysql> SET foreign_key_checks = 0;
mysql> SOURCE dump_file_name;
mysql> SET foreign_key_checks = 1;
```

This enables you to import the tables in any order if the dump file contains tables that are not correctly ordered for foreign keys. It also speeds up the import operation. Setting `foreign_key_checks` to 0 can also be useful for ignoring foreign key constraints during `LOAD DATA` and `ALTER TABLE` operations. However, even if `foreign_key_checks = 0`, MySQL does not permit the creation of a foreign key constraint where a column references a nonmatching column type. Also, if a table has foreign key constraints, `ALTER TABLE` cannot be used to alter the table to use another storage engine. To change the storage engine, you must drop any foreign key constraints first.

You cannot issue `DROP TABLE` for a table that is referenced by a `FOREIGN KEY` constraint, unless you do `SET foreign_key_checks = 0`. When you drop a table, any constraints that were defined in the statement used to create that table are also dropped.

If you re-create a table that was dropped, it must have a definition that conforms to the foreign key constraints referencing it. It must have the correct column names and types, and it must have indexes on the referenced keys, as stated earlier. If these are not satisfied, MySQL returns Error 1005 and refers to Error 150 in the error message, which means that a foreign key constraint was not correctly formed. Similarly, if an `ALTER TABLE` fails due to Error 150, this means that a foreign key definition would be incorrectly formed for the altered table.

For `InnoDB` tables, you can obtain a detailed explanation of the most recent `InnoDB` foreign key error in the MySQL Server, by checking the output of `SHOW ENGINE INNODB STATUS`.

Important

For users familiar with the ANSI/ISO SQL Standard, please note that no storage engine, including `InnoDB`, recognizes or enforces the `MATCH` clause used in referential-integrity constraint definitions. Use of an explicit `MATCH` clause will not have the specified effect, and also causes `ON DELETE` and `ON UPDATE` clauses to be ignored. For these reasons, specifying `MATCH` should be avoided.

The `MATCH` clause in the SQL standard controls how `NULL` values in a composite (multiple-column) foreign key are handled when comparing to a

primary key. MySQL essentially implements the semantics defined by `MATCH SIMPLE`, which permit a foreign key to be all or partially `NULL`. In that case, the (child table) row containing such a foreign key is permitted to be inserted, and does not match any row in the referenced (parent) table. It is possible to implement other semantics using triggers.

Additionally, MySQL requires that the referenced columns be indexed for performance reasons. However, the system does not enforce a requirement that the referenced columns be `UNIQUE` or be declared `NOT NULL`. The handling of foreign key references to nonunique keys or keys that contain `NULL` values is not well defined for operations such as `UPDATE` or `DELETE CASCADE`. You are advised to use foreign keys that reference only `UNIQUE` (including `PRIMARY`) and `NOT NULL` keys.

Furthermore, MySQL parses but ignores “inline `REFERENCES` specifications” (as defined in the SQL standard) where the references are defined as part of the column specification. MySQL accepts `REFERENCES` clauses only when specified as part of a separate `FOREIGN KEY` specification. For storage engines that do not support foreign keys (such as `MyISAM`), MySQL Server parses and ignores foreign key specifications.

13.1.15.7 Silent Column Specification Changes

In some cases, MySQL silently changes column specifications from those given in a `CREATE TABLE` or `ALTER TABLE` statement. These might be changes to a data type, to attributes associated with a data type, or to an index specification.

All changes are subject to the internal row-size limit of 65,535 bytes, which may cause some attempts at data type changes to fail. See [Section C.10.4, “Limits on Table Column Count and Row Size”](#).

- Columns that are part of a `PRIMARY KEY` are made `NOT NULL` even if not declared that way.
- Trailing spaces are automatically deleted from `ENUM` and `SET` member values when the table is created.
- MySQL maps certain data types used by other SQL database vendors to MySQL types. See [Section 11.10, “Using Data Types from Other Database Engines”](#).
- If you include a `USING` clause to specify an index type that is not permitted for a given storage engine, but there is another index type available that the engine can use without affecting query results, the engine uses the available type.
- If strict SQL mode is not enabled, a `VARCHAR` column with a length specification greater than 65535 is converted to `TEXT`, and a `VARBINARY` column with a length specification greater than 65535 is converted to `BLOB`. Otherwise, an error occurs in either of these cases.
- Specifying the `CHARACTER SET binary` attribute for a character data type causes the column to be created as the corresponding binary data type: `CHAR` becomes `BINARY`, `VARCHAR` becomes `VARBINARY`, and `TEXT` becomes `BLOB`. For the `ENUM` and `SET` data types, this does not occur; they are created as declared. Suppose that you specify a table using this definition:

```
CREATE TABLE t
(
  c1 VARCHAR(10) CHARACTER SET binary,
  c2 TEXT CHARACTER SET binary,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

The resulting table has this definition:

```
CREATE TABLE t
(
  c1 VARBINARY(10),
  c2 BLOB,
  c3 ENUM('a','b','c') CHARACTER SET binary
);
```

To see whether MySQL used a data type other than the one you specified, issue a [DESCRIBE](#) or [SHOW CREATE TABLE](#) statement after creating or altering the table.

Certain other data type changes can occur if you compress a table using [myisampack](#). See [Section 16.2.3.3, “Compressed Table Characteristics”](#).

13.1.15.8 CREATE TABLE and Generated Columns

[CREATE TABLE](#) supports the specification of generated columns. Values of a generated column are computed from an expression included in the column definition.

The following simple example shows a table that stores the lengths of the sides of right triangles in the [sidea](#) and [sideb](#) columns, and computes the length of the hypotenuse in [sidec](#) (the square root of the sums of the squares of the other sides):

```
CREATE TABLE triangle (
  sidea DOUBLE,
  sideb DOUBLE,
  sidec DOUBLE AS (SQRT(sidea * sidea + sideb * sideb))
);
INSERT INTO triangle (sidea, sideb) VALUES(1,1),(3,4),(6,8);
```

Selecting from the table yields this result:

```
mysql> SELECT * FROM triangle;
+-----+-----+-----+
| sidea | sideb | sidec |
+-----+-----+-----+
| 1     | 1     | 1.4142135623730951 |
| 3     | 4     | 5 |
| 6     | 8     | 10 |
+-----+-----+-----+
```

Any application that uses the [triangle](#) table has access to the hypotenuse values without having to specify the expression that calculates them.

Generated column definitions have this syntax:

```
col_name data_type [GENERATED ALWAYS] AS (expression)
[VIRTUAL | STORED] [UNIQUE [KEY]] [COMMENT comment]
[[NOT] NULL] [[PRIMARY] KEY]
```

[AS \(expression\)](#) indicates that the column is generated and defines the expression used to compute column values. [AS](#) may be preceded by [GENERATED ALWAYS](#) to make the generated nature of the column more explicit. Constructs that are permitted or prohibited in the expression are discussed later.

The [VIRTUAL](#) or [STORED](#) keyword indicates how column values are stored, which has implications for column use:

- [VIRTUAL](#): Column values are not stored, but are evaluated when rows are read, immediately after any [BEFORE](#) triggers. A virtual column takes no storage.

[InnoDB](#) supports secondary indexes on virtual columns. See [Section 13.1.15.9, “Secondary Indexes and Generated Columns”](#).

- **STORED**: Column values are evaluated and stored when rows are inserted or updated. A stored column does not require storage space and can be indexed.

The default is **VIRTUAL** if neither keyword is specified.

It is permitted to mix **VIRTUAL** and **STORED** columns within a table.

Other attributes may be given to indicate whether the column is indexed or can be **NULL**, or provide a comment. (Note that the order of these attributes differs from their order in nongenerated column definitions.)

Generated column expressions must adhere to the following rules. An error occurs if an expression contains disallowed constructs.

- Literals, deterministic built-in functions, and operators are permitted. A function is deterministic if, given the same data in tables, multiple invocations produce the same result, independently of the connected user. Examples of functions that fail this definition: **CONNECTION_ID()**, **CURRENT_USER()**, **NOW()**.
- Subqueries, parameters, variables, stored functions, and user-defined functions are not permitted.
- A generated column definition can refer to other generated columns, but only those occurring earlier in the table definition. A generated column definition can refer to any base (nongenerated) column in the table whether its definition occurs earlier or later.
- The **AUTO_INCREMENT** attribute cannot be used in a generated column definition.
- An **AUTO_INCREMENT** column cannot be used as a base column in a generated column definition.
- If expression evaluation causes truncation or provides incorrect input to a function, the **CREATE TABLE** statement terminates with an error and the DDL operation is rejected.

If the expression evaluates to a data type that differs from the declared column type, coercion to the declared type occurs according to the usual MySQL type-conversion rules. See [Section 12.2, “Type Conversion in Expression Evaluation”](#).

Note

If any component of the expression depends on the SQL mode, different results may occur for different uses of the table unless the SQL mode is the same during all uses.

For **CREATE TABLE ... LIKE**, the destination table preserves generated column information from the original table.

For **CREATE TABLE ... SELECT**, the destination table does not preserve information about whether columns in the selected-from table are generated columns. The **SELECT** part of the statement cannot assign values to generated columns in the destination table.

Partitioning by generated columns is permitted. See [Creating Partitioned Tables](#).

A foreign key constraint on a stored generated column cannot use **ON UPDATE CASCADE**, **ON DELETE SET NULL**, **ON UPDATE SET NULL**, **ON DELETE SET DEFAULT**, or **ON UPDATE SET DEFAULT**.

A foreign key constraint cannot reference a virtual generated column.

For **InnoDB** restrictions related to foreign keys and generated columns, see [Section 15.8.1.6, “InnoDB and FOREIGN KEY Constraints”](#).

Triggers cannot use **NEW.col_name** or use **OLD.col_name** to refer to generated columns.

For [INSERT](#), [REPLACE](#), and [UPDATE](#), if a generated column is inserted into, replaced, or updated explicitly, the only permitted value is [DEFAULT](#).

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is [DEFAULT](#).

Generated columns have several use cases, such as these:

- Virtual generated columns can be used as a way to simplify and unify queries. A complicated condition can be defined as a generated column and referred to from multiple queries on the table to ensure that all of them use exactly the same condition.
- Stored generated columns can be used as a materialized cache for complicated conditions that are costly to calculate on the fly.
- Generated columns can simulate functional indexes: Use a stored column to define a functional expression and index it. This can be useful for working with columns of types that cannot be indexed directly, such as [JSON](#) columns; see [Indexing a Generated Column to Provide a JSON Column Index](#), for a detailed example.

The disadvantage of such an approach is that values are stored twice; once as the value of the generated column and once in the index.

- If a generated column is indexed, the optimizer recognizes query expressions that match the column definition and uses indexes from the column as appropriate during query execution, even if a query does not refer to the column directly by name. For details, see [Section 8.3.10, “Optimizer Use of Generated Column Indexes”](#).

Example:

Suppose that a table `t1` contains `first_name` and `last_name` columns and that applications frequently construct the full name using an expression like this:

```
SELECT CONCAT(first_name, ' ', last_name) AS full_name FROM t1;
```

One way to avoid writing out the expression is to create a view `v1` on `t1`, which simplifies applications by enabling them to select `full_name` directly without using an expression:

```
CREATE VIEW v1 AS
SELECT *, CONCAT(first_name, ' ', last_name) AS full_name FROM t1;

SELECT full_name FROM v1;
```

A generated column also enables applications to select `full_name` directly without the need to define a view:

```
CREATE TABLE t1 (
  first_name VARCHAR(10),
  last_name VARCHAR(10),
  full_name VARCHAR(255) AS (CONCAT(first_name, ' ', last_name))
);

SELECT full_name FROM t1;
```

13.1.15.9 Secondary Indexes and Generated Columns

[InnoDB](#) supports secondary indexes on virtual generated columns. Other index types are not supported. A secondary index defined on a virtual column is sometimes referred to as a “virtual index”.

A secondary index may be created on one or more virtual columns or on a combination of virtual columns and regular columns or stored generated columns. Secondary indexes that include virtual columns may be defined as [UNIQUE](#).

When a secondary index is created on a virtual generated column, generated column values are materialized in the records of the index. If the index is a [covering index](#) (one that includes all the columns retrieved by a query), generated column values are retrieved from materialized values in the index structure instead of computed “on the fly”.

There are additional write costs to consider when using a secondary index on a virtual column due to computation performed when materializing virtual column values in secondary index records during [INSERT](#) and [UPDATE](#) operations. Even with additional write costs, secondary indexes on virtual columns may be preferable to generated *stored* columns, which are materialized in the clustered index, resulting in larger tables that require more disk space and memory. If a secondary index is not defined on a virtual column, there are additional costs for reads, as virtual column values must be computed each time the column's row is examined.

Values of an indexed virtual column are MVCC-logged to avoid unnecessary recomputation of generated column values during rollback or during a purge operation. The data length of logged values is limited by the index key limit of 767 bytes for [COMPACT](#) and [REDUNDANT](#) row formats, and 3072 bytes for [DYNAMIC](#) and [COMPRESSED](#) row formats.

Adding or dropping a secondary index on a virtual column is an in-place operation.

Indexing a Generated Column to Provide a JSON Column Index

As noted elsewhere, [JSON](#) columns cannot be indexed directly. To create an index that references such a column indirectly, you can define a generated column that extracts the information that should be indexed, then create an index on the generated column, as shown in this example:

```
mysql> CREATE TABLE jemp (
  ->   c JSON,
  ->   g INT GENERATED ALWAYS AS (c->"$.id"),
  ->   INDEX i (g)
  -> );
Query OK, 0 rows affected (0.28 sec)

mysql> INSERT INTO jemp (c) VALUES
  >   ('{"id": "1", "name": "Fred"}'), ('{"id": "2", "name": "Wilma"}'),
  >   ('{"id": "3", "name": "Barney"}'), ('{"id": "4", "name": "Betty"}');
Query OK, 4 rows affected (0.04 sec)
Records: 4  Duplicates: 0  Warnings: 0

mysql> SELECT c->"$.name" AS name
  >   FROM jemp WHERE g > 2;
+-----+
| name  |
+-----+
| Barney|
| Betty |
+-----+
2 rows in set (0.00 sec)

mysql> EXPLAIN SELECT c->"$.name" AS name
  >   FROM jemp WHERE g > 2\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: jemp
  partitions: NULL
         type: range
possible_keys: i
          key: i
         key_len: 5
          ref: NULL
         rows: 2
   filtered: 100.00
      Extra: Using where
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
```

```

***** 1. row *****
Level: Note
Code: 1003
Message: /* select#1 */ select json_unquote(json_extract(`test`.`jemp`.`c`, '$.name'))
AS `name` from `test`.`jemp` where (`test`.`jemp`.`g` > 2)
1 row in set (0.00 sec)

```

(We have wrapped the output from the last statement in this example to fit the viewing area.)

When you use `EXPLAIN` on a `SELECT` or other SQL statement containing one or more expressions that use the `->` or `->>` operator, these expressions are translated into their equivalents using `JSON_EXTRACT()` and (if needed) `JSON_UNQUOTE()` instead, as shown here in the output from `SHOW WARNINGS` immediately following this `EXPLAIN` statement:

```

mysql> EXPLAIN SELECT c->>"$.name"
> FROM jemp WHERE g > 2 ORDER BY c->"$.name"\G
***** 1. row *****
id: 1
select_type: SIMPLE
table: jemp
partitions: NULL
type: range
possible_keys: i
key: i
key_len: 5
ref: NULL
rows: 2
filtered: 100.00
Extra: Using where; Using filesort
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Note
Code: 1003
Message: /* select#1 */ select json_unquote(json_extract(`test`.`jemp`.`c`, '$.name')) AS
`c->>"$.name"` from `test`.`jemp` where (`test`.`jemp`.`g` > 2) order by
json_extract(`test`.`jemp`.`c`, '$.name')
1 row in set (0.00 sec)

```

See the descriptions of the `->` and `->>` operators, as well as those of the `JSON_EXTRACT()` and `JSON_UNQUOTE()` functions, for additional information and examples.

This technique also can be used to provide indexes that indirectly reference columns of other types that cannot be indexed directly, such as `GEOMETRY` columns.

13.1.16 CREATE TABLESPACE Syntax

```

CREATE TABLESPACE tablespace_name
ADD DATAFILE 'file_name'
[FILE_BLOCK_SIZE = value]
[ENGINE [=] engine_name]

```

This statement is used to create an `InnoDB` tablespace. An `InnoDB` tablespace created using `CREATE TABLESPACE` is referred to as *general tablespace*.

A general tablespace is a shared tablespace, similar to the system tablespace. It can hold multiple tables, and supports all table row formats. General tablespaces can also be created in a location relative to or independent of the MySQL data directory.

After creating an `InnoDB` general tablespace, you can use `CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name` or `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` to add tables to the tablespace.

For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

**Note**

`CREATE TABLESPACE` is supported with `InnoDB`. In earlier releases, `CREATE TABLESPACE` only supported `NDB`, which is the MySQL NDB Cluster storage engine.

Options

- `ADD DATAFILE`: Defines the name of the tablespace data file. A data file must be specified with the `CREATE TABLESPACE` statement, and the data file name must have a `.ibd` extension. An `InnoDB` general tablespace only supports a single data file.

To place the data file in a location outside of the MySQL data directory (`DATADIR`), include an absolute directory path or a path relative to the MySQL data directory. If you do not specify a path, the general tablespace is created in the MySQL data directory.

To avoid conflicts with implicitly created file-per-table tablespaces, creating a general tablespace in a subdirectory under the MySQL data directory is not supported. Also, when creating a general tablespace outside of the MySQL data directory, the directory must exist prior to creating the tablespace.

The `file_name`, including the path (optional), must be quoted with single or double quotations marks. File names (not counting the `.ibd` extension) and directory names must be at least one byte in length. Zero length file names and directory names are not supported.

- `FILE_BLOCK_SIZE`: Defines the block size of the tablespace data file. If you do not specify this option, `FILE_BLOCK_SIZE` defaults to `innodb_page_size`. The `FILE_BLOCK_SIZE` setting is only required if you will use the tablespace to store compressed `InnoDB` tables (`ROW_FORMAT=COMPRESSED`). In this case, you must define the tablespace `FILE_BLOCK_SIZE` when creating the tablespace.

If `FILE_BLOCK_SIZE` is equal `innodb_page_size`, the tablespace can only contain tables with an uncompressed row format (`COMPACT`, `REDUNDANT`, and `DYNAMIC` row formats). Tables with a `COMPRESSED` row format have a different physical page size than uncompressed tables. Therefore, compressed tables cannot coexist in the same tablespace as uncompressed tables.

For a general tablespace to contain compressed tables, `FILE_BLOCK_SIZE` must be specified, and the `FILE_BLOCK_SIZE` value must be a valid compressed page size in relation to the `innodb_page_size` value. Also, the physical page size of the compressed table (`KEY_BLOCK_SIZE`) must be equal to `FILE_BLOCK_SIZE/1024`. For example, if `innodb_page_size=16K`, and `FILE_BLOCK_SIZE=8K`, the `KEY_BLOCK_SIZE` of the table must be 8. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

- `ENGINE`: Defines the storage engine which uses the tablespace, where `engine_name` is the name of the storage engine. Currently, only the `InnoDB` storage engine is supported. `ENGINE = InnoDB` must be defined as part of the `CREATE TABLESPACE` statement or `InnoDB` must be defined as the default storage engine (`default_storage_engine=InnoDB`).

Notes

- `tablespace_name` is a case-sensitive identifier for the tablespace. It may be quoted or unquoted. The forward slash character (“/”) is not permitted. Names beginning with `innodb_` are either not permitted or are reserved for special use.
- Creation of temporary general tablespaces is not supported.
- General tablespaces do not support temporary tables.
- The `TABLESPACE` option may be used with `CREATE TABLE` or `ALTER TABLE` to assign `InnoDB` table partitions or subpartitions to a [general tablespace](#), a separate file-per-table tablespace, or the

system tablespace. All partitions must belong to the same storage engine. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

- General tablespaces support the addition of tables of any row format using `CREATE TABLE ... TABLESPACE`. `innodb_file_per_table` does not need to be enabled.
- `innodb_strict_mode` is not applicable to general tablespaces. Tablespace management rules are strictly enforced independently of `innodb_strict_mode`. If `CREATE TABLESPACE` parameters are incorrect or incompatible, the operation fails regardless of the `innodb_strict_mode` setting. When a table is added to a general tablespace using `CREATE TABLE ... TABLESPACE` or `ALTER TABLE ... TABLESPACE`, `innodb_strict_mode` is ignored but the statement is evaluated as if `innodb_strict_mode` is enabled.
- Use `DROP TABLESPACE` to remove a general tablespace. All tables must be dropped from a general tablespace using `DROP TABLE` prior to dropping the tablespace.
- All parts of a table added to a general tablespace reside in the general tablespace, including indexes and `BLOB` pages.
- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace `.ibd data file` which can only be used for new `InnoDB` data. Space is not released back to the operating system as it is for file-per-table tablespaces.
- A general tablespace is not associated with any database or schema.
- `ALTER TABLE ... DISCARD TABLESPACE` and `ALTER TABLE ... IMPORT TABLESPACE` are not supported for tables that belong to a general tablespace.
- The server uses tablespace-level metadata locking for DDL that references general tablespaces. By comparison, the server uses table-level metadata locking for DDL that references file-per-table tablespaces.
- A generated or existing tablespace cannot be changed to a general tablespace.
- There is no conflict between general tablespace names and file-per-table tablespace names. The “/” character, which is present in file-per-table tablespace names, is not permitted in general tablespace names.

Examples

This example demonstrates creating a general tablespace and adding three uncompressed tables of different row formats.

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=REDUNDANT;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t2 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=COMPACT;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t3 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=DYNAMIC;
Query OK, 0 rows affected (0.00 sec)
```

This example demonstrates creating a general tablespace and adding a compressed table. The example assumes a default `innodb_page_size` of 16K. The `FILE_BLOCK_SIZE` of 8192 requires that the compressed table have a `KEY_BLOCK_SIZE` of 8.

```
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)
```

```
mysql> CREATE TABLE t4 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED
KEY_BLOCK_SIZE=8;
Query OK, 0 rows affected (0.00 sec)
```

13.1.17 CREATE TRIGGER Syntax

```
CREATE
  [DEFINER = { user | CURRENT_USER }]
  TRIGGER trigger_name
  trigger_time trigger_event
  ON tbl_name FOR EACH ROW
  [trigger_order]
  trigger_body

trigger_time: { BEFORE | AFTER }

trigger_event: { INSERT | UPDATE | DELETE }

trigger_order: { FOLLOWS | PRECEDES } other_trigger_name
```

This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. The trigger becomes associated with the table named *tbl_name*, which must refer to a permanent table. You cannot associate a trigger with a [TEMPORARY](#) table or a view.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

This section describes [CREATE TRIGGER](#) syntax. For additional discussion, see [Section 23.3.1, “Trigger Syntax and Examples”](#).

[CREATE TRIGGER](#) requires the [TRIGGER](#) privilege for the table associated with the trigger. The statement might also require the [SET_USER_ID](#) or [SUPER](#) privilege, depending on the [DEFINER](#) value, as described later in this section. If binary logging is enabled, [CREATE TRIGGER](#) might require the [SUPER](#) privilege, as described in [Section 23.7, “Binary Logging of Stored Programs”](#).

The [DEFINER](#) clause determines the security context to be used when checking access privileges at trigger activation time, as described later in this section.

trigger_time is the trigger action time. It can be [BEFORE](#) or [AFTER](#) to indicate that the trigger activates before or after each row to be modified.

Basic column value checks occur prior to trigger activation, so you cannot use [BEFORE](#) triggers to convert values inappropriate for the column type to valid values.

trigger_event indicates the kind of operation that activates the trigger. These *trigger_event* values are permitted:

- [INSERT](#): The trigger activates whenever a new row is inserted into the table; for example, through [INSERT](#), [LOAD DATA](#), and [REPLACE](#) statements.
- [UPDATE](#): The trigger activates whenever a row is modified; for example, through [UPDATE](#) statements.
- [DELETE](#): The trigger activates whenever a row is deleted from the table; for example, through [DELETE](#) and [REPLACE](#) statements. [DROP TABLE](#) and [TRUNCATE TABLE](#) statements on the table do *not* activate this trigger, because they do not use [DELETE](#). Dropping a partition does not activate [DELETE](#) triggers, either.

The *trigger_event* does not represent a literal type of SQL statement that activates the trigger so much as it represents a type of table operation. For example, an [INSERT](#) trigger activates not only for [INSERT](#) statements but also [LOAD DATA](#) statements because both statements insert rows into a table.

A potentially confusing example of this is the `INSERT INTO ... ON DUPLICATE KEY UPDATE ...` syntax: a `BEFORE INSERT` trigger activates for every row, followed by either an `AFTER INSERT` trigger or both the `BEFORE UPDATE` and `AFTER UPDATE` triggers, depending on whether there was a duplicate key for the row.

Note

Cascaded foreign key actions do not activate triggers.

It is possible to define multiple triggers for a given table that have the same trigger event and action time. For example, you can have two `BEFORE UPDATE` triggers for a table. By default, triggers that have the same trigger event and action time activate in the order they were created. To affect trigger order, specify a `trigger_order` clause that indicates `FOLLOWS` or `PRECEDES` and the name of an existing trigger that also has the same trigger event and action time. With `FOLLOWS`, the new trigger activates after the existing trigger. With `PRECEDES`, the new trigger activates before the existing trigger.

`trigger_body` is the statement to execute when the trigger activates. To execute multiple statements, use the `BEGIN ... END` compound statement construct. This also enables you to use the same statements that are permitted within stored routines. See [Section 13.6.1, “BEGIN ... END Compound-Statement Syntax”](#). Some statements are not permitted in triggers; see [Section C.1, “Restrictions on Stored Programs”](#).

Within the trigger body, you can refer to columns in the subject table (the table associated with the trigger) by using the aliases `OLD` and `NEW`. `OLD.col_name` refers to a column of an existing row before it is updated or deleted. `NEW.col_name` refers to the column of a new row to be inserted or an existing row after it is updated.

Triggers cannot use `NEW.col_name` or use `OLD.col_name` to refer to generated columns. For information about generated columns, see [Section 13.1.15.8, “CREATE TABLE and Generated Columns”](#).

MySQL stores the `sql_mode` system variable setting in effect when a trigger is created, and always executes the trigger body with this setting in force, *regardless of the current server SQL mode when the trigger begins executing*.

The `DEFINER` clause specifies the MySQL account to be used when checking access privileges at trigger activation time. If a `user` value is given, it should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE TRIGGER` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If you specify the `DEFINER` clause, these rules determine the valid `DEFINER` user values:

- If you do not have the `SET_USER_ID` or `SUPER` privilege, the only permitted `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SET_USER_ID` or `SUPER` privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.
- Although it is possible to create a trigger with a nonexistent `DEFINER` account, it is not a good idea for such triggers to be activated until the account actually does exist. Otherwise, the behavior with respect to privilege checking is undefined.

MySQL takes the `DEFINER` user into account when checking trigger privileges as follows:

- At `CREATE TRIGGER` time, the user who issues the statement must have the `TRIGGER` privilege.
- At trigger activation time, privileges are checked against the `DEFINER` user. This user must have these privileges:

- The `TRIGGER` privilege for the subject table.
- The `SELECT` privilege for the subject table if references to table columns occur using `OLD.col_name` or `NEW.col_name` in the trigger body.
- The `UPDATE` privilege for the subject table if table columns are targets of `SET NEW.col_name = value` assignments in the trigger body.
- Whatever other privileges normally are required for the statements executed by the trigger.

For more information about trigger security, see [Section 23.6, “Access Control for Stored Programs and Views”](#).

Within a trigger body, the `CURRENT_USER()` function returns the account used to check privileges at trigger activation time. This is the `DEFINER` user, not the user whose actions caused the trigger to be activated. For information about user auditing within triggers, see [Section 6.3.13, “SQL-Based MySQL Account Activity Auditing”](#).

If you use `LOCK TABLES` to lock a table that has triggers, the tables used within the trigger are also locked, as described in [Section 13.3.5.2, “LOCK TABLES and Triggers”](#).

For additional discussion of trigger use, see [Section 23.3.1, “Trigger Syntax and Examples”](#).

13.1.18 CREATE VIEW Syntax

```
CREATE
  [OR REPLACE]
  [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
  [DEFINER = { user | CURRENT_USER }]
  [SQL SECURITY { DEFINER | INVOKER }]
  VIEW view_name [(column_list)]
  AS select_statement
  [WITH [CASCADED | LOCAL] CHECK OPTION]
```

The `CREATE VIEW` statement creates a new view, or replaces an existing view if the `OR REPLACE` clause is given. If the view does not exist, `CREATE OR REPLACE VIEW` is the same as `CREATE VIEW`. If the view does exist, `CREATE OR REPLACE VIEW` is the same as `ALTER VIEW`.

For information about restrictions on view use, see [Section C.5, “Restrictions on Views”](#).

The `select_statement` is a `SELECT` statement that provides the definition of the view. (Selecting from the view selects, in effect, using the `SELECT` statement.) The `select_statement` can select from base tables or other views.

The view definition is “frozen” at creation time and is not affected by subsequent changes to the definitions of the underlying tables. For example, if a view is defined as `SELECT *` on a table, new columns added to the table later do not become part of the view, and columns dropped from the table will result in an error when selecting from the view.

The `ALGORITHM` clause affects how MySQL processes the view. The `DEFINER` and `SQL SECURITY` clauses specify the security context to be used when checking access privileges at view invocation time. The `WITH CHECK OPTION` clause can be given to constrain inserts or updates to rows in tables referenced by the view. These clauses are described later in this section.

The `CREATE VIEW` statement requires the `CREATE VIEW` privilege for the view, and some privilege for each column selected by the `SELECT` statement. For columns used elsewhere in the `SELECT` statement, you must have the `SELECT` privilege. If the `OR REPLACE` clause is present, you must also have the `DROP` privilege for the view. `CREATE VIEW` might also require the `SET_USER_ID` or `SUPER` privilege, depending on the `DEFINER` value, as described later in this section.

When a view is referenced, privilege checking occurs as described later in this section.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, use `db_name.view_name` syntax to qualify the view name with the database name:

```
CREATE VIEW test.v AS SELECT * FROM t;
```

Unqualified table or view names in the `SELECT` statement are also interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the appropriate database name.

Within a database, base tables and views share the same namespace, so a base table and a view cannot have the same name.

Columns retrieved by the `SELECT` statement can be simple references to table columns, or expressions that use functions, constant values, operators, and so forth.

A view must have unique column names with no duplicates, just like a base table. By default, the names of the columns retrieved by the `SELECT` statement are used for the view column names. To define explicit names for the view columns, specify the optional `column_list` clause as a list of comma-separated identifiers. The number of names in `column_list` must be the same as the number of columns retrieved by the `SELECT` statement.

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables:

```
CREATE VIEW v_today (today) AS SELECT CURRENT_DATE;
```

The following example defines a view that selects two columns from another table as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+-----+-----+-----+
| qty | price | value |
+-----+-----+-----+
| 3 | 50 | 150 |
+-----+-----+-----+
```

A view definition is subject to the following restrictions:

- The `SELECT` statement cannot refer to system variables or user-defined variables.
- Within a stored program, the `SELECT` statement cannot refer to program parameters or local variables.
- The `SELECT` statement cannot refer to prepared statement parameters.
- Any table or view referred to in the definition must exist. If, after the view has been created, a table or view that the definition refers to is dropped, use of the view results in an error. To check a view definition for problems of this kind, use the `CHECK TABLE` statement.
- The definition cannot refer to a `TEMPORARY` table, and you cannot create a `TEMPORARY` view.
- You cannot associate a trigger with a view.
- Aliases for column names in the `SELECT` statement are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).

`ORDER BY` is permitted in a view definition, but it is ignored if you select from a view using a statement that has its own `ORDER BY`.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a `LIMIT` clause, and you select from the view using a statement that has its own `LIMIT` clause, it is undefined which limit applies. This same principle applies to options such as `ALL`, `DISTINCT`, or `SQL_SMALL_RESULT` that follow the `SELECT` keyword, and to clauses such as `INTO`, `FOR UPDATE`, `FOR SHARE`, `LOCK IN SHARE MODE`, and `PROCEDURE`.

The results obtained from a view may be affected if you change the query processing environment by changing system variables:

```
mysql> CREATE VIEW v (mycol) AS SELECT 'abc';
Query OK, 0 rows affected (0.01 sec)

mysql> SET sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-----+
| mycol |
+-----+
| mycol |
+-----+
1 row in set (0.01 sec)

mysql> SET sql_mode = 'ANSI_QUOTES';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT "mycol" FROM v;
+-----+
| mycol |
+-----+
| abc   |
+-----+
1 row in set (0.00 sec)
```

The `DEFINER` and `SQL SECURITY` clauses determine which MySQL account to use when checking access privileges for the view when a statement is executed that references the view. The valid `SQL SECURITY` characteristic values are `DEFINER` (the default) and `INVOKER`. These indicate that the required privileges must be held by the user who defined or invoked the view, respectively.

If a `user` value is given for the `DEFINER` clause, it should be a MySQL account specified as `'user_name'@'host_name'`, `CURRENT_USER`, or `CURRENT_USER()`. The default `DEFINER` value is the user who executes the `CREATE VIEW` statement. This is the same as specifying `DEFINER = CURRENT_USER` explicitly.

If the `DEFINER` clause is present, these rules determine the valid `DEFINER` user values:

- If you do not have the `SET_USER_ID` or `SUPER` privilege, the only valid `user` value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.
- If you have the `SET_USER_ID` or `SUPER` privilege, you can specify any syntactically valid account name. If the account does not exist, a warning is generated.
- Although it is possible to create a view with a nonexistent `DEFINER` account, an error occurs when the view is referenced if the `SQL SECURITY` value is `DEFINER` but the definer account does not exist.

For more information about view security, see [Section 23.6, “Access Control for Stored Programs and Views”](#).

Within a view definition, `CURRENT_USER` returns the view's `DEFINER` value by default. For views defined with the `SQL SECURITY INVOKER` characteristic, `CURRENT_USER` returns the account for

the view's invoker. For information about user auditing within views, see [Section 6.3.13, “SQL-Based MySQL Account Activity Auditing”](#).

Within a stored routine that is defined with the `SQL SECURITY DEFINER` characteristic, `CURRENT_USER` returns the routine's `DEFINER` value. This also affects a view defined within such a routine, if the view definition contains a `DEFINER` value of `CURRENT_USER`.

MySQL checks view privileges like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to table columns, the creator must have some privilege for each column in the select list of the definition, and the `SELECT` privilege for each column used elsewhere in the definition. If the definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required at function invocation time can be checked only as it executes: For different invocations, different execution paths within the function might be taken.
- The user who references a view must have appropriate privileges to access it (`SELECT` to select from it, `INSERT` to insert into it, and so forth.)
- When a view has been referenced, privileges for objects accessed by the view are checked against the privileges held by the view `DEFINER` account or invoker, depending on whether the `SQL SECURITY` characteristic is `DEFINER` or `INVOKER`, respectively.
- If reference to a view causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function `SQL SECURITY` characteristic is `DEFINER` or `INVOKER`. If the security characteristic is `DEFINER`, the function runs with the privileges of the `DEFINER` account. If the characteristic is `INVOKER`, the function runs with the privileges determined by the view's `SQL SECURITY` characteristic.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function `f()`:

```
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);
```

Suppose that `f()` contains a statement such as this:

```
IF name IS NULL then
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within `f()` need to be checked when `f()` executes. This might mean that privileges are needed for `p1()` or `p2()`, depending on the execution path within `f()`. Those privileges must be checked at runtime, and the user who must possess the privileges is determined by the `SQL SECURITY` values of the view `v` and the function `f()`.

The `DEFINER` and `SQL SECURITY` clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for `SQL SECURITY DEFINER`. The standard says that the definer of the view, which is the same as the owner of the view's schema, gets applicable privileges on the view (for example, `SELECT`) and may grant them. MySQL has no concept of a schema “owner”, so MySQL adds a clause to identify the definer. The `DEFINER` clause is an extension where the intent is to have what the standard has; that is, a permanent record of who defined the view. This is why the default `DEFINER` value is the account of the view creator.

The optional `ALGORITHM` clause is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`. For more information, see [Section 23.5.2, “View Processing Algorithms”](#), as well as [Section 8.2.2.3, “Optimizing Derived Tables, View References, and Common Table Expressions”](#).

Some views are updatable. That is, you can use them in statements such as [UPDATE](#), [DELETE](#), or [INSERT](#) to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable.

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is [DEFAULT](#). For information about generated columns, see [Section 13.1.15.8, “CREATE TABLE and Generated Columns”](#).

The [WITH CHECK OPTION](#) clause can be given for an updatable view to prevent inserts or updates to rows except those for which the [WHERE](#) clause in the *select_statement* is true.

In a [WITH CHECK OPTION](#) clause for an updatable view, the [LOCAL](#) and [CASCADED](#) keywords determine the scope of check testing when the view is defined in terms of another view. The [LOCAL](#) keyword restricts the [CHECK OPTION](#) only to the view being defined. [CASCADED](#) causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is [CASCADED](#).

For more information about updatable views and the [WITH CHECK OPTION](#) clause, see [Section 23.5.3, “Updatable and Insertable Views”](#), and [Section 23.5.4, “The View WITH CHECK OPTION Clause”](#).

13.1.19 DROP DATABASE Syntax

```
DROP {DATABASE | SCHEMA} [IF EXISTS] db_name
```

[DROP DATABASE](#) drops all tables in the database and deletes the database. Be very careful with this statement! To use [DROP DATABASE](#), you need the [DROP](#) privilege on the database. [DROP SCHEMA](#) is a synonym for [DROP DATABASE](#).

Important

When a database is dropped, user privileges on the database are *not* automatically dropped. See [Section 13.7.1.6, “GRANT Syntax”](#).

[IF EXISTS](#) is used to prevent an error from occurring if the database does not exist.

If the default database is dropped, the default database is unset (the [DATABASE\(\)](#) function returns [NULL](#)).

If you use [DROP DATABASE](#) on a symbolically linked database, both the link and the original database are deleted.

[DROP DATABASE](#) returns the number of tables that were removed.

The [DROP DATABASE](#) statement removes from the given database directory those files and directories that MySQL itself may create during normal operation. This includes all files with the extensions shown in the following table.

.BAK	.DAT	.HSH	.MRG
.MYD	.MYI	.cfg	.db
.ibd	.ndb		

If other files or directories remain in the database directory after MySQL removes those just listed, the database directory cannot be removed. In this case, you must remove any remaining files or directories manually and issue the [DROP DATABASE](#) statement again.

Dropping a database does not remove any [TEMPORARY](#) tables that were created in that database. [TEMPORARY](#) tables are automatically removed when the session that created them ends. See [Section 13.1.15.3, “CREATE TEMPORARY TABLE Syntax”](#).

You can also drop databases with `mysqladmin`. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

13.1.20 DROP EVENT Syntax

```
DROP EVENT [IF EXISTS] event_name
```

This statement drops the event named *event_name*. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error `ERROR 1517 (HY000): Unknown event 'event_name'` results. You can override this and cause the statement to generate a warning for nonexistent events instead using `IF EXISTS`.

This statement requires the `EVENT` privilege for the schema to which the event to be dropped belongs.

13.1.21 DROP FUNCTION Syntax

The `DROP FUNCTION` statement is used to drop stored functions and user-defined functions (UDFs):

- For information about dropping stored functions, see [Section 13.1.23, “DROP PROCEDURE and DROP FUNCTION Syntax”](#).
- For information about dropping user-defined functions, see [Section 13.7.3.2, “DROP FUNCTION Syntax”](#).

13.1.22 DROP INDEX Syntax

```
DROP INDEX index_name ON tbl_name
    [algorithm_option | lock_option] ...

algorithm_option:
    ALGORITHM [=] {DEFAULT|INPLACE|COPY}

lock_option:
    LOCK [=] {DEFAULT|NONE|SHARED|EXCLUSIVE}
```

`DROP INDEX` drops the index named *index_name* from the table *tbl_name*. This statement is mapped to an `ALTER TABLE` statement to drop the index. See [Section 13.1.7, “ALTER TABLE Syntax”](#).

To drop a primary key, the index name is always `PRIMARY`, which must be specified as a quoted identifier because `PRIMARY` is a reserved word:

```
DROP INDEX `PRIMARY` ON t;
```

`ALGORITHM` and `LOCK` clauses may be given. These influence the table copying method and level of concurrency for reading and writing the table while its indexes are being modified. They have the same meaning as for the `ALTER TABLE` statement. For more information, see [Section 13.1.7, “ALTER TABLE Syntax”](#)

13.1.23 DROP PROCEDURE and DROP FUNCTION Syntax

```
DROP {PROCEDURE | FUNCTION} [IF EXISTS] sp_name
```

This statement is used to drop a stored procedure or function. That is, the specified routine is removed from the server. You must have the `ALTER ROUTINE` privilege for the routine. (If the

`automatic_sp_privileges` system variable is enabled, that privilege and `EXECUTE` are granted automatically to the routine creator when the routine is created and dropped from the creator when the routine is dropped. See [Section 23.2.2, “Stored Routines and MySQL Privileges”](#).)

The `IF EXISTS` clause is a MySQL extension. It prevents an error from occurring if the procedure or function does not exist. A warning is produced that can be viewed with `SHOW WARNINGS`.

`DROP FUNCTION` is also used to drop user-defined functions (see [Section 13.7.3.2, “DROP FUNCTION Syntax”](#)).

13.1.24 DROP SERVER Syntax

```
DROP SERVER [ IF EXISTS ] server_name
```

Drops the server definition for the server named `server_name`. The corresponding row in the `mysql.servers` table is deleted. This statement requires the `SUPER` privilege.

Dropping a server for a table does not affect any `FEDERATED` tables that used this connection information when they were created. See [Section 13.1.14, “CREATE SERVER Syntax”](#).

`DROP SERVER` does not cause an automatic commit.

`DROP SERVER` is not written to the binary log, regardless of the logging format that is in use.

13.1.25 DROP TABLE Syntax

```
DROP [TEMPORARY] TABLE [IF EXISTS]
  tbl_name [, tbl_name] ...
  [RESTRICT | CASCADE]
```

`DROP TABLE` removes one or more tables. You must have the `DROP` privilege for each table. All table data and the table definition are *removed*, so *be careful* with this statement! If any of the tables named in the argument list do not exist, MySQL returns an error indicating by name which nonexisting tables it was unable to drop, but it also drops all of the tables in the list that do exist.

Important

When a table is dropped, user privileges on the table are *not* automatically dropped. See [Section 13.7.1.6, “GRANT Syntax”](#).

For a partitioned table, `DROP TABLE` permanently removes the table definition, all of its partitions, and all of the data which was stored in those partitions. It also removes partition definitions associated with the dropped table.

Use `IF EXISTS` to prevent an error from occurring for tables that do not exist. A `NOTE` is generated for each nonexistent table when using `IF EXISTS`. See [Section 13.7.5.40, “SHOW WARNINGS Syntax”](#).

`IF EXISTS` can be useful for dropping tables in unusual circumstances under which there is an entry in the data dictionary but no table managed by the storage engine. (For example, if an abnormal server exit occurs after removal of the table from the storage engine but before removal of the data dictionary entry.)

`RESTRICT` and `CASCADE` are permitted to make porting easier. In MySQL 8.0, they do nothing.

Note

`DROP TABLE` automatically commits the current active transaction, unless you use the `TEMPORARY` keyword.

The `TEMPORARY` keyword has the following effects:

- The statement drops only `TEMPORARY` tables.
- The statement does not end an ongoing transaction.
- No access rights are checked. (A `TEMPORARY` table is visible only to the session that created it, so no check is necessary.)

Using `TEMPORARY` is a good way to ensure that you do not accidentally drop a non-`TEMPORARY` table.

`DROP TABLE` is not supported with all `innodb_force_recovery` settings. See [Section 15.20.2, “Forcing InnoDB Recovery”](#).

13.1.26 DROP TABLESPACE Syntax

```
DROP TABLESPACE tablespace_name
[ENGINE [=] engine_name]
```

This statement is used to drop an `InnoDB` general tablespace that was created using `CREATE TABLESPACE` (see [Section 13.1.16, “CREATE TABLESPACE Syntax”](#)).

All tables must be dropped from the tablespace prior to a `DROP TABLESPACE` operation. If the tablespace is not empty, `DROP TABLESPACE` returns an error.

tablespace_name is a case-sensitive identifier in MySQL.

ENGINE: Defines the storage engine that uses the tablespace, where *engine_name* is the name of the storage engine. Currently, only the `InnoDB` storage engine is supported. You do not need to specify `ENGINE = InnoDB` if `InnoDB` is defined as the default storage engine (`default_storage_engine=InnoDB`).

`DROP TABLESPACE` is supported with `InnoDB`. In earlier releases, `DROP TABLESPACE` supports `NDB`, which is the MySQL Cluster storage engine. `DROP TABLESPACE` will support `NDB` in MySQL 5.7 when MySQL Cluster is branched from the MySQL 5.7 code base. The latest version of MySQL Cluster is based on MySQL 5.6.

Notes

- A general `InnoDB` tablespace is not deleted automatically when the last table in the tablespace is dropped. The tablespace must be dropped explicitly using `DROP TABLESPACE tablespace_name`.
- A `DROP DATABASE` operation can drop tables that belong to a general tablespace but it cannot drop the tablespace, even if the operation drops all tables that belong to the tablespace. The tablespace must be dropped explicitly using `DROP TABLESPACE tablespace_name`.
- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace `.ibd data file` which can only be used for new `InnoDB` data. Space is not released back to the operating system as it is for file-per-table tablespaces.

Example

This example demonstrates how to drop an `InnoDB` general tablespace. The general tablespace `ts1` is created with a single table. Before dropping the tablespace, the table must be dropped.

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts10 Engine=InnoDB;
Query OK, 0 rows affected (0.02 sec)

mysql> DROP TABLE t1;
```

```
Query OK, 0 rows affected (0.01 sec)

mysql> DROP TABLESPACE ts1;
Query OK, 0 rows affected (0.01 sec)
```

13.1.27 DROP TRIGGER Syntax

```
DROP TRIGGER [IF EXISTS] [schema_name.]trigger_name
```

This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. `DROP TRIGGER` requires the `TRIGGER` privilege for the table associated with the trigger.

Use `IF EXISTS` to prevent an error from occurring for a trigger that does not exist. A `NOTE` is generated for a nonexistent trigger when using `IF EXISTS`. See [Section 13.7.5.40, "SHOW WARNINGS Syntax"](#).

Triggers for a table are also dropped if you drop the table.

13.1.28 DROP VIEW Syntax

```
DROP VIEW [IF EXISTS]
  view_name [, view_name] ...
  [RESTRICT | CASCADE]
```

`DROP VIEW` removes one or more views. You must have the `DROP` privilege for each view. If any of the views named in the argument list do not exist, MySQL returns an error indicating by name which nonexistent views it was unable to drop, but it also drops all of the views in the list that do exist.

The `IF EXISTS` clause prevents an error from occurring for views that don't exist. When this clause is given, a `NOTE` is generated for each nonexistent view. See [Section 13.7.5.40, "SHOW WARNINGS Syntax"](#).

`RESTRICT` and `CASCADE`, if given, are parsed and ignored.

13.1.29 RENAME TABLE Syntax

```
RENAME TABLE tbl_name TO new_tbl_name
  [, tbl_name2 TO new_tbl_name2] ...
```

This statement renames one or more tables. The rename operation is done atomically, which means that no other session can access any of the tables while the rename is running.

For example, a table named `old_table` can be renamed to `new_table` as shown here:

```
RENAME TABLE old_table TO new_table;
```

This statement is equivalent to the following `ALTER TABLE` statement:

```
ALTER TABLE old_table RENAME new_table;
```

If the statement renames more than one table, renaming operations are done from left to right. If you want to swap two table names, you can do so like this (assuming that `tmp_table` does not already exist):

```
RENAME TABLE old_table TO tmp_table,
  new_table TO old_table,
```

```
tmp_table TO new_table;
```

MySQL checks the destination table name before checking whether the source table exists. For example, if `new_table` already exists and `old_table` does not, the following statement fails as shown here:

```
mysql> SHOW TABLES;
+-----+
| Tables_in_mydb |
+-----+
| table_a        |
+-----+
1 row in set (0.00 sec)

mysql> RENAME TABLE table_b TO table_a;
ERROR 1050 (42S01): Table 'table_a' already exists
```

As long as two databases are on the same file system, you can use `RENAME TABLE` to move a table from one database to another:

```
RENAME TABLE current_db.tbl_name TO other_db.tbl_name;
```

You can use this method to move all tables from one database to a different one, in effect renaming the database. (MySQL has no single statement to perform this task.)

If there are any triggers associated with a table which is moved to a different database using `RENAME TABLE`, then the statement fails with the error `Trigger in wrong schema`.

`RENAME TABLE` changes internally generated foreign key constraint names and user-defined foreign key constraint names that contain the string `"tbl_name_ibfk_"` to reflect the new table name. `InnoDB` interprets foreign key constraint names that contain the string `"tbl_name_ibfk_"` as internally generated names.

Foreign keys that point to the renamed table are not automatically updated. In such cases, you must drop and re-create the foreign keys in order for them to function properly.

`RENAME TABLE` also works for views, as long as you do not try to rename a view into a different database.

Any privileges granted specifically for the renamed table or view are not migrated to the new name. They must be changed manually.

When you execute `RENAME TABLE`, you cannot have any locked tables or active transactions. You must also have the `ALTER` and `DROP` privileges on the original table, and the `CREATE` and `INSERT` privileges on the new table.

If MySQL encounters any errors in a multiple-table rename, it does a reverse rename for all renamed tables to return everything to its original state.

You cannot use `RENAME TABLE` to rename a `TEMPORARY` table. However, you can use `ALTER TABLE` with temporary tables.

Like `RENAME TABLE`, `ALTER TABLE ... RENAME` can also be used to move a table to a different database. Regardless of the statement used to perform the rename, if the rename operation would move the table to a database located on a different file system, the success of the outcome is platform specific and depends on the underlying operating system calls used to move the table files.

13.1.30 TRUNCATE TABLE Syntax

```
TRUNCATE [TABLE] tbl_name
```

`TRUNCATE TABLE` empties a table completely. It requires the `DROP` privilege. Logically, `TRUNCATE TABLE` is similar to a `DELETE` statement that deletes all rows, or a sequence of `DROP TABLE` and `CREATE TABLE` statements.

Warning

In MySQL 8.0, `TRUNCATE TABLE` is mapped to `DROP TABLE` and `CREATE TABLE`. As a result of this change, `TRUNCATE TABLE` is temporarily non-atomic. A server exit during a `TRUNCATE TABLE` operation can result in a dropped table and orphaned foreign key constraints in the `InnoDB SYS_FOREIGN` and `SYS_FOREIGN_COLS` system tables.

To achieve high performance, `TRUNCATE TABLE` bypasses the DML method of deleting data. Thus, it cannot be rolled back, it does not cause `ON DELETE` triggers to fire, and it cannot be performed for `InnoDB` tables with parent-child foreign key relationships.

Although `TRUNCATE TABLE` is similar to `DELETE`, it is classified as a DDL statement rather than a DML statement. It differs from `DELETE` in the following ways:

- Truncate operations drop and re-create the table, which is much faster than deleting rows one by one, particularly for large tables.
- Truncate operations cause an implicit commit, and so cannot be rolled back.
- Truncation operations cannot be performed if the session holds an active table lock.
- `TRUNCATE TABLE` fails for an `InnoDB` table or `NDB` table if there are any `FOREIGN KEY` constraints from other tables that reference the table. Foreign key constraints between columns of the same table are permitted.
- Truncation operations do not return a meaningful value for the number of deleted rows. The usual result is “0 rows affected,” which should be interpreted as “no information.”
- As long as the table definition is valid, the table can be re-created as an empty table with `TRUNCATE TABLE`, even if the data or index files have become corrupted.
- Any `AUTO_INCREMENT` value is reset to its start value. This is true even for `MyISAM` and `InnoDB`, which normally do not reuse sequence values.
- When used with partitioned tables, `TRUNCATE TABLE` preserves the partitioning; that is, the data and index files are dropped and re-created, while the partition definitions are unaffected.
- The `TRUNCATE TABLE` statement does not invoke `ON DELETE` triggers.

`TRUNCATE TABLE` for a table closes all handlers for the table that were opened with `HANDLER OPEN`.

`TRUNCATE TABLE` is treated for purposes of binary logging and replication as `DROP TABLE` followed by `CREATE TABLE`—that is, as DDL rather than DML. This is due to the fact that, when using `InnoDB` and other transactional storage engines where the transaction isolation level does not permit statement-based logging (`READ COMMITTED` or `READ UNCOMMITTED`), the statement was not logged and replicated when using `STATEMENT` or `MIXED` logging mode. (Bug #36763) However, it is still applied on replication slaves using `InnoDB` in the manner described previously.

In MySQL 5.7 and earlier, on a system with a large buffer pool and `innodb_adaptive_hash_index` enabled, a `TRUNCATE TABLE` operation could cause a temporary drop in system performance due to an LRU scan that occurred when removing the table's adaptive hash index entries (Bug #68184). The remapping of `TRUNCATE TABLE` to `DROP TABLE` and `CREATE TABLE` in MySQL 8.0 avoids the problematic LRU scan.

`TRUNCATE TABLE` can be used with Performance Schema summary tables, but the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. See [Section 25.11.15, “Performance Schema Summary Tables”](#).

13.2 Data Manipulation Statements

13.2.1 CALL Syntax

```
CALL sp_name([parameter[,...]])
CALL sp_name[()]
```

The `CALL` statement invokes a stored procedure that was defined previously with `CREATE PROCEDURE`.

Stored procedures that take no arguments can be invoked without parentheses. That is, `CALL p()` and `CALL p` are equivalent.

`CALL` can pass back values to its caller using parameters that are declared as `OUT` or `INOUT` parameters. When the procedure returns, a client program can also obtain the number of rows affected for the final statement executed within the routine: At the SQL level, call the `ROW_COUNT()` function; from the C API, call the `mysql_affected_rows()` function.

To get back a value from a procedure using an `OUT` or `INOUT` parameter, pass the parameter by means of a user variable, and then check the value of the variable after the procedure returns. (If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `IN` or `INOUT` parameter.) For an `INOUT` parameter, initialize its value before passing it to the procedure. The following procedure has an `OUT` parameter that the procedure sets to the current server version, and an `INOUT` value that the procedure increments by one from its current value:

```
CREATE PROCEDURE p (OUT ver_param VARCHAR(25), INOUT incr_param INT)
BEGIN
  # Set value of OUT parameter
  SELECT VERSION() INTO ver_param;
  # Increment value of INOUT parameter
  SET incr_param = incr_param + 1;
END;
```

Before calling the procedure, initialize the variable to be passed as the `INOUT` parameter. After calling the procedure, the values of the two variables will have been set or modified:

```
mysql> SET @increment = 10;
mysql> CALL p(@version, @increment);
mysql> SELECT @version, @increment;
+-----+-----+
| @version | @increment |
+-----+-----+
| 5.5.3-m3-log | 11 |
+-----+-----+
```

In prepared `CALL` statements used with `PREPARE` and `EXECUTE`, placeholders can be used for `IN` parameters, `OUT`, and `INOUT` parameters. These types of parameters can be used as follows:

```
mysql> SET @increment = 10;
mysql> PREPARE s FROM 'CALL p(?, ?)';
mysql> EXECUTE s USING @version, @increment;
mysql> SELECT @version, @increment;
+-----+-----+
| @version | @increment |
+-----+-----+
| 5.5.3-m3-log | 11 |
+-----+-----+
```

To write C programs that use the `CALL` SQL statement to execute stored procedures that produce result sets, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns

a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure. `CLIENT_MULTI_RESULTS` must also be enabled if `CALL` is used to execute any stored procedure that contains prepared statements. It cannot be determined when such a procedure is loaded whether those statements will produce result sets, so it is necessary to assume that they will.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). In MySQL 8.0, `CLIENT_MULTI_RESULTS` is enabled by default.

To process the result of a `CALL` statement executed using `mysql_query()` or `mysql_real_query()`, use a loop that calls `mysql_next_result()` to determine whether there are more results. For an example, see [Section 27.7.20, “C API Support for Multiple Statement Execution”](#).

In MySQL 8.0, C programs can use the prepared-statement interface to execute `CALL` statements and access `OUT` and `INOUT` parameters. This is done by processing the result of a `CALL` statement using a loop that calls `mysql_stmt_next_result()` to determine whether there are more results. For an example, see [Section 27.7.23, “C API Support for Prepared CALL Statements”](#). Languages that provide a MySQL interface can use prepared `CALL` statements to directly retrieve `OUT` and `INOUT` procedure parameters.

In MySQL 8.0, metadata changes to objects referred to by stored programs are detected and cause automatic reparsing of the affected statements when the program is next executed. For more information, see [Section 8.10.4, “Caching of Prepared Statements and Stored Programs”](#).

13.2.2 DELETE Syntax

`DELETE` is a DML statement that removes rows from a table.

A `DELETE` statement can start with a `WITH` clause to define common table expressions accessible within the `DELETE`. See [Section 13.2.11.9, “WITH Syntax \(Common Table Expressions\)”](#).

Single-Table Syntax

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE] FROM tbl_name
    [PARTITION (partition_name,...)]
    [WHERE where_condition]
    [ORDER BY ...]
    [LIMIT row_count]
```

The `DELETE` statement deletes rows from `tbl_name` and returns the number of deleted rows. To check the number of deleted rows, call the `ROW_COUNT()` function described in [Section 12.14, “Information Functions”](#).

Main Clauses

The conditions in the optional `WHERE` clause identify which rows to delete. With no `WHERE` clause, all rows are deleted.

`where_condition` is an expression that evaluates to true for each row to be deleted. It is specified as described in [Section 13.2.10, “SELECT Syntax”](#).

If the `ORDER BY` clause is specified, the rows are deleted in the order that is specified. The `LIMIT` clause places a limit on the number of rows that can be deleted. These clauses apply to single-table deletes, but not multi-table deletes.

Multiple-Table Syntax

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
      tbl_name[.*] [, tbl_name[.*]] ...
FROM table_references
[WHERE where_condition]
```

Or:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
      FROM tbl_name[.*] [, tbl_name[.*]] ...
      USING table_references
      [WHERE where_condition]
```

Privileges

You need the [DELETE](#) privilege on a table to delete rows from it. You need only the [SELECT](#) privilege for any columns that are only read, such as those named in the [WHERE](#) clause.

Performance

When you do not need to know the number of deleted rows, the [TRUNCATE TABLE](#) statement is a faster way to empty a table than a [DELETE](#) statement with no [WHERE](#) clause. Unlike [DELETE](#), [TRUNCATE TABLE](#) cannot be used within a transaction or if you have a lock on the table. See [Section 13.1.30, “TRUNCATE TABLE Syntax”](#) and [Section 13.3.5, “LOCK TABLES and UNLOCK TABLES Syntax”](#).

The speed of delete operations may also be affected by factors discussed in [Section 8.2.5.3, “Optimizing DELETE Statements”](#).

To ensure that a given [DELETE](#) statement does not take too much time, the MySQL-specific [LIMIT row_count](#) clause for [DELETE](#) specifies the maximum number of rows to be deleted. If the number of rows to delete is larger than the limit, repeat the [DELETE](#) statement until the number of affected rows is less than the [LIMIT](#) value.

Subqueries

You cannot delete from a table and select from the same table in a subquery.

Partitioned Tables

[DELETE](#) supports explicit partition selection using the [PARTITION](#) option, which takes a comma-separated list of the names of one or more partitions or subpartitions (or both) from which to select rows to be dropped. Partitions not included in the list are ignored. Given a partitioned table *t* with a partition named *p0*, executing the statement [DELETE FROM t PARTITION \(p0\)](#) has the same effect on the table as executing [ALTER TABLE t TRUNCATE PARTITION \(p0\)](#); in both cases, all rows in partition *p0* are dropped.

[PARTITION](#) can be used along with a [WHERE](#) condition, in which case the condition is tested only on rows in the listed partitions. For example, [DELETE FROM t PARTITION \(p0\) WHERE c < 5](#) deletes rows only from partition *p0* for which the condition *c < 5* is true; rows in any other partitions are not checked and thus not affected by the [DELETE](#).

The [PARTITION](#) option can also be used in multiple-table [DELETE](#) statements. You can use up to one such option per table named in the [FROM](#) option.

See [Section 22.5, “Partition Selection”](#), for more information and examples.

Auto-Increment Columns

If you delete the row containing the maximum value for an [AUTO_INCREMENT](#) column, the value is not reused for a [MyISAM](#) or [InnoDB](#) table. If you delete all rows in the table with [DELETE FROM](#)

tbl_name (without a `WHERE` clause) in `autocommit` mode, the sequence starts over for all storage engines except `InnoDB` and `MyISAM`. There are some exceptions to this behavior for `InnoDB` tables, as discussed in [Section 15.8.1.5, “AUTO_INCREMENT Handling in InnoDB”](#).

For `MyISAM` tables, you can specify an `AUTO_INCREMENT` secondary column in a multiple-column key. In this case, reuse of values deleted from the top of the sequence occurs even for `MyISAM` tables. See [Section 3.6.9, “Using AUTO_INCREMENT”](#).

Modifiers

The `DELETE` statement supports the following modifiers:

- If you specify `LOW_PRIORITY`, the server delays execution of the `DELETE` until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).
- For `MyISAM` tables, if you use the `QUICK` modifier, the storage engine does not merge index leaves during delete, which may speed up some kinds of delete operations.
- The `IGNORE` modifier causes MySQL to ignore errors during the process of deleting rows. (Errors encountered during the parsing stage are processed in the usual manner.) Errors that are ignored due to the use of `IGNORE` are returned as warnings. For more information, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).

Order of Deletion

If the `DELETE` statement includes an `ORDER BY` clause, rows are deleted in the order specified by the clause. This is useful primarily in conjunction with `LIMIT`. For example, the following statement finds rows matching the `WHERE` clause, sorts them by `timestamp_column`, and deletes the first (oldest) one:

```
DELETE FROM somelog WHERE user = 'jcole'
ORDER BY timestamp_column LIMIT 1;
```

`ORDER BY` also helps to delete rows in an order required to avoid referential integrity violations.

InnoDB Tables

If you are deleting many rows from a large table, you may exceed the lock table size for an `InnoDB` table. To avoid this problem, or simply to minimize the time that the table remains locked, the following strategy (which does not use `DELETE` at all) might be helpful:

1. Select the rows *not* to be deleted into an empty table that has the same structure as the original table:

```
INSERT INTO t_copy SELECT * FROM t WHERE ... ;
```

2. Use `RENAME TABLE` to atomically move the original table out of the way and rename the copy to the original name:

```
RENAME TABLE t TO t_old, t_copy TO t;
```

3. Drop the original table:

```
DROP TABLE t_old;
```

No other sessions can access the tables involved while `RENAME TABLE` executes, so the rename operation is not subject to concurrency problems. See [Section 13.1.29, “RENAME TABLE Syntax”](#).

MyISAM Tables

In **MyISAM** tables, deleted rows are maintained in a linked list and subsequent **INSERT** operations reuse old row positions. To reclaim unused space and reduce file sizes, use the **OPTIMIZE TABLE** statement or the `myisamchk` utility to reorganize tables. **OPTIMIZE TABLE** is easier to use, but `myisamchk` is faster. See [Section 13.7.2.4, “OPTIMIZE TABLE Syntax”](#), and [Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#).

The **QUICK** modifier affects whether index leaves are merged for delete operations. **DELETE QUICK** is most useful for applications where index values for deleted rows are replaced by similar index values from rows inserted later. In this case, the holes left by deleted values are reused.

DELETE QUICK is not useful when deleted values lead to underfilled index blocks spanning a range of index values for which new inserts occur again. In this case, use of **QUICK** can lead to wasted space in the index that remains unreclaimed. Here is an example of such a scenario:

1. Create a table that contains an indexed **AUTO_INCREMENT** column.
2. Insert many rows into the table. Each insert results in an index value that is added to the high end of the index.
3. Delete a block of rows at the low end of the column range using **DELETE QUICK**.

In this scenario, the index blocks associated with the deleted index values become underfilled but are not merged with other index blocks due to the use of **QUICK**. They remain underfilled when new inserts occur, because new rows do not have index values in the deleted range. Furthermore, they remain underfilled even if you later use **DELETE** without **QUICK**, unless some of the deleted index values happen to lie in index blocks within or adjacent to the underfilled blocks. To reclaim unused index space under these circumstances, use **OPTIMIZE TABLE**.

If you are going to delete many rows from a table, it might be faster to use **DELETE QUICK** followed by **OPTIMIZE TABLE**. This rebuilds the index rather than performing many index block merge operations.

Multi-Table Deletes

You can specify multiple tables in a **DELETE** statement to delete rows from one or more tables depending on the condition in the **WHERE** clause. You cannot use **ORDER BY** or **LIMIT** in a multiple-table **DELETE**. The *table_references* clause lists the tables involved in the join, as described in [Section 13.2.10.2, “JOIN Syntax”](#).

For the first multiple-table syntax, only matching rows from the tables listed before the **FROM** clause are deleted. For the second multiple-table syntax, only matching rows from the tables listed in the **FROM** clause (before the **USING** clause) are deleted. The effect is that you can delete rows from many tables at the same time and have additional tables that are used only for searching:

```
DELETE t1, t2 FROM t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

Or:

```
DELETE FROM t1, t2 USING t1 INNER JOIN t2 INNER JOIN t3
WHERE t1.id=t2.id AND t2.id=t3.id;
```

These statements use all three tables when searching for rows to delete, but delete matching rows only from tables `t1` and `t2`.

The preceding examples use **INNER JOIN**, but multiple-table **DELETE** statements can use other types of join permitted in **SELECT** statements, such as **LEFT JOIN**. For example, to delete rows that exist in `t1` that have no match in `t2`, use a **LEFT JOIN**:

```
DELETE t1 FROM t1 LEFT JOIN t2 ON t1.id=t2.id WHERE t2.id IS NULL;
```

The syntax permits `.*` after each *tbl_name* for compatibility with [Access](#).

If you use a multiple-table `DELETE` statement involving [InnoDB](#) tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, you should delete from a single table and rely on the `ON DELETE` capabilities that [InnoDB](#) provides to cause the other tables to be modified accordingly.

Note

If you declare an alias for a table, you must use the alias when referring to the table:

```
DELETE t1 FROM test AS t1, test2 WHERE ...
```

Table aliases in a multiple-table `DELETE` should be declared only in the *table_references* part of the statement. Elsewhere, alias references are permitted but not alias declarations.

Correct:

```
DELETE a1, a2 FROM t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;

DELETE FROM a1, a2 USING t1 AS a1 INNER JOIN t2 AS a2
WHERE a1.id=a2.id;
```

Incorrect:

```
DELETE t1 AS a1, t2 AS a2 FROM t1 INNER JOIN t2
WHERE a1.id=a2.id;

DELETE FROM t1 AS a1, t2 AS a2 USING t1 INNER JOIN t2
WHERE a1.id=a2.id;
```

13.2.3 DO Syntax

```
DO expr [, expr] ...
```

`DO` executes the expressions but does not return any results. In most respects, `DO` is shorthand for `SELECT expr, ...`, but has the advantage that it is slightly faster when you do not care about the result.

`DO` is useful primarily with functions that have side effects, such as `RELEASE_LOCK()`.

Example: This `SELECT` statement pauses, but also produces a result set:

```
mysql> SELECT SLEEP(5);
+-----+
| SLEEP(5) |
+-----+
|          0 |
+-----+
1 row in set (5.02 sec)
```

`DO`, on the other hand, pauses without producing a result set.:

```
mysql> DO SLEEP(5);
```

```
Query OK, 0 rows affected (4.99 sec)
```

This could be useful, for example in a stored function or trigger, which prohibit statements that produce result sets.

`DO` only executes expressions. It cannot be used in all cases where `SELECT` can be used. For example, `DO id FROM t1` is invalid because it references a table.

13.2.4 HANDLER Syntax

```
HANDLER tbl_name OPEN [ [AS] alias]

HANDLER tbl_name READ index_name { = | <= | >= | < | > } (value1,value2,...)
  [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ index_name { FIRST | NEXT | PREV | LAST }
  [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ { FIRST | NEXT }
  [ WHERE where_condition ] [LIMIT ... ]

HANDLER tbl_name CLOSE
```

The `HANDLER` statement provides direct access to table storage engine interfaces. It is available for `InnoDB` and `MyISAM` tables.

The `HANDLER ... OPEN` statement opens a table, making it accessible using subsequent `HANDLER ... READ` statements. This table object is not shared by other sessions and is not closed until the session calls `HANDLER ... CLOSE` or the session terminates.

If you open the table using an alias, further references to the open table with other `HANDLER` statements must use the alias rather than the table name. If you do not use an alias, but open the table using a table name qualified by the database name, further references must use the unqualified table name. For example, for a table opened using `mydb.mytable`, further references must use `mytable`.

The first `HANDLER ... READ` syntax fetches a row where the index specified satisfies the given values and the `WHERE` condition is met. If you have a multiple-column index, specify the index column values as a comma-separated list. Either specify values for all the columns in the index, or specify values for a leftmost prefix of the index columns. Suppose that an index `my_idx` includes three columns named `col_a`, `col_b`, and `col_c`, in that order. The `HANDLER` statement can specify values for all three columns in the index, or for the columns in a leftmost prefix. For example:

```
HANDLER ... READ my_idx = (col_a_val,col_b_val,col_c_val) ...
HANDLER ... READ my_idx = (col_a_val,col_b_val) ...
HANDLER ... READ my_idx = (col_a_val) ...
```

To employ the `HANDLER` interface to refer to a table's `PRIMARY KEY`, use the quoted identifier ``PRIMARY``:

```
HANDLER tbl_name READ `PRIMARY` ...
```

The second `HANDLER ... READ` syntax fetches a row from the table in index order that matches the `WHERE` condition.

The third `HANDLER ... READ` syntax fetches a row from the table in natural row order that matches the `WHERE` condition. It is faster than `HANDLER tbl_name READ index_name` when a full table scan is desired. Natural row order is the order in which rows are stored in a `MyISAM` table data file. This statement works for `InnoDB` tables as well, but there is no such concept because there is no separate data file.

Without a `LIMIT` clause, all forms of `HANDLER ... READ` fetch a single row if one is available. To return a specific number of rows, include a `LIMIT` clause. It has the same syntax as for the `SELECT` statement. See [Section 13.2.10, “SELECT Syntax”](#).

`HANDLER ... CLOSE` closes a table that was opened with `HANDLER ... OPEN`.

There are several reasons to use the `HANDLER` interface instead of normal `SELECT` statements:

- `HANDLER` is faster than `SELECT`:
 - A designated storage engine handler object is allocated for the `HANDLER ... OPEN`. The object is reused for subsequent `HANDLER` statements for that table; it need not be reinitialized for each one.
 - There is less parsing involved.
 - There is no optimizer or query-checking overhead.
 - The handler interface does not have to provide a consistent look of the data (for example, [dirty reads](#) are permitted), so the storage engine can use optimizations that `SELECT` does not normally permit.
- `HANDLER` makes it easier to port to MySQL applications that use a low-level `ISAM`-like interface. (See [Section 15.19, “InnoDB memcached Plugin”](#) for an alternative way to adapt applications that use the key-value store paradigm.)
- `HANDLER` enables you to traverse a database in a manner that is difficult (or even impossible) to accomplish with `SELECT`. The `HANDLER` interface is a more natural way to look at data when working with applications that provide an interactive user interface to the database.

`HANDLER` is a somewhat low-level statement. For example, it does not provide consistency. That is, `HANDLER ... OPEN` does *not* take a snapshot of the table, and does *not* lock the table. This means that after a `HANDLER ... OPEN` statement is issued, table data can be modified (by the current session or other sessions) and these modifications might be only partially visible to `HANDLER ... NEXT` or `HANDLER ... PREV` scans.

An open handler can be closed and marked for reopen, in which case the handler loses its position in the table. This occurs when both of the following circumstances are true:

- Any session executes `FLUSH TABLES` or DDL statements on the handler's table.
- The session in which the handler is open executes non-`HANDLER` statements that use tables.

`TRUNCATE TABLE` for a table closes all handlers for the table that were opened with `HANDLER OPEN`.

If a table is flushed with `FLUSH TABLES tbl_name WITH READ LOCK` was opened with `HANDLER`, the handler is implicitly flushed and loses its position.

13.2.5 IMPORT TABLE Syntax

```
IMPORT TABLE FROM sdi_file [, sdi_file] ...
```

The `IMPORT TABLE` statement imports `MyISAM` tables based on information contained in `.SDI` (Serialized Dictionary Information) metadata files. `IMPORT TABLE` requires the `FILE` privilege to read the `.SDI` and table content files, and the `CREATE` privilege for the table to be created.

Tables can be exported from one server using `mysqldump` to write a file of SQL statements and imported into another server using `mysql` to process the dump file. `IMPORT TABLE` provides a faster alternative using the “raw” table files.

Prior to import, the files that provide the table content must be placed in the appropriate schema directory for the import server, and the `.SDI` file must be located in a directory accessible to the server. For example, the `.SDI` file can be placed in the directory named by the `secure_file_priv` system variable, or (if `secure_file_priv` is empty) in a directory under the server data directory.

The following example describes how to export `MyISAM` tables named `employees` and `managers` from the `hr` schema of one server and import them into the `hr` schema of another server. The example uses these assumptions (to perform a similar operation on your own system, modify the path names as appropriate):

- For the export server, `export_basedir` represents its base directory, and its data directory is `export_basedir/data`.
- For the import server, `import_basedir` represents its base directory, and its data directory is `import_basedir/data`.
- Table files are exported from the export server into the `/tmp/export` directory and this directory is secure (not accessible to other users).
- The import server uses `/tmp/mysql-files` as the directory named by its `secure_file_priv` system variable.

To export tables from the export server, use this procedure:

1. Ensure a consistent snapshot by executing this statement to lock the tables so that they cannot be modified during export:

```
mysql> FLUSH TABLES hr.employees, hr.managers WITH READ LOCK;
```

While the lock is in effect, the tables can still be used, but only for read access.

2. At the file system level, copy the `.SDI` and table content files from the `hr` schema directory to the secure export directory:
 - The `.SDI` file is located in the `hr` schema directory, but might not have exactly the same basename as the table name. For example, the `.SDI` files for the `employees` and `managers` tables might be named `employees_125.SDI` and `managers_238.SDI`.
 - For a `MyISAM` table, the content files are its `.MYD` data file and `.MYI` index file.

Given those file names, the copy commands look like this:

```
shell> cd export_basedir/data/hr
shell> cp employees_125.SDI /tmp/export
shell> cp managers_238.SDI /tmp/export
shell> cp employees.{MYD,MYI} /tmp/export
shell> cp managers.{MYD,MYI} /tmp/export
```

3. Unlock the tables:

```
mysql> UNLOCK TABLES;
```

To import tables into the import server, use this procedure:

1. The import schema must exist. If necessary, execute this statement to create it:

```
mysql> CREATE SCHEMA hr;
```

2. At the file system level, copy the `.SDI` files to the import server `secure_file_priv` directory, `/tmp/mysql-files`. Also, copy the table content files to the `hr` schema directory:

```
shell> cd /tmp/export
shell> cp employees_125.SDI /tmp/mysql-files
shell> cp managers_238.SDI /tmp/mysql-files
shell> cp employees.{MYD,MYI} import_basedir/data/hr
```

```
shell> cp managers.{MYD,MYI} import_basedir/data/hr
```

3. Import the tables by executing an `IMPORT TABLE` statement that names the `.SDI` files:

```
mysql> IMPORT TABLE FROM
      '/tmp/mysql-files/employees.SDI',
      '/tmp/mysql-files/managers.SDI';
```

The `.SDI` file need not be placed in the import server directory named by the `secure_file_priv` system variable if that variable is empty; it can be in any directory accessible to the server, including the schema directory for the imported table. If the `.SDI` file is placed in that directory, however, it may be rewritten; the import operation creates a new `.SDI` file for the table, which will overwrite the old `.SDI` file if the operation uses the same file name for the new file.

Each `sdi_file` value must be a string literal that names the `.SDI` file for a table or is a pattern that matches `.SDI` files. If the string is a pattern, any leading directory path and the `.SDI` file name suffix must be given literally. Pattern characters are permitted only in the base name part of the file name:

- `?` matches any single character
- `*` matches any sequence of characters, including no characters

Using a pattern, the previous `IMPORT TABLE` statement could have been written like this (assuming that the `/tmp/mysql-files` directory contains no other `.SDI` files matching the pattern):

```
IMPORT TABLE FROM '/tmp/mysql-files/*.SDI';
```

To interpret the location of `.SDI` file path names, the server uses the same rules for `IMPORT TABLE` as the server-side rules for `LOAD DATA` (that is, the non-`LOCAL` rules). See [Section 13.2.7, “LOAD DATA INFILE Syntax”](#), paying particular attention to the rules used to interpret relative path names.

`IMPORT TABLE` fails if the `.SDI` or table files cannot be located. After importing a table, the server attempts to open it and reports as warnings any problems detected. To attempt a repair to correct any reported issues, use `REPAIR TABLE`.

`IMPORT TABLE` is not written to the binary log.

Restrictions and Limitations

`IMPORT TABLE` applies only to non-`TEMPORARY MyISAM` tables. It does not apply to tables created with a transactional storage engine, tables created with `CREATE TEMPORARY TABLE`, or views.

The table data and index files must be placed in the schema directory for the import server prior to the import operation, unless the table as defined on the export server uses the `DATA DIRECTORY` or `INDEX DIRECTORY` table options. In that case, modify the import procedure using one of these alternatives before executing the `IMPORT TABLE` statement:

- Put the data and index files into the same directory on the import server host as on the export server host, and create symlinks in the import server schema directory to those files.
- Put the data and index files into an import server host directory different from that on the export server host, and create symlinks in the import server schema directory to those files. In addition, modify the `.SDI` file to reflect the different file locations.
- Put the data and index files into the schema directory on the import server host, and modify the `.SDI` file to remove the data and index directory table options.

Any collation IDs stored in the `.SDI` file must refer to the same collations on the export and import servers.

Trigger information for a table is not serialized into the table `.SDI` file, so triggers are not restored by the import operation.

Some edits to an `.SDI` file are permissible prior to executing the `IMPORT TABLE` statement, whereas others are problematic or may even cause the import operation to fail:

- Changing the data directory and index directory table options is required if the locations of the data and index files differ between the export and import servers.
- Changing the schema name is required to import the table into a different schema on the import server than on the export server.
- Changing schema and table names may be required to accommodate differences between file system case-sensitivity semantics on the export and import servers or differences in `lower_case_table_names` settings. Changing the table names in the `.SDI` file may require renaming the table files as well.
- In some cases, changes to column definitions are permitted. Changing data types is likely to cause problems.

13.2.6 INSERT Syntax

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  [(col_name,...)]
  {VALUES | VALUE} ({expr | DEFAULT},...),(...),...
  [ ON DUPLICATE KEY UPDATE
    col_name=expr
    [, col_name=expr] ... ]
```

Or:

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  SET col_name={expr | DEFAULT}, ...
  [ ON DUPLICATE KEY UPDATE
    col_name=expr
    [, col_name=expr] ... ]
```

Or:

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  [(col_name,...)]
  SELECT ...
  [ ON DUPLICATE KEY UPDATE
    col_name=expr
    [, col_name=expr] ... ]
```

`INSERT` inserts new rows into an existing table. The `INSERT ... VALUES` and `INSERT ... SET` forms of the statement insert rows based on explicitly specified values. The `INSERT ... SELECT` form inserts rows selected from another table or tables. `INSERT ... SELECT` is discussed further in [Section 13.2.6.1, “INSERT ... SELECT Syntax”](#).

When inserting into a partitioned table, you can control which partitions and subpartitions accept new rows. The `PARTITION` option takes a comma-separated list of the names of one or more partitions or subpartitions (or both) of the table. If any of the rows to be inserted by a given `INSERT` statement do not match one of the partitions listed, the `INSERT` statement fails with the error `Found a row not matching the given partition set`. See [Section 22.5, “Partition Selection”](#), for more information and examples.

In MySQL 8.0, the `DELAYED` keyword is accepted but ignored by the server. See [Section 13.2.6.2, “INSERT DELAYED Syntax”](#), for the reasons for this.

You can use `REPLACE` instead of `INSERT` to overwrite old rows. `REPLACE` is the counterpart to `INSERT IGNORE` in the treatment of new rows that contain unique key values that duplicate old rows: The new rows are used to replace the old rows rather than being discarded. See [Section 13.2.9, “REPLACE Syntax”](#).

`tbl_name` is the table into which rows should be inserted. The columns for which the statement provides values can be specified as follows:

- You can provide a comma-separated list of column names following the table name. In this case, a value for each named column must be provided by the `VALUES` list or the `SELECT` statement.
- If you do not specify a list of column names for `INSERT ... VALUES` or `INSERT ... SELECT`, values for every column in the table must be provided by the `VALUES` list or the `SELECT` statement. If you do not know the order of the columns in the table, use `DESCRIBE tbl_name` to find out.
- The `SET` clause indicates the column names explicitly.

Column values can be given in several ways:

- If you are not running in strict SQL mode, any column not explicitly given a value is set to its default (explicit or implicit) value. For example, if you specify a column list that does not name all the columns in the table, unnamed columns are set to their default values. Default value assignment is described in [Section 11.7, “Data Type Default Values”](#). See also [Section 1.8.3.3, “Constraints on Invalid Data”](#).

If you want an `INSERT` statement to generate an error unless you explicitly specify values for all columns that do not have a default value, you should use strict mode. See [Section 5.1.8, “Server SQL Modes”](#).

- Use the keyword `DEFAULT` to set a column explicitly to its default value. This makes it easier to write `INSERT` statements that assign values to all but a few columns, because it enables you to avoid writing an incomplete `VALUES` list that does not include a value for each column in the table. Otherwise, you would have to write out the list of column names corresponding to each value in the `VALUES` list.

You can also use `DEFAULT(col_name)` as a more general form that can be used in expressions to produce a given column's default value.

- If both the column list and the `VALUES` list are empty, `INSERT` creates a row with each column set to its default value:

```
INSERT INTO tbl_name () VALUES();
```

In strict mode, an error occurs if any column doesn't have a default value. Otherwise, MySQL uses the implicit default value for any column that does not have an explicitly defined default.

- You can specify an expression `expr` to provide a column value. This might involve type conversion if the type of the expression does not match the type of the column, and conversion of a given value can result in different inserted values depending on the data type. For example, inserting the string `'1999.0e-2'` into an `INT`, `FLOAT`, `DECIMAL(10,6)`, or `YEAR` column results in the values `1999`, `19.9921`, `19.992100`, and `1999` being inserted, respectively. The reason the value stored in the `INT` and `YEAR` columns is `1999` is that the string-to-integer conversion looks only at as much of the initial part of the string as may be considered a valid integer or year. For the floating-point and fixed-point columns, the string-to-floating-point conversion considers the entire string a valid floating-point value.

An expression `expr` can refer to any column that was set earlier in a value list. For example, you can do this because the value for `col2` refers to `col1`, which has previously been assigned:

```
INSERT INTO tbl_name (col1,col2) VALUES(15,col1*2);
```

But the following is not legal, because the value for `col1` refers to `col2`, which is assigned after `col1`:

```
INSERT INTO tbl_name (col1,col2) VALUES(col2*2,15);
```

One exception involves columns that contain `AUTO_INCREMENT` values. Because the `AUTO_INCREMENT` value is generated after other value assignments, any reference to an `AUTO_INCREMENT` column in the assignment returns a 0.

`INSERT` statements that use `VALUES` syntax can insert multiple rows. To do this, include multiple lists of column values, each enclosed within parentheses and separated by commas. Example:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3),(4,5,6),(7,8,9);
```

The values list for each row must be enclosed within parentheses. The following statement is illegal because the number of values in the list does not match the number of column names:

```
INSERT INTO tbl_name (a,b,c) VALUES(1,2,3,4,5,6,7,8,9);
```

`VALUE` is a synonym for `VALUES` in this context. Neither implies anything about the number of values lists, and either may be used whether there is a single values list or multiple lists.

The affected-rows value for an `INSERT` can be obtained using the `ROW_COUNT()` function (see [Section 12.14, “Information Functions”](#)), or the `mysql_affected_rows()` C API function (see [Section 27.7.7.1, “mysql_affected_rows\(\)”](#)).

If you use an `INSERT ... VALUES` statement with multiple value lists or `INSERT ... SELECT`, the statement returns an information string in this format:

```
Records: 100 Duplicates: 0 Warnings: 0
```

`Records` indicates the number of rows processed by the statement. (This is not necessarily the number of rows actually inserted because `Duplicates` can be nonzero.) `Duplicates` indicates the number of rows that could not be inserted because they would duplicate some existing unique index value. `Warnings` indicates the number of attempts to insert column values that were problematic in some way. Warnings can occur under any of the following conditions:

- Inserting `NULL` into a column that has been declared `NOT NULL`. For multiple-row `INSERT` statements or `INSERT INTO ... SELECT` statements, the column is set to the implicit default value for the column data type. This is 0 for numeric types, the empty string (' ') for string types, and the “zero” value for date and time types. `INSERT INTO ... SELECT` statements are handled the same way as multiple-row inserts because the server does not examine the result set from the `SELECT` to see whether it returns a single row. (For a single-row `INSERT`, no warning occurs when `NULL` is inserted into a `NOT NULL` column. Instead, the statement fails with an error.)
- Setting a numeric column to a value that lies outside the column's range. The value is clipped to the closest endpoint of the range.
- Assigning a value such as '10.34 a' to a numeric column. The trailing nonnumeric text is stripped off and the remaining numeric part is inserted. If the string value has no leading numeric part, the column is set to 0.
- Inserting a string into a string column (`CHAR`, `VARCHAR`, `TEXT`, or `BLOB`) that exceeds the column's maximum length. The value is truncated to the column's maximum length.

- Inserting a value into a date or time column that is illegal for the data type. The column is set to the appropriate zero value for the type.

If a generated column is inserted into explicitly, the only permitted value is `DEFAULT`. For information about generated columns, see [Section 13.1.15.8, “CREATE TABLE and Generated Columns”](#).

If you are using the C API, the information string can be obtained by invoking the `mysql_info()` function. See [Section 27.7.7.36, “mysql_info\(\)”](#).

If `INSERT` inserts a row into a table that has an `AUTO_INCREMENT` column, you can find the value used for that column by using the SQL `LAST_INSERT_ID()` function. From within the C API, use the `mysql_insert_id()` function. However, you should note that the two functions do not always behave identically. The behavior of `INSERT` statements with respect to `AUTO_INCREMENT` columns is discussed further in [Section 12.14, “Information Functions”](#), and [Section 27.7.7.38, “mysql_insert_id\(\)”](#).

The `INSERT` statement supports the following modifiers:

- `INSERT DELAYED` was deprecated in MySQL 5.7, and is scheduled for eventual removal. In MySQL 8.0, the `DELAYED` modifier is accepted but ignored. Use `INSERT` (without `DELAYED`) instead. See [Section 13.2.6.2, “INSERT DELAYED Syntax”](#).
- If you use the `LOW_PRIORITY` modifier, execution of the `INSERT` is delayed until no other clients are reading from the table. This includes other clients that began reading while existing clients are reading, and while the `INSERT LOW_PRIORITY` statement is waiting. It is possible, therefore, for a client that issues an `INSERT LOW_PRIORITY` statement to wait for a very long time.

Note

`LOW_PRIORITY` should normally not be used with `MyISAM` tables because doing so disables concurrent inserts. See [Section 8.11.3, “Concurrent Inserts”](#).

If you specify `HIGH_PRIORITY`, it overrides the effect of the `--low-priority-updates` option if the server was started with that option. It also causes concurrent inserts not to be used. See [Section 8.11.3, “Concurrent Inserts”](#).

`LOW_PRIORITY` and `HIGH_PRIORITY` affect only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

- If you use the `IGNORE` modifier, errors that occur while executing the `INSERT` statement are ignored. For example, without `IGNORE`, a row that duplicates an existing `UNIQUE` index or `PRIMARY KEY` value in the table causes a duplicate-key error and the statement is aborted. With `IGNORE`, the row is discarded and no error occurs. Ignored errors generate warnings instead.

`IGNORE` has a similar effect on inserts into partitioned tables where no partition matching a given value is found. Without `IGNORE`, such `INSERT` statements are aborted with an error; however, when `INSERT IGNORE` is used, the insert operation fails silently for the row containing the unmatched value, but any rows that are matched are inserted. For an example, see [Section 22.2.2, “LIST Partitioning”](#).

Data conversions that would trigger errors abort the statement if `IGNORE` is not specified. With `IGNORE`, invalid values are adjusted to the closest values and inserted; warnings are produced but the statement does not abort. You can determine with the `mysql_info()` C API function how many rows were actually inserted into the table.

For more information, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).

- If you specify `ON DUPLICATE KEY UPDATE`, and a row is inserted that would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, an `UPDATE` of the old row is performed. The affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and

0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is 1 (not 0) if an existing row is set to its current values. See [Section 13.2.6.3, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).

Inserting into a table requires the `INSERT` privilege for the table. If the `ON DUPLICATE KEY UPDATE` clause is used and a duplicate key causes an `UPDATE` to be performed instead, the statement requires the `UPDATE` privilege for the columns to be updated. For columns that are read but not modified you need only the `SELECT` privilege (such as for a column referenced only on the right hand side of an `col_name=expr` assignment in an `ON DUPLICATE KEY UPDATE` clause).

In MySQL 8.0, an `INSERT` statement affecting a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions into which rows are actually inserted. (For storage engines such as `InnoDB` that employ row-level locking, no locking of partitions takes place.) For more information, see [Partitioning and Locking](#).

13.2.6.1 INSERT ... SELECT Syntax

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  [(col_name,...)]
  SELECT ...
  [ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

With `INSERT ... SELECT`, you can quickly insert many rows into a table from one or many tables. For example:

```
INSERT INTO tbl_temp2 (fld_id)
  SELECT tbl_temp1.fld_order_id
  FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

The following conditions hold for a `INSERT ... SELECT` statements:

- Specify `IGNORE` to ignore rows that would cause duplicate-key violations.
- The target table of the `INSERT` statement may appear in the `FROM` clause of the `SELECT` part of the query. (This was not possible in some older versions of MySQL.) However, you cannot insert into a table and select from the same table in a subquery.

When selecting from and inserting into a table at the same time, MySQL creates a temporary table to hold the rows from the `SELECT` and then inserts those rows into the target table. However, it remains true that you cannot use `INSERT INTO t ... SELECT ... FROM t` when `t` is a `TEMPORARY` table, because `TEMPORARY` tables cannot be referred to twice in the same statement (see [Section B.5.6.2, “TEMPORARY Table Problems”](#)).

- `AUTO_INCREMENT` columns work as usual.
- To ensure that the binary log can be used to re-create the original tables, MySQL does not permit concurrent inserts for `INSERT ... SELECT` statements (see [Section 8.11.3, “Concurrent Inserts”](#)).
- To avoid ambiguous column reference problems when the `SELECT` and the `INSERT` refer to the same table, provide a unique alias for each table used in the `SELECT` part, and qualify column names in that part with the appropriate alias.

You can explicitly select which partitions or subpartitions (or both) of the source or target table (or both) are to be used with a `PARTITION` option following the name of the table. When `PARTITION` is used with the name of the source table in the `SELECT` portion of the statement, rows are selected only from the partitions or subpartitions named in its partition list. When `PARTITION` is used with the name of the target table for the `INSERT` portion of the statement, then it must be possible to insert all rows selected

into the partitions or subpartitions named in the partition list following the option, else the `INSERT ... SELECT` statement fails. For more information and examples, see [Section 22.5, “Partition Selection”](#).

In the values part of `ON DUPLICATE KEY UPDATE`, you can refer to columns in other tables, as long as you do not use `GROUP BY` in the `SELECT` part. One side effect is that you must qualify nonunique column names in the values part.

The order in which rows are returned by a `SELECT` statement with no `ORDER BY` clause is not determined. This means that, when using replication, there is no guarantee that such a `SELECT` returns rows in the same order on the master and the slave; this can lead to inconsistencies between them. To prevent this from occurring, you should always write `INSERT ... SELECT` statements that are to be replicated as `INSERT ... SELECT ... ORDER BY column`. The choice of `column` does not matter as long as the same order for returning the rows is enforced on both the master and the slave. See also [Section 18.4.1.17, “Replication and LIMIT”](#).

Due to this issue, `INSERT ... SELECT ON DUPLICATE KEY UPDATE` and `INSERT IGNORE ... SELECT` statements are flagged as unsafe for statement-based replication. With this change, such statements produce a warning in the log when using statement-based mode and are logged using the row-based format when using `MIXED` mode. (Bug #11758262, Bug #50439)

See also [Section 18.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

In MySQL 8.0, an `INSERT ... SELECT` statement that acted on partitioned tables using a storage engine such as `MyISAM` that employs table-level locks locks all partitions of the target table; however, only those partitions that are actually read from the source table are locked. (This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking.) See [Partitioning and Locking](#), for more information.

13.2.6.2 INSERT DELAYED Syntax

```
INSERT DELAYED ...
```

The `DELAYED` option for the `INSERT` statement is a MySQL extension to standard SQL. In previous versions of MySQL, it can be used for certain kinds of tables (such as `MyISAM`), such that when a client uses `INSERT DELAYED`, it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

`DELAYED` inserts and replaces were deprecated in MySQL 5.6.6. In MySQL 8.0, `DELAYED` is not supported. The server recognizes but ignores the `DELAYED` keyword, handles the insert as a nondelayed insert, and generates an `ER_WARN_LEGACY_SYNTAX_CONVERTED` warning (“INSERT DELAYED is no longer supported. The statement was converted to INSERT”). The `DELAYED` keyword is scheduled for removal in a future release.

13.2.6.3 INSERT ... ON DUPLICATE KEY UPDATE Syntax

If you specify `ON DUPLICATE KEY UPDATE`, and a row is inserted that would cause a duplicate value in a `UNIQUE` index or `PRIMARY KEY`, MySQL performs an `UPDATE` of the old row. For example, if column `a` is declared as `UNIQUE` and contains the value `1`, the following two statements have similar effect:

```
INSERT INTO table (a,b,c) VALUES (1,2,3)
  ON DUPLICATE KEY UPDATE c=c+1;

UPDATE table SET c=c+1 WHERE a=1;
```

(The effects are not identical for an `InnoDB` table where `a` is an auto-increment column. With an auto-increment column, an `INSERT` statement increases the auto-increment value but `UPDATE` does not.)

The `ON DUPLICATE KEY UPDATE` clause can contain multiple column assignments, separated by commas.

With `ON DUPLICATE KEY UPDATE`, the affected-rows value per row is 1 if the row is inserted as a new row, 2 if an existing row is updated, and 0 if an existing row is set to its current values. If you specify the `CLIENT_FOUND_ROWS` flag to `mysql_real_connect()` when connecting to `mysqld`, the affected-rows value is 1 (not 0) if an existing row is set to its current values.

If column `b` is also unique, the `INSERT` is equivalent to this `UPDATE` statement instead:

```
UPDATE table SET c=c+1 WHERE a=1 OR b=2 LIMIT 1;
```

If `a=1 OR b=2` matches several rows, only *one* row is updated. In general, you should try to avoid using an `ON DUPLICATE KEY UPDATE` clause on tables with multiple unique indexes.

You can use the `VALUES(col_name)` function in the `UPDATE` clause to refer to column values from the `INSERT` portion of the `INSERT ... ON DUPLICATE KEY UPDATE` statement. In other words, `VALUES(col_name)` in the `ON DUPLICATE KEY UPDATE` clause refers to the value of `col_name` that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts. The `VALUES()` function is meaningful only in `INSERT ... UPDATE` statements and returns `NULL` otherwise. Example:

```
INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

That statement is identical to the following two statements:

```
INSERT INTO table (a,b,c) VALUES (1,2,3)
ON DUPLICATE KEY UPDATE c=3;
INSERT INTO table (a,b,c) VALUES (4,5,6)
ON DUPLICATE KEY UPDATE c=9;
```

If a table contains an `AUTO_INCREMENT` column and `INSERT ... ON DUPLICATE KEY UPDATE` inserts or updates a row, the `LAST_INSERT_ID()` function returns the `AUTO_INCREMENT` value.

The `DELAYED` option is ignored when you use `ON DUPLICATE KEY UPDATE`.

Because the results of `INSERT ... SELECT` statements depend on the ordering of rows from the `SELECT` and this order cannot always be guaranteed, it is possible when logging `INSERT ... SELECT ON DUPLICATE KEY UPDATE` statements for the master and the slave to diverge. Thus, `INSERT ... SELECT ON DUPLICATE KEY UPDATE` statements are flagged as unsafe for statement-based replication. With this change, such statements produce a warning in the log when using statement-based mode and are logged using the row-based format when using `MIXED` mode. In addition, an `INSERT ... ON DUPLICATE KEY UPDATE` statement against a table having more than one unique or primary key is also marked as unsafe. (Bug #11765650, Bug #58637) See also [Section 18.2.1.1, "Advantages and Disadvantages of Statement-Based and Row-Based Replication"](#).

In MySQL 8.0, an `INSERT ... ON DUPLICATE KEY UPDATE` on a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks any partitions of the table in which a partitioning key column is updated. (This does not occur with tables using storage engines such as `InnoDB` that employ row-level locking.) See [Partitioning and Locking](#), for more information.

13.2.7 LOAD DATA INFILE Syntax

```
LOAD DATA [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
[REPLACE | IGNORE]
INTO TABLE tbl_name
[PARTITION (partition_name,...)]
[CHARACTER SET charset_name]
[ {FIELDS | COLUMNS}
```

```

[TERMINATED BY 'string']
[[OPTIONALLY] ENCLOSED BY 'char']
[ESCAPED BY 'char']
]
[LINES
  [STARTING BY 'string']
  [TERMINATED BY 'string']
]
[IGNORE number {LINES | ROWS}]
[(col_name_or_user_var,...)]
[SET col_name = expr,...]

```

The `LOAD DATA INFILE` statement reads rows from a text file into a table at a very high speed. `LOAD DATA INFILE` is the complement of `SELECT ... INTO OUTFILE`. (See [Section 13.2.10.1, “SELECT ... INTO Syntax”](#).) To write data from a table to a file, use `SELECT ... INTO OUTFILE`. To read the file back into a table, use `LOAD DATA INFILE`. The syntax of the `FIELDS` and `LINES` clauses is the same for both statements. Both clauses are optional, but `FIELDS` must precede `LINES` if both are specified.

You can also load data files by using the `mysqlimport` utility; it operates by sending a `LOAD DATA INFILE` statement to the server. The `--local` option causes `mysqlimport` to read data files from the client host. You can specify the `--compress` option to get better performance over slow networks if the client and server support the compressed protocol. See [Section 4.5.5, “mysqlimport — A Data Import Program”](#).

For more information about the efficiency of `INSERT` versus `LOAD DATA INFILE` and speeding up `LOAD DATA INFILE`, see [Section 8.2.5.1, “Optimizing INSERT Statements”](#).

The file name must be given as a literal string. On Windows, specify backslashes in path names as forward slashes or doubled backslashes. The `character_set_filesystem` system variable controls the interpretation of the file name.

`LOAD DATA` supports explicit partition selection using the `PARTITION` option with a comma-separated list of one or more names of partitions, subpartitions, or both. When this option is used, if any rows from the file cannot be inserted into any of the partitions or subpartitions named in the list, the statement fails with the error `Found a row not matching the given partition set`. For more information, see [Section 22.5, “Partition Selection”](#).

For partitioned tables using storage engines that employ table locks, such as `MyISAM`, `LOAD DATA` cannot prune any partition locks. This does not apply to tables using storage engines which employ row-level locking, such as `InnoDB`. For more information, see [Partitioning and Locking](#).

The server uses the character set indicated by the `character_set_database` system variable to interpret the information in the file. `SET NAMES` and the setting of `character_set_client` do not affect interpretation of input. If the contents of the input file use a character set that differs from the default, it is usually preferable to specify the character set of the file by using the `CHARACTER SET` clause. A character set of `binary` specifies “no conversion.”

`LOAD DATA INFILE` interprets all fields in the file as having the same character set, regardless of the data types of the columns into which field values are loaded. For proper interpretation of file contents, you must ensure that it was written with the correct character set. For example, if you write a data file with `mysqldump -T` or by issuing a `SELECT ... INTO OUTFILE` statement in `mysql`, be sure to use a `--default-character-set` option so that output is written in the character set to be used when the file is loaded with `LOAD DATA INFILE`.

Note

It is not possible to load data files that use the `ucs2`, `utf16`, `utf16le`, or `utf32` character set.

If you use `LOW_PRIORITY`, execution of the `LOAD DATA` statement is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

If you specify `CONCURRENT` with a `MyISAM` table that satisfies the condition for concurrent inserts (that is, it contains no free blocks in the middle), other threads can retrieve data from the table while `LOAD DATA` is executing. This option affects the performance of `LOAD DATA` a bit, even if no other thread is using the table at the same time.

With row-based replication, `CONCURRENT` is replicated regardless of MySQL version. With statement-based replication `CONCURRENT` is not replicated prior to MySQL 5.5.1 (see Bug #34628). For more information, see [Section 18.4.1.18, “Replication and LOAD DATA INFILE”](#).

The `LOCAL` keyword affects expected location of the file and error handling, as described later. `LOCAL` works only if your server and your client both have been configured to permit it. For example, if `mysqld` was started with the `local_infile` system variable disabled, `LOCAL` does not work. See [Section 6.1.6, “Security Issues with LOAD DATA LOCAL”](#).

The `LOCAL` keyword affects where the file is expected to be found:

- If `LOCAL` is specified, the file is read by the client program on the client host and sent to the server. The file can be given as a full path name to specify its exact location. If given as a relative path name, the name is interpreted relative to the directory in which the client program was started.

When using `LOCAL` with `LOAD DATA`, a copy of the file is created in the server's temporary directory. This is *not* the directory determined by the value of `tmpdir` or `slave_load_tmpdir`, but rather the operating system's temporary directory, and is not configurable in the MySQL Server. (Typically the system temporary directory is `/tmp` on Linux systems and `C:\WINDOWS\TEMP` on Windows.) Lack of sufficient space for the copy in this directory can cause the `LOAD DATA LOCAL` statement to fail.

- If `LOCAL` is not specified, the file must be located on the server host and is read directly by the server. The server uses the following rules to locate the file:
 - If the file name is an absolute path name, the server uses it as given.
 - If the file name is a relative path name with one or more leading components, the server searches for the file relative to the server's data directory.
 - If a file name with no leading components is given, the server looks for the file in the database directory of the default database.

In the non-`LOCAL` case, these rules mean that a file named as `./myfile.txt` is read from the server's data directory, whereas the file named as `myfile.txt` is read from the database directory of the default database. For example, if `db1` is the default database, the following `LOAD DATA` statement reads the file `data.txt` from the database directory for `db1`, even though the statement explicitly loads the file into a table in the `db2` database:

```
LOAD DATA INFILE 'data.txt' INTO TABLE db2.my_table;
```

Note

The server also use the non-`LOCAL` rules to locate `.SDI` files for the `IMPORT TABLE` statement.

Non-`LOCAL` load operations read text files located on the server. For security reasons, such operations require that you have the `FILE` privilege. See [Section 6.2.1, “Privileges Provided by MySQL”](#). Also, non-`LOCAL` load operations are subject to the `secure_file_priv` system variable setting. If the variable value is a nonempty directory name, the file to be loaded must be located in that directory. If the variable value is empty (which is insecure), the file need only be readable by the server.

Using `LOCAL` is a bit slower than letting the server access the files directly, because the contents of the file must be sent over the connection by the client to the server. On the other hand, you do not need the `FILE` privilege to load local files.

`LOCAL` also affects error handling:

- With `LOAD DATA INFILE`, data-interpretation and duplicate-key errors terminate the operation.
- With `LOAD DATA LOCAL INFILE`, data-interpretation and duplicate-key errors become warnings and the operation continues because the server has no way to stop transmission of the file in the middle of the operation. For duplicate-key errors, this is the same as if `IGNORE` is specified. `IGNORE` is explained further later in this section.

The `REPLACE` and `IGNORE` keywords control handling of input rows that duplicate existing rows on unique key values:

- If you specify `REPLACE`, input rows replace existing rows. In other words, rows that have the same value for a primary key or unique index as an existing row. See [Section 13.2.9, “REPLACE Syntax”](#).
- If you specify `IGNORE`, rows that duplicate an existing row on a unique key value are discarded. For more information, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).
- If you do not specify either option, the behavior depends on whether the `LOCAL` keyword is specified. Without `LOCAL`, an error occurs when a duplicate key value is found, and the rest of the text file is ignored. With `LOCAL`, the default behavior is the same as if `IGNORE` is specified; this is because the server has no way to stop transmission of the file in the middle of the operation.

To ignore foreign key constraints during the load operation, issue a `SET foreign_key_checks = 0` statement before executing `LOAD DATA`.

If you use `LOAD DATA INFILE` on an empty `MyISAM` table, all nonunique indexes are created in a separate batch (as for `REPAIR TABLE`). Normally, this makes `LOAD DATA INFILE` much faster when you have many indexes. In some extreme cases, you can create the indexes even faster by turning them off with `ALTER TABLE ... DISABLE KEYS` before loading the file into the table and using `ALTER TABLE ... ENABLE KEYS` to re-create the indexes after loading the file. See [Section 8.2.5.1, “Optimizing INSERT Statements”](#).

For both the `LOAD DATA INFILE` and `SELECT ... INTO OUTFILE` statements, the syntax of the `FIELDS` and `LINES` clauses is the same. Both clauses are optional, but `FIELDS` must precede `LINES` if both are specified.

If you specify a `FIELDS` clause, each of its subclauses (`TERMINATED BY`, `[OPTIONALLY] ENCLOSED BY`, and `ESCAPED BY`) is also optional, except that you must specify at least one of them.

If you specify no `FIELDS` or `LINES` clause, the defaults are the same as if you had written this:

```
FIELDS TERMINATED BY '\t' ENCLOSED BY '' ESCAPED BY '\\'
LINES TERMINATED BY '\n' STARTING BY ''
```

(Backslash is the MySQL escape character within strings in SQL statements, so to specify a literal backslash, you must specify two backslashes for the value to be interpreted as a single backslash. The escape sequences `'\t'` and `'\n'` specify tab and newline characters, respectively.)

In other words, the defaults cause `LOAD DATA INFILE` to act as follows when reading input:

- Look for line boundaries at newlines.
- Do not skip over any line prefix.
- Break lines into fields at tabs.
- Do not expect fields to be enclosed within any quoting characters.
- Interpret characters preceded by the escape character `\` as escape sequences. For example, `\t`, `\n`, and `\\` signify tab, newline, and backslash, respectively. See the discussion of `FIELDS ESCAPED BY` later for the full list of escape sequences.

Conversely, the defaults cause `SELECT ... INTO OUTFILE` to act as follows when writing output:

- Write tabs between fields.
- Do not enclose fields within any quoting characters.
- Use `\` to escape instances of tab, newline, or `\` that occur within field values.
- Write newlines at the ends of lines.

Note

If you have generated the text file on a Windows system, you might have to use `LINES TERMINATED BY '\r\n'` to read the file properly, because Windows programs typically use two characters as a line terminator. Some programs, such as `WordPad`, might use `\r` as a line terminator when writing files. To read such files, use `LINES TERMINATED BY '\r'`.

If all the lines you want to read in have a common prefix that you want to ignore, you can use `LINES STARTING BY 'prefix_string'` to skip over the prefix, *and anything before it*. If a line does not include the prefix, the entire line is skipped. Suppose that you issue the following statement:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test
  FIELDS TERMINATED BY ',' LINES STARTING BY 'xxx';
```

If the data file looks like this:

```
xxx"abc",1
something xxx"def",2
"ghi",3
```

The resulting rows will be `("abc",1)` and `("def",2)`. The third row in the file is skipped because it does not contain the prefix.

The `IGNORE number LINES` option can be used to ignore lines at the start of the file. For example, you can use `IGNORE 1 LINES` to skip over an initial header line containing column names:

```
LOAD DATA INFILE '/tmp/test.txt' INTO TABLE test IGNORE 1 LINES;
```

When you use `SELECT ... INTO OUTFILE` in tandem with `LOAD DATA INFILE` to write data from a database into a file and then read the file back into the database later, the field- and line-handling options for both statements must match. Otherwise, `LOAD DATA INFILE` will not interpret the contents of the file properly. Suppose that you use `SELECT ... INTO OUTFILE` to write a file with fields delimited by commas:

```
SELECT * INTO OUTFILE 'data.txt'
  FIELDS TERMINATED BY ','
  FROM table2;
```

To read the comma-delimited file back in, the correct statement would be:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
  FIELDS TERMINATED BY ',';
```

If instead you tried to read in the file with the statement shown following, it wouldn't work because it instructs `LOAD DATA INFILE` to look for tabs between fields:

```
LOAD DATA INFILE 'data.txt' INTO TABLE table2
```

```
FIELDS TERMINATED BY '\t';
```

The likely result is that each input line would be interpreted as a single field.

`LOAD DATA INFILE` can be used to read files obtained from external sources. For example, many programs can export data in comma-separated values (CSV) format, such that lines have fields separated by commas and enclosed within double quotation marks, with an initial line of column names. If the lines in such a file are terminated by carriage return/newline pairs, the statement shown here illustrates the field- and line-handling options you would use to load the file:

```
LOAD DATA INFILE 'data.txt' INTO TABLE tbl_name
  FIELDS TERMINATED BY ',' ENCLOSED BY '"'
  LINES TERMINATED BY '\r\n'
  IGNORE 1 LINES;
```

If the input values are not necessarily enclosed within quotation marks, use `OPTIONALLY` before the `ENCLOSED BY` keywords.

Any of the field- or line-handling options can specify an empty string (' '). If not empty, the `FIELDS [OPTIONALLY] ENCLOSED BY` and `FIELDS ESCAPED BY` values must be a single character. The `FIELDS TERMINATED BY`, `LINES STARTING BY`, and `LINES TERMINATED BY` values can be more than one character. For example, to write lines that are terminated by carriage return/linefeed pairs, or to read a file containing such lines, specify a `LINES TERMINATED BY '\r\n'` clause.

To read a file containing jokes that are separated by lines consisting of `%%`, you can do this

```
CREATE TABLE jokes
  (a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  joke TEXT NOT NULL);
LOAD DATA INFILE '/tmp/jokes.txt' INTO TABLE jokes
  FIELDS TERMINATED BY ''
  LINES TERMINATED BY '\n%%\n' (joke);
```

`FIELDS [OPTIONALLY] ENCLOSED BY` controls quoting of fields. For output (`SELECT ... INTO OUTFILE`), if you omit the word `OPTIONALLY`, all fields are enclosed by the `ENCLOSED BY` character. An example of such output (using a comma as the field delimiter) is shown here:

```
"1","a string",100.20
"2","a string containing a , comma",102.20
"3","a string containing a \" quote",102.20
"4","a string containing a \", quote and comma",102.20
```

If you specify `OPTIONALLY`, the `ENCLOSED BY` character is used only to enclose values from columns that have a string data type (such as `CHAR`, `BINARY`, `TEXT`, or `ENUM`):

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a \" quote",102.20
4,"a string containing a \", quote and comma",102.20
```

Occurrences of the `ENCLOSED BY` character within a field value are escaped by prefixing them with the `ESCAPED BY` character. Also, if you specify an empty `ESCAPED BY` value, it is possible to inadvertently generate output that cannot be read properly by `LOAD DATA INFILE`. For example, the preceding output just shown would appear as follows if the escape character is empty. Observe that the second field in the fourth line contains a comma following the quote, which (erroneously) appears to terminate the field:

```
1,"a string",100.20
2,"a string containing a , comma",102.20
3,"a string containing a " quote",102.20
4,"a string containing a ", quote and comma",102.20
```

For input, the `ENCLOSED BY` character, if present, is stripped from the ends of field values. (This is true regardless of whether `OPTIONALLY` is specified; `OPTIONALLY` has no effect on input interpretation.) Occurrences of the `ENCLOSED BY` character preceded by the `ESCAPED BY` character are interpreted as part of the current field value.

If the field begins with the `ENCLOSED BY` character, instances of that character are recognized as terminating a field value only if followed by the field or line `TERMINATED BY` sequence. To avoid ambiguity, occurrences of the `ENCLOSED BY` character within a field value can be doubled and are interpreted as a single instance of the character. For example, if `ENCLOSED BY '''` is specified, quotation marks are handled as shown here:

```
"The ""BIG"" boss" -> The "BIG" boss
The "BIG" boss     -> The "BIG" boss
The ""BIG"" boss  -> The ""BIG"" boss
```

`FIELDS ESCAPED BY` controls how to read or write special characters:

- For input, if the `FIELDS ESCAPED BY` character is not empty, occurrences of that character are stripped and the following character is taken literally as part of a field value. Some two-character sequences that are exceptions, where the first character is the escape character. These sequences are shown in the following table (using `\` for the escape character). The rules for `NULL` handling are described later in this section.

Character	Escape Sequence
<code>\0</code>	An ASCII NUL (<code>x'00'</code>) character
<code>\b</code>	A backspace character
<code>\n</code>	A newline (linefeed) character
<code>\r</code>	A carriage return character
<code>\t</code>	A tab character.
<code>\z</code>	ASCII 26 (Control+Z)
<code>\N</code>	NULL

For more information about `\`-escape syntax, see [Section 9.1.1, “String Literals”](#).

If the `FIELDS ESCAPED BY` character is empty, escape-sequence interpretation does not occur.

- For output, if the `FIELDS ESCAPED BY` character is not empty, it is used to prefix the following characters on output:
 - The `FIELDS ESCAPED BY` character
 - The `FIELDS [OPTIONALLY] ENCLOSED BY` character
 - The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values
 - ASCII 0 (what is actually written following the escape character is ASCII 0, not a zero-valued byte)

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

In certain cases, field- and line-handling options interact:

- If `LINES TERMINATED BY` is an empty string and `FIELDS TERMINATED BY` is nonempty, lines are also terminated with `FIELDS TERMINATED BY`.
- If the `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` values are both empty (`''`), a fixed-row (nondelimited) format is used. With fixed-row format, no delimiters are used between fields

(but you can still have a line terminator). Instead, column values are read and written using a field width wide enough to hold all values in the field. For `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`, the field widths are 4, 6, 8, 11, and 20, respectively, no matter what the declared display width is.

`LINES TERMINATED BY` is still used to separate lines. If a line does not contain all fields, the rest of the columns are set to their default values. If you do not have a line terminator, you should set this to `' '`. In this case, the text file must contain all fields for each row.

Fixed-row format also affects handling of `NULL` values, as described later.

Note

Fixed-size format does not work if you are using a multibyte character set.

Handling of `NULL` values varies according to the `FIELDS` and `LINES` options in use:

- For the default `FIELDS` and `LINES` values, `NULL` is written as a field value of `\N` for output, and a field value of `\N` is read as `NULL` for input (assuming that the `ESCAPED BY` character is `\`).
- If `FIELDS ENCLOSED BY` is not empty, a field containing the literal word `NULL` as its value is read as a `NULL` value. This differs from the word `NULL` enclosed within `FIELDS ENCLOSED BY` characters, which is read as the string `'NULL'`.
- If `FIELDS ESCAPED BY` is empty, `NULL` is written as the word `NULL`.
- With fixed-row format (which is used when `FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` are both empty), `NULL` is written as an empty string. This causes both `NULL` values and empty strings in the table to be indistinguishable when written to the file because both are written as empty strings. If you need to be able to tell the two apart when reading the file back in, you should not use fixed-row format.

An attempt to load `NULL` into a `NOT NULL` column causes assignment of the implicit default value for the column's data type and a warning, or an error in strict SQL mode. Implicit default values are discussed in [Section 11.7, "Data Type Default Values"](#).

Some cases are not supported by `LOAD DATA INFILE`:

- Fixed-size rows (`FIELDS TERMINATED BY` and `FIELDS ENCLOSED BY` both empty) and `BLOB` or `TEXT` columns.
- If you specify one separator that is the same as or a prefix of another, `LOAD DATA INFILE` cannot interpret the input properly. For example, the following `FIELDS` clause would cause problems:

```
FIELDS TERMINATED BY ' ' ENCLOSED BY ' '
```

- If `FIELDS ESCAPED BY` is empty, a field value that contains an occurrence of `FIELDS ENCLOSED BY` or `LINES TERMINATED BY` followed by the `FIELDS TERMINATED BY` value causes `LOAD DATA INFILE` to stop reading a field or line too early. This happens because `LOAD DATA INFILE` cannot properly determine where the field or line value ends.

The following example loads all columns of the `persondata` table:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata;
```

By default, when no column list is provided at the end of the `LOAD DATA INFILE` statement, input lines are expected to contain a field for each table column. If you want to load only some of a table's columns, specify a column list:

```
LOAD DATA INFILE 'persondata.txt' INTO TABLE persondata (col1,col2,...);
```

You must also specify a column list if the order of the fields in the input file differs from the order of the columns in the table. Otherwise, MySQL cannot tell how to match input fields with table columns.

The column list can contain either column names or user variables. With user variables, the `SET` clause enables you to perform transformations on their values before assigning the result to columns.

User variables in the `SET` clause can be used in several ways. The following example uses the first input column directly for the value of `t1.column1`, and assigns the second input column to a user variable that is subjected to a division operation before being used for the value of `t1.column2`:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @var1)
  SET column2 = @var1/100;
```

The `SET` clause can be used to supply values not derived from the input file. The following statement sets `column3` to the current date and time:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, column2)
  SET column3 = CURRENT_TIMESTAMP;
```

You can also discard an input value by assigning it to a user variable and not assigning the variable to a table column:

```
LOAD DATA INFILE 'file.txt'
  INTO TABLE t1
  (column1, @dummy, column2, @dummy, column3);
```

Use of the column/variable list and `SET` clause is subject to the following restrictions:

- Assignments in the `SET` clause should have only column names on the left hand side of assignment operators.
- You can use subqueries in the right hand side of `SET` assignments. A subquery that returns a value to be assigned to a column may be a scalar subquery only. Also, you cannot use a subquery to select from the table that is being loaded.
- Lines ignored by an `IGNORE` clause are not processed for the column/variable list or `SET` clause.
- User variables cannot be used when loading data with fixed-row format because user variables do not have a display width.

When processing an input line, `LOAD DATA` splits it into fields and uses the values according to the column/variable list and the `SET` clause, if they are present. Then the resulting row is inserted into the table. If there are `BEFORE INSERT` or `AFTER INSERT` triggers for the table, they are activated before or after inserting the row, respectively.

If an input line has too many fields, the extra fields are ignored and the number of warnings is incremented.

If an input line has too few fields, the table columns for which input fields are missing are set to their default values. Default value assignment is described in [Section 11.7, “Data Type Default Values”](#).

An empty field value is interpreted different from a missing field:

- For string types, the column is set to the empty string.
- For numeric types, the column is set to 0.
- For date and time types, the column is set to the appropriate “zero” value for the type. See [Section 11.3, “Date and Time Types”](#).

These are the same values that result if you assign an empty string explicitly to a string, numeric, or date or time type explicitly in an `INSERT` or `UPDATE` statement.

Treatment of empty or incorrect field values differs from that just described if the SQL mode is set to a restrictive value. For example, if `sql_mode` is set to `TRADITIONAL`, conversion of an empty value or a value such as `'x'` for a numeric column results in an error, not conversion to 0. (With `LOCAL` or `IGNORE`, warnings occur rather than errors, even with a restrictive `sql_mode` value, and the row is inserted using the same closest-value behavior used for nonrestrictive SQL modes. This occurs because the server has no way to stop transmission of the file in the middle of the operation.)

`TIMESTAMP` columns are set to the current date and time only if there is a `NULL` value for the column (that is, `\N`) and the column is not declared to permit `NULL` values, or if the `TIMESTAMP` column's default value is the current timestamp and it is omitted from the field list when a field list is specified.

`LOAD DATA INFILE` regards all input as strings, so you cannot use numeric values for `ENUM` or `SET` columns the way you can with `INSERT` statements. All `ENUM` and `SET` values must be specified as strings.

`BIT` values cannot be loaded directly using binary notation (for example, `b'011010'`). To work around this, use the `SET` clause to strip off the leading `b'` and trailing `'` and perform a base-2 to base-10 conversion so that MySQL loads the values into the `BIT` column properly:

```
shell> cat /tmp/bit_test.txt
b'10'
b'1111111'
shell> mysql test
mysql> LOAD DATA INFILE '/tmp/bit_test.txt'
      INTO TABLE bit_test (@var1)
      SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-3), 2, 10) AS UNSIGNED);
Query OK, 2 rows affected (0.00 sec)
Records: 2  Deleted: 0  Skipped: 0  Warnings: 0

mysql> SELECT BIN(b+0) FROM bit_test;
+-----+
| BIN(b+0) |
+-----+
| 10      |
| 1111111 |
+-----+
2 rows in set (0.00 sec)
```

For `BIT` values in `0b` binary notation (for example, `0b011010`), use this `SET` clause instead to strip off the leading `0b`:

```
SET b = CAST(CONV(MID(@var1, 3, LENGTH(@var1)-2), 2, 10) AS UNSIGNED)
```

On Unix, if you need `LOAD DATA` to read from a pipe, you can use the following technique (the example loads a listing of the `/` directory into the table `db1.t1`):

```
mkfifo /mysql/data/db1/ls.dat
chmod 666 /mysql/data/db1/ls.dat
find / -ls > /mysql/data/db1/ls.dat &
mysql -e "LOAD DATA INFILE 'ls.dat' INTO TABLE t1" db1
```

Here you must run the command that generates the data to be loaded and the `mysql` commands either on separate terminals, or run the data generation process in the background (as shown in the preceding example). If you do not do this, the pipe will block until data is read by the `mysql` process.

When the `LOAD DATA INFILE` statement finishes, it returns an information string in the following format:

```
Records: 1  Deleted: 0  Skipped: 0  Warnings: 0
```

Warnings occur under the same circumstances as when values are inserted using the `INSERT` statement (see [Section 13.2.6, “INSERT Syntax”](#)), except that `LOAD DATA INFILE` also generates warnings when there are too few or too many fields in the input row.

You can use `SHOW WARNINGS` to get a list of the first `max_error_count` warnings as information about what went wrong. See [Section 13.7.5.40, “SHOW WARNINGS Syntax”](#).

If you are using the C API, you can get information about the statement by calling the `mysql_info()` function. See [Section 27.7.7.36, “mysql_info\(\)”](#).

13.2.8 LOAD XML Syntax

```
LOAD XML [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
[REPLACE | IGNORE]
INTO TABLE [db_name.]tbl_name
[CHARACTER SET charset_name]
[ROWS IDENTIFIED BY '<tagname>']
[IGNORE number {LINES | ROWS}]
[(field_name_or_user_var,...)]
[SET col_name = expr,...]
```

The `LOAD XML` statement reads data from an XML file into a table. The `file_name` must be given as a literal string. The `tagname` in the optional `ROWS IDENTIFIED BY` clause must also be given as a literal string, and must be surrounded by angle brackets (< and >).

`LOAD XML` acts as the complement of running the `mysql` client in XML output mode (that is, starting the client with the `--xml` option). To write data from a table to an XML file, you can invoke the `mysql` client with the `--xml` and `-e` options from the system shell, as shown here:

```
shell> mysql --xml -e 'SELECT * FROM mydb.mytable' > file.xml
```

To read the file back into a table, use `LOAD XML INFILE`. By default, the `<row>` element is considered to be the equivalent of a database table row; this can be changed using the `ROWS IDENTIFIED BY` clause.

This statement supports three different XML formats:

- Column names as attributes and column values as attribute values:

```
<row column1="value1" column2="value2" .../>
```

- Column names as tags and column values as the content of these tags:

```
<row>
  <column1>value1</column1>
  <column2>value2</column2>
</row>
```

- Column names are the `name` attributes of `<field>` tags, and values are the contents of these tags:

```
<row>
  <field name='column1'>value1</field>
  <field name='column2'>value2</field>
</row>
```

This is the format used by other MySQL tools, such as `mysqldump`.

All three formats can be used in the same XML file; the import routine automatically detects the format for each row and interprets it correctly. Tags are matched based on the tag or attribute name and the column name.

The following clauses work essentially the same way for `LOAD XML` as they do for `LOAD DATA`:

- `LOW_PRIORITY` or `CONCURRENT`
- `LOCAL`
- `REPLACE` or `IGNORE`
- `CHARACTER SET`
- `SET`

See [Section 13.2.7, “LOAD DATA INFILE Syntax”](#), for more information about these clauses.

`(field_name_or_user_var, ...)` is a comma-separated list of one or more XML fields or user variables. The name of a user variable used for this purpose must match the name of a field from the XML file, prefixed with `@`. You can use field names to select only desired fields. User variables can be employed to store the corresponding field values for subsequent re-use.

The `IGNORE number LINES` or `IGNORE number ROWS` clause causes the first `number` rows in the XML file to be skipped. It is analogous to the `LOAD DATA` statement's `IGNORE ... LINES` clause.

Suppose that we have a table named `person`, created as shown here:

```
USE test;

CREATE TABLE person (
  person_id INT NOT NULL PRIMARY KEY,
  fname VARCHAR(40) NULL,
  lname VARCHAR(40) NULL,
  created TIMESTAMP
);
```

Suppose further that this table is initially empty.

Now suppose that we have a simple XML file `person.xml`, whose contents are as shown here:

```
<list>
  <person person_id="1" fname="Kapek" lname="Sainnouine"/>
  <person person_id="2" fname="Sajon" lname="Rondela"/>
  <person person_id="3"><fname>Likame</fname><lname>Örrtmons</lname></person>
  <person person_id="4"><fname>Slar</fname><lname>Manlanth</lname></person>
  <person><field name="person_id">5</field><field name="fname">Stoma</field>
  <field name="lname">Milu</field></person>
  <person><field name="person_id">6</field><field name="fname">Nirtam</field>
  <field name="lname">Sklöd</field></person>
  <person person_id="7"><fname>Sungam</fname><lname>Dulbåd</lname></person>
  <person person_id="8" fname="Sraref" lname="Encmelt"/>
</list>
```

Each of the permissible XML formats discussed previously is represented in this example file.

To import the data in `person.xml` into the `person` table, you can use this statement:

```
mysql> LOAD XML LOCAL INFILE 'person.xml'
-> INTO TABLE person
-> ROWS IDENTIFIED BY '<person>';

Query OK, 8 rows affected (0.00 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0
```

Here, we assume that `person.xml` is located in the MySQL data directory. If the file cannot be found, the following error results:

```
ERROR 2 (HY000): File '/person.xml' not found (Errcode: 2)
```

The `ROWS IDENTIFIED BY '<person>'` clause means that each `<person>` element in the XML file is considered equivalent to a row in the table into which the data is to be imported. In this case, this is the `person` table in the `test` database.

As can be seen by the response from the server, 8 rows were imported into the `test.person` table. This can be verified by a simple `SELECT` statement:

```
mysql> SELECT * FROM person;
+-----+-----+-----+-----+
| person_id | fname | lname | created |
+-----+-----+-----+-----+
|          1 | Kapek | Sainnouine | 2007-07-13 16:18:47 |
|          2 | Sajon | Rondela | 2007-07-13 16:18:47 |
|          3 | Likame | Örrtmons | 2007-07-13 16:18:47 |
|          4 | Slar | Manlanth | 2007-07-13 16:18:47 |
|          5 | Stoma | Nilu | 2007-07-13 16:18:47 |
|          6 | Nirtam | Sklöd | 2007-07-13 16:18:47 |
|          7 | Sungam | Dulbåd | 2007-07-13 16:18:47 |

+-----+-----+-----+-----+
8 rows in set (0.00 sec)
```

This shows, as stated earlier in this section, that any or all of the 3 permitted XML formats may appear in a single file and be read in using `LOAD XML`.

The inverse of the import operation just shown—that is, dumping MySQL table data into an XML file—can be accomplished using the `mysql` client from the system shell, as shown here:

```
shell> mysql --xml -e "SELECT * FROM test.person" > person-dump.xml
shell> cat person-dump.xml
<?xml version="1.0"?>

<resultset statement="SELECT * FROM test.person" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <row>
    <field name="person_id">1</field>
    <field name="fname">Kapek</field>
    <field name="lname">Sainnouine</field>
  </row>

  <row>
    <field name="person_id">2</field>
    <field name="fname">Sajon</field>
    <field name="lname">Rondela</field>
  </row>

  <row>
    <field name="person_id">3</field>
    <field name="fname">Likema</field>
    <field name="lname">Örrtmons</field>
  </row>

  <row>
    <field name="person_id">4</field>
    <field name="fname">Slar</field>
    <field name="lname">Manlanth</field>
  </row>

  <row>
    <field name="person_id">5</field>
    <field name="fname">Stoma</field>
    <field name="lname">Nilu</field>
  </row>

  <row>
    <field name="person_id">6</field>
```

```

<field name="fname">Nirtam</field>
<field name="lname">Sklöd</field>
</row>

<row>
<field name="person_id">7</field>
<field name="fname">Sungam</field>
<field name="lname">Dulbåd</field>
</row>

<row>
<field name="person_id">8</field>
<field name="fname">Sreraf</field>
<field name="lname">Encmelt</field>
</row>
</resultset>

```

Note

The `--xml` option causes the `mysql` client to use XML formatting for its output; the `-e` option causes the client to execute the SQL statement immediately following the option. See [Section 4.5.1, “mysql — The MySQL Command-Line Tool”](#).

You can verify that the dump is valid by creating a copy of the `person` table and importing the dump file into the new table, like this:

```

mysql> USE test;
mysql> CREATE TABLE person2 LIKE person;
Query OK, 0 rows affected (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml'
-> INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT * FROM person2;
+-----+-----+-----+-----+
| person_id | fname | lname | created |
+-----+-----+-----+-----+
| 1 | Kapek | Sainnouine | 2007-07-13 16:18:47 |
| 2 | Sajon | Rondela | 2007-07-13 16:18:47 |
| 3 | Likema | Örrtmons | 2007-07-13 16:18:47 |
| 4 | Slar | Manlanth | 2007-07-13 16:18:47 |
| 5 | Stoma | Nilu | 2007-07-13 16:18:47 |
| 6 | Nirtam | Sklöd | 2007-07-13 16:18:47 |
| 7 | Sungam | Dulbåd | 2007-07-13 16:18:47 |
| 8 | Sreraf | Encmelt | 2007-07-13 16:18:47 |
+-----+-----+-----+-----+
8 rows in set (0.00 sec)

```

There is no requirement that every field in the XML file be matched with a column in the corresponding table. Fields which have no corresponding columns are skipped. You can see this by first emptying the `person2` table and dropping the `created` column, then using the same `LOAD XML` statement we just employed previously, like this:

```

mysql> TRUNCATE person2;
Query OK, 8 rows affected (0.26 sec)

mysql> ALTER TABLE person2 DROP COLUMN created;
Query OK, 0 rows affected (0.52 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW CREATE TABLE person2\G
***** 1. row *****
Table: person2
Create Table: CREATE TABLE `person2` (
  `person_id` int(11) NOT NULL,

```

```

`fname` varchar(40) DEFAULT NULL,
`lname` varchar(40) DEFAULT NULL,
PRIMARY KEY (`person_id`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8
1 row in set (0.00 sec)

mysql> LOAD XML LOCAL INFILE 'person-dump.xml'
-> INTO TABLE person2;
Query OK, 8 rows affected (0.01 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT * FROM person2;
+-----+-----+-----+
| person_id | fname | lname |
+-----+-----+-----+
|          1 | Kapek | Sainnouine |
|          2 | Sajon | Rondela |
|          3 | Likema | Örrtmons |
|          4 | Slar | Manlanth |
|          5 | Stoma | Nilu |
|          6 | Nirtam | Sklöd |
|          7 | Sungam | Dulbåd |
|          8 | Sreraf | Encmelt |
+-----+-----+-----+
8 rows in set (0.00 sec)

```

The order in which the fields are given within each row of the XML file does not affect the operation of `LOAD XML`; the field order can vary from row to row, and is not required to be in the same order as the corresponding columns in the table.

As mentioned previously, you can use a (*field_name_or_user_var, ...*) list of one or more XML fields (to select desired fields only) or user variables (to store the corresponding field values for later use). User variables can be especially useful when you want to insert data from an XML file into table columns whose names do not match those of the XML fields. To see how this works, we first create a table named `individual` whose structure matches that of the `person` table, but whose columns are named differently:

```

mysql> CREATE TABLE individual (
-> individual_id INT NOT NULL PRIMARY KEY,
-> name1 VARCHAR(40) NULL,
-> name2 VARCHAR(40) NULL,
-> made TIMESTAMP
-> );
Query OK, 0 rows affected (0.42 sec)

```

In this case, you cannot simply load the XML file directly into the table, because the field and column names do not match:

```

mysql> LOAD XML INFILE '../bin/person-dump.xml' INTO TABLE test.individual;
ERROR 1263 (22004): Column set to default value; NULL supplied to NOT NULL column 'individual_id' at row 1

```

This happens because the MySQL server looks for field names matching the column names of the target table. You can work around this problem by selecting the field values into user variables, then setting the target table's columns equal to the values of those variables using `SET`. You can perform both of these operations in a single statement, as shown here:

```

mysql> LOAD XML INFILE '../bin/person-dump.xml'
-> INTO TABLE test.individual (@person_id, @fname, @lname, @created)
-> SET individual_id=@person_id, name1=@fname, name2=@lname, made=@created;
Query OK, 8 rows affected (0.05 sec)
Records: 8 Deleted: 0 Skipped: 0 Warnings: 0

mysql> SELECT * FROM individual;
+-----+-----+-----+-----+
| individual_id | name1 | name2 | made |
+-----+-----+-----+-----+

```

```

+-----+-----+-----+-----+
|      1 | Kapek | Sainnouine | 2007-07-13 16:18:47 |
|      2 | Sajon | Rondela    | 2007-07-13 16:18:47 |
|      3 | Likema | Örrtmons   | 2007-07-13 16:18:47 |
|      4 | Slar   | Manlanth   | 2007-07-13 16:18:47 |
|      5 | Stoma  | Nilu       | 2007-07-13 16:18:47 |
|      6 | Nirtam | Sklöd      | 2007-07-13 16:18:47 |
|      7 | Sungam | Dulbåd     | 2007-07-13 16:18:47 |
|      8 | Srraf  | Encmelt    | 2007-07-13 16:18:47 |
+-----+-----+-----+-----+
8 rows in set (0.00 sec)

```

The names of the user variables *must* match those of the corresponding fields from the XML file, with the addition of the required @ prefix to indicate that they are variables. The user variables need not be listed or assigned in the same order as the corresponding fields.

Using a `ROWS IDENTIFIED BY '<tagname>'` clause, it is possible to import data from the same XML file into database tables with different definitions. For this example, suppose that you have a file named `address.xml` which contains the following XML:

```

<?xml version="1.0"?>

<list>
  <person person_id="1">
    <fname>Robert</fname>
    <lname>Jones</lname>
    <address address_id="1" street="Mill Creek Road" zip="45365" city="Sidney"/>
    <address address_id="2" street="Main Street" zip="28681" city="Taylorsville"/>
  </person>

  <person person_id="2">
    <fname>Mary</fname>
    <lname>Smith</lname>
    <address address_id="3" street="River Road" zip="80239" city="Denver"/>
    <!-- <address address_id="4" street="North Street" zip="37920" city="Knoxville"/> -->
  </person>
</list>

```

You can again use the `test.person` table as defined previously in this section, after clearing all the existing records from the table and then showing its structure as shown here:

```

mysql> TRUNCATE person;
Query OK, 0 rows affected (0.04 sec)

mysql> SHOW CREATE TABLE person\G
***** 1. row *****
      Table: person
Create Table: CREATE TABLE `person` (
  `person_id` int(11) NOT NULL,
  `fname` varchar(40) DEFAULT NULL,
  `lname` varchar(40) DEFAULT NULL,
  `created` timestamp NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  PRIMARY KEY (`person_id`)
) ENGINE=MyISAM DEFAULT CHARSET=utf8mb4
1 row in set (0.00 sec)

```

Now create an `address` table in the `test` database using the following `CREATE TABLE` statement:

```

CREATE TABLE address (
  address_id INT NOT NULL PRIMARY KEY,
  person_id INT NULL,
  street VARCHAR(40) NULL,
  zip INT NULL,
  city VARCHAR(40) NULL,
  created TIMESTAMP
);

```

To import the data from the XML file into the `person` table, execute the following `LOAD XML` statement, which specifies that rows are to be specified by the `<person>` element, as shown here;

```
mysql> LOAD XML LOCAL INFILE 'address.xml'
-> INTO TABLE person
-> ROWS IDENTIFIED BY '<person>';
Query OK, 2 rows affected (0.00 sec)
Records: 2 Deleted: 0 Skipped: 0 Warnings: 0
```

You can verify that the records were imported using a `SELECT` statement:

```
mysql> SELECT * FROM person;
+-----+-----+-----+-----+
| person_id | fname | lname | created |
+-----+-----+-----+-----+
|          1 | Robert | Jones | 2007-07-24 17:37:06 |
|          2 | Mary  | Smith | 2007-07-24 17:37:06 |
+-----+-----+-----+-----+
2 rows in set (0.00 sec)
```

Since the `<address>` elements in the XML file have no corresponding columns in the `person` table, they are skipped.

To import the data from the `<address>` elements into the `address` table, use the `LOAD XML` statement shown here:

```
mysql> LOAD XML LOCAL INFILE 'address.xml'
-> INTO TABLE address
-> ROWS IDENTIFIED BY '<address>';
Query OK, 3 rows affected (0.00 sec)
Records: 3 Deleted: 0 Skipped: 0 Warnings: 0
```

You can see that the data was imported using a `SELECT` statement such as this one:

```
mysql> SELECT * FROM address;
+-----+-----+-----+-----+-----+-----+
| address_id | person_id | street          | zip  | city          | created |
+-----+-----+-----+-----+-----+-----+
|          1 |          1 | Mill Creek Road | 45365 | Sidney        | 2007-07-24 17:37:37 |
|          2 |          1 | Main Street     | 28681 | Taylorsville  | 2007-07-24 17:37:37 |
|          3 |          2 | River Road      | 80239 | Denver        | 2007-07-24 17:37:37 |
+-----+-----+-----+-----+-----+-----+
3 rows in set (0.00 sec)
```

The data from the `<address>` element that is enclosed in XML comments is not imported. However, since there is a `person_id` column in the `address` table, the value of the `person_id` attribute from the parent `<person>` element for each `<address>` is imported into the `address` table.

Security Considerations. As with the `LOAD DATA` statement, the transfer of the XML file from the client host to the server host is initiated by the MySQL server. In theory, a patched server could be built that would tell the client program to transfer a file of the server's choosing rather than the file named by the client in the `LOAD XML` statement. Such a server could access any file on the client host to which the client user has read access.

In a Web environment, clients usually connect to MySQL from a Web server. A user that can run any command against the MySQL server can use `LOAD XML LOCAL` to read any files to which the Web server process has read access. In this environment, the client with respect to the MySQL server is actually the Web server, not the remote program being run by the user who connects to the Web server.

You can disable loading of XML files from clients by starting the server with `--local-infile=0` or `--local-infile=OFF`. This option can also be used when starting the `mysql` client to disable `LOAD XML` for the duration of the client session.

To prevent a client from loading XML files from the server, do not grant the `FILE` privilege to the corresponding MySQL user account, or revoke this privilege if the client user account already has it.

Important

Revoking the `FILE` privilege (or not granting it in the first place) keeps the user only from executing the `LOAD XML INFILE` statement (as well as the `LOAD_FILE()` function; it does *not* prevent the user from executing `LOAD XML LOCAL INFILE`. To disallow this statement, you must start the server or the client with `--local-infile=OFF`.

In other words, the `FILE` privilege affects only whether the client can read files on the server; it has no bearing on whether the client can read files on the local file system.

For partitioned tables using storage engines that employ table locks, such as `MyISAM`, any locks caused by `LOAD XML` perform locks on all partitions of the table. This does not apply to tables using storage engines which employ row-level locking, such as `InnoDB`. For more information, see [Partitioning and Locking](#).

13.2.9 REPLACE Syntax

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  [(col_name,...)]
  {VALUES | VALUE} ({expr | DEFAULT},...),(...),...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  SET col_name={expr | DEFAULT}, ...
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
  [INTO] tbl_name
  [PARTITION (partition_name,...)]
  [(col_name,...)]
  SELECT ...
```

`REPLACE` works exactly like `INSERT`, except that if an old row in the table has the same value as a new row for a `PRIMARY KEY` or a `UNIQUE` index, the old row is deleted before the new row is inserted. See [Section 13.2.6, “INSERT Syntax”](#).

`REPLACE` is a MySQL extension to the SQL standard. It either inserts, or *deletes* and inserts. For another MySQL extension to standard SQL—that either inserts or *updates*—see [Section 13.2.6.3, “INSERT ... ON DUPLICATE KEY UPDATE Syntax”](#).

`DELAYED` inserts and replaces were deprecated in MySQL 5.6.6. In MySQL 8.0, `DELAYED` is not supported. The server recognizes but ignores the `DELAYED` keyword, handles the replace as a nondelayed replace, and generates an `ER_WARN_LEGACY_SYNTAX_CONVERTED` warning. (“REPLACE DELAYED is no longer supported. The statement was converted to REPLACE.”) The `DELAYED` keyword will be removed in a future release.

Note

`REPLACE` makes sense only if a table has a `PRIMARY KEY` or `UNIQUE` index. Otherwise, it becomes equivalent to `INSERT`, because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values specified in the `REPLACE` statement. Any missing columns are set to their default values, just as happens for `INSERT`. You cannot refer to values from the current row and use them in the new row. If you use an assignment such as `SET col_name = col_name + 1`, the reference to the column name on the right hand side is treated as `DEFAULT(col_name)`, so the assignment is equivalent to `SET col_name = DEFAULT(col_name) + 1`.

If a generated column is replaced explicitly, the only permitted value is `DEFAULT`. For information about generated columns, see [Section 13.1.15.8, “CREATE TABLE and Generated Columns”](#).

To use `REPLACE`, you must have both the `INSERT` and `DELETE` privileges for the table.

`REPLACE` supports explicit partition selection using the `PARTITION` keyword with a comma-separated list of names of partitions, subpartitions, or both. As with `INSERT`, if it is not possible to insert the new row into any of these partitions or subpartitions, the `REPLACE` statement fails with the error `Found a row not matching the given partition set`. See [Section 22.5, “Partition Selection”](#), for more information.

The `REPLACE` statement returns a count to indicate the number of rows affected. This is the sum of the rows deleted and inserted. If the count is 1 for a single-row `REPLACE`, a row was inserted and no rows were deleted. If the count is greater than 1, one or more old rows were deleted before the new row was inserted. It is possible for a single row to replace more than one old row if the table contains multiple unique indexes and the new row duplicates values for different old rows in different unique indexes.

The affected-rows count makes it easy to determine whether `REPLACE` only added a row or whether it also replaced any rows: Check whether the count is 1 (added) or greater (replaced).

If you are using the C API, the affected-rows count can be obtained using the `mysql_affected_rows()` function.

You cannot replace into a table and select from the same table in a subquery.

MySQL uses the following algorithm for `REPLACE` (and `LOAD DATA ... REPLACE`):

1. Try to insert the new row into the table
2. While the insertion fails because a duplicate-key error occurs for a primary key or unique index:
 - a. Delete from the table the conflicting row that has the duplicate key value
 - b. Try again to insert the new row into the table

It is possible that in the case of a duplicate-key error, a storage engine may perform the `REPLACE` as an update rather than a delete plus insert, but the semantics are the same. There are no user-visible effects other than a possible difference in how the storage engine increments `Handler_xxx` status variables.

Because the results of `REPLACE ... SELECT` statements depend on the ordering of rows from the `SELECT` and this order cannot always be guaranteed, it is possible when logging these statements for the master and the slave to diverge. For this reason, `REPLACE ... SELECT` statements are flagged as unsafe for statement-based replication. With this change, such statements produce a warning in the log when using the `STATEMENT` binary logging mode, and are logged using the row-based format when using `MIXED` mode. See also [Section 18.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

When modifying an existing table that is not partitioned to accommodate partitioning, or, when modifying the partitioning of an already partitioned table, you may consider altering the table's primary key (see [Section 22.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#)). You should be aware that, if you do this, the results of `REPLACE` statements may be affected, just as they would be if you modified the primary key of a nonpartitioned table. Consider the table created by the following `CREATE TABLE` statement:

```
CREATE TABLE test (
  id INT UNSIGNED NOT NULL AUTO_INCREMENT,
  data VARCHAR(64) DEFAULT NULL,
  ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  PRIMARY KEY (id)
);
```

When we create this table and run the statements shown in the mysql client, the result is as follows:

```
mysql> REPLACE INTO test VALUES (1, 'Old', '2014-08-20 18:47:00');
Query OK, 1 row affected (0.04 sec)

mysql> REPLACE INTO test VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 2 rows affected (0.04 sec)

mysql> SELECT * FROM test;
+----+-----+-----+
| id | data | ts                |
+----+-----+-----+
|  1 | New  | 2014-08-20 18:47:42 |
+----+-----+-----+
1 row in set (0.00 sec)
```

Now we create a second table almost identical to the first, except that the primary key now covers 2 columns, as shown here (emphasized text):

```
CREATE TABLE test2 (
  id INT UNSIGNED NOT NULL AUTO_INCREMENT,
  data VARCHAR(64) DEFAULT NULL,
  ts TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
  PRIMARY KEY (id, ts)
);
```

When we run on `test2` the same two `REPLACE` statements as we did on the original `test` table, we obtain a different result:

```
mysql> REPLACE INTO test2 VALUES (1, 'Old', '2014-08-20 18:47:00');
Query OK, 1 row affected (0.05 sec)

mysql> REPLACE INTO test2 VALUES (1, 'New', '2014-08-20 18:47:42');
Query OK, 1 row affected (0.06 sec)

mysql> SELECT * FROM test2;
+----+-----+-----+
| id | data | ts                |
+----+-----+-----+
|  1 | Old  | 2014-08-20 18:47:00 |
|  1 | New  | 2014-08-20 18:47:42 |
+----+-----+-----+
2 rows in set (0.00 sec)
```

This is due to the fact that, when run on `test2`, both the `id` and `ts` column values must match those of an existing row for the row to be replaced; otherwise, a row is inserted.

In MySQL 8.0, a `REPLACE` statement affecting a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions containing rows that match the `REPLACE` statement's `WHERE` clause, as long as none of the table's partitioning columns are updated; otherwise the entire table is locked. (For storage engines such as `InnoDB` that employ row-level locking, no locking of partitions takes place.) For more information, see [Partitioning and Locking](#).

13.2.10 SELECT Syntax

```
SELECT
```

```

[ALL | DISTINCT | DISTINCTROW ]
  [HIGH_PRIORITY]
  [STRAIGHT_JOIN]
  [SQL_SMALL_RESULT] [SQL_BIG_RESULT] [SQL_BUFFER_RESULT]
  [SQL_CACHE | SQL_NO_CACHE] [SQL_CALC_FOUND_ROWS]
select_expr [, select_expr ...]
[FROM table_references
  [PARTITION partition_list]
[WHERE where_condition]
[GROUP BY {col_name | expr | position}
  [ASC | DESC], ... [WITH ROLLUP]]
[HAVING where_condition]
[WINDOW window_name AS (window_spec)
  [, window_name AS (window_spec)] ...]
[ORDER BY {col_name | expr | position}
  [ASC | DESC], ...]
[LIMIT {[offset,] row_count | row_count OFFSET offset}]
[INTO OUTFILE 'file_name'
  [CHARACTER SET charset_name]
  export_options
  | INTO DUMPFILE 'file_name'
  | INTO var_name [, var_name]]
[FOR UPDATE | LOCK IN SHARE MODE]]
[FOR {UPDATE | SHARE} [OF tbl_name [, tbl_name] ...] [NOWAIT | SKIP LOCKED]
  | LOCK IN SHARE MODE]]

```

SELECT is used to retrieve rows selected from one or more tables, and can include **UNION** statements and subqueries. See [Section 13.2.10.3, “UNION Syntax”](#), and [Section 13.2.11, “Subquery Syntax”](#). A **SELECT** statement can start with a **WITH** clause to define common table expressions accessible within the **SELECT**. See [Section 13.2.11.9, “WITH Syntax \(Common Table Expressions\)”](#).

The most commonly used clauses of **SELECT** statements are these:

- Each *select_expr* indicates a column that you want to retrieve. There must be at least one *select_expr*.
- *table_references* indicates the table or tables from which to retrieve rows. Its syntax is described in [Section 13.2.10.2, “JOIN Syntax”](#).
- **SELECT** supports explicit partition selection using the **PARTITION** with a list of partitions or subpartitions (or both) following the name of the table in a *table_reference* (see [Section 13.2.10.2, “JOIN Syntax”](#)). In this case, rows are selected only from the partitions listed, and any other partitions of the table are ignored. For more information and examples, see [Section 22.5, “Partition Selection”](#).

SELECT ... PARTITION from tables using storage engines such as **MyISAM** that perform table-level locks (and thus partition locks) lock only the partitions or subpartitions named by the **PARTITION** option.

See [Partitioning and Locking](#), for more information.

- The **WHERE** clause, if given, indicates the condition or conditions that rows must satisfy to be selected. *where_condition* is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no **WHERE** clause.

In the **WHERE** expression, you can use any of the functions and operators that MySQL supports, except for aggregate (summary) functions. See [Section 9.5, “Expression Syntax”](#), and [Chapter 12, Functions and Operators](#).

SELECT can also be used to retrieve rows computed without reference to any table.

For example:

```
mysql> SELECT 1 + 1;
```

```
-> 2
```

You are permitted to specify `DUAL` as a dummy table name in situations where no tables are referenced:

```
mysql> SELECT 1 + 1 FROM DUAL;
-> 2
```

`DUAL` is purely for the convenience of people who require that all `SELECT` statements should have `FROM` and possibly other clauses. MySQL may ignore the clauses. MySQL does not require `FROM DUAL` if no tables are referenced.

In general, clauses used must be given in exactly the order shown in the syntax description. For example, a `HAVING` clause must come after any `GROUP BY` clause and before any `ORDER BY` clause. The exception is that the `INTO` clause can appear either as shown in the syntax description or immediately following the `select_expr` list. For more information about `INTO`, see [Section 13.2.10.1, “SELECT ... INTO Syntax”](#).

The list of `select_expr` terms comprises the select list that indicates which columns to retrieve. Terms specify a column or expression or can use `*`-shorthand:

- A select list consisting only of a single unqualified `*` can be used as shorthand to select all columns from all tables:

```
SELECT * FROM t1 INNER JOIN t2 ...
```

- `tbl_name.*` can be used as a qualified shorthand to select all columns from the named table:

```
SELECT t1.*, t2.* FROM t1 INNER JOIN t2 ...
```

- Use of an unqualified `*` with other items in the select list may produce a parse error. To avoid this problem, use a qualified `tbl_name.*` reference

```
SELECT AVG(score), t1.* FROM t1 ...
```

The following list provides additional information about other `SELECT` clauses:

- A `select_expr` can be given an alias using `AS alias_name`. The alias is used as the expression's column name and can be used in `GROUP BY`, `ORDER BY`, or `HAVING` clauses. For example:

```
SELECT CONCAT(last_name, ' ', first_name) AS full_name
FROM mytable ORDER BY full_name;
```

The `AS` keyword is optional when aliasing a `select_expr` with an identifier. The preceding example could have been written like this:

```
SELECT CONCAT(last_name, ' ', first_name) full_name
FROM mytable ORDER BY full_name;
```

However, because the `AS` is optional, a subtle problem can occur if you forget the comma between two `select_expr` expressions: MySQL interprets the second as an alias name. For example, in the following statement, `columnb` is treated as an alias name:

```
SELECT columna columnb FROM mytable;
```

For this reason, it is good practice to be in the habit of using `AS` explicitly when specifying column aliases.

It is not permissible to refer to a column alias in a `WHERE` clause, because the column value might not yet be determined when the `WHERE` clause is executed. See [Section B.5.4.4, “Problems with Column Aliases”](#).

- The `FROM table_references` clause indicates the table or tables from which to retrieve rows. If you name more than one table, you are performing a join. For information on join syntax, see [Section 13.2.10.2, “JOIN Syntax”](#). For each table specified, you can optionally specify an alias.

```
tbl_name [[AS] alias] [index_hint]
```

The use of index hints provides the optimizer with information about how to choose indexes during query processing. For a description of the syntax for specifying these hints, see [Section 8.9.4, “Index Hints”](#).

You can use `SET max_seeks_for_key=value` as an alternative way to force MySQL to prefer key scans instead of table scans. See [Section 5.1.5, “Server System Variables”](#).

- You can refer to a table within the default database as `tbl_name`, or as `db_name.tbl_name` to specify a database explicitly. You can refer to a column as `col_name`, `tbl_name.col_name`, or `db_name.tbl_name.col_name`. You need not specify a `tbl_name` or `db_name.tbl_name` prefix for a column reference unless the reference would be ambiguous. See [Section 9.2.1, “Identifier Qualifiers”](#), for examples of ambiguity that require the more explicit column reference forms.
- A table reference can be aliased using `tbl_name AS alias_name` or `tbl_name alias_name:`

```
SELECT t1.name, t2.salary FROM employee AS t1, info AS t2
WHERE t1.name = t2.name;

SELECT t1.name, t2.salary FROM employee t1, info t2
WHERE t1.name = t2.name;
```

- Columns selected for output can be referred to in `ORDER BY` and `GROUP BY` clauses using column names, column aliases, or column positions. Column positions are integers and begin with 1:

```
SELECT college, region, seed FROM tournament
ORDER BY region, seed;

SELECT college, region AS r, seed AS s FROM tournament
ORDER BY r, s;

SELECT college, region, seed FROM tournament
ORDER BY 2, 3;
```

To sort in reverse order, add the `DESC` (descending) keyword to the name of the column in the `ORDER BY` clause that you are sorting by. The default is ascending order; this can be specified explicitly using the `ASC` keyword.

If `ORDER BY` occurs within a subquery and also is applied in the outer query, the outermost `ORDER BY` takes precedence. For example, results for the following statement are sorted in descending order, not ascending order:

```
(SELECT ... ORDER BY a) ORDER BY a DESC;
```

Use of column positions is deprecated because the syntax has been removed from the SQL standard.

- If you use `GROUP BY`, output rows are sorted according to the `GROUP BY` columns as if you had an `ORDER BY` for the same columns. To avoid the overhead of sorting that `GROUP BY` produces, add `ORDER BY NULL:`

```
SELECT a, COUNT(b) FROM test_table GROUP BY a ORDER BY NULL;
```

Previously, relying on implicit `GROUP BY` sorting was deprecated but `GROUP BY` did sort by default (that is, in the absence of `ASC` or `DESC` designators). In MySQL 8.0, `GROUP BY` no longer sorts by default, so query results may differ from previous MySQL versions. To produce a given sort order, use explicit `ASC` or `DESC` designators for `GROUP BY` columns or provide an `ORDER BY` clause.

- When you use `ORDER BY` or `GROUP BY` to sort a column in a `SELECT`, the server sorts values using only the initial number of bytes indicated by the `max_sort_length` system variable.
- MySQL extends the `GROUP BY` clause so that you can also specify `ASC` and `DESC` after columns named in the clause:

```
SELECT a, COUNT(b) FROM test_table GROUP BY a DESC;
```

- MySQL extends the use of `GROUP BY` to permit selecting fields that are not mentioned in the `GROUP BY` clause. If you are not getting the results that you expect from your query, please read the description of `GROUP BY` found in [Section 12.18, “Aggregate \(GROUP BY\) Functions”](#).
- `GROUP BY` permits a `WITH ROLLUP` modifier. See [Section 12.18.2, “GROUP BY Modifiers”](#).
- The `HAVING` clause is applied nearly last, just before items are sent to the client, with no optimization. (`LIMIT` is applied after `HAVING`.)

The SQL standard requires that `HAVING` must reference only columns in the `GROUP BY` clause or columns used in aggregate functions. However, MySQL supports an extension to this behavior, and permits `HAVING` to refer to columns in the `SELECT` list and columns in outer subqueries as well.

If the `HAVING` clause refers to a column that is ambiguous, a warning occurs. In the following statement, `col2` is ambiguous because it is used as both an alias and a column name:

```
SELECT COUNT(col1) AS col2 FROM t GROUP BY col2 HAVING col2 = 2;
```

Preference is given to standard SQL behavior, so if a `HAVING` column name is used both in `GROUP BY` and as an aliased column in the output column list, preference is given to the column in the `GROUP BY` column.

- Do not use `HAVING` for items that should be in the `WHERE` clause. For example, do not write the following:

```
SELECT col_name FROM tbl_name HAVING col_name > 0;
```

Write this instead:

```
SELECT col_name FROM tbl_name WHERE col_name > 0;
```

- The `HAVING` clause can refer to aggregate functions, which the `WHERE` clause cannot:

```
SELECT user, MAX(salary) FROM users
GROUP BY user HAVING MAX(salary) > 10;
```

(This did not work in some older versions of MySQL.)

- MySQL permits duplicate column names. That is, there can be more than one `select_expr` with the same name. This is an extension to standard SQL. Because MySQL also permits `GROUP BY` and `HAVING` to refer to `select_expr` values, this can result in an ambiguity:

```
SELECT 12 AS a, a FROM t GROUP BY a;
```

In that statement, both columns have the name `a`. To ensure that the correct column is used for grouping, use different names for each `select_expr`.

- The `WINDOW` clause, if present, defines named windows that can be referred to by window functions. For details, see [Section 12.19.4, “Named Windows”](#).
- MySQL resolves unqualified column or alias references in `ORDER BY` clauses by searching in the `select_expr` values, then in the columns of the tables in the `FROM` clause. For `GROUP BY` or `HAVING` clauses, it searches the `FROM` clause before searching in the `select_expr` values. (For `GROUP BY` and `HAVING`, this differs from the pre-MySQL 5.0 behavior that used the same rules as for `ORDER BY`.)
- The `LIMIT` clause can be used to constrain the number of rows returned by the `SELECT` statement. `LIMIT` takes one or two numeric arguments, which must both be nonnegative integer constants, with these exceptions:
 - Within prepared statements, `LIMIT` parameters can be specified using `?` placeholder markers.
 - Within stored programs, `LIMIT` parameters can be specified using integer-valued routine parameters or local variables.

With two arguments, the first argument specifies the offset of the first row to return, and the second specifies the maximum number of rows to return. The offset of the initial row is 0 (not 1):

```
SELECT * FROM tbl LIMIT 5,10; # Retrieve rows 6-15
```

To retrieve all rows from a certain offset up to the end of the result set, you can use some large number for the second parameter. This statement retrieves all rows from the 96th row to the last:

```
SELECT * FROM tbl LIMIT 95,18446744073709551615;
```

With one argument, the value specifies the number of rows to return from the beginning of the result set:

```
SELECT * FROM tbl LIMIT 5; # Retrieve first 5 rows
```

In other words, `LIMIT row_count` is equivalent to `LIMIT 0, row_count`.

For prepared statements, you can use placeholders. The following statements will return one row from the `tbl` table:

```
SET @a=1;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?';
EXECUTE STMT USING @a;
```

The following statements will return the second to sixth row from the `tbl` table:

```
SET @skip=1; SET @numrows=5;
PREPARE STMT FROM 'SELECT * FROM tbl LIMIT ?, ?';
EXECUTE STMT USING @skip, @numrows;
```

For compatibility with PostgreSQL, MySQL also supports the `LIMIT row_count OFFSET offset` syntax.

If `LIMIT` occurs within a subquery and also is applied in the outer query, the outermost `LIMIT` takes precedence. For example, the following statement produces two rows, not one:

```
(SELECT ... LIMIT 1) LIMIT 2;
```

- The `SELECT ... INTO` form of `SELECT` enables the query result to be written to a file or stored in variables. For more information, see [Section 13.2.10.1, “SELECT ... INTO Syntax”](#).
- If you use `FOR UPDATE` with a storage engine that uses page or row locks, rows examined by the query are write-locked until the end of the current transaction.

You cannot use `FOR UPDATE` as part of the `SELECT` in a statement such as `CREATE TABLE new_table SELECT ... FROM old_table ...` (If you attempt to do so, the statement is rejected with the error `Can't update table 'old_table' while 'new_table' is being created.`)

`FOR SHARE` and `LOCK IN SHARE MODE` set shared locks that permit other transactions to read the examined rows but not to update or delete them. `FOR SHARE` and `LOCK IN SHARE MODE` are equivalent. However, `FOR SHARE`, like `FOR UPDATE`, supports `NOWAIT`, `SKIP LOCKED`, and `OF tbl_name` options. `FOR SHARE` is a replacement for `LOCK IN SHARE MODE`, but `LOCK IN SHARE MODE` remains available for backward compatibility.

`NOWAIT` causes a `FOR UPDATE` or `FOR SHARE` query to execute immediately, returning an error if a row lock cannot be obtained due to a lock held by another transaction.

`SKIP LOCKED` causes a `FOR UPDATE` or `FOR SHARE` query to execute immediately, excluding rows from the result set that are locked by another transaction.

`NOWAIT` and `SKIP LOCKED` options are unsafe for statement-based replication.

Note

Queries that skip locked rows return an inconsistent view of the data. `SKIP LOCKED` is therefore not suitable for general transactional work. However, it may be used to avoid lock contention when multiple sessions access the same queue-like table.

`OF tbl_name` applies `FOR UPDATE` and `FOR SHARE` queries to named tables. For example:

```
SELECT * FROM t1, t2 FOR SHARE OF t1 FOR UPDATE OF t2;
```

All tables referenced by the query block are locked when `OF tbl_name` is omitted. Consequently, using a locking clause without `OF tbl_name` in combination with another locking clause returns an error. Specifying the same table in multiple locking clauses returns an error. If an alias is specified as the table name in the `SELECT` statement, a locking clause may only use the alias. If the `SELECT` statement does not specify an alias explicitly, the locking clause may only specify the actual table name.

For more information about `FOR UPDATE` and `FOR SHARE`, see [Section 15.5.2.4, “Locking Reads”](#). For additional information about `NOWAIT` and `SKIP LOCKED` options, see [Locking Read Concurrency with NOWAIT and SKIP LOCKED](#).

Following the `SELECT` keyword, you can use a number of modifiers that affect the operation of the statement. `HIGH_PRIORITY`, `STRAIGHT_JOIN`, and modifiers beginning with `SQL_` are MySQL extensions to standard SQL.

- The `ALL` and `DISTINCT` modifiers specify whether duplicate rows should be returned. `ALL` (the default) specifies that all matching rows should be returned, including duplicates. `DISTINCT` specifies removal of duplicate rows from the result set. It is an error to specify both modifiers. `DISTINCTROW` is a synonym for `DISTINCT`.
- `HIGH_PRIORITY` gives the `SELECT` higher priority than a statement that updates a table. You should use this only for queries that are very fast and must be done at once. A `SELECT HIGH_PRIORITY` query that is issued while the table is locked for reading runs even if there is an update statement

waiting for the table to be free. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).

`HIGH_PRIORITY` cannot be used with `SELECT` statements that are part of a `UNION`.

- `STRAIGHT_JOIN` forces the optimizer to join the tables in the order in which they are listed in the `FROM` clause. You can use this to speed up a query if the optimizer joins the tables in nonoptimal order. `STRAIGHT_JOIN` also can be used in the `table_references` list. See [Section 13.2.10.2, “JOIN Syntax”](#).

`STRAIGHT_JOIN` does not apply to any table that the optimizer treats as a `const` or `system` table. Such a table produces a single row, is read during the optimization phase of query execution, and references to its columns are replaced with the appropriate column values before query execution proceeds. These tables will appear first in the query plan displayed by `EXPLAIN`. See [Section 8.8.1, “Optimizing Queries with EXPLAIN”](#). This exception may not apply to `const` or `system` tables that are used on the `NULL`-complemented side of an outer join (that is, the right-side table of a `LEFT JOIN` or the left-side table of a `RIGHT JOIN`).

- `SQL_BIG_RESULT` or `SQL_SMALL_RESULT` can be used with `GROUP BY` or `DISTINCT` to tell the optimizer that the result set has many rows or is small, respectively. For `SQL_BIG_RESULT`, MySQL directly uses disk-based temporary tables if needed, and prefers sorting to using a temporary table with a key on the `GROUP BY` elements. For `SQL_SMALL_RESULT`, MySQL uses fast temporary tables to store the resulting table instead of using sorting. This should not normally be needed.
- `SQL_BUFFER_RESULT` forces the result to be put into a temporary table. This helps MySQL free the table locks early and helps in cases where it takes a long time to send the result set to the client. This modifier can be used only for top-level `SELECT` statements, not for subqueries or following `UNION`.
- `SQL_CALC_FOUND_ROWS` tells MySQL to calculate how many rows there would be in the result set, disregarding any `LIMIT` clause. The number of rows can then be retrieved with `SELECT FOUND_ROWS()`. See [Section 12.14, “Information Functions”](#).
- The `SQL_CACHE` and `SQL_NO_CACHE` modifiers affect caching of query results in the query cache (see [Section 8.10.3, “The MySQL Query Cache”](#)). `SQL_CACHE` tells MySQL to store the result in the query cache if it is cacheable and the value of the `query_cache_type` system variable is `2` or `DEMAND`. With `SQL_NO_CACHE`, the server does not use the query cache. It neither checks the query cache to see whether the result is already cached, nor does it cache the query result.

These two modifiers are mutually exclusive and an error occurs if they are both specified. Also, these modifiers are not permitted in subqueries (including subqueries in the `FROM` clause), and `SELECT` statements in unions other than the first `SELECT`.

For views, `SQL_NO_CACHE` applies if it appears in any `SELECT` in the query. For a cacheable query, `SQL_CACHE` applies if it appears in the first `SELECT` of a view referred to by the query.

In MySQL 8.0, a `SELECT` from a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions containing rows that match the `SELECT` statement's `WHERE` clause. (This does not occur with storage engines such as `InnoDB` that employ row-level locking.) For more information, see [Partitioning and Locking](#).

13.2.10.1 SELECT ... INTO Syntax

The `SELECT ... INTO` form of `SELECT` enables a query result to be stored in variables or written to a file:

- `SELECT ... INTO var_list` selects column values and stores them into variables.
- `SELECT ... INTO OUTFILE` writes the selected rows to a file. Column and line terminators can be specified to produce a specific output format.

- `SELECT ... INTO DUMPFILE` writes a single row to a file without any formatting.

The `SELECT` syntax description (see [Section 13.2.10, “SELECT Syntax”](#)) shows the `INTO` clause near the end of the statement. It is also possible to use `INTO` immediately following the `select_expr` list.

An `INTO` clause should not be used in a nested `SELECT` because such a `SELECT` must return its result to the outer context.

The `INTO` clause can name a list of one or more variables, which can be user-defined variables, stored procedure or function parameters, or stored program local variables. (Within a prepared `SELECT ... INTO OUTFILE` statement, only user-defined variables are permitted; see [Section 13.6.4.2, “Local Variable Scope and Resolution”](#).)

The selected values are assigned to the variables. The number of variables must match the number of columns. The query should return a single row. If the query returns no rows, a warning with error code 1329 occurs (`No data`), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (`Result consisted of more than one row`). If it is possible that the statement may retrieve multiple rows, you can use `LIMIT 1` to limit the result set to a single row.

```
SELECT id, data INTO @x, @y FROM test.t1 LIMIT 1;
```

User variable names are not case sensitive. See [Section 9.4, “User-Defined Variables”](#).

The `SELECT ... INTO OUTFILE 'file_name'` form of `SELECT` writes the selected rows to a file. The file is created on the server host, so you must have the `FILE` privilege to use this syntax. `file_name` cannot be an existing file, which among other things prevents files such as `/etc/passwd` and database tables from being destroyed. The `character_set_filesystem` system variable controls the interpretation of the file name.

The `SELECT ... INTO OUTFILE` statement is intended primarily to let you very quickly dump a table to a text file on the server machine. If you want to create the resulting file on some other host than the server host, you normally cannot use `SELECT ... INTO OUTFILE` since there is no way to write a path to the file relative to the server host's file system.

However, if the MySQL client software is installed on the remote machine, you can instead use a client command such as `mysql -e "SELECT ..." > file_name` to generate the file on the client host.

It is also possible to create the resulting file on a different host other than the server host, if the location of the file on the remote host can be accessed using a network-mapped path on the server's file system. In this case, the presence of `mysql` (or some other MySQL client program) is not required on the target host.

`SELECT ... INTO OUTFILE` is the complement of `LOAD DATA INFILE`. Column values are written converted to the character set specified in the `CHARACTER SET` clause. If no such clause is present, values are dumped using the `binary` character set. In effect, there is no character set conversion. If a result set contains columns in several character sets, the output data file will as well and you may not be able to reload the file correctly.

The syntax for the `export_options` part of the statement consists of the same `FIELDS` and `LINES` clauses that are used with the `LOAD DATA INFILE` statement. See [Section 13.2.7, “LOAD DATA INFILE Syntax”](#), for information about the `FIELDS` and `LINES` clauses, including their default values and permissible values.

`FIELDS ESCAPED BY` controls how to write special characters. If the `FIELDS ESCAPED BY` character is not empty, it is used when necessary to avoid ambiguity as a prefix that precedes following characters on output:

- The `FIELDS ESCAPED BY` character

- The `FIELDS [OPTIONALLY] ENCLOSED BY` character
- The first character of the `FIELDS TERMINATED BY` and `LINES TERMINATED BY` values
- ASCII `NUL` (the zero-valued byte; what is actually written following the escape character is ASCII 0, not a zero-valued byte)

The `FIELDS TERMINATED BY`, `ENCLOSED BY`, `ESCAPED BY`, or `LINES TERMINATED BY` characters *must* be escaped so that you can read the file back in reliably. ASCII `NUL` is escaped to make it easier to view with some pagers.

The resulting file does not have to conform to SQL syntax, so nothing else need be escaped.

If the `FIELDS ESCAPED BY` character is empty, no characters are escaped and `NULL` is output as `NULL`, not `\N`. It is probably not a good idea to specify an empty escape character, particularly if field values in your data contain any of the characters in the list just given.

Here is an example that produces a file in the comma-separated values (CSV) format used by many programs:

```
SELECT a,b,a+b INTO OUTFILE '/tmp/result.txt'
  FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
  LINES TERMINATED BY '\n'
FROM test_table;
```

If you use `INTO DUMPFILE` instead of `INTO OUTFILE`, MySQL writes only one row into the file, without any column or line termination and without performing any escape processing. This is useful if you want to store a `BLOB` value in a file.

Note

Any file created by `INTO OUTFILE` or `INTO DUMPFILE` is writable by all users on the server host. The reason for this is that the MySQL server cannot create a file that is owned by anyone other than the user under whose account it is running. (You should *never* run `mysqld` as `root` for this and other reasons.) The file thus must be world-writable so that you can manipulate its contents.

If the `secure_file_priv` system variable is set to a nonempty directory name, the file to be written must be located in that directory.

In the context of `SELECT ... INTO` statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For additional information, see [Section 23.4.5, “Event Scheduler Status”](#).

13.2.10.2 JOIN Syntax

MySQL supports the following `JOIN` syntax for the `table_references` part of `SELECT` statements and multiple-table `DELETE` and `UPDATE` statements:

```
table_references:
  escaped_table_reference [, escaped_table_reference] ...

escaped_table_reference:
  table_reference
  | { OJ table_reference }

table_reference:
  table_factor
```

```

| join_table

table_factor:
  tbl_name [PARTITION (partition_names)]
    [[AS] alias] [index_hint_list]
| table_subquery [AS] alias [(col_list)]
| ( table_references )

join_table:
  table_reference [INNER | CROSS] JOIN table_factor [join_condition]
| table_reference STRAIGHT_JOIN table_factor
| table_reference STRAIGHT_JOIN table_factor ON conditional_expr
| table_reference {LEFT|RIGHT} [OUTER] JOIN table_reference join_condition
| table_reference NATURAL [INNER | {LEFT|RIGHT} [OUTER]] JOIN table_factor

join_condition:
  ON conditional_expr
| USING (column_list)

index_hint_list:
  index_hint [, index_hint] ...

index_hint:
  USE {INDEX|KEY}
    [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)
| IGNORE {INDEX|KEY}
    [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)
| FORCE {INDEX|KEY}
    [FOR {JOIN|ORDER BY|GROUP BY}] (index_list)

index_list:
  index_name [, index_name] ...

```

A table reference is also known as a join expression.

A table reference (when it refers to a partitioned table) may contain a [PARTITION](#) option, including a comma-separated list of partitions, subpartitions, or both. This option follows the name of the table and precedes any alias declaration. The effect of this option is that rows are selected only from the listed partitions or subpartitions. Any partitions or subpartitions not named in the list are ignored. For more information, see [Section 22.5, “Partition Selection”](#).

The syntax of *table_factor* is extended in MySQL in comparison with standard SQL. The standard accepts only *table_reference*, not a list of them inside a pair of parentheses.

This is a conservative extension if each comma in a list of *table_reference* items is considered as equivalent to an inner join. For example:

```

SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
    ON (t2.a = t1.a AND t3.b = t1.b AND t4.c = t1.c)

```

is equivalent to:

```

SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
    ON (t2.a = t1.a AND t3.b = t1.b AND t4.c = t1.c)

```

In MySQL, [JOIN](#), [CROSS JOIN](#), and [INNER JOIN](#) are syntactic equivalents (they can replace each other). In standard SQL, they are not equivalent. [INNER JOIN](#) is used with an [ON](#) clause, [CROSS JOIN](#) is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. MySQL also supports nested joins. See [Section 8.2.1.7, “Nested Join Optimization”](#).

Index hints can be specified to affect how the MySQL optimizer makes use of indexes. For more information, see [Section 8.9.4, “Index Hints”](#). Optimizer hints and the [optimizer_switch](#) system

variable are other ways to influence optimizer use of indexes. See [Section 8.9.2, “Optimizer Hints”](#), and [Section 8.9.3, “Switchable Optimizations”](#).

The following list describes general factors to take into account when writing joins:

- A table reference can be aliased using `tbl_name AS alias_name` or `tbl_name alias_name`:

```
SELECT t1.name, t2.salary
  FROM employee AS t1 INNER JOIN info AS t2 ON t1.name = t2.name;

SELECT t1.name, t2.salary
  FROM employee t1 INNER JOIN info t2 ON t1.name = t2.name;
```

- A `table_subquery` is also known as a derived table or subquery in the `FROM` clause. See [Section 13.2.11.8, “Derived Tables \(Subqueries in the FROM Clause\)”](#). Such subqueries *must* include an alias to give the subquery result a table name, and may optionally include a list of table column names in parentheses. A trivial example follows:

```
SELECT * FROM (SELECT 1, 2, 3) AS t1;
```

- `INNER JOIN` and `,` (comma) are semantically equivalent in the absence of a join condition: both produce a Cartesian product between the specified tables (that is, each and every row in the first table is joined to each and every row in the second table).

However, the precedence of the comma operator is less than that of `INNER JOIN`, `CROSS JOIN`, `LEFT JOIN`, and so on. If you mix comma joins with the other join types when there is a join condition, an error of the form `Unknown column 'col_name' in 'on clause'` may occur. Information about dealing with this problem is given later in this section.

- The `conditional_expr` used with `ON` is any conditional expression of the form that can be used in a `WHERE` clause. Generally, the `ON` clause serves for conditions that specify how to join tables, and the `WHERE` clause restricts which rows to include in the result set.
- If there is no matching row for the right table in the `ON` or `USING` part in a `LEFT JOIN`, a row with all columns set to `NULL` is used for the right table. You can use this fact to find rows in a table that have no counterpart in another table:

```
SELECT left_tbl.*
  FROM left_tbl LEFT JOIN right_tbl ON left_tbl.id = right_tbl.id
 WHERE right_tbl.id IS NULL;
```

This example finds all rows in `left_tbl` with an `id` value that is not present in `right_tbl` (that is, all rows in `left_tbl` with no corresponding row in `right_tbl`). See [Section 8.2.1.8, “Left Join and Right Join Optimization”](#).

- The `USING(column_list)` clause names a list of columns that must exist in both tables. If tables `a` and `b` both contain columns `c1`, `c2`, and `c3`, the following join compares corresponding columns from the two tables:

```
a LEFT JOIN b USING (c1, c2, c3)
```

- The `NATURAL [LEFT] JOIN` of two tables is defined to be semantically equivalent to an `INNER JOIN` or a `LEFT JOIN` with a `USING` clause that names all columns that exist in both tables.
- `RIGHT JOIN` works analogously to `LEFT JOIN`. To keep code portable across databases, it is recommended that you use `LEFT JOIN` instead of `RIGHT JOIN`.
- The `{ OJ ... }` syntax shown in the join syntax description exists only for compatibility with ODBC. The curly braces in the syntax should be written literally; they are not metasyntax as used elsewhere in syntax descriptions.

```
SELECT left_tbl.*
   FROM { OJ left_tbl LEFT OUTER JOIN right_tbl ON left_tbl.id = right_tbl.id }
   WHERE right_tbl.id IS NULL;
```

You can use other types of joins within { OJ ... }, such as [INNER JOIN](#) or [RIGHT OUTER JOIN](#). This helps with compatibility with some third-party applications, but is not official ODBC syntax.

- [STRAIGHT_JOIN](#) is similar to [JOIN](#), except that the left table is always read before the right table. This can be used for those (few) cases for which the join optimizer processes the tables in a suboptimal order.

Some join examples:

```
SELECT * FROM table1, table2;

SELECT * FROM table1 INNER JOIN table2 ON table1.id = table2.id;

SELECT * FROM table1 LEFT JOIN table2 ON table1.id = table2.id;

SELECT * FROM table1 LEFT JOIN table2 USING (id);

SELECT * FROM table1 LEFT JOIN table2 ON table1.id = table2.id
   LEFT JOIN table3 ON table2.id = table3.id;
```

Natural joins and joins with [USING](#), including outer join variants, are processed according to the SQL:2003 standard:

- Redundant columns of a [NATURAL](#) join do not appear. Consider this set of statements:

```
CREATE TABLE t1 (i INT, j INT);
CREATE TABLE t2 (k INT, j INT);
INSERT INTO t1 VALUES(1, 1);
INSERT INTO t2 VALUES(1, 1);
SELECT * FROM t1 NATURAL JOIN t2;
SELECT * FROM t1 JOIN t2 USING (j);
```

In the first [SELECT](#) statement, column [j](#) appears in both tables and thus becomes a join column, so, according to standard SQL, it should appear only once in the output, not twice. Similarly, in the second [SELECT](#) statement, column [j](#) is named in the [USING](#) clause and should appear only once in the output, not twice.

Thus, the statements produce this output:

```
+-----+-----+-----+
| j    | i    | k    |
+-----+-----+-----+
|  1  |  1  |  1  |
+-----+-----+-----+
| j    | i    | k    |
+-----+-----+-----+
|  1  |  1  |  1  |
+-----+-----+-----+
```

Redundant column elimination and column ordering occurs according to standard SQL, producing this display order:

- First, coalesced common columns of the two joined tables, in the order in which they occur in the first table
- Second, columns unique to the first table, in order in which they occur in that table

- Third, columns unique to the second table, in order in which they occur in that table

The single result column that replaces two common columns is defined using the coalesce operation. That is, for two `t1.a` and `t2.a` the resulting single join column `a` is defined as `a = COALESCE(t1.a, t2.a)`, where:

```
COALESCE(x, y) = (CASE WHEN x IS NOT NULL THEN x ELSE y END)
```

If the join operation is any other join, the result columns of the join consist of the concatenation of all columns of the joined tables.

A consequence of the definition of coalesced columns is that, for outer joins, the coalesced column contains the value of the non-NULL column if one of the two columns is always NULL. If neither or both columns are NULL, both common columns have the same value, so it doesn't matter which one is chosen as the value of the coalesced column. A simple way to interpret this is to consider that a coalesced column of an outer join is represented by the common column of the inner table of a JOIN. Suppose that the tables `t1(a, b)` and `t2(a, c)` have the following contents:

```
t1      t2
----  ----
1 x    2 z
2 y    3 w
```

Then, for this join, column `a` contains the values of `t1.a`:

```
mysql> SELECT * FROM t1 NATURAL LEFT JOIN t2;
+-----+-----+-----+
| a     | b     | c     |
+-----+-----+-----+
| 1     | x     | NULL  |
| 2     | y     | z     |
+-----+-----+-----+
```

By contrast, for this join, column `a` contains the values of `t2.a`.

```
mysql> SELECT * FROM t1 NATURAL RIGHT JOIN t2;
+-----+-----+-----+
| a     | c     | b     |
+-----+-----+-----+
| 2     | z     | y     |
| 3     | w     | NULL  |
+-----+-----+-----+
```

Compare those results to the otherwise equivalent queries with `JOIN ... ON`:

```
mysql> SELECT * FROM t1 LEFT JOIN t2 ON (t1.a = t2.a);
+-----+-----+-----+-----+
| a     | b     | a     | c     |
+-----+-----+-----+-----+
| 1     | x     | NULL  | NULL  |
| 2     | y     | 2     | z     |
+-----+-----+-----+-----+
```

```
mysql> SELECT * FROM t1 RIGHT JOIN t2 ON (t1.a = t2.a);
+-----+-----+-----+-----+
| a     | b     | a     | c     |
+-----+-----+-----+-----+
| 2     | y     | 2     | z     |
| NULL  | NULL  | 3     | w     |
+-----+-----+-----+-----+
```

- A `USING` clause can be rewritten as an `ON` clause that compares corresponding columns. However, although `USING` and `ON` are similar, they are not quite the same. Consider the following two queries:

```
a LEFT JOIN b USING (c1, c2, c3)
a LEFT JOIN b ON a.c1 = b.c1 AND a.c2 = b.c2 AND a.c3 = b.c3
```

With respect to determining which rows satisfy the join condition, both joins are semantically identical.

With respect to determining which columns to display for `SELECT *` expansion, the two joins are not semantically identical. The `USING` join selects the coalesced value of corresponding columns, whereas the `ON` join selects all columns from all tables. For the `USING` join, `SELECT *` selects these values:

```
COALESCE(a.c1, b.c1), COALESCE(a.c2, b.c2), COALESCE(a.c3, b.c3)
```

For the `ON` join, `SELECT *` selects these values:

```
a.c1, a.c2, a.c3, b.c1, b.c2, b.c3
```

With an inner join, `COALESCE(a.c1, b.c1)` is the same as either `a.c1` or `b.c1` because both columns will have the same value. With an outer join (such as `LEFT JOIN`), one of the two columns can be `NULL`. That column is omitted from the result.

- An `ON` clause can refer only to its operands.

Example:

```
CREATE TABLE t1 (i1 INT);
CREATE TABLE t2 (i2 INT);
CREATE TABLE t3 (i3 INT);
SELECT * FROM t1 JOIN t2 ON (i1 = i3) JOIN t3;
```

The statement fails with an `Unknown column 'i3' in 'on clause'` error because `i3` is a column in `t3`, which is not an operand of the `ON` clause. To enable the join to be processed, rewrite the statement as follows:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (i1 = i3);
```

- `JOIN` has higher precedence than the comma operator (`,`), so the join expression `t1, t2 JOIN t3` is interpreted as `(t1, (t2 JOIN t3))`, not as `((t1, t2) JOIN t3)`. This affects statements that use an `ON` clause because that clause can refer only to columns in the operands of the join, and the precedence affects interpretation of what those operands are.

Example:

```
CREATE TABLE t1 (i1 INT, j1 INT);
CREATE TABLE t2 (i2 INT, j2 INT);
CREATE TABLE t3 (i3 INT, j3 INT);
INSERT INTO t1 VALUES(1, 1);
INSERT INTO t2 VALUES(1, 1);
INSERT INTO t3 VALUES(1, 1);
SELECT * FROM t1, t2 JOIN t3 ON (t1.i1 = t3.i3);
```

The `JOIN` takes precedence over the comma operator, so the operands for the `ON` clause are `t2` and `t3`. Because `t1.i1` is not a column in either of the operands, the result is an `Unknown column 't1.i1' in 'on clause'` error.

- Group the first two tables explicitly with parentheses so that the operands for the `ON` clause are `(t1, t2)` and `t3`:

```
SELECT * FROM (t1, t2) JOIN t3 ON (t1.i1 = t3.i3);
```

- Avoid the use of the comma operator and use `JOIN` instead:

```
SELECT * FROM t1 JOIN t2 JOIN t3 ON (t1.i1 = t3.i3);
```

The same precedence interpretation also applies to statements that mix the comma operator with `INNER JOIN`, `CROSS JOIN`, `LEFT JOIN`, and `RIGHT JOIN`, all of which have higher precedence than the comma operator.

- A MySQL extension compared to the SQL:2003 standard is that MySQL permits you to qualify the common (coalesced) columns of `NATURAL` or `USING` joins, whereas the standard disallows that.

13.2.10.3 UNION Syntax

```
SELECT ...
UNION [ALL | DISTINCT] SELECT ...
[UNION [ALL | DISTINCT] SELECT ...]
```

`UNION` is used to combine the result from multiple `SELECT` statements into a single result set.

The column names from the first `SELECT` statement are used as the column names for the results returned. Selected columns listed in corresponding positions of each `SELECT` statement should have the same data type. (For example, the first column selected by the first statement should have the same type as the first column selected by the other statements.)

If the data types of corresponding `SELECT` columns do not match, the types and lengths of the columns in the `UNION` result take into account the values retrieved by all of the `SELECT` statements. For example, consider the following:

```
mysql> SELECT REPEAT('a',1) UNION SELECT REPEAT('b',10);
+-----+
| REPEAT('a',1) |
+-----+
| a             |
| bbbbbbbbbbb  |
+-----+
```

The `SELECT` statements are normal select statements, but with the following restrictions:

- Only the last `SELECT` statement can use `INTO OUTFILE`. (However, the entire `UNION` result is written to the file.)
- `HIGH_PRIORITY` cannot be used with `SELECT` statements that are part of a `UNION`. If you specify it for the first `SELECT`, it has no effect. If you specify it for any subsequent `SELECT` statements, a syntax error results.

The default behavior for `UNION` is that duplicate rows are removed from the result. The optional `DISTINCT` keyword has no effect other than the default because it also specifies duplicate-row removal. With the optional `ALL` keyword, duplicate-row removal does not occur and the result includes all matching rows from all the `SELECT` statements.

You can mix `UNION ALL` and `UNION DISTINCT` in the same query. Mixed `UNION` types are treated such that a `DISTINCT` union overrides any `ALL` union to its left. A `DISTINCT` union can be produced explicitly by using `UNION DISTINCT` or implicitly by using `UNION` with no following `DISTINCT` or `ALL` keyword.

To apply `ORDER BY` or `LIMIT` to an individual `SELECT`, place the clause inside the parentheses that enclose the `SELECT`:

```
(SELECT a FROM t1 WHERE a=10 AND B=1 ORDER BY a LIMIT 10)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2 ORDER BY a LIMIT 10);
```

However, use of `ORDER BY` for individual `SELECT` statements implies nothing about the order in which the rows appear in the final result because `UNION` by default produces an unordered set of rows. Therefore, the use of `ORDER BY` in this context is typically in conjunction with `LIMIT`, so that it is used to determine the subset of the selected rows to retrieve for the `SELECT`, even though it does not necessarily affect the order of those rows in the final `UNION` result. If `ORDER BY` appears without `LIMIT` in a `SELECT`, it is optimized away because it will have no effect anyway.

To use an `ORDER BY` or `LIMIT` clause to sort or limit the entire `UNION` result, parenthesize the individual `SELECT` statements and place the `ORDER BY` or `LIMIT` after the last one. The following example uses both clauses:

```
(SELECT a FROM t1 WHERE a=10 AND B=1)
UNION
(SELECT a FROM t2 WHERE a=11 AND B=2)
ORDER BY a LIMIT 10;
```

A statement without parentheses is equivalent to one parenthesized as just shown.

This kind of `ORDER BY` cannot use column references that include a table name (that is, names in `tbl_name.col_name` format). Instead, provide a column alias in the first `SELECT` statement and refer to the alias in the `ORDER BY`. (Alternatively, refer to the column in the `ORDER BY` using its column position. However, use of column positions is deprecated.)

Also, if a column to be sorted is aliased, the `ORDER BY` clause *must* refer to the alias, not the column name. The first of the following statements will work, but the second will fail with an `Unknown column 'a' in 'order clause'` error:

```
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY b;
(SELECT a AS b FROM t) UNION (SELECT ...) ORDER BY a;
```

To cause rows in a `UNION` result to consist of the sets of rows retrieved by each `SELECT` one after the other, select an additional column in each `SELECT` to use as a sort column and add an `ORDER BY` following the last `SELECT`:

```
(SELECT 1 AS sort_col, colla, collb, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col;
```

To additionally maintain sort order within individual `SELECT` results, add a secondary column to the `ORDER BY` clause:

```
(SELECT 1 AS sort_col, colla, collb, ... FROM t1)
UNION
(SELECT 2, col2a, col2b, ... FROM t2) ORDER BY sort_col, colla;
```

Use of an additional column also enables you to determine which `SELECT` each row comes from. Extra columns can provide other identifying information as well, such as a string that indicates a table name.

`UNION` queries with an aggregate function in an `ORDER BY` clause are rejected with an `ER_AGGREGATE_ORDER_FOR_UNION` error. Example:

```
SELECT 1 AS foo UNION SELECT 2 ORDER BY MAX(1);
```

13.2.11 Subquery Syntax

A subquery is a `SELECT` statement within another statement.

All subquery forms and operations that the SQL standard requires are supported, as well as a few features that are MySQL-specific.

Here is an example of a subquery:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

In this example, `SELECT * FROM t1 ...` is the *outer query* (or *outer statement*), and `(SELECT column1 FROM t2)` is the *subquery*. We say that the subquery is *nested* within the outer query, and in fact it is possible to nest subqueries within other subqueries, to a considerable depth. A subquery must always appear within parentheses.

The main advantages of subqueries are:

- They allow queries that are *structured* so that it is possible to isolate each part of a statement.
- They provide alternative ways to perform operations that would otherwise require complex joins and unions.
- Many people find subqueries more readable than complex joins or unions. Indeed, it was the innovation of subqueries that gave people the original idea of calling the early SQL “Structured Query Language.”

Here is an example statement that shows the major points about subquery syntax as specified by the SQL standard and supported in MySQL:

```
DELETE FROM t1
WHERE s11 > ANY
  (SELECT COUNT(*) /* no hint */ FROM t2
   WHERE NOT EXISTS
    (SELECT * FROM t3
     WHERE ROW(5*t2.s1,77)=
      (SELECT 50,11*s1 FROM t4 UNION SELECT 50,77 FROM
       (SELECT * FROM t5) AS t5)));
```

A subquery can return a scalar (a single value), a single row, a single column, or a table (one or more rows of one or more columns). These are called scalar, column, row, and table subqueries. Subqueries that return a particular kind of result often can be used only in certain contexts, as described in the following sections.

There are few restrictions on the type of statements in which subqueries can be used. A subquery can contain many of the keywords or clauses that an ordinary `SELECT` can contain: `DISTINCT`, `GROUP BY`, `ORDER BY`, `LIMIT`, joins, index hints, `UNION` constructs, comments, functions, and so on.

A subquery's outer statement can be any one of: `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `SET`, or `DO`.

In MySQL, you cannot modify a table and select from the same table in a subquery. This applies to statements such as `DELETE`, `INSERT`, `REPLACE`, `UPDATE`, and (because subqueries can be used in the `SET` clause) `LOAD DATA INFILE`.

For information about how the optimizer handles subqueries, see [Section 8.2.2, “Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions”](#). For a discussion of restrictions on subquery use, including performance issues for certain forms of subquery syntax, see [Section C.4, “Restrictions on Subqueries”](#).

13.2.11.1 The Subquery as Scalar Operand

In its simplest form, a subquery is a scalar subquery that returns a single value. A scalar subquery is a simple operand, and you can use it almost anywhere a single column value or literal is legal, and you can expect it to have those characteristics that all operands have: a data type, a length, an indication that it can be `NULL`, and so on. For example:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5) NOT NULL);
INSERT INTO t1 VALUES(100, 'abcde');
SELECT (SELECT s2 FROM t1);
```

The subquery in this `SELECT` returns a single value (`'abcde'`) that has a data type of `CHAR`, a length of 5, a character set and collation equal to the defaults in effect at `CREATE TABLE` time, and an indication that the value in the column can be `NULL`. Nullability of the value selected by a scalar subquery is not copied because if the subquery result is empty, the result is `NULL`. For the subquery just shown, if `t1` were empty, the result would be `NULL` even though `s2` is `NOT NULL`.

There are a few contexts in which a scalar subquery cannot be used. If a statement permits only a literal value, you cannot use a subquery. For example, `LIMIT` requires literal integer arguments, and `LOAD DATA INFILE` requires a literal string file name. You cannot use subqueries to supply these values.

When you see examples in the following sections that contain the rather spartan construct (`SELECT column1 FROM t1`), imagine that your own code contains much more diverse and complex constructions.

Suppose that we make two tables:

```
CREATE TABLE t1 (s1 INT);
INSERT INTO t1 VALUES (1);
CREATE TABLE t2 (s1 INT);
INSERT INTO t2 VALUES (2);
```

Then perform a `SELECT`:

```
SELECT (SELECT s1 FROM t2) FROM t1;
```

The result is `2` because there is a row in `t2` containing a column `s1` that has a value of `2`.

A scalar subquery can be part of an expression, but remember the parentheses, even if the subquery is an operand that provides an argument for a function. For example:

```
SELECT UPPER((SELECT s1 FROM t1)) FROM t2;
```

13.2.11.2 Comparisons Using Subqueries

The most common use of a subquery is in the form:

```
non_subquery_operand comparison_operator (subquery)
```

Where *comparison_operator* is one of these operators:

```
= > < >= <= <> != <=>
```

For example:

```
... WHERE 'a' = (SELECT column1 FROM t1)
```

MySQL also permits this construct:

```
non_subquery_operand LIKE (subquery)
```

At one time the only legal place for a subquery was on the right side of a comparison, and you might still find some old DBMSs that insist on this.

Here is an example of a common-form subquery comparison that you cannot do with a join. It finds all the rows in table `t1` for which the `column1` value is equal to a maximum value in table `t2`:

```
SELECT * FROM t1
WHERE column1 = (SELECT MAX(column2) FROM t2);
```

Here is another example, which again is impossible with a join because it involves aggregating for one of the tables. It finds all rows in table `t1` containing a value that occurs twice in a given column:

```
SELECT * FROM t1 AS t
WHERE 2 = (SELECT COUNT(*) FROM t1 WHERE t1.id = t.id);
```

For a comparison of the subquery to a scalar, the subquery must return a scalar. For a comparison of the subquery to a row constructor, the subquery must be a row subquery that returns a row with the same number of values as the row constructor. See [Section 13.2.11.5, “Row Subqueries”](#).

13.2.11.3 Subqueries with ANY, IN, or SOME

Syntax:

```
operand comparison_operator ANY (subquery)
operand IN (subquery)
operand comparison_operator SOME (subquery)
```

Where *comparison_operator* is one of these operators:

```
= > < >= <= <> !=
```

The `ANY` keyword, which must follow a comparison operator, means “return `TRUE` if the comparison is `TRUE` for `ANY` of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ANY (SELECT s1 FROM t2);
```

Suppose that there is a row in table `t1` containing `(10)`. The expression is `TRUE` if table `t2` contains `(21,14,7)` because there is a value `7` in `t2` that is less than `10`. The expression is `FALSE` if table `t2` contains `(20,10)`, or if table `t2` is empty. The expression is *unknown* (that is, `NULL`) if table `t2` contains `(NULL,NULL,NULL)`.

When used with a subquery, the word `IN` is an alias for `= ANY`. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 = ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 IN (SELECT s1 FROM t2);
```

`IN` and `= ANY` are not synonyms when used with an expression list. `IN` can take an expression list, but `= ANY` cannot. See [Section 12.3.2, “Comparison Functions and Operators”](#).

`NOT IN` is not an alias for `<> ANY`, but for `<> ALL`. See [Section 13.2.11.4, “Subqueries with ALL”](#).

The word `SOME` is an alias for `ANY`. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ANY (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 <> SOME (SELECT s1 FROM t2);
```

Use of the word **SOME** is rare, but this example shows why it might be useful. To most people, the English phrase “a is not equal to any b” means “there is no b which is equal to a,” but that is not what is meant by the SQL syntax. The syntax means “there is some b to which a is not equal.” Using **<> SOME** instead helps ensure that everyone understands the true meaning of the query.

13.2.11.4 Subqueries with ALL

Syntax:

```
operand comparison_operator ALL (subquery)
```

The word **ALL**, which must follow a comparison operator, means “return **TRUE** if the comparison is **TRUE** for **ALL** of the values in the column that the subquery returns.” For example:

```
SELECT s1 FROM t1 WHERE s1 > ALL (SELECT s1 FROM t2);
```

Suppose that there is a row in table **t1** containing (10). The expression is **TRUE** if table **t2** contains (-5, 0, +5) because 10 is greater than all three values in **t2**. The expression is **FALSE** if table **t2** contains (12, 6, NULL, -100) because there is a single value 12 in table **t2** that is greater than 10. The expression is *unknown* (that is, **NULL**) if table **t2** contains (0, NULL, 1).

Finally, the expression is **TRUE** if table **t2** is empty. So, the following expression is **TRUE** when table **t2** is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT s1 FROM t2);
```

But this expression is **NULL** when table **t2** is empty:

```
SELECT * FROM t1 WHERE 1 > (SELECT s1 FROM t2);
```

In addition, the following expression is **NULL** when table **t2** is empty:

```
SELECT * FROM t1 WHERE 1 > ALL (SELECT MAX(s1) FROM t2);
```

In general, *tables containing NULL values* and *empty tables* are “edge cases.” When writing subqueries, always consider whether you have taken those two possibilities into account.

NOT IN is an alias for **<> ALL**. Thus, these two statements are the same:

```
SELECT s1 FROM t1 WHERE s1 <> ALL (SELECT s1 FROM t2);
SELECT s1 FROM t1 WHERE s1 NOT IN (SELECT s1 FROM t2);
```

13.2.11.5 Row Subqueries

Scalar or column subqueries return a single value or a column of values. A *row subquery* is a subquery variant that returns a single row and can thus return more than one column value. Legal operators for row subquery comparisons are:

```
= > < >= <= <> != <=>
```

Here are two examples:

```
SELECT * FROM t1
WHERE (col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
SELECT * FROM t1
WHERE ROW(col1,col2) = (SELECT col3, col4 FROM t2 WHERE id = 10);
```

For both queries, if the table `t2` contains a single row with `id = 10`, the subquery returns a single row. If this row has `col3` and `col4` values equal to the `col1` and `col2` values of any rows in `t1`, the `WHERE` expression is `TRUE` and each query returns those `t1` rows. If the `t2` row `col3` and `col4` values are not equal the `col1` and `col2` values of any `t1` row, the expression is `FALSE` and the query returns an empty result set. The expression is *unknown* (that is, `NULL`) if the subquery produces no rows. An error occurs if the subquery produces multiple rows because a row subquery can return at most one row.

For information about how each operator works for row comparisons, see [Section 12.3.2, “Comparison Functions and Operators”](#).

The expressions `(1,2)` and `ROW(1,2)` are sometimes called *row constructors*. The two are equivalent. The row constructor and the row returned by the subquery must contain the same number of values.

A row constructor is used for comparisons with subqueries that return two or more columns. When a subquery returns a single column, this is regarded as a scalar value and not as a row, so a row constructor cannot be used with a subquery that does not return at least two columns. Thus, the following query fails with a syntax error:

```
SELECT * FROM t1 WHERE ROW(1) = (SELECT column1 FROM t2)
```

Row constructors are legal in other contexts. For example, the following two statements are semantically equivalent (and are handled in the same way by the optimizer):

```
SELECT * FROM t1 WHERE (column1,column2) = (1,1);
SELECT * FROM t1 WHERE column1 = 1 AND column2 = 1;
```

The following query answers the request, “find all rows in table `t1` that also exist in table `t2`”:

```
SELECT column1,column2,column3
FROM t1
WHERE (column1,column2,column3) IN
      (SELECT column1,column2,column3 FROM t2);
```

For more information about the optimizer and row constructors, see [Section 8.2.1.19, “Row Constructor Expression Optimization”](#)

13.2.11.6 Subqueries with EXISTS or NOT EXISTS

If a subquery returns any rows at all, `EXISTS subquery` is `TRUE`, and `NOT EXISTS subquery` is `FALSE`. For example:

```
SELECT column1 FROM t1 WHERE EXISTS (SELECT * FROM t2);
```

Traditionally, an `EXISTS` subquery starts with `SELECT *`, but it could begin with `SELECT 5` or `SELECT column1` or anything at all. MySQL ignores the `SELECT` list in such a subquery, so it makes no difference.

For the preceding example, if `t2` contains any rows, even rows with nothing but `NULL` values, the `EXISTS` condition is `TRUE`. This is actually an unlikely example because a `[NOT] EXISTS` subquery almost always contains correlations. Here are some more realistic examples:

- What kind of store is present in one or more cities?

```
SELECT DISTINCT store_type FROM stores
WHERE EXISTS (SELECT * FROM cities_stores
              WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in no cities?

```
SELECT DISTINCT store_type FROM stores
WHERE NOT EXISTS (SELECT * FROM cities_stores
                  WHERE cities_stores.store_type = stores.store_type);
```

- What kind of store is present in all cities?

```
SELECT DISTINCT store_type FROM stores s1
WHERE NOT EXISTS (
  SELECT * FROM cities WHERE NOT EXISTS (
    SELECT * FROM cities_stores
    WHERE cities_stores.city = cities.city
    AND cities_stores.store_type = stores.store_type));
```

The last example is a double-nested `NOT EXISTS` query. That is, it has a `NOT EXISTS` clause within a `NOT EXISTS` clause. Formally, it answers the question “does a city exist with a store that is not in *Stores*”? But it is easier to say that a nested `NOT EXISTS` answers the question “is *x* `TRUE` for all *y*?”

13.2.11.7 Correlated Subqueries

A *correlated subquery* is a subquery that contains a reference to a table that also appears in the outer query. For example:

```
SELECT * FROM t1
WHERE column1 = ANY (SELECT column1 FROM t2
                    WHERE t2.column2 = t1.column2);
```

Notice that the subquery contains a reference to a column of `t1`, even though the subquery's `FROM` clause does not mention a table `t1`. So, MySQL looks outside the subquery, and finds `t1` in the outer query.

Suppose that table `t1` contains a row where `column1 = 5` and `column2 = 6`; meanwhile, table `t2` contains a row where `column1 = 5` and `column2 = 7`. The simple expression `... WHERE column1 = ANY (SELECT column1 FROM t2)` would be `TRUE`, but in this example, the `WHERE` clause within the subquery is `FALSE` (because `(5,6)` is not equal to `(5,7)`), so the expression as a whole is `FALSE`.

Scoping rule: MySQL evaluates from inside to outside. For example:

```
SELECT column1 FROM t1 AS x
WHERE x.column1 = (SELECT column1 FROM t2 AS x
                  WHERE x.column1 = (SELECT column1 FROM t3
                                    WHERE x.column2 = t3.column1));
```

In this statement, `x.column2` must be a column in table `t2` because `SELECT column1 FROM t2 AS x ...` renames `t2`. It is not a column in table `t1` because `SELECT column1 FROM t1 ...` is an outer query that is *farther out*.

For subqueries in `HAVING` or `ORDER BY` clauses, MySQL also looks for column names in the outer select list.

For certain cases, a correlated subquery is optimized. For example:

```
val IN (SELECT key_val FROM tbl_name WHERE correlated_condition)
```

Otherwise, they are inefficient and likely to be slow. Rewriting the query as a join might improve performance.

Aggregate functions in correlated subqueries may contain outer references, provided the function contains nothing but outer references, and provided the function is not contained in another function or expression.

13.2.11.8 Derived Tables (Subqueries in the FROM Clause)

A derived table is a subquery in a `SELECT` statement `FROM` clause:

```
SELECT ... FROM (subquery) [AS] tbl_name ...
```

The `[AS] tbl_name` clause is mandatory because every table in a `FROM` clause must have a name. Any columns in the `subquery` select list must have unique names. Alternatively, `tbl_name` may be followed by a parenthesized list of names for the derived table columns:

```
SELECT ... FROM (subquery) [AS] tbl_name (col_list) ...
```

The number of names must be the same as the number of table columns.

For the sake of illustration, assume that you have this table:

```
CREATE TABLE t1 (s1 INT, s2 CHAR(5), s3 FLOAT);
```

Here is how to use a subquery in the `FROM` clause, using the example table:

```
INSERT INTO t1 VALUES (1,'1',1.0);
INSERT INTO t1 VALUES (2,'2',2.0);
SELECT sb1,sb2,sb3
  FROM (SELECT s1 AS sb1, s2 AS sb2, s3*2 AS sb3 FROM t1) AS sb
 WHERE sb1 > 1;
```

Result: 2, '2', 4.0.

Here is another example: Suppose that you want to know the average of a set of sums for a grouped table. This does not work:

```
SELECT AVG(SUM(column1)) FROM t1 GROUP BY column1;
```

However, this query provides the desired information:

```
SELECT AVG(sum_column1)
  FROM (SELECT SUM(column1) AS sum_column1
        FROM t1 GROUP BY column1) AS t1;
```

Notice that the column name used within the subquery (`sum_column1`) is recognized in the outer query.

The column names for this derived table come from its select list:

```
mysql> SELECT * FROM (SELECT 1, 2, 3, 4) AS dt;
+----+----+----+----+
| 1  | 2  | 3  | 4  |
+----+----+----+----+
```

```
| 1 | 2 | 3 | 4 |
+---+---+---+---+
```

To provide column names, follow the derived table name with a parenthesized list of column names:

```
mysql> SELECT * FROM (SELECT 1, 2, 3, 4) AS dt (a, b, c, d);
+---+---+---+---+
| a | b | c | d |
+---+---+---+---+
| 1 | 2 | 3 | 4 |
+---+---+---+---+
```

Derived tables can return a scalar, column, row, or table.

Derived tables cannot be correlated subqueries, or contain outer references or references to other tables of the same `SELECT`.

The optimizer determines information about derived tables in such a way that materialization of them does not occur for `EXPLAIN`. See [Section 8.2.2.3, “Optimizing Derived Tables, View References, and Common Table Expressions”](#).

It is possible under certain circumstances that using `EXPLAIN SELECT` will modify table data. This can occur if the outer query accesses any tables and an inner query invokes a stored function that changes one or more rows of a table. Suppose that there are two tables `t1` and `t2` in database `d1`, and a stored function `f1` that modifies `t2`, created as shown here:

```
CREATE DATABASE d1;
USE d1;
CREATE TABLE t1 (c1 INT);
CREATE TABLE t2 (c1 INT);
CREATE FUNCTION f1(p1 INT) RETURNS INT
BEGIN
    INSERT INTO t2 VALUES (p1);
    RETURN p1;
END;
```

Referencing the function directly in an `EXPLAIN SELECT` has no effect on `t2`, as shown here:

```
mysql> SELECT * FROM t2;
Empty set (0.02 sec)

mysql> EXPLAIN SELECT f1(5)\G
***** 1. row *****
      id: 1
    select_type: SIMPLE
      table: NULL
    partitions: NULL
       type: NULL
possible_keys: NULL
        key: NULL
       key_len: NULL
         ref: NULL
        rows: NULL
   filtered: NULL
   Extra: No tables used
1 row in set (0.01 sec)

mysql> SELECT * FROM t2;
Empty set (0.01 sec)
```

This is because the `SELECT` statement did not reference any tables, as can be seen in the `table` and `Extra` columns of the output. This is also true of the following nested `SELECT`:

```
mysql> EXPLAIN SELECT NOW() AS a1, (SELECT f1(5)) AS a2\G
```

```

***** 1. row *****
  id: 1
  select_type: PRIMARY
  table: NULL
  type: NULL
possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
  rows: NULL
  filtered: NULL
  Extra: No tables used
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Note  | 1249 | Select 2 was reduced during optimization |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)

```

However, if the outer `SELECT` references any tables, the optimizer executes the statement in the subquery as well:

```

mysql> EXPLAIN SELECT * FROM t1 AS a1, (SELECT f1(5)) AS a2\G
***** 1. row *****
  id: 1
  select_type: PRIMARY
  table: <derived2>
  partitions: NULL
  type: system
possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
  rows: 1
  filtered: 100.00
  Extra: NULL
***** 2. row *****
  id: 1
  select_type: PRIMARY
  table: a1
  partitions: NULL
  type: ALL
possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
  rows: 1
  filtered: 100.00
  Extra: NULL
***** 3. row *****
  id: 2
  select_type: DERIVED
  table: NULL
  partitions: NULL
  type: NULL
possible_keys: NULL
  key: NULL
  key_len: NULL
  ref: NULL
  rows: NULL
  filtered: NULL
  Extra: No tables used
3 rows in set (0.00 sec)

mysql> SELECT * FROM t2;

```

```
+-----+
| c1    |
+-----+
|      5 |
+-----+
1 row in set (0.00 sec)
```

This also means that an `EXPLAIN SELECT` statement such as the one shown here may take a long time to execute because the `BENCHMARK()` function is executed once for each row in `t1`:

```
EXPLAIN SELECT * FROM t1 AS a1, (SELECT BENCHMARK(1000000, MD5(NOW())));
```

13.2.11.9 WITH Syntax (Common Table Expressions)

A common table expression (CTE) is a named temporary result set that exists within the scope of a single statement and that can be referred to later within that statement, possibly multiple times. The following discussion describes how to write statements that use CTEs.

- [Common Table Expression Syntax](#)
- [Recursive Common Table Expressions](#)
- [Recursive Common Table Expression Examples](#)
- [Common Table Expressions Compared to Similar Constructs](#)

For information about CTE optimization, see [Section 8.2.2.3, “Optimizing Derived Tables, View References, and Common Table Expressions”](#).

Common Table Expression Syntax

To specify common table expressions, use a `WITH` clause that has one or more comma-separated subclauses, each of which provides a subquery that produces a result set and a name associated with the subquery. The following example defines CTEs named `cte1` and `cte2` in the `WITH` clause, and refers to them in the top-level `SELECT` that follows the `WITH` clause:

```
WITH
  cte1 AS (SELECT a, b FROM table1),
  cte2 AS (SELECT c, d FROM table2)
SELECT b, d FROM cte1 JOIN cte2
WHERE cte1.a = cte2.c;
```

In the statement containing the `WITH` clause, each CTE name can be referenced to access the corresponding CTE result set.

A CTE name can be referenced in other CTEs, enabling CTEs to be defined based on other CTEs.

A CTE can refer to itself to define a recursive CTE. Common applications of recursive CTEs include series generation and traversal of hierarchical or tree-structured data.

Common table expressions are an optional part of the syntax for DML statements. They are defined using a `WITH` clause:

```
with_clause:
  WITH [RECURSIVE]
      cte_name [(col_name [, col_name] ...)] AS (subquery)
      [, cte_name [(col_name [, col_name] ...)] AS (subquery)] ...
```

`cte_name` names a single common table expression and can be used as a table reference in the statement containing the `WITH` clause.

The *subquery* part of *AS (subquery)* is called the “subquery of the CTE” and is what produces the CTE result set. The parentheses following *AS* are required.

A common table expression is recursive if its subquery refers to its own name. The *RECURSIVE* keyword must be included if any CTE in the *WITH* clause is recursive. For more information, see [Recursive Common Table Expressions](#).

Determination of column names for a given CTE occurs as follows:

- If a parenthesized list of names follows the CTE name, those names are the column names:

```
WITH cte (col1, col2) AS
(
  SELECT 1, 2
  UNION ALL
  SELECT 3, 4
)
SELECT col1, col2 FROM cte;
```

The number of names in the list must be the same as the number of columns in the result set.

- Otherwise, the column names come from the select list of the first *SELECT* within the *AS (subquery)* part:

```
WITH cte AS
(
  SELECT 1 AS col1, 2 AS col2
  UNION ALL
  SELECT 3, 4
)
SELECT col1, col2 FROM cte;
```

A *WITH* clause is permitted in these contexts:

- At the beginning of *SELECT*, *UPDATE*, and *DELETE* statements.

```
WITH ... SELECT ...
WITH ... UPDATE ...
WITH ... DELETE ...
```

- At the beginning of subqueries (including derived table subqueries):

```
SELECT ... WHERE id IN (WITH ... SELECT ...) ...
SELECT * FROM (WITH ... SELECT ...) AS dt ...
```

- Immediately preceding *SELECT* for statements that include a *SELECT* statement:

```
INSERT ... WITH ... SELECT ...
REPLACE ... WITH ... SELECT ...
CREATE TABLE ... WITH ... SELECT ...
CREATE VIEW ... WITH ... SELECT ...
DECLARE CURSOR ... WITH ... SELECT ...
EXPLAIN ... WITH ... SELECT ...
```

Only one *WITH* clause is permitted at the same level. *WITH* followed by *WITH* at the same level is not permitted, so this is illegal:

```
WITH cte1 AS (...) WITH cte2 AS (...) SELECT ...
```

However, a statement can contain multiple *WITH* clauses if they occur at different levels:

```
WITH cte1 AS (SELECT 1)
```

```
SELECT * FROM (WITH cte2 AS (SELECT 2) SELECT * FROM cte2 JOIN cte1) AS dt;
```

A [WITH](#) clause can define one or more common table expressions, but each CTE name must be unique to the clause. This is illegal:

```
WITH cte1 AS (...), cte1 AS (...) SELECT ...
```

To make the statement legal, define the CTEs with unique names:

```
WITH cte1 AS (...), cte2 AS (...) SELECT ...
```

A CTE can refer to itself or to other CTEs:

- A self-referencing CTE is recursive.
- A CTE can refer to CTEs defined earlier in the same [WITH](#) clause, but not those defined later.

This constraint rules out mutually-recursive CTEs, where `cte1` references `cte2` and `cte2` references `cte1` because one of those references must be to a CTE defined later.

- A CTE in a given query block can refer to CTEs defined in query blocks at a more outer level, but not CTEs defined in query blocks at a more inner level.

For resolving references to objects with the same names, derived tables hide CTEs; and CTEs hide base tables, [TEMPORARY](#) tables, and views. Name resolution occurs by searching for objects in the same query block, then proceeding to outer blocks in turn while no object with the name is found.

A CTE cannot contain outer references. As with derived tables, which also prohibit outer references, this is a MySQL restriction, not a restriction of the SQL standard. For additional syntax considerations specific to recursive CTEs, see [Recursive Common Table Expressions](#).

Recursive Common Table Expressions

A recursive common table expression is one having a subquery that refers to its own name. For example:

```
WITH RECURSIVE cte (n) AS
(
  SELECT 1
  UNION ALL
  SELECT n + 1 FROM cte WHERE n < 5
)
SELECT * FROM cte;
```

When executed, the statement produces this result, a single column containing a simple linear sequence:

```
+-----+
|  n  |
+-----+
|  1  |
|  2  |
|  3  |
|  4  |
|  5  |
+-----+
```

A recursive CTE has this structure:

- The [WITH](#) clause must begin with [WITH RECURSIVE](#) if any CTE in the [WITH](#) clause refers to itself. (If no CTE refers to itself, [RECURSIVE](#) is permitted but not required.)

If you forget [RECURSIVE](#) for a recursive CTE, this error is a likely result:

```
ERROR 1146 (42S02): Table 'cte_name' doesn't exist
```

- The recursive CTE subquery has two parts, separated by `UNION [ALL]` or `UNION DISTINCT`:

```
SELECT ...      -- return initial row set
UNION ALL
SELECT ...      -- return additional row sets
```

The first `SELECT` produces the initial row or rows for the CTE and does not refer to the CTE name. The second `SELECT` produces additional rows and recurses by referring to the CTE name in its `FROM` clause. Recursion ends when this part produces no new rows. Thus, a recursive CTE consists of a nonrecursive `SELECT` part followed by a recursive `SELECT` part.

Either `SELECT` part can itself be a union of multiple `SELECT` statements.

- The types of the CTE result columns are inferred from the column types of the nonrecursive `SELECT` part only, and the columns are all nullable. For type determination, the recursive `SELECT` part is ignored.
- If the nonrecursive and recursive parts are separated by `UNION DISTINCT`, duplicate rows are eliminated. This is useful for queries that perform transitive closures, to avoid infinite loops.
- Each iteration of the recursive part operates only on the rows produced by the previous iteration. If the recursive part has multiple query blocks, they all operate for each iteration on the rows produced by the previous iteration, and their results are concatenated for the next iteration.

The recursive CTE subquery shown earlier has this nonrecursive part that retrieves a single row to produce the initial row set:

```
SELECT 1
```

The CTE subquery also has this recursive part:

```
SELECT n + 1 FROM cte WHERE n < 5
```

At each iteration, that `SELECT` produces a row with a new value one greater than the value of `n` from the previous row set. The first iteration operates on the initial row set (1) and produces `1+1=2`; the second iteration operates on the first iteration's row set (2) and produces `2+1=3`; and so forth. This continues until recursion ends, when `n` is no longer less than 5.

If the recursive part of a CTE produces wider values for a column than the nonrecursive part, it may be necessary to widen the column in the nonrecursive part to avoid data truncation. Consider this statement:

```
WITH RECURSIVE cte AS
(
  SELECT 1 AS n, 'abc' AS str
  UNION ALL
  SELECT n + 1, CONCAT(str, str) FROM cte WHERE n < 3
)
SELECT * FROM cte;
```

In nonstrict SQL mode, the statement produces this output:

```
+-----+-----+
| n    | str  |
+-----+-----+
| 1    | abc  |
| 2    | abc  |
```

```
| 3 | abc |
+-----+
```

The `str` column values are all `'abc'` because the nonrecursive `SELECT` determines the column widths. Consequently, the wider `str` values produced by the recursive `SELECT` are truncated.

In strict SQL mode, the statement produces an error:

```
ERROR 1406 (22001): Data too long for column 'str' at row 1
```

To address this issue, use `CAST()` in the nonrecursive `SELECT` to make the `str` column wider:

```
WITH RECURSIVE cte AS
(
  SELECT 1 AS n, CAST('abc' AS CHAR(20)) AS str
  UNION ALL
  SELECT n + 1, CONCAT(str, str) FROM cte WHERE n < 3
)
SELECT * FROM cte;
```

Now the statement produces this result, without truncation:

```
+-----+
| n  | str          |
+-----+
| 1  | abc          |
| 2  | abcabc      |
| 3  | abcabcabc   |
+-----+
```

Columns are accessed by name, not position, which means that columns in the recursive part can access columns in the nonrecursive part that have a different position, as this CTE illustrates:

```
WITH RECURSIVE cte AS
(
  SELECT 1 AS n, 1 AS p, -1 AS q
  UNION ALL
  SELECT n + 1, q * 2, p * 2 FROM cte WHERE n < 5
)
SELECT * FROM cte;
```

Because `p` in one row is derived from `q` in the previous row, and vice versa, the positive and negative values swap positions in each successive row of the output:

```
+-----+
| n  | p  | q  |
+-----+
| 1  | 1  | -1 |
| 2  | -2 | 2  |
| 3  | 4  | -4 |
| 4  | -8 | 8  |
| 5  | 16 | -16|
+-----+
```

Some syntax constraints apply within recursive CTE subqueries:

- The recursive `SELECT` part must not contain these constructs:
 - Aggregate functions such as `SUM()`
 - `GROUP BY`
 - `ORDER BY`

- `LIMIT`
- `DISTINCT`

This constraint does not apply to the nonrecursive `SELECT` part of a recursive CTE. The prohibition on `DISTINCT` applies only to `UNION` members; `UNION DISTINCT` is permitted.

- The recursive `SELECT` part must reference the CTE only once and only in its `FROM` clause, not in any subquery. It can reference tables other than the CTE and join them with the CTE. If used in a join like this, the CTE must not be on the right side of a `LEFT JOIN`.

These constraints come from the SQL standard, other than the MySQL-specific exclusions of `ORDER BY`, `LIMIT`, and `DISTINCT`.

It is important for recursive CTEs that the recursive `SELECT` part include a condition to terminate recursion. Otherwise, recursion terminates only if some kind of resource exhaustion occurs. As a development technique to guard against a runaway recursive CTE, you can force termination by placing a limit on execution time:

- The `max_execution_time` system variable enforces an execution timeout for all `SELECT` statements executed within the current session.
- The `MAX_EXECUTION_TIME` optimizer hint enforces a per-query execution timeout for the `SELECT` statement in which it appears.

Suppose that a recursive CTE is mistakenly written with no recursion execution termination condition:

```
WITH RECURSIVE cte (n) AS
(
  SELECT 1
  UNION ALL
  SELECT n + 1 FROM cte
)
SELECT * FROM cte;
```

To guard against infinite recursion, set a per-session timeout by executing a statement like this prior to executing the CTE statement:

```
SET max_execution_time = 1000; -- impose one second timeout
```

Alternatively, include an optimizer hint within the CTE statement itself:

```
WITH RECURSIVE cte (n) AS
(
  SELECT 1
  UNION ALL
  SELECT n + 1 FROM cte
)
SELECT /*+ MAX_EXECUTION_TIME(1000) */ * FROM cte;
```

If a recursive query without an execution time limit enters an infinite loop, you can terminate it from another session using `KILL QUERY`. Within the session itself, the client program used to run the query might provide a way to kill the query. For example, in `mysql`, typing **Control+C** interrupts the current statement.

For recursive CTEs, `EXPLAIN` output rows for recursive `SELECT` parts display `Recursive` in the `Extra` column.

Cost estimates displayed by `EXPLAIN` represent cost per iteration, which might differ considerably from total cost. The optimizer cannot predict the number of iterations because it cannot predict when the `WHERE` clause will become false.

CTE actual cost may also be affected by result set size. A CTE that produces many rows may require an internal temporary table large enough to be converted from in-memory to on-disk format and may suffer a performance penalty. If so, increasing the permitted in-memory temporary table size may improve performance; see [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).

Recursive Common Table Expression Examples

As mentioned previously, recursive common table expressions (CTEs) are frequently used for series generation and traversing hierarchical or tree-structured data. This section shows some simple examples of these techniques.

- [Fibonacci Series Generation](#)
- [Date Series Generation](#)
- [Hierarchical Data Traversal](#)

Fibonacci Series Generation

A Fibonacci series begins with the two numbers 0 and 1 (or 1 and 1) and each number after that is the sum of the previous two numbers. A recursive common table expression can generate a Fibonacci series if each row produced by the recursive `SELECT` has access to the two previous numbers from the series. The following CTE generates a 10-number series using 0 and 1 as the first two numbers:

```
WITH RECURSIVE fibonacci (n, fib_n, next_fib_n) AS
(
  SELECT 1, 0, 1
  UNION ALL
  SELECT n + 1, next_fib_n, fib_n + next_fib_n
     FROM fibonacci WHERE n < 10
)
SELECT * FROM fibonacci;
```

The CTE produces this result:

n	fib_n	next_fib_n
1	0	1
2	1	1
3	1	2
4	2	3
5	3	5
6	5	8
7	8	13
8	13	21
9	21	34
10	34	55

How the CTE works:

- `n` is a display column to indicate that the row contains the `n`-th Fibonacci number. For example, the 8th Fibonacci number is 13.
- The `fib_n` column displays Fibonacci number `n`.
- The `next_fib_n` column displays the next Fibonacci number after number `n`. This column provides the next series value to the next row, so that row can produce the sum of the two previous series values in its `fib_n` column.
- Recursion ends when `n` reaches 10. This is an arbitrary choice, to limit the output to a small set of rows.

The preceding output shows the entire CTE result. To select just part of it, add an appropriate `WHERE` clause to the top-level `SELECT`. For example, to select the 8th Fibonacci number, do this:

```
mysql> WITH RECURSIVE fibonacci ...
      ...
      SELECT fib_n FROM fibonacci WHERE n = 8;
+-----+
| fib_n |
+-----+
|    13 |
+-----+
```

Date Series Generation

A common table expression can generate a series of successive dates, which is useful for generating summaries that include a row for all dates in the series, including dates not represented in the summarized data.

Suppose that a table of sales numbers contains these rows:

```
mysql> SELECT * FROM sales ORDER BY date, price;
+-----+-----+
| date       | price  |
+-----+-----+
| 2017-01-03 | 100.00 |
| 2017-01-03 | 200.00 |
| 2017-01-06 |  50.00 |
| 2017-01-08 |  10.00 |
| 2017-01-08 |  20.00 |
| 2017-01-08 | 150.00 |
| 2017-01-10 |   5.00 |
+-----+-----+
```

This query summarizes the sales per day:

```
mysql> SELECT date, SUM(price) AS sum_price
      FROM sales
      GROUP BY date
      ORDER BY date;
+-----+-----+
| date       | sum_price |
+-----+-----+
| 2017-01-03 |    300.00 |
| 2017-01-06 |    50.00  |
| 2017-01-08 |    180.00 |
| 2017-01-10 |    5.00  |
+-----+-----+
```

However, that result contains “holes” for dates not represented in the range of dates spanned by the table. A result that represents all dates in the range can be produced using a recursive CTE to generate that set of dates, joined with a `LEFT JOIN` to the sales data.

Here is the CTE to generate the date range series:

```
WITH RECURSIVE dates (date) AS
(
  SELECT MIN(date) FROM sales
  UNION ALL
  SELECT date + INTERVAL 1 DAY FROM dates
  WHERE date + INTERVAL 1 DAY <= (SELECT MAX(date) FROM sales)
)
SELECT * FROM dates;
```

The CTE produces this result:

```

+-----+
| date   |
+-----+
| 2017-01-03 |
| 2017-01-04 |
| 2017-01-05 |
| 2017-01-06 |
| 2017-01-07 |
| 2017-01-08 |
| 2017-01-09 |
| 2017-01-10 |
+-----+

```

How the CTE works:

- The nonrecursive `SELECT` produces the lowest date in the date range spanned by the `sales` table.
- Each row produced by the recursive `SELECT` adds one day to the date produced by the previous row.
- Recursion ends after the dates reach the highest date in the date range spanned by the `sales` table.

Joining the CTE with a `LEFT JOIN` against the `sales` table produces the sales summary with a row for each date in the range:

```

WITH RECURSIVE dates (date) AS
(
  SELECT MIN(date) FROM sales
  UNION ALL
  SELECT date + INTERVAL 1 DAY FROM dates
  WHERE date + INTERVAL 1 DAY <= (SELECT MAX(date) FROM sales)
)
SELECT dates.date, COALESCE(SUM(price), 0) AS sum_price
FROM dates LEFT JOIN sales ON dates.date = sales.date
GROUP BY dates.date
ORDER BY dates.date;

```

The output looks like this:

```

+-----+-----+
| date       | sum_price |
+-----+-----+
| 2017-01-03 |    300.00 |
| 2017-01-04 |     0.00 |
| 2017-01-05 |     0.00 |

+-----+-----+

```

Some points to note:

- Are the queries inefficient, particularly the one with the `MAX()` subquery executed for each row in the recursive `SELECT`? Checking with `EXPLAIN` shows that the subqueries are optimized away for efficiency.
- The use of `COALESCE()` avoids displaying `NULL` in the `sum_price` column on days for which no sales data occur in the `sales` table.

Hierarchical Data Traversal

Recursive common table expressions are useful for traversing data that forms a hierarchy. Consider these statements that create a small data set that shows, for each employee in a company, the

employee name and ID number, and the ID of the employee's manager. The top-level employee (the CEO), has a manager ID of `NULL` (no manager).

```
CREATE TABLE employees (
  id          INT PRIMARY KEY NOT NULL,
  name       VARCHAR(100) NOT NULL,
  manager_id INT NULL,
  INDEX (manager_id),
  FOREIGN KEY (manager_id) REFERENCES EMPLOYEES (id)
);
INSERT INTO employees VALUES
(333, "Yasmina", NULL), # Yasmina is the CEO (manager_id is NULL)
(198, "John", 333),     # John has ID 198 and reports to 333 (Yasmina)
(692, "Tarek", 333),
(29, "Pedro", 198),
(4610, "Sarah", 29),
(72, "Pierre", 29),
(123, "Adil", 692);
```

The resulting data set looks like this:

```
mysql> SELECT * FROM employees ORDER BY id;
+-----+-----+-----+
| id  | name  | manager_id |
+-----+-----+-----+
| 29  | Pedro | 198        |
| 72  | Pierre| 29         |
| 123 | Adil  | 692        |
| 198 | John  | 333        |
| 333 | Yasmina| NULL       |
| 692 | Tarek | 333        |
| 4610| Sarah | 29         |
+-----+-----+-----+
```

To produce the organizational chart with the management chain for each employee (that is, the path from CEO to employee), use a recursive CTE:

```
WITH RECURSIVE employee_paths (id, name, path) AS
(
  SELECT id, name, CAST(id AS CHAR(200))
  FROM employees
  WHERE manager_id IS NULL
  UNION ALL
  SELECT e.id, e.name, CONCAT(ep.path, ',', e.id)
  FROM employee_paths AS ep JOIN employees AS e
  ON ep.id = e.manager_id
)
SELECT * FROM employee_paths ORDER BY path;
```

The CTE produces this output:

```
+-----+-----+-----+
| id  | name  | path          |
+-----+-----+-----+
| 333 | Yasmina | 333          |
| 198 | John    | 333,198      |
| 29  | Pedro   | 333,198,29   |
| 4610| Sarah   | 333,198,29,4610 |
| 72  | Pierre  | 333,198,29,72 |
| 692 | Tarek   | 333,692      |
| 123 | Adil    | 333,692,123  |
+-----+-----+-----+
```

How the CTE works:

- The nonrecursive `SELECT` produces the row for the CEO (the row with a `NULL` manager ID).

The `path` column is widened to `CHAR(200)` to ensure that there is room for the longer `path` values produced by the recursive `SELECT`.

- Each row produced by the recursive `SELECT` finds all employees who report directly to an employee produced by a previous row. For each such employee, the row includes the employee ID and name, and the employee management chain. The chain is the manager's chain, with the employee ID added to the end.
- Recursion ends when employees have no others who report to them.

To find the path for a specific employee or employees, add a `WHERE` clause to the top-level `SELECT`. For example, to display the results for Tarek and Sarah, modify that `SELECT` like this:

```
mysql> WITH RECURSIVE ...
...
SELECT * FROM employees_extended
WHERE id IN (692, 4610)
ORDER BY path;
```

id	name	path
4610	Sarah	333,198,29,4610
692	Tarek	333,692

Common Table Expressions Compared to Similar Constructs

Common table expressions (CTEs) are similar to derived tables in some ways:

- Both constructs are named.
- Both constructs exist for the scope of a single statement.

Because of these similarities, CTEs and derived tables often can be used interchangeably. As a trivial example, these statements are equivalent:

```
WITH cte AS (SELECT 1) SELECT * FROM cte;
SELECT * FROM (SELECT 1) AS dt;
```

However, CTEs have some advantages over derived tables:

- A derived table can be referenced only a single time within a query. A CTE can be referenced multiple times. To use multiple instances of a derived table result, you must derive the result multiple times.
- A CTE can be self-referencing (recursive).
- One CTE can refer to another.
- A CTE may be easier to read when its definition appears at the beginning of the statement rather than embedded within it.

CTEs are similar to tables created with `CREATE [TEMPORARY] TABLE` but need not be defined or dropped explicitly. For a CTE, you need no privileges to create tables.

13.2.11.10 Subquery Errors

There are some errors that apply only to subqueries. This section describes them.

- Unsupported subquery syntax:

```
ERROR 1235 (ER_NOT_SUPPORTED_YET)
SQLSTATE = 42000
Message = "This version of MySQL doesn't yet support
'LIMIT & IN/ALL/ANY/SOME subquery'"
```

This means that MySQL does not support statements of the following form:

```
SELECT * FROM t1 WHERE s1 IN (SELECT s2 FROM t2 ORDER BY s1 LIMIT 1)
```

- Incorrect number of columns from subquery:

```
ERROR 1241 (ER_OPERAND_COL)
SQLSTATE = 21000
Message = "Operand should contain 1 column(s)"
```

This error occurs in cases like this:

```
SELECT (SELECT column1, column2 FROM t2) FROM t1;
```

You may use a subquery that returns multiple columns, if the purpose is row comparison. In other contexts, the subquery must be a scalar operand. See [Section 13.2.11.5, "Row Subqueries"](#).

- Incorrect number of rows from subquery:

```
ERROR 1242 (ER_SUBSELECT_NO_1_ROW)
SQLSTATE = 21000
Message = "Subquery returns more than 1 row"
```

This error occurs for statements where the subquery must return at most one row but returns multiple rows. Consider the following example:

```
SELECT * FROM t1 WHERE column1 = (SELECT column1 FROM t2);
```

If `SELECT column1 FROM t2` returns just one row, the previous query will work. If the subquery returns more than one row, error 1242 will occur. In that case, the query should be rewritten as:

```
SELECT * FROM t1 WHERE column1 = ANY (SELECT column1 FROM t2);
```

- Incorrectly used table in subquery:

```
Error 1093 (ER_UPDATE_TABLE_USED)
SQLSTATE = HY000
Message = "You can't specify target table 'x'
for update in FROM clause"
```

This error occurs in cases such as the following, which attempts to modify a table and select from the same table in the subquery:

```
UPDATE t1 SET column2 = (SELECT MAX(column1) FROM t1);
```

You can use a subquery for assignment within an `UPDATE` statement because subqueries are legal in `UPDATE` and `DELETE` statements as well as in `SELECT` statements. However, you cannot use the same table (in this case, table `t1`) for both the subquery `FROM` clause and the update target.

For transactional storage engines, the failure of a subquery causes the entire statement to fail. For nontransactional storage engines, data modifications made before the error was encountered are preserved.

13.2.11.11 Optimizing Subqueries

Development is ongoing, so no optimization tip is reliable for the long term. The following list provides some interesting tricks that you might want to play with. See also [Section 8.2.2, “Optimizing Subqueries, Derived Tables, View References, and Common Table Expressions”](#).

- Use subquery clauses that affect the number or order of the rows in the subquery. For example:

```
SELECT * FROM t1 WHERE t1.column1 IN
  (SELECT column1 FROM t2 ORDER BY column1);
SELECT * FROM t1 WHERE t1.column1 IN
  (SELECT DISTINCT column1 FROM t2);
SELECT * FROM t1 WHERE EXISTS
  (SELECT * FROM t2 LIMIT 1);
```

- Replace a join with a subquery. For example, try this:

```
SELECT DISTINCT column1 FROM t1 WHERE t1.column1 IN (
  SELECT column1 FROM t2);
```

Instead of this:

```
SELECT DISTINCT t1.column1 FROM t1, t2
  WHERE t1.column1 = t2.column1;
```

- Some subqueries can be transformed to joins for compatibility with older versions of MySQL that do not support subqueries. However, in some cases, converting a subquery to a join may improve performance. See [Section 13.2.11.12, “Rewriting Subqueries as Joins”](#).
- Move clauses from outside to inside the subquery. For example, use this query:

```
SELECT * FROM t1
  WHERE s1 IN (SELECT s1 FROM t1 UNION ALL SELECT s1 FROM t2);
```

Instead of this query:

```
SELECT * FROM t1
  WHERE s1 IN (SELECT s1 FROM t1) OR s1 IN (SELECT s1 FROM t2);
```

For another example, use this query:

```
SELECT (SELECT column1 + 5 FROM t1) FROM t2;
```

Instead of this query:

```
SELECT (SELECT column1 FROM t1) + 5 FROM t2;
```

- Use a row subquery instead of a correlated subquery. For example, use this query:

```
SELECT * FROM t1
  WHERE (column1,column2) IN (SELECT column1,column2 FROM t2);
```

Instead of this query:

```
SELECT * FROM t1
  WHERE EXISTS (SELECT * FROM t2 WHERE t2.column1=t1.column1
    AND t2.column2=t1.column2);
```

- Use `NOT (a = ANY (...))` rather than `a <> ALL (...)`.

- Use `x = ANY (table containing (1,2))` rather than `x=1 OR x=2`.
- Use `= ANY` rather than `EXISTS`.
- For uncorrelated subqueries that always return one row, `IN` is always slower than `=`. For example, use this query:

```
SELECT * FROM t1
WHERE t1.col_name = (SELECT a FROM t2 WHERE b = some_const);
```

Instead of this query:

```
SELECT * FROM t1
WHERE t1.col_name IN (SELECT a FROM t2 WHERE b = some_const);
```

These tricks might cause programs to go faster or slower. Using MySQL facilities like the `BENCHMARK()` function, you can get an idea about what helps in your own situation. See [Section 12.14, “Information Functions”](#).

Some optimizations that MySQL itself makes are:

- MySQL executes uncorrelated subqueries only once. Use `EXPLAIN` to make sure that a given subquery really is uncorrelated.
- MySQL rewrites `IN`, `ALL`, `ANY`, and `SOME` subqueries in an attempt to take advantage of the possibility that the select-list columns in the subquery are indexed.
- MySQL replaces subqueries of the following form with an index-lookup function, which `EXPLAIN` describes as a special join type (`unique_subquery` or `index_subquery`):

```
... IN (SELECT indexed_column FROM single_table ...)
```

- MySQL enhances expressions of the following form with an expression involving `MIN()` or `MAX()`, unless `NULL` values or empty sets are involved:

```
value {ALL|ANY|SOME} {> | < | >= | <=} (uncorrelated subquery)
```

For example, this `WHERE` clause:

```
WHERE 5 > ALL (SELECT x FROM t)
```

might be treated by the optimizer like this:

```
WHERE 5 > (SELECT MAX(x) FROM t)
```

See also [MySQL Internals: How MySQL Transforms Subqueries](#).

13.2.11.12 Rewriting Subqueries as Joins

Sometimes there are other ways to test membership in a set of values than by using a subquery. Also, on some occasions, it is not only possible to rewrite a query without a subquery, but it can be more efficient to make use of some of these techniques rather than to use subqueries. One of these is the `IN()` construct:

For example, this query:

```
SELECT * FROM t1 WHERE id IN (SELECT id FROM t2);
```

Can be rewritten as:

```
SELECT DISTINCT t1.* FROM t1, t2 WHERE t1.id=t2.id;
```

The queries:

```
SELECT * FROM t1 WHERE id NOT IN (SELECT id FROM t2);
SELECT * FROM t1 WHERE NOT EXISTS (SELECT id FROM t2 WHERE t1.id=t2.id);
```

Can be rewritten as:

```
SELECT table1.*
   FROM table1 LEFT JOIN table2 ON table1.id=table2.id
   WHERE table2.id IS NULL;
```

A [LEFT \[OUTER\] JOIN](#) can be faster than an equivalent subquery because the server might be able to optimize it better—a fact that is not specific to MySQL Server alone. Prior to SQL-92, outer joins did not exist, so subqueries were the only way to do certain things. Today, MySQL Server and many other modern database systems offer a wide range of outer join types.

MySQL Server supports multiple-table [DELETE](#) statements that can be used to efficiently delete rows based on information from one table or even from many tables at the same time. Multiple-table [UPDATE](#) statements are also supported. See [Section 13.2.2, “DELETE Syntax”](#), and [Section 13.2.12, “UPDATE Syntax”](#).

13.2.12 UPDATE Syntax

[UPDATE](#) is a DML statement that modifies rows in a table.

An [UPDATE](#) statement can start with a [WITH](#) clause to define common table expressions accessible within the [UPDATE](#). See [Section 13.2.11.9, “WITH Syntax \(Common Table Expressions\)”](#).

Single-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_reference
   SET col_name1={expr1|DEFAULT} [, col_name2={expr2|DEFAULT}] ...
   [WHERE where_condition]
   [ORDER BY ...]
   [LIMIT row_count]
```

Multiple-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_references
   SET col_name1={expr1|DEFAULT} [, col_name2={expr2|DEFAULT}] ...
   [WHERE where_condition]
```

For the single-table syntax, the [UPDATE](#) statement updates columns of existing rows in the named table with new values. The [SET](#) clause indicates which columns to modify and the values they should be given. Each value can be given as an expression, or the keyword [DEFAULT](#) to set a column explicitly to its default value. The [WHERE](#) clause, if given, specifies the conditions that identify which rows to update. With no [WHERE](#) clause, all rows are updated. If the [ORDER BY](#) clause is specified, the rows are updated in the order that is specified. The [LIMIT](#) clause places a limit on the number of rows that can be updated.

For the multiple-table syntax, [UPDATE](#) updates rows in each table named in *table_references* that satisfy the conditions. Each matching row is updated once, even if it matches the conditions multiple times. For multiple-table syntax, [ORDER BY](#) and [LIMIT](#) cannot be used.

For partitioned tables, both the single-table and multiple-table forms of this statement support the use of a [PARTITION](#) option as part of a table reference. This option takes a list of one or more partitions

or subpartitions (or both). Only the partitions (or subpartitions) listed are checked for matches, and a row that is not in any of these partitions or subpartitions is not updated, whether it satisfies the *where_condition* or not.

Note

Unlike the case when using `PARTITION` with an `INSERT` or `REPLACE` statement, an otherwise valid `UPDATE ... PARTITION` statement is considered successful even if no rows in the listed partitions (or subpartitions) match the *where_condition*.

See [Section 22.5, “Partition Selection”](#), for more information and examples.

where_condition is an expression that evaluates to true for each row to be updated. For expression syntax, see [Section 9.5, “Expression Syntax”](#).

table_references and *where_condition* are specified as described in [Section 13.2.10, “SELECT Syntax”](#).

You need the `UPDATE` privilege only for columns referenced in an `UPDATE` that are actually updated. You need only the `SELECT` privilege for any columns that are read but not modified.

The `UPDATE` statement supports the following modifiers:

- With the `LOW_PRIORITY` modifier, execution of the `UPDATE` is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (such as `MyISAM`, `MEMORY`, and `MERGE`).
- With the `IGNORE` modifier, the update statement does not abort even if errors occur during the update. Rows for which duplicate-key conflicts occur on a unique key value are not updated. Rows updated to values that would cause data conversion errors are updated to the closest valid values instead. For more information, see [Comparison of the IGNORE Keyword and Strict SQL Mode](#).

`UPDATE IGNORE` statements, including those having an `ORDER BY` clause, are flagged as unsafe for statement-based replication. (This is because the order in which the rows are updated determines which rows are ignored.) With this change, such statements produce a warning in the log when using statement-based mode and are logged using the row-based format when using `MIXED` mode. (Bug #11758262, Bug #50439) See [Section 18.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#), for more information.

If you access a column from the table to be updated in an expression, `UPDATE` uses the current value of the column. For example, the following statement sets `col1` to one more than its current value:

```
UPDATE t1 SET col1 = col1 + 1;
```

The second assignment in the following statement sets `col2` to the current (updated) `col1` value, not the original `col1` value. The result is that `col1` and `col2` have the same value. This behavior differs from standard SQL.

```
UPDATE t1 SET col1 = col1 + 1, col2 = col1;
```

Single-table `UPDATE` assignments are generally evaluated from left to right. For multiple-table updates, there is no guarantee that assignments are carried out in any particular order.

If you set a column to the value it currently has, MySQL notices this and does not update it.

If you update a column that has been declared `NOT NULL` by setting to `NULL`, an error occurs if strict SQL mode is enabled; otherwise, the column is set to the implicit default value for the column data type and the warning count is incremented. The implicit default value is `0` for numeric types, the empty string

(' ') for string types, and the “zero” value for date and time types. See [Section 11.7, “Data Type Default Values”](#).

If a generated column is updated explicitly, the only permitted value is `DEFAULT`. For information about generated columns, see [Section 13.1.15.8, “CREATE TABLE and Generated Columns”](#).

`UPDATE` returns the number of rows that were actually changed. The `mysql_info()` C API function returns the number of rows that were matched and updated and the number of warnings that occurred during the `UPDATE`.

You can use `LIMIT row_count` to restrict the scope of the `UPDATE`. A `LIMIT` clause is a rows-matched restriction. The statement stops as soon as it has found `row_count` rows that satisfy the `WHERE` clause, whether or not they actually were changed.

If an `UPDATE` statement includes an `ORDER BY` clause, the rows are updated in the order specified by the clause. This can be useful in certain situations that might otherwise result in an error. Suppose that a table `t` contains a column `id` that has a unique index. The following statement could fail with a duplicate-key error, depending on the order in which rows are updated:

```
UPDATE t SET id = id + 1;
```

For example, if the table contains 1 and 2 in the `id` column and 1 is updated to 2 before 2 is updated to 3, an error occurs. To avoid this problem, add an `ORDER BY` clause to cause the rows with larger `id` values to be updated before those with smaller values:

```
UPDATE t SET id = id + 1 ORDER BY id DESC;
```

You can also perform `UPDATE` operations covering multiple tables. However, you cannot use `ORDER BY` or `LIMIT` with a multiple-table `UPDATE`. The `table_references` clause lists the tables involved in the join. Its syntax is described in [Section 13.2.10.2, “JOIN Syntax”](#). Here is an example:

```
UPDATE items,month SET items.price=month.price
WHERE items.id=month.id;
```

The preceding example shows an inner join that uses the comma operator, but multiple-table `UPDATE` statements can use any type of join permitted in `SELECT` statements, such as `LEFT JOIN`.

If you use a multiple-table `UPDATE` statement involving `InnoDB` tables for which there are foreign key constraints, the MySQL optimizer might process tables in an order that differs from that of their parent/child relationship. In this case, the statement fails and rolls back. Instead, update a single table and rely on the `ON UPDATE` capabilities that `InnoDB` provides to cause the other tables to be modified accordingly. See [Section 15.8.1.6, “InnoDB and FOREIGN KEY Constraints”](#).

You cannot update a table and select from the same table in a subquery.

In MySQL 8.0, an `UPDATE` on a partitioned table using a storage engine such as `MyISAM` that employs table-level locks locks only those partitions containing rows that match the `UPDATE` statement's `WHERE` clause, as long as none of the table's partitioning columns are updated. (For storage engines such as `InnoDB` that employ row-level locking, no locking of partitions takes place.) For more information, see [Partitioning and Locking](#).

13.3 Transactional and Locking Statements

MySQL supports local transactions (within a given client session) through statements such as `SET autocommit`, `START TRANSACTION`, `COMMIT`, and `ROLLBACK`. See [Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#). XA transaction support enables MySQL to participate in distributed transactions as well. See [Section 13.3.7, “XA Transactions”](#).

13.3.1 START TRANSACTION, COMMIT, and ROLLBACK Syntax

```

START TRANSACTION
  [transaction_characteristic [, transaction_characteristic] ...]

transaction_characteristic:
  WITH CONSISTENT SNAPSHOT
  | READ WRITE
  | READ ONLY

BEGIN [WORK]
COMMIT [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
ROLLBACK [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
SET autocommit = {0 | 1}

```

These statements provide control over use of [transactions](#):

- `START TRANSACTION` or `BEGIN` start a new transaction.
- `COMMIT` commits the current transaction, making its changes permanent.
- `ROLLBACK` rolls back the current transaction, canceling its changes.
- `SET autocommit` disables or enables the default autocommit mode for the current session.

By default, MySQL runs with [autocommit](#) mode enabled. This means that as soon as you execute a statement that updates (modifies) a table, MySQL stores the update on disk to make it permanent. The change cannot be rolled back.

To disable autocommit mode implicitly for a single series of statements, use the `START TRANSACTION` statement:

```

START TRANSACTION;
SELECT @A:=SUM(salary) FROM table1 WHERE type=1;
UPDATE table2 SET summary=@A WHERE type=1;
COMMIT;

```

With `START TRANSACTION`, autocommit remains disabled until you end the transaction with `COMMIT` or `ROLLBACK`. The autocommit mode then reverts to its previous state.

`START TRANSACTION` permits several modifiers that control transaction characteristics. To specify multiple modifiers, separate them by commas.

- The `WITH CONSISTENT SNAPSHOT` modifier starts a [consistent read](#) for storage engines that are capable of it. This applies only to `InnoDB`. The effect is the same as issuing a `START TRANSACTION` followed by a `SELECT` from any `InnoDB` table. See [Section 15.5.2.3, “Consistent Nonlocking Reads”](#). The `WITH CONSISTENT SNAPSHOT` modifier does not change the current transaction [isolation level](#), so it provides a consistent snapshot only if the current isolation level is one that permits a consistent read. The only isolation level that permits a consistent read is `REPEATABLE READ`. For all other isolation levels, the `WITH CONSISTENT SNAPSHOT` clause is ignored. A warning is generated when the `WITH CONSISTENT SNAPSHOT` clause is ignored.
- The `READ WRITE` and `READ ONLY` modifiers set the transaction access mode. They permit or prohibit changes to tables used in the transaction. The `READ ONLY` restriction prevents the transaction from modifying or locking both transactional and nontransactional tables that are visible to other transactions; the transaction can still modify or lock temporary tables.

MySQL enables extra optimizations for queries on `InnoDB` tables when the transaction is known to be read-only. Specifying `READ ONLY` ensures these optimizations are applied in cases where the read-only status cannot be determined automatically. See [Section 8.5.3, “Optimizing InnoDB Read-Only Transactions”](#) for more information.

If no access mode is specified, the default mode applies. Unless the default has been changed, it is read/write. It is not permitted to specify both `READ WRITE` and `READ ONLY` in the same statement.

In read-only mode, it remains possible to change tables created with the `TEMPORARY` keyword using DML statements. Changes made with DDL statements are not permitted, just as with permanent tables.

For additional information about transaction access mode, including ways to change the default mode, see [Section 13.3.6, “SET TRANSACTION Syntax”](#).

If the `read_only` system variable is enabled, explicitly starting a transaction with `START TRANSACTION READ WRITE` requires the `SUPER` privilege.

Important

Many APIs used for writing MySQL client applications (such as JDBC) provide their own methods for starting transactions that can (and sometimes should) be used instead of sending a `START TRANSACTION` statement from the client. See [Chapter 27, Connectors and APIs](#), or the documentation for your API, for more information.

To disable autocommit mode explicitly, use the following statement:

```
SET autocommit=0;
```

After disabling autocommit mode by setting the `autocommit` variable to zero, changes to transaction-safe tables (such as those for `InnoDB` or `NDB`) are not made permanent immediately. You must use `COMMIT` to store your changes to disk or `ROLLBACK` to ignore the changes.

`autocommit` is a session variable and must be set for each session. To disable autocommit mode for each new connection, see the description of the `autocommit` system variable at [Section 5.1.5, “Server System Variables”](#).

`BEGIN` and `BEGIN WORK` are supported as aliases of `START TRANSACTION` for initiating a transaction. `START TRANSACTION` is standard SQL syntax, is the recommended way to start an ad-hoc transaction, and permits modifiers that `BEGIN` does not.

The `BEGIN` statement differs from the use of the `BEGIN` keyword that starts a `BEGIN ... END` compound statement. The latter does not begin a transaction. See [Section 13.6.1, “BEGIN ... END Compound-Statement Syntax”](#).

Note

Within all stored programs (stored procedures and functions, triggers, and events), the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. Begin a transaction in this context with `START TRANSACTION` instead.

The optional `WORK` keyword is supported for `COMMIT` and `ROLLBACK`, as are the `CHAIN` and `RELEASE` clauses. `CHAIN` and `RELEASE` can be used for additional control over transaction completion. The value of the `completion_type` system variable determines the default completion behavior. See [Section 5.1.5, “Server System Variables”](#).

The `AND CHAIN` clause causes a new transaction to begin as soon as the current one ends, and the new transaction has the same isolation level as the just-terminated transaction. The `RELEASE` clause causes the server to disconnect the current client session after terminating the current transaction. Including the `NO` keyword suppresses `CHAIN` or `RELEASE` completion, which can be useful if the `completion_type` system variable is set to cause chaining or release completion by default.

Beginning a transaction causes any pending transaction to be committed. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#), for more information.

Beginning a transaction also causes table locks acquired with `LOCK TABLES` to be released, as though you had executed `UNLOCK TABLES`. Beginning a transaction does not release a global read lock acquired with `FLUSH TABLES WITH READ LOCK`.

For best results, transactions should be performed using only tables managed by a single transaction-safe storage engine. Otherwise, the following problems can occur:

- If you use tables from more than one transaction-safe storage engine (such as `InnoDB`), and the transaction isolation level is not `SERIALIZABLE`, it is possible that when one transaction commits, another ongoing transaction that uses the same tables will see only some of the changes made by the first transaction. That is, the atomicity of transactions is not guaranteed with mixed engines and inconsistencies can result. (If mixed-engine transactions are infrequent, you can use `SET TRANSACTION ISOLATION LEVEL` to set the isolation level to `SERIALIZABLE` on a per-transaction basis as necessary.)
- If you use tables that are not transaction-safe within a transaction, changes to those tables are stored at once, regardless of the status of autocommit mode.
- If you issue a `ROLLBACK` statement after updating a nontransactional table within a transaction, an `ER_WARNING_NOT_COMPLETE_ROLLBACK` warning occurs. Changes to transaction-safe tables are rolled back, but not changes to nontransaction-safe tables.

Each transaction is stored in the binary log in one chunk, upon `COMMIT`. Transactions that are rolled back are not logged. (**Exception:** Modifications to nontransactional tables cannot be rolled back. If a transaction that is rolled back includes modifications to nontransactional tables, the entire transaction is logged with a `ROLLBACK` statement at the end to ensure that modifications to the nontransactional tables are replicated.) See [Section 5.4.4, “The Binary Log”](#).

You can change the isolation level or access mode for transactions with the `SET TRANSACTION` statement. See [Section 13.3.6, “SET TRANSACTION Syntax”](#).

Rolling back can be a slow operation that may occur implicitly without the user having explicitly asked for it (for example, when an error occurs). Because of this, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the session, not only for explicit rollbacks performed with the `ROLLBACK` statement but also for implicit rollbacks.

Note

In MySQL 8.0, `BEGIN`, `COMMIT`, and `ROLLBACK` are not affected by `--replicate-do-db` or `--replicate-ignore-db` rules.

13.3.2 Statements That Cannot Be Rolled Back

Some statements cannot be rolled back. In general, these include data definition language (DDL) statements, such as those that create or drop databases, those that create, drop, or alter tables or stored routines.

You should design your transactions not to include such statements. If you issue a statement early in a transaction that cannot be rolled back, and then another statement later fails, the full effect of the transaction cannot be rolled back in such cases by issuing a `ROLLBACK` statement.

13.3.3 Statements That Cause an Implicit Commit

The statements listed in this section (and any synonyms for them) implicitly end any transaction active in the current session, as if you had done a `COMMIT` before executing the statement.

Most of these statements also cause an implicit commit after executing. The intent is to handle each such statement in its own special transaction because it cannot be rolled back anyway. Transaction-control and locking statements are exceptions: If an implicit commit occurs before execution, another does not occur after.

- **Data definition language (DDL) statements that define or modify database objects.** ALTER EVENT, ALTER FUNCTION, ALTER PROCEDURE, ALTER SERVER, ALTER TABLE, ALTER VIEW, CREATE DATABASE, CREATE EVENT, CREATE FUNCTION, CREATE INDEX, CREATE PROCEDURE, CREATE ROLE, CREATE SERVER, CREATE TABLE, CREATE TRIGGER, CREATE VIEW, DROP DATABASE, DROP EVENT, DROP FUNCTION, DROP INDEX, DROP PROCEDURE, DROP ROLE, DROP SERVER, DROP TABLE, DROP TRIGGER, DROP VIEW, INSTALL PLUGIN, RENAME TABLE, TRUNCATE TABLE, UNINSTALL PLUGIN.

CREATE TABLE and DROP TABLE statements do not commit a transaction if the TEMPORARY keyword is used. (This does not apply to other operations on temporary tables such as ALTER TABLE and CREATE INDEX, which do cause a commit.) However, although no implicit commit occurs, neither can the statement be rolled back, which means that the use of such statements causes transactional atomicity to be violated. For example, if you use CREATE TEMPORARY TABLE and then roll back the transaction, the table remains in existence.

The CREATE TABLE statement in InnoDB is processed as a single transaction. This means that a ROLLBACK from the user does not undo CREATE TABLE statements the user made during that transaction.

CREATE TABLE ... SELECT causes an implicit commit before and after the statement is executed when you are creating nontemporary tables. (No commit occurs for CREATE TEMPORARY TABLE ... SELECT.) This is to prevent an issue during replication where the table could be created on the master after a rollback, but fail to be recorded in the binary log, and therefore not replicated to the slave.

- **Statements that implicitly use or modify tables in the mysql database.** ALTER USER, CREATE USER, DROP USER, GRANT, RENAME USER, REVOKE, SET PASSWORD.
- **Transaction-control and locking statements.** BEGIN, LOCK TABLES, SET autocommit = 1 (if the value is not already 1), START TRANSACTION, UNLOCK TABLES.

UNLOCK TABLES commits a transaction only if any tables currently have been locked with LOCK TABLES to acquire nontransactional table locks. A commit does not occur for UNLOCK TABLES following FLUSH TABLES WITH READ LOCK because the latter statement does not acquire table-level locks.

Transactions cannot be nested. This is a consequence of the implicit commit performed for any current transaction when you issue a START TRANSACTION statement or one of its synonyms.

Statements that cause an implicit commit cannot be used in an XA transaction while the transaction is in an ACTIVE state.

The BEGIN statement differs from the use of the BEGIN keyword that starts a BEGIN ... END compound statement. The latter does not cause an implicit commit. See [Section 13.6.1, “BEGIN ... END Compound-Statement Syntax”](#).

- **Data loading statements.** LOAD DATA INFILE. LOAD DATA INFILE causes an implicit commit only for tables using the NDB storage engine.
- **Administrative statements.** ANALYZE TABLE, CACHE INDEX, CHECK TABLE, FLUSH, LOAD INDEX INTO CACHE, OPTIMIZE TABLE, REPAIR TABLE, RESET.
- **Replication control statements.** START SLAVE, STOP SLAVE, RESET SLAVE, CHANGE MASTER TO.

13.3.4 SAVEPOINT, ROLLBACK TO SAVEPOINT, and RELEASE SAVEPOINT Syntax

SAVEPOINT *identifier*

```
ROLLBACK [WORK] TO [SAVEPOINT] identifier
RELEASE SAVEPOINT identifier
```

InnoDB supports the SQL statements `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, `RELEASE SAVEPOINT` and the optional `WORK` keyword for `ROLLBACK`.

The `SAVEPOINT` statement sets a named transaction savepoint with a name of *identifier*. If the current transaction has a savepoint with the same name, the old savepoint is deleted and a new one is set.

The `ROLLBACK TO SAVEPOINT` statement rolls back a transaction to the named savepoint without terminating the transaction. Modifications that the current transaction made to rows after the savepoint was set are undone in the rollback, but InnoDB does *not* release the row locks that were stored in memory after the savepoint. (For a new inserted row, the lock information is carried by the transaction ID stored in the row; the lock is not separately stored in memory. In this case, the row lock is released in the undo.) Savepoints that were set at a later time than the named savepoint are deleted.

If the `ROLLBACK TO SAVEPOINT` statement returns the following error, it means that no savepoint with the specified name exists:

```
ERROR 1305 (42000): SAVEPOINT identifier does not exist
```

The `RELEASE SAVEPOINT` statement removes the named savepoint from the set of savepoints of the current transaction. No commit or rollback occurs. It is an error if the savepoint does not exist.

All savepoints of the current transaction are deleted if you execute a `COMMIT`, or a `ROLLBACK` that does not name a savepoint.

A new savepoint level is created when a stored function is invoked or a trigger is activated. The savepoints on previous levels become unavailable and thus do not conflict with savepoints on the new level. When the function or trigger terminates, any savepoints it created are released and the previous savepoint level is restored.

13.3.5 LOCK TABLES and UNLOCK TABLES Syntax

```
LOCK TABLES
  tbl_name [[AS] alias] lock_type
  [, tbl_name [[AS] alias] lock_type] ...

lock_type:
  READ [LOCAL]
  | [LOW_PRIORITY] WRITE

UNLOCK TABLES
```

MySQL enables client sessions to acquire table locks explicitly for the purpose of cooperating with other sessions for access to tables, or to prevent other sessions from modifying tables during periods when a session requires exclusive access to them. A session can acquire or release locks only for itself. One session cannot acquire locks for another session or release locks held by another session.

Locks may be used to emulate transactions or to get more speed when updating tables. This is explained in more detail later in this section.

`LOCK TABLES` explicitly acquires table locks for the current client session. Table locks can be acquired for base tables or views. You must have the `LOCK TABLES` privilege, and the `SELECT` privilege for each object to be locked.

For view locking, `LOCK TABLES` adds all base tables used in the view to the set of tables to be locked and locks them automatically. If you lock a table explicitly with `LOCK TABLES`, any tables used in triggers are also locked implicitly, as described in [Section 13.3.5.2, “LOCK TABLES and Triggers”](#).

`UNLOCK TABLES` explicitly releases any table locks held by the current session. `LOCK TABLES` implicitly releases any table locks held by the current session before acquiring new locks.

Another use for `UNLOCK TABLES` is to release the global read lock acquired with the `FLUSH TABLES WITH READ LOCK` statement, which enables you to lock all tables in all databases. See [Section 13.7.6.3, “FLUSH Syntax”](#). (This is a very convenient way to get backups if you have a file system such as Veritas that can take snapshots in time.)

A table lock protects only against inappropriate reads or writes by other sessions. A session holding a `WRITE` lock can perform table-level operations such as `DROP TABLE` or `TRUNCATE TABLE`. For sessions holding a `READ` lock, `DROP TABLE` and `TRUNCATE TABLE` operations are not permitted.

The following discussion applies only to non-`TEMPORARY` tables. `LOCK TABLES` is permitted (but ignored) for a `TEMPORARY` table. The table can be accessed freely by the session within which it was created, regardless of what other locking may be in effect. No lock is necessary because no other session can see the table.

For information about other conditions on the use of `LOCK TABLES` and statements that cannot be used while `LOCK TABLES` is in effect, see [Section 13.3.5.3, “Table-Locking Restrictions and Conditions”](#)

Rules for Lock Acquisition

To acquire table locks within the current session, use the `LOCK TABLES` statement. The following lock types are available:

`READ [LOCAL]` lock:

- The session that holds the lock can read the table (but not write it).
- Multiple sessions can acquire a `READ` lock for the table at the same time.
- Other sessions can read the table without explicitly acquiring a `READ` lock.
- The `LOCAL` modifier enables nonconflicting `INSERT` statements (concurrent inserts) by other sessions to execute while the lock is held. (See [Section 8.11.3, “Concurrent Inserts”](#).) However, `READ LOCAL` cannot be used if you are going to manipulate the database using processes external to the server while you hold the lock. For `InnoDB` tables, `READ LOCAL` is the same as `READ`.

`[LOW_PRIORITY] WRITE` lock:

- The session that holds the lock can read and write the table.
- Only the session that holds the lock can access the table. No other session can access it until the lock is released.
- Lock requests for the table by other sessions block while the `WRITE` lock is held.
- The `LOW_PRIORITY` modifier has no effect. In previous versions of MySQL, it affected locking behavior, but this is no longer true. It is now deprecated and its use produces a warning. Use `WRITE` without `LOW_PRIORITY` instead.

If the `LOCK TABLES` statement must wait due to locks held by other sessions on any of the tables, it blocks until all locks can be acquired.

A session that requires locks must acquire all the locks that it needs in a single `LOCK TABLES` statement. While the locks thus obtained are held, the session can access only the locked tables. For example, in the following sequence of statements, an error occurs for the attempt to access `t2` because it was not locked in the `LOCK TABLES` statement:

```
mysql> LOCK TABLES t1 READ;
mysql> SELECT COUNT(*) FROM t1;
```

```

+-----+
| COUNT(*) |
+-----+
|      3 |
+-----+
mysql> SELECT COUNT(*) FROM t2;
ERROR 1100 (HY000): Table 't2' was not locked with LOCK TABLES

```

Tables in the `INFORMATION_SCHEMA` database are an exception. They can be accessed without being locked explicitly even while a session holds table locks obtained with `LOCK TABLES`.

You cannot refer to a locked table multiple times in a single query using the same name. Use aliases instead, and obtain a separate lock for the table and each alias:

```

mysql> LOCK TABLE t WRITE, t AS t1 READ;
mysql> INSERT INTO t SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> INSERT INTO t SELECT * FROM t AS t1;

```

The error occurs for the first `INSERT` because there are two references to the same name for a locked table. The second `INSERT` succeeds because the references to the table use different names.

If your statements refer to a table by means of an alias, you must lock the table using that same alias. It does not work to lock the table without specifying the alias:

```

mysql> LOCK TABLE t READ;
mysql> SELECT * FROM t AS myalias;
ERROR 1100: Table 'myalias' was not locked with LOCK TABLES

```

Conversely, if you lock a table using an alias, you must refer to it in your statements using that alias:

```

mysql> LOCK TABLE t AS myalias READ;
mysql> SELECT * FROM t;
ERROR 1100: Table 't' was not locked with LOCK TABLES
mysql> SELECT * FROM t AS myalias;

```

`WRITE` locks normally have higher priority than `READ` locks to ensure that updates are processed as soon as possible. This means that if one session obtains a `READ` lock and then another session requests a `WRITE` lock, subsequent `READ` lock requests wait until the session that requested the `WRITE` lock has obtained the lock and released it.

`LOCK TABLES` acquires locks as follows:

1. Sort all tables to be locked in an internally defined order. From the user standpoint, this order is undefined.
2. If a table is to be locked with a read and a write lock, put the write lock request before the read lock request.
3. Lock one table at a time until the session gets all locks.

This policy ensures that table locking is deadlock free.

Note

`LOCK TABLES` or `UNLOCK TABLES`, when applied to a partitioned table, always locks or unlocks the entire table; these statements do not support partition lock pruning. See [Partitioning and Locking](#).

Rules for Lock Release

When the table locks held by a session are released, they are all released at the same time. A session can release its locks explicitly, or locks may be released implicitly under certain conditions.

- A session can release its locks explicitly with `UNLOCK TABLES`.
- If a session issues a `LOCK TABLES` statement to acquire a lock while already holding locks, its existing locks are released implicitly before the new locks are granted.
- If a session begins a transaction (for example, with `START TRANSACTION`), an implicit `UNLOCK TABLES` is performed, which causes existing locks to be released. (For additional information about the interaction between table locking and transactions, see [Section 13.3.5.1, “Interaction of Table Locking and Transactions”](#).)

If the connection for a client session terminates, whether normally or abnormally, the server implicitly releases all table locks held by the session (transactional and nontransactional). If the client reconnects, the locks will no longer be in effect. In addition, if the client had an active transaction, the server rolls back the transaction upon disconnect, and if reconnect occurs, the new session begins with autocommit enabled. For this reason, clients may wish to disable auto-reconnect. With auto-reconnect in effect, the client is not notified if reconnect occurs but any table locks or current transaction will have been lost. With auto-reconnect disabled, if the connection drops, an error occurs for the next statement issued. The client can detect the error and take appropriate action such as reacquiring the locks or redoing the transaction. See [Section 27.7.19, “Controlling Automatic Reconnection Behavior”](#).

Note

If you use `ALTER TABLE` on a locked table, it may become unlocked. For example, if you attempt a second `ALTER TABLE` operation, the result may be an error `Table 'tbl_name' was not locked with LOCK TABLES`. To handle this, lock the table again prior to the second alteration. See also [Section B.5.6.1, “Problems with ALTER TABLE”](#).

13.3.5.1 Interaction of Table Locking and Transactions

`LOCK TABLES` and `UNLOCK TABLES` interact with the use of transactions as follows:

- `LOCK TABLES` is not transaction-safe and implicitly commits any active transaction before attempting to lock the tables.
- `UNLOCK TABLES` implicitly commits any active transaction, but only if `LOCK TABLES` has been used to acquire table locks. For example, in the following set of statements, `UNLOCK TABLES` releases the global read lock but does not commit the transaction because no table locks are in effect:

```
FLUSH TABLES WITH READ LOCK;
START TRANSACTION;
SELECT ... ;
UNLOCK TABLES;
```

- Beginning a transaction (for example, with `START TRANSACTION`) implicitly commits any current transaction and releases existing table locks.
- `FLUSH TABLES WITH READ LOCK` acquires a global read lock and not table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits. For example, `START TRANSACTION` does not release the global read lock. See [Section 13.7.6.3, “FLUSH Syntax”](#).
- Other statements that implicitly cause transactions to be committed do not release existing table locks. For a list of such statements, see [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).
- The correct way to use `LOCK TABLES` and `UNLOCK TABLES` with transactional tables, such as InnoDB tables, is to begin a transaction with `SET autocommit = 0` (not `START TRANSACTION`) followed by `LOCK TABLES`, and to not call `UNLOCK TABLES` until you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

```
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

When you call `LOCK TABLES`, InnoDB internally takes its own table lock, and MySQL takes its own table lock. InnoDB releases its internal table lock at the next commit, but for MySQL to release its table lock, you have to call `UNLOCK TABLES`. You should not have `autocommit = 1`, because then InnoDB releases its internal table lock immediately after the call of `LOCK TABLES`, and deadlocks can very easily happen. InnoDB does not acquire the internal table lock at all if `autocommit = 1`, to help old applications avoid unnecessary deadlocks.

- `ROLLBACK` does not release table locks.

13.3.5.2 LOCK TABLES and Triggers

If you lock a table explicitly with `LOCK TABLES`, any tables used in triggers are also locked implicitly:

- The locks are taken at the same time as those acquired explicitly with the `LOCK TABLES` statement.
- The lock on a table used in a trigger depends on whether the table is used only for reading. If so, a read lock suffices. Otherwise, a write lock is used.
- If a table is locked explicitly for reading with `LOCK TABLES`, but needs to be locked for writing because it might be modified within a trigger, a write lock is taken rather than a read lock. (That is, an implicit write lock needed due to the table's appearance within a trigger causes an explicit read lock request for the table to be converted to a write lock request.)

Suppose that you lock two tables, `t1` and `t2`, using this statement:

```
LOCK TABLES t1 WRITE, t2 READ;
```

If `t1` or `t2` have any triggers, tables used within the triggers will also be locked. Suppose that `t1` has a trigger defined like this:

```
CREATE TRIGGER t1_a_ins AFTER INSERT ON t1 FOR EACH ROW
BEGIN
  UPDATE t4 SET count = count+1
    WHERE id = NEW.id AND EXISTS (SELECT a FROM t3);
  INSERT INTO t2 VALUES(1, 2);
END;
```

The result of the `LOCK TABLES` statement is that `t1` and `t2` are locked because they appear in the statement, and `t3` and `t4` are locked because they are used within the trigger:

- `t1` is locked for writing per the `WRITE` lock request.
- `t2` is locked for writing, even though the request is for a `READ` lock. This occurs because `t2` is inserted into within the trigger, so the `READ` request is converted to a `WRITE` request.
- `t3` is locked for reading because it is only read from within the trigger.
- `t4` is locked for writing because it might be updated within the trigger.

13.3.5.3 Table-Locking Restrictions and Conditions

You can safely use `KILL` to terminate a session that is waiting for a table lock. See [Section 13.7.6.4, “KILL Syntax”](#).

`LOCK TABLES` and `UNLOCK TABLES` cannot be used within stored programs.

Tables in the `performance_schema` database cannot be locked with `LOCK TABLES`, except the `setup_xxx` tables.

The following statements are prohibited while a `LOCK TABLES` statement is in effect: `CREATE TABLE`, `CREATE TABLE ... LIKE`, `CREATE VIEW`, `DROP VIEW`, and DDL statements on stored functions and procedures and events.

For some operations, system tables in the `mysql` database must be accessed. For example, the `HELP` statement requires the contents of the server-side help tables, and `CONVERT_TZ()` might need to read the time zone tables. The server implicitly locks the system tables for reading as necessary so that you need not lock them explicitly. These tables are treated as just described:

```
mysql.help_category
mysql.help_keyword
mysql.help_relation
mysql.help_topic
mysql.proc
mysql.time_zone
mysql.time_zone_leap_second
mysql.time_zone_name
mysql.time_zone_transition
mysql.time_zone_transition_type
```

If you want to explicitly place a `WRITE` lock on any of those tables with a `LOCK TABLES` statement, the table must be the only one locked; no other table can be locked with the same statement.

Normally, you do not need to lock tables, because all single `UPDATE` statements are atomic; no other session can interfere with any other currently executing SQL statement. However, there are a few cases when locking tables may provide an advantage:

- If you are going to run many operations on a set of `MyISAM` tables, it is much faster to lock the tables you are going to use. Locking `MyISAM` tables speeds up inserting, updating, or deleting on them because MySQL does not flush the key cache for the locked tables until `UNLOCK TABLES` is called. Normally, the key cache is flushed after each SQL statement.

The downside to locking the tables is that no session can update a `READ`-locked table (including the one holding the lock) and no session can access a `WRITE`-locked table other than the one holding the lock.

- If you are using tables for a nontransactional storage engine, you must use `LOCK TABLES` if you want to ensure that no other session modifies the tables between a `SELECT` and an `UPDATE`. The example shown here requires `LOCK TABLES` to execute safely:

```
LOCK TABLES trans READ, customer WRITE;
SELECT SUM(value) FROM trans WHERE customer_id=some_id;
UPDATE customer
  SET total_value=sum_from_previous_statement
  WHERE customer_id=some_id;
UNLOCK TABLES;
```

Without `LOCK TABLES`, it is possible that another session might insert a new row in the `trans` table between execution of the `SELECT` and `UPDATE` statements.

You can avoid using `LOCK TABLES` in many cases by using relative updates (`UPDATE customer SET value=value+new_value`) or the `LAST_INSERT_ID()` function.

You can also avoid locking tables in some cases by using the user-level advisory lock functions `GET_LOCK()` and `RELEASE_LOCK()`. These locks are saved in a hash table in the server and implemented with `pthread_mutex_lock()` and `pthread_mutex_unlock()` for high speed. See [Section 12.21, “Miscellaneous Functions”](#).

See [Section 8.11.1, “Internal Locking Methods”](#), for more information on locking policy.

13.3.6 SET TRANSACTION Syntax

```
SET [GLOBAL | SESSION] TRANSACTION
    transaction_characteristic [, transaction_characteristic] ...

transaction_characteristic:
    ISOLATION LEVEL level
    | READ WRITE
    | READ ONLY

level:
    REPEATABLE READ
    | READ COMMITTED
    | READ UNCOMMITTED
    | SERIALIZABLE
```

This statement specifies [transaction](#) characteristics. It takes a list of one or more characteristic values separated by commas. These characteristics set the transaction [isolation level](#) or access mode. The isolation level is used for operations on [InnoDB](#) tables. The access mode may be specified as to whether transactions operate in read/write or read-only mode.

In addition, `SET TRANSACTION` can include an optional `GLOBAL` or `SESSION` keyword to indicate the scope of the statement.

Scope of Transaction Characteristics

You can set transaction characteristics globally, for the current session, or for the next transaction:

- With the `GLOBAL` keyword, the statement applies globally for all subsequent sessions. Existing sessions are unaffected.
- With the `SESSION` keyword, the statement applies to all subsequent transactions performed within the current session.
- Without any `SESSION` or `GLOBAL` keyword, the statement applies to the next (not started) transaction performed within the current session. Subsequent transactions revert to using the `SESSION` isolation level.

A global change to transaction characteristics requires the `SUPER` privilege. Any session is free to change its session characteristics (even in the middle of a transaction), or the characteristics for its next transaction.

`SET TRANSACTION` without `GLOBAL` or `SESSION` is not permitted while there is an active transaction:

```
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.02 sec)

mysql> SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
ERROR 1568 (25001): Transaction characteristics can't be changed
while a transaction is in progress
```

To set the global default isolation level at server startup, use the `--transaction-isolation=level` option to `mysqld` on the command line or in an option file. Values of *level* for this option use dashes rather than spaces, so the permissible values are `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, or `SERIALIZABLE`. For example, to set the default isolation level to `REPEATABLE READ`, use these lines in the `[mysqld]` section of an option file:

```
[mysqld]
transaction-isolation = REPEATABLE-READ
```

It is possible to check or set the global and session transaction isolation levels at runtime by using the `tx_isolation` system variable:

```
SELECT @@GLOBAL.tx_isolation, @@tx_isolation;
SET GLOBAL tx_isolation='REPEATABLE-READ';
SET SESSION tx_isolation='SERIALIZABLE';
```

Similarly, to set the transaction access mode at server startup or at runtime, use the `--transaction-read-only` option or `tx_read_only` system variable. By default, these are `OFF` (the mode is read/write) but can be set to `ON` for a default mode of read only.

Setting the global or session value of `tx_isolation` or `tx_read_only` is equivalent to setting the isolation level or access mode with `SET GLOBAL TRANSACTION` or `SET SESSION TRANSACTION`.

Transaction Isolation Levels

For information about transaction isolation levels, see [Section 15.5.2.1, “Transaction Isolation Levels”](#).

Transaction Access Mode

The transaction access mode may be specified with `SET TRANSACTION`. By default, a transaction takes place in read/write mode, with both reads and writes permitted to tables used in the transaction. This mode may be specified explicitly using an access mode of `READ WRITE`.

If the transaction access mode is set to `READ ONLY`, changes to tables are prohibited. This may enable storage engines to make performance improvements that are possible when writes are not permitted.

It is not permitted to specify both `READ WRITE` and `READ ONLY` in the same statement.

In read-only mode, it remains possible to change tables created with the `TEMPORARY` keyword using DML statements. Changes made with DDL statements are not permitted, just as with permanent tables.

The `READ WRITE` and `READ ONLY` access modes also may be specified for an individual transaction using the `START TRANSACTION` statement.

13.3.7 XA Transactions

Support for XA transactions is available for the `InnoDB` storage engine. The MySQL XA implementation is based on the X/Open CAE document *Distributed Transaction Processing: The XA Specification*. This document is published by The Open Group and available at <http://www.opengroup.org/public/pubs/catalog/c193.htm>. Limitations of the current XA implementation are described in [Section C.6, “Restrictions on XA Transactions”](#).

On the client side, there are no special requirements. The XA interface to a MySQL server consists of SQL statements that begin with the `XA` keyword. MySQL client programs must be able to send SQL statements and to understand the semantics of the XA statement interface. They do not need to be linked against a recent client library. Older client libraries also will work.

Among the MySQL Connectors, MySQL Connector/J 5.0.0 and higher supports XA directly, by means of a class interface that handles the XA SQL statement interface for you.

XA supports distributed transactions, that is, the ability to permit multiple separate transactional resources to participate in a global transaction. Transactional resources often are RDBMSs but may be other kinds of resources.

A global transaction involves several actions that are transactional in themselves, but that all must either complete successfully as a group, or all be rolled back as a group. In essence, this extends ACID properties “up a level” so that multiple ACID transactions can be executed in concert as components of a global operation that also has ACID properties. (As with nondistributed transactions, `SERIALIZABLE` may be preferred if your applications are sensitive to read phenomena. `REPEATABLE READ` may not be sufficient for distributed transactions.)

Some examples of distributed transactions:

- An application may act as an integration tool that combines a messaging service with an RDBMS. The application makes sure that transactions dealing with message sending, retrieval, and processing that also involve a transactional database all happen in a global transaction. You can think of this as “transactional email.”
- An application performs actions that involve different database servers, such as a MySQL server and an Oracle server (or multiple MySQL servers), where actions that involve multiple servers must happen as part of a global transaction, rather than as separate transactions local to each server.
- A bank keeps account information in an RDBMS and distributes and receives money through automated teller machines (ATMs). It is necessary to ensure that ATM actions are correctly reflected in the accounts, but this cannot be done with the RDBMS alone. A global transaction manager integrates the ATM and database resources to ensure overall consistency of financial transactions.

Applications that use global transactions involve one or more Resource Managers and a Transaction Manager:

- A Resource Manager (RM) provides access to transactional resources. A database server is one kind of resource manager. It must be possible to either commit or roll back transactions managed by the RM.
- A Transaction Manager (TM) coordinates the transactions that are part of a global transaction. It communicates with the RMs that handle each of these transactions. The individual transactions within a global transaction are “branches” of the global transaction. Global transactions and their branches are identified by a naming scheme described later.

The MySQL implementation of XA enables a MySQL server to act as a Resource Manager that handles XA transactions within a global transaction. A client program that connects to the MySQL server acts as the Transaction Manager.

To carry out a global transaction, it is necessary to know which components are involved, and bring each component to a point when it can be committed or rolled back. Depending on what each component reports about its ability to succeed, they must all commit or roll back as an atomic group. That is, either all components must commit, or all components must roll back. To manage a global transaction, it is necessary to take into account that any component or the connecting network might fail.

The process for executing a global transaction uses two-phase commit (2PC). This takes place after the actions performed by the branches of the global transaction have been executed.

1. In the first phase, all branches are prepared. That is, they are told by the TM to get ready to commit. Typically, this means each RM that manages a branch records the actions for the branch in stable storage. The branches indicate whether they are able to do this, and these results are used for the second phase.
2. In the second phase, the TM tells the RMs whether to commit or roll back. If all branches indicated when they were prepared that they will be able to commit, all branches are told to commit. If any branch indicated when it was prepared that it will not be able to commit, all branches are told to roll back.

In some cases, a global transaction might use one-phase commit (1PC). For example, when a Transaction Manager finds that a global transaction consists of only one transactional resource (that is, a single branch), that resource can be told to prepare and commit at the same time.

13.3.7.1 XA Transaction SQL Syntax

To perform XA transactions in MySQL, use the following statements:

```

XA {START|BEGIN} xid [JOIN|RESUME]

XA END xid [SUSPEND [FOR MIGRATE]]

XA PREPARE xid

XA COMMIT xid [ONE PHASE]

XA ROLLBACK xid

XA RECOVER [CONVERT XID]

```

For `XA START`, the `JOIN` and `RESUME` clauses are not supported.

For `XA END` the `SUSPEND [FOR MIGRATE]` clause is not supported.

Each XA statement begins with the `XA` keyword, and most of them require an `xid` value. An `xid` is an XA transaction identifier. It indicates which transaction the statement applies to. `xid` values are supplied by the client, or generated by the MySQL server. An `xid` value has from one to three parts:

```

xid: gtrid [, bqual [, formatID ]]

```

`gtrid` is a global transaction identifier, `bqual` is a branch qualifier, and `formatID` is a number that identifies the format used by the `gtrid` and `bqual` values. As indicated by the syntax, `bqual` and `formatID` are optional. The default `bqual` value is `' '` if not given. The default `formatID` value is 1 if not given.

`gtrid` and `bqual` must be string literals, each up to 64 bytes (not characters) long. `gtrid` and `bqual` can be specified in several ways. You can use a quoted string (`'ab'`), hex string (`X'6162'`, `0x6162`), or bit value (`b'nnnn'`).

`formatID` is an unsigned integer.

The `gtrid` and `bqual` values are interpreted in bytes by the MySQL server's underlying XA support routines. However, while an SQL statement containing an XA statement is being parsed, the server works with some specific character set. To be safe, write `gtrid` and `bqual` as hex strings.

`xid` values typically are generated by the Transaction Manager. Values generated by one TM must be different from values generated by other TMs. A given TM must be able to recognize its own `xid` values in a list of values returned by the `XA RECOVER` statement.

For `XA START xid` starts an XA transaction with the given `xid` value. Each XA transaction must have a unique `xid` value, so the value must not currently be used by another XA transaction. Uniqueness is assessed using the `gtrid` and `bqual` values. All following XA statements for the XA transaction must be specified using the same `xid` value as that given in the `XA START` statement. If you use any of those statements but specify an `xid` value that does not correspond to some existing XA transaction, an error occurs.

One or more XA transactions can be part of the same global transaction. All XA transactions within a given global transaction must use the same `gtrid` value in the `xid` value. For this reason, `gtrid` values must be globally unique so that there is no ambiguity about which global transaction a given XA transaction is part of. The `bqual` part of the `xid` value must be different for each XA transaction within a global transaction. (The requirement that `bqual` values be different is a limitation of the current MySQL XA implementation. It is not part of the XA specification.)

The `XA RECOVER` statement returns information for those XA transactions on the MySQL server that are in the `PREPARED` state. (See [Section 13.3.7.2, “XA Transaction States”](#).) The output includes a row for each such XA transaction on the server, regardless of which client started it.

As of MySQL 8.0.2, `XA RECOVER` requires the `XA_RECOVER_ADMIN` privilege. This privilege requirement prevents users from discovering the XID values for outstanding prepared XA transactions

other than their own. It does not affect normal commit or rollback of an XA transaction because the user who started it knows its XID.

`XA RECOVER` output rows look like this (for an example `xid` value consisting of the parts 'abc', 'def', and 7):

```
mysql> XA RECOVER;
+-----+-----+-----+-----+
| formatID | gtrid_length | bqual_length | data |
+-----+-----+-----+-----+
|          7 |              3 |              3 | abcdef |
+-----+-----+-----+-----+
```

The output columns have the following meanings:

- `formatID` is the `formatID` part of the transaction `xid`
- `gtrid_length` is the length in bytes of the `gtrid` part of the `xid`
- `bqual_length` is the length in bytes of the `bqual` part of the `xid`
- `data` is the concatenation of the `gtrid` and `bqual` parts of the `xid`

XID values may contain nonprintable characters. `XA RECOVER` permits an optional `CONVERT XID` clause so that clients can request XID values in hexadecimal.

13.3.7.2 XA Transaction States

An XA transaction progresses through the following states:

1. Use `XA START` to start an XA transaction and put it in the `ACTIVE` state.
2. For an `ACTIVE` XA transaction, issue the SQL statements that make up the transaction, and then issue an `XA END` statement. `XA END` puts the transaction in the `IDLE` state.
3. For an `IDLE` XA transaction, you can issue either an `XA PREPARE` statement or an `XA COMMIT ... ONE PHASE` statement:
 - `XA PREPARE` puts the transaction in the `PREPARED` state. An `XA RECOVER` statement at this point will include the transaction's `xid` value in its output, because `XA RECOVER` lists all XA transactions that are in the `PREPARED` state.
 - `XA COMMIT ... ONE PHASE` prepares and commits the transaction. The `xid` value will not be listed by `XA RECOVER` because the transaction terminates.
4. For a `PREPARED` XA transaction, you can issue an `XA COMMIT` statement to commit and terminate the transaction, or `XA ROLLBACK` to roll back and terminate the transaction.

Here is a simple XA transaction that inserts a row into a table as part of a global transaction:

```
mysql> XA START 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO mytable (i) VALUES(10);
Query OK, 1 row affected (0.04 sec)

mysql> XA END 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA PREPARE 'xatest';
Query OK, 0 rows affected (0.00 sec)

mysql> XA COMMIT 'xatest';
```

```
Query OK, 0 rows affected (0.00 sec)
```

Within the context of a given client connection, XA transactions and local (non-XA) transactions are mutually exclusive. For example, if `XA START` has been issued to begin an XA transaction, a local transaction cannot be started until the XA transaction has been committed or rolled back. Conversely, if a local transaction has been started with `START TRANSACTION`, no XA statements can be used until the transaction has been committed or rolled back.

If an XA transaction is in the `ACTIVE` state, you cannot issue any statements that cause an implicit commit. That would violate the XA contract because you could not roll back the XA transaction. You will receive the following error if you try to execute such a statement:

```
ERROR 1399 (XAE07): XAER_RMFAIL: The command cannot be executed
when global transaction is in the ACTIVE state
```

Statements to which the preceding remark applies are listed at [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

13.4 Replication Statements

Replication can be controlled through the SQL interface using the statements described in this section. Statements are split into a group which controls master servers, a group which controls slave servers, and a group which can be applied to any replication servers.

13.4.1 SQL Statements for Controlling Master Servers

This section discusses statements for managing master replication servers. [Section 13.4.2, “SQL Statements for Controlling Slave Servers”](#), discusses statements for managing slave servers.

In addition to the statements described here, the following `SHOW` statements are used with master servers in replication. For information about these statements, see [Section 13.7.5, “SHOW Syntax”](#).

- `SHOW BINARY LOGS`
- `SHOW BINLOG EVENTS`
- `SHOW MASTER STATUS`
- `SHOW SLAVE HOSTS`

13.4.1.1 PURGE BINARY LOGS Syntax

```
PURGE { BINARY | MASTER } LOGS
      { TO 'log_name' | BEFORE datetime_expr }
```

The binary log is a set of files that contain information about data modifications made by the MySQL server. The log consists of a set of binary log files, plus an index file (see [Section 5.4.4, “The Binary Log”](#)).

The `PURGE BINARY LOGS` statement deletes all the binary log files listed in the log index file prior to the specified log file name or date. `BINARY` and `MASTER` are synonyms. Deleted log files also are removed from the list recorded in the index file, so that the given log file becomes the first in the list.

This statement has no effect if the server was not started with the `--log-bin` option to enable binary logging.

Examples:

```
PURGE BINARY LOGS TO 'mysql-bin.010';
PURGE BINARY LOGS BEFORE '2008-04-02 22:46:26';
```

The `BEFORE` variant's `datetime_expr` argument should evaluate to a `DATETIME` value (a value in `'YYYY-MM-DD hh:mm:ss'` format).

This statement is safe to run while slaves are replicating. You need not stop them. If you have an active slave that currently is reading one of the log files you are trying to delete, this statement does nothing and it raises a warning in such cases. However, if a slave is not connected and you happen to purge one of the log files it has yet to read, the slave will be unable to replicate after it reconnects.

To safely purge binary log files, follow this procedure:

1. On each slave server, use `SHOW SLAVE STATUS` to check which log file it is reading.
2. Obtain a listing of the binary log files on the master server with `SHOW BINARY LOGS`.
3. Determine the earliest log file among all the slaves. This is the target file. If all the slaves are up to date, this is the last log file on the list.
4. Make a backup of all the log files you are about to delete. (This step is optional, but always advisable.)
5. Purge all log files up to but not including the target file.

You can also set the `expire_logs_days` system variable to expire binary log files automatically after a given number of days (see [Section 5.1.5, “Server System Variables”](#)). If you are using replication, you should set the variable no lower than the maximum number of days your slaves might lag behind the master.

`PURGE BINARY LOGS TO` and `PURGE BINARY LOGS BEFORE` both fail with an error when binary log files listed in the `.index` file had been removed from the system by some other means (such as using `rm` on Linux). (Bug #18199, Bug #18453) To handle such errors, edit the `.index` file (which is a simple text file) manually to ensure that it lists only the binary log files that are actually present, then run again the `PURGE BINARY LOGS` statement that failed.

13.4.1.2 RESET MASTER Syntax

```
RESET MASTER [TO binary_log_file_index_number]
```

`RESET MASTER` enables you to delete any binary log files and their related binary log index file, returning the master to its state before binary logging was started.

Warning

Use this statement with caution to ensure you do not lose binary log file data.

Issuing `RESET MASTER` without the optional `TO` clause deletes all binary log files listed in the index file, resets the binary log index file to be empty, and creates a new binary log file starting at `1`. Use the optional `TO` clause to start the binary log file index from a number other than `1` after the reset. Issuing `RESET MASTER` also clears the values of the `gtid_purged` system variable and the `gtid_executed` system variable; that is, issuing this statement sets each of these values to an empty string (`' '`). This statement also clears the `mysql.gtid_executed` table (see [mysql.gtid_executed Table](#)).

Using `RESET MASTER` with the `TO` clause to specify a binary log file index number to start from simplifies failover by providing a single statement alternative to the `FLUSH BINARY LOGS` and `PURGE BINARY LOGS TO` statements.

The following example demonstrates `TO` clause usage:

```
RESET MASTER TO 1234;

SHOW BINARY LOGS;
+-----+-----+
```

Log_name	File_size
master-bin.001234	154

Important

The effects of `RESET MASTER` without the `TO` clause differ from those of `PURGE BINARY LOGS` in 2 key ways:

1. `RESET MASTER` removes *all* binary log files that are listed in the index file, leaving only a single, empty binary log file with a numeric suffix of `.000001`, whereas the numbering is not reset by `PURGE BINARY LOGS`.
2. `RESET MASTER` is *not* intended to be used while any replication slaves are running. The behavior of `RESET MASTER` when used while slaves are running is undefined (and thus unsupported), whereas `PURGE BINARY LOGS` may be safely used while replication slaves are running.

See also [Section 13.4.1.1, “PURGE BINARY LOGS Syntax”](#).

`RESET MASTER` without the `TO` clause can prove useful when you first set up the master and the slave, so that you can verify the setup as follows:

1. Start the master and slave, and start replication (see [Section 18.1.2, “Setting Up Binary Log File Position Based Replication”](#)).
2. Execute a few test queries on the master.
3. Check that the queries were replicated to the slave.
4. When replication is running correctly, issue `STOP SLAVE` followed by `RESET SLAVE` on the slave, then verify that no unwanted data from the test queries exists on the slave.
5. Issue `RESET MASTER` on the master to clean up the test queries.

After verifying the setup, resetting the master and slave and ensuring that no unwanted data or binary log files generated by testing remain on the master or slave, you can start the slave and begin replicating.

13.4.1.3 SET sql_log_bin Syntax

```
SET sql_log_bin = {0|1}
```

The `sql_log_bin` variable controls whether logging to the binary log is done. The default value is 1 (do logging). To change logging for the current session, change the session value of this variable. The session user must have the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege to set this variable. Set this variable to 0 for a session to temporarily disable binary logging while making changes to the master which you do not want to replicate to the slave.

As of MySQL 5.5, `sql_log_bin` can be set as a global or session variable. Setting `sql_log_bin` globally is only detected when a new session is started. Any sessions previously running are not impacted when setting `sql_log_bin` globally.

Warning

Incorrect use of `sql_log_bin` with a global scope means any changes made in an already running session are *still* being recorded to the binary log and therefore replicated. Exercise extreme caution using `sql_log_bin` with a global scope as the above situation could cause unexpected results including replication failure.

In MySQL 5.7, it is not possible to set `@session.sql_log_bin` within a transaction or subquery. (Bug #53437)

13.4.2 SQL Statements for Controlling Slave Servers

This section discusses statements for managing slave replication servers. [Section 13.4.1, “SQL Statements for Controlling Master Servers”](#), discusses statements for managing master servers.

In addition to the statements described here, `SHOW SLAVE STATUS` and `SHOW RELAYLOG EVENTS` are also used with replication slaves. For information about these statements, see [Section 13.7.5.34, “SHOW SLAVE STATUS Syntax”](#), and [Section 13.7.5.32, “SHOW RELAYLOG EVENTS Syntax”](#).

13.4.2.1 CHANGE MASTER TO Syntax

```
CHANGE MASTER TO option [, option] ... [ channel_option ]
```

option:

```
MASTER_BIND = 'interface_name'
| MASTER_HOST = 'host_name'
| MASTER_USER = 'user_name'
| MASTER_PASSWORD = 'password'
| MASTER_PORT = port_num
| MASTER_CONNECT_RETRY = interval
| MASTER_RETRY_COUNT = count
| MASTER_DELAY = interval
| MASTER_HEARTBEAT_PERIOD = interval
| MASTER_LOG_FILE = 'master_log_name'
| MASTER_LOG_POS = master_log_pos
| MASTER_AUTO_POSITION = {0|1}
| RELAY_LOG_FILE = 'relay_log_name'
| RELAY_LOG_POS = relay_log_pos
| MASTER_SSL = {0|1}
| MASTER_SSL_CA = 'ca_file_name'
| MASTER_SSL_CAPATH = 'ca_directory_name'
| MASTER_SSL_CERT = 'cert_file_name'
| MASTER_SSL_CRL = 'crl_file_name'
| MASTER_SSL_CRLPATH = 'crl_directory_name'
| MASTER_SSL_KEY = 'key_file_name'
| MASTER_SSL_CIPHER = 'cipher_list'
| MASTER_SSL_VERIFY_SERVER_CERT = {0|1}
| MASTER_TLS_VERSION = 'protocol_list'
| IGNORE_SERVER_IDS = (server_id_list)
```

channel_option:

```
FOR CHANNEL channel
```

server_id_list:

```
[server_id [, server_id] ... ]
```

`CHANGE MASTER TO` changes the parameters that the slave server uses for connecting to the master server, for reading the master binary log, and reading the slave relay log. It also updates the contents of the master info and relay log info repositories (see [Section 18.2.4, “Replication Relay and Status Logs”](#)). `CHANGE MASTER TO` requires the `REPLICATION_SLAVE_ADMIN` or `SUPER` privilege.

You can issue `CHANGE MASTER TO` statements on a running slave without first stopping it, depending on the states of the slave SQL thread and slave I/O thread. The rules governing such use are provided later in this section.

When using a multi-threaded slave (in other words `slave_parallel_workers` is greater than 0), stopping the slave can cause “gaps” in the sequence of transactions that have been executed from the relay log, regardless of whether the slave was stopped intentionally or otherwise. When such gaps exist, issuing `CHANGE MASTER TO` fails. The solution in this situation is to issue `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` which ensures that the gaps are closed.

The optional `FOR CHANNEL channel` clause enables you to choose which replication channel the statement applies to. If no clause is set and no extra channels exist, the statement applies to the

default channel and behaves the same as versions of MySQL prior to 5.7.6. Providing a `FOR CHANNEL channel` clause applies the `CHANGE MASTER TO` statement to a specific replication channel, and is used to add a new channel or modify an existing channel. For example, to add a new channel called `channel2`:

```
CHANGE MASTER TO MASTER_HOST=host1, MASTER_PORT=3002 FOR CHANNEL 'channel2'
```

When using multiple replication channels, if a `CHANGE MASTER TO` statement does not have a channel defined using a `FOR CHANNEL channel` clause an error is generated. See [Section 18.2.3, “Replication Channels”](#) for more information.

Options not specified retain their value, except as indicated in the following discussion. Thus, in most cases, there is no need to specify options that do not change.

`MASTER_HOST`, `MASTER_USER`, `MASTER_PASSWORD`, and `MASTER_PORT` provide information to the slave about how to connect to its master:

- `MASTER_HOST` and `MASTER_PORT` are the host name (or IP address) of the master host and its TCP/IP port.

Note

Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

If you specify the `MASTER_HOST` or `MASTER_PORT` option, the slave assumes that the master server is different from before (even if the option value is the same as its current value.) In this case, the old values for the master binary log file name and position are considered no longer applicable, so if you do not specify `MASTER_LOG_FILE` and `MASTER_LOG_POS` in the statement, `MASTER_LOG_FILE= ''` and `MASTER_LOG_POS=4` are silently appended to it.

Setting `MASTER_HOST= ''` (that is, setting its value explicitly to an empty string) is *not* the same as not setting `MASTER_HOST` at all. Beginning with MySQL 5.5, trying to set `MASTER_HOST` to an empty string fails with an error. Previously, setting `MASTER_HOST` to an empty string caused `START SLAVE` subsequently to fail. (Bug #28796)

Values used for `MASTER_HOST` and other `CHANGE MASTER TO` options are checked for linefeed (`\n` or `0x0A`) characters; the presence of such characters in these values causes the statement to fail with `ER_MASTER_INFO`. (Bug #11758581, Bug #50801)

- `MASTER_USER` and `MASTER_PASSWORD` are the user name and password of the account to use for connecting to the master.

`MASTER_USER` cannot be made empty; setting `MASTER_USER = ''` or leaving it unset when setting a value for `MASTER_PASSWORD` causes an error (Bug #13427949).

The password used for a MySQL Replication slave account in a `CHANGE MASTER TO` statement is limited to 32 characters in length; trying to use a password of more than 32 characters causes `CHANGE MASTER TO` to fail.

Note

Prior to MySQL 5.7.5, if the password was longer, the statement succeeded but any excess characters were silently truncated.

The text of a running `CHANGE MASTER TO` statement, including values for `MASTER_USER` and `MASTER_PASSWORD`, can be seen in the output of a concurrent `SHOW PROCESSLIST` statement. (The complete text of a `START SLAVE` statement is also visible to `SHOW PROCESSLIST`.)

The `MASTER_SSL_XXX` options provide information about using SSL for the connection. They correspond to the `--ssl-xxx` options described in [Section 6.4.5, “Command Options for Secure](#)

Connections”, and [Section 18.3.9, “Setting Up Replication to Use Secure Connections”](#). These options can be changed even on slaves that are compiled without SSL support. They are saved to the master info repository, but are ignored if the slave does not have SSL support enabled.

The `MASTER_SSL=1` is prescriptive, not advisory. When given, the slave connection to the master must use SSL or the connection attempt fails.

The `MASTER_TLS_VERSION` option specifies the encryption protocols permitted by the master for slave connections. The value is like that for the `tls_version` system variable: A comma-separated list containing one or more protocol names. The protocols that can be named for this option depend on the SSL library used to compile MySQL. For details, see [Section 6.4.3, “Secure Connection Protocols and Ciphers”](#).

`MASTER_CONNECT_RETRY` specifies how many seconds to wait between connect retries. The default is 60.

`MASTER_RETRY_COUNT` limits the *number* of reconnection attempts and updates the value of the `Master_Retry_Count` column in the output of `SHOW SLAVE STATUS`. The default value is $24 * 3600 = 86400$. `MASTER_RETRY_COUNT` is intended to replace the older `--master-retry-count` server option, and is now the preferred method for setting this limit. You are encouraged not to rely on `--master-retry-count` in new applications and, when upgrading to MySQL 8.0, to update any existing applications that rely on it, so that they use `CHANGE MASTER TO ... MASTER_RETRY_COUNT` instead.

`MASTER_DELAY` specifies how many seconds behind the master the slave must lag. An event received from the master is not executed until at least *interval* seconds later than its execution on the master. The default is 0. An error occurs if *interval* is not a nonnegative integer in the range from 0 to $2^{31}-1$. For more information, see [Section 18.3.11, “Delayed Replication”](#).

A `CHANGE MASTER TO` statement employing the `MASTER_DELAY` option can be executed on a running slave when the slave SQL thread is stopped.

`MASTER_BIND` is for use on replication slaves having multiple network interfaces, and determines which of the slave’s network interfaces is chosen for connecting to the master.

The address configured with this option, if any, can be seen in the `Master_Bind` column of the output from `SHOW SLAVE STATUS`. If you are using slave status log tables (server started with `--master-info-repository=TABLE`), the value can also be seen as the `Master_bind` column of the `mysql.slave_master_info` table.

`MASTER_HEARTBEAT_PERIOD` sets the interval in seconds between replication heartbeats. Whenever the master’s binary log is updated with an event, the waiting period for the next heartbeat is reset. *interval* is a decimal value having the range 0 to 4294967 seconds and a resolution in milliseconds; the smallest nonzero value is 0.001. Heartbeats are sent by the master only if there are no unsent events in the binary log file for a period longer than *interval*.

If you are logging master connection information to tables, `MASTER_HEARTBEAT_PERIOD` can be seen as the value of the `Heartbeat` column of the `mysql.slave_master_info` table.

Setting *interval* to 0 disables heartbeats altogether. The default value for *interval* is equal to the value of `slave_net_timeout` divided by 2.

Setting `@@global.slave_net_timeout` to a value less than that of the current heartbeat interval results in a warning being issued. The effect of issuing `RESET SLAVE` on the heartbeat interval is to reset it to the default value.

`MASTER_LOG_FILE` and `MASTER_LOG_POS` are the coordinates at which the slave I/O thread should begin reading from the master the next time the thread starts. `RELAY_LOG_FILE` and `RELAY_LOG_POS` are the coordinates at which the slave SQL thread should begin reading from the relay log the next time the thread starts. If you specify either of `MASTER_LOG_FILE` or

`MASTER_LOG_POS`, you cannot specify `RELAY_LOG_FILE` or `RELAY_LOG_POS`. If you specify either of `MASTER_LOG_FILE` or `MASTER_LOG_POS`, you also cannot specify `MASTER_AUTO_POSITION = 1` (described later in this section). If neither of `MASTER_LOG_FILE` or `MASTER_LOG_POS` is specified, the slave uses the last coordinates of the *slave SQL thread* before `CHANGE MASTER TO` was issued. This ensures that there is no discontinuity in replication, even if the slave SQL thread was late compared to the slave I/O thread, when you merely want to change, say, the password to use.

A `CHANGE MASTER TO` statement employing `RELAY_LOG_FILE`, `RELAY_LOG_POS`, or both options can be executed on a running slave when the slave SQL thread is stopped.

If `MASTER_AUTO_POSITION = 1` is used with `CHANGE MASTER TO`, the slave attempts to connect to the master using the GTID-based replication protocol. This option can be employed by `CHANGE MASTER TO` only if both the slave SQL and slave I/O threads are stopped.

When using GTIDs, the slave tells the master which transactions it has already received, executed, or both. To compute this set, it reads the global value of `gtid_executed` and the value of the `Retrieved_gtid_set` column from `SHOW SLAVE STATUS`. Since the GTID of the last transmitted transaction is included in `Retrieved_gtid_set` even if the transaction was only partially transmitted, the last received GTID is subtracted from this set. Thus, the slave computes the following set:

```
UNION(@@global.gtid_executed, Retrieved_gtid_set - last_received_GTID)
```

This set is sent to the master as part of the initial handshake, and the master sends back all transactions that it has executed which are not part of the set. If any of these transactions have been already purged from the master's binary log, the master sends the error `ER_MASTER_HAS_PURGED_REQUIRED_GTIDS` to the slave, and replication does not start.

When GTID-based replication is employed, the coordinates represented by `MASTER_LOG_FILE` and `MASTER_LOG_POS` are not used, and global transaction identifiers are used instead. Thus the use of either or both of these options together with `MASTER_AUTO_POSITION` causes an error.

You can see whether replication is running with autopositioning enabled by checking the output of `SHOW SLAVE STATUS`.

`gtid_mode` must also be enabled before issuing `CHANGE MASTER TO ... MASTER_AUTO_POSITION = 1`. Otherwise, the statement fails with an error.

To revert to the older file-based replication protocol after using GTIDs, you can issue a new `CHANGE MASTER TO` statement that specifies `MASTER_AUTO_POSITION = 0`, as well as at least one of `MASTER_LOG_FILE` or `MASTER_LOG_POSITION`.

Relay logs are preserved if at least one of the slave SQL thread and the slave I/O thread is running; if both threads are stopped, all relay log files are deleted unless at least one of `RELAY_LOG_FILE` or `RELAY_LOG_POS` is specified.

`RELAY_LOG_FILE` can use either an absolute or relative path, and uses the same base name as `MASTER_LOG_FILE`. (Bug #12190)

`IGNORE_SERVER_IDS` takes a comma-separated list of 0 or more server IDs. Events originating from the corresponding servers are ignored, with the exception of log rotation and deletion events, which are still recorded in the relay log.

In circular replication, the originating server normally acts as the terminator of its own events, so that they are not applied more than once. Thus, this option is useful in circular replication when one of the servers in the circle is removed. Suppose that you have a circular replication setup with 4 servers, having server IDs 1, 2, 3, and 4, and server 3 fails. When bridging the gap by starting replication from server 2 to server 4, you can include `IGNORE_SERVER_IDS = (3)` in the `CHANGE MASTER TO` statement that you issue on server 4 to tell it to use server 2 as its master instead of server 3. Doing so causes it to ignore and not to propagate any statements that originated with the server that is no longer in use.

If a `CHANGE MASTER TO` statement is issued without any `IGNORE_SERVER_IDS` option, any existing list is preserved. To clear the list of ignored servers, it is necessary to use the option with an empty list:

```
CHANGE MASTER TO IGNORE_SERVER_IDS = ( );
```

`RESET SLAVE ALL` clears `IGNORE_SERVER_IDS`. Before MySQL 5.7, it did not.

If `IGNORE_SERVER_IDS` contains the server's own ID and the server was started with the `--replicate-same-server-id` option enabled, an error results.

In MySQL 8.0, the master info repository and the output of `SHOW SLAVE STATUS` provide the list of servers that are currently ignored. For more information, see [Section 18.2.4.2, “Slave Status Logs”](#), and [Section 13.7.5.34, “SHOW SLAVE STATUS Syntax”](#).

In MySQL 8.0, invoking `CHANGE MASTER TO` causes the previous values for `MASTER_HOST`, `MASTER_PORT`, `MASTER_LOG_FILE`, and `MASTER_LOG_POS` to be written to the error log, along with other information about the slave's state prior to execution.

In MySQL 8.0, `CHANGE MASTER TO` causes an implicit commit of an ongoing transaction. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

The strict requirement to execute `STOP SLAVE` prior to issuing any `CHANGE MASTER TO` statement (and `START SLAVE` afterward) is removed. Instead of depending on whether the slave is stopped, the behavior of `CHANGE MASTER TO` depends on the states of the slave SQL thread and slave I/O threads; which of these threads is stopped or running now determines the options that can or cannot be used with a `CHANGE MASTER TO` statement at a given point in time. The rules for making this determination are listed here:

- If the SQL thread is stopped, you can execute `CHANGE MASTER TO` using any combination that is otherwise allowed of `RELAY_LOG_FILE`, `RELAY_LOG_POS`, and `MASTER_DELAY` options, even if the slave I/O thread is running. No other options may be used with this statement when the I/O thread is running.
- If the I/O thread is stopped, you can execute `CHANGE MASTER TO` using any of the options for this statement (in any allowed combination) *except* `RELAY_LOG_FILE`, `RELAY_LOG_POS`, or `MASTER_DELAY`, even when the SQL thread is running. These three options may not be used when the I/O thread is running.
- Both the SQL thread and the I/O thread must be stopped before issuing a `CHANGE MASTER TO` statement that employs `MASTER_AUTO_POSITION = 1`.

You can check the current state of the slave SQL and I/O threads using `SHOW SLAVE STATUS`.

For more information, see [Section 18.3.8, “Switching Masters During Failover”](#).

If you are using statement-based replication and temporary tables, it is possible for a `CHANGE MASTER TO` statement following a `STOP SLAVE` statement to leave behind temporary tables on the slave. A warning (`ER_WARN_OPEN_TEMP_TABLES_MUST_BE_ZERO`) is now issued whenever this occurs. You can avoid this in such cases by making sure that the value of the `Slave_open_temp_tables` system status variable is equal to 0 prior to executing such a `CHANGE MASTER TO` statement.

`CHANGE MASTER TO` is useful for setting up a slave when you have the snapshot of the master and have recorded the master binary log coordinates corresponding to the time of the snapshot. After loading the snapshot into the slave to synchronize it with the master, you can run `CHANGE MASTER TO MASTER_LOG_FILE='log_name', MASTER_LOG_POS=log_pos` on the slave to specify the coordinates at which the slave should begin reading the master binary log.

The following example changes the master server the slave uses and establishes the master binary log coordinates from which the slave begins reading. This is used when you want to set up the slave to replicate the master:

```
CHANGE MASTER TO
  MASTER_HOST='master2.mycompany.com',
  MASTER_USER='replication',
  MASTER_PASSWORD='big3cret',
  MASTER_PORT=3306,
  MASTER_LOG_FILE='master2-bin.001',
  MASTER_LOG_POS=4,
  MASTER_CONNECT_RETRY=10;
```

The next example shows an operation that is less frequently employed. It is used when the slave has relay log files that you want it to execute again for some reason. To do this, the master need not be reachable. You need only use `CHANGE MASTER TO` and start the SQL thread (`START SLAVE SQL_THREAD`):

```
CHANGE MASTER TO
  RELAY_LOG_FILE='slave-relay-bin.006',
  RELAY_LOG_POS=4025;
```

You can even use the second operation in a nonreplication setup with a standalone, nonslave server for recovery following a crash. Suppose that your server has crashed and you have restored it from a backup. You want to replay the server's own binary log files (not relay log files, but regular binary log files), named (for example) `myhost-bin.*`. First, make a backup copy of these binary log files in some safe place, in case you don't exactly follow the procedure below and accidentally have the server purge the binary log. Use `SET GLOBAL relay_log_purge=0` for additional safety. Then start the server without the `--log-bin` option. Instead, use the `--replicate-same-server-id`, `--relay-log=myhost-bin` (to make the server believe that these regular binary log files are relay log files) and `--skip-slave-start` options. After the server starts, issue these statements:

```
CHANGE MASTER TO
  RELAY_LOG_FILE='myhost-bin.153',
  RELAY_LOG_POS=410,
  MASTER_HOST='some_dummy_string';
START SLAVE SQL_THREAD;
```

The server reads and executes its own binary log files, thus achieving crash recovery. Once the recovery is finished, run `STOP SLAVE`, shut down the server, clear the master info and relay log info repositories, and restart the server with its original options.

Specifying the `MASTER_HOST` option (even with a dummy value) is required to make the server think it is a slave.

The following table shows the maximum permissible length for the string-valued options.

Option	Maximum Length
<code>MASTER_HOST</code>	60
<code>MASTER_USER</code>	16
<code>MASTER_PASSWORD</code>	32
<code>MASTER_LOG_FILE</code>	255
<code>RELAY_LOG_FILE</code>	255
<code>MASTER_SSL_CA</code>	255
<code>MASTER_SSL_CAPATH</code>	255
<code>MASTER_SSL_CERT</code>	255
<code>MASTER_SSL_CRL</code>	255
<code>MASTER_SSL_CRLPATH</code>	255
<code>MASTER_SSL_KEY</code>	255

Option	Maximum Length
MASTER_SSL_CIPHER	511

13.4.2.2 CHANGE REPLICATION FILTER Syntax

```
CHANGE REPLICATION FILTER filter [, filter]
  [, ...] [FOR CHANNEL channel_name]

filter:
  REPLICATE_DO_DB = (db_list)
  | REPLICATE_IGNORE_DB = (db_list)
  | REPLICATE_DO_TABLE = (tbl_list)
  | REPLICATE_IGNORE_TABLE = (tbl_list)
  | REPLICATE_WILD_DO_TABLE = (wild_tbl_list)
  | REPLICATE_WILD_IGNORE_TABLE = (wild_tbl_list)
  | REPLICATE_REWRITE_DB = (db_pair_list)

db_list:
  db_name [, db_name] [, ...]

tbl_list:
  db_name.table_name [, db_table_name] [, ...]

wild_tbl_list:
  'db_pattern.table_pattern' [, 'db_pattern.table_pattern'] [, ...]

db_pair_list:
  (db_pair) [, (db_pair)] [, ...]

db_pair:
  from_db, to_db
```

`CHANGE REPLICATION FILTER` sets one or more replication filtering rules on the slave in the same way as starting the slave `mysqld` with replication filtering options such as `--replicate-do-db` or `--replicate-wild-ignore-table`. Unlike the case with the server options, this statement does not require restarting the server to take effect, only that the slave SQL thread be stopped using `STOP SLAVE SQL_THREAD` first (and restarted with `START SLAVE SQL_THREAD` afterwards). `CHANGE REPLICATION FILTER` requires the `REPLICATION_SLAVE_ADMIN` or `SUPER` privilege. Use the `FOR CHANNEL channel_name` clause to make a replication filter specific to a replication channel, for example on a multi-source replication slave. Filters applied without a specific `FOR CHANNEL` clause are considered global filters, meaning that they are applied to all replication channels.

The following list shows the `CHANGE REPLICATION FILTER` options and how they relate to `--replicate-*` server options:

- `REPLICATE_DO_DB`: Include updates based on database name. Equivalent to `--replicate-do-db`.
- `REPLICATE_IGNORE_DB`: Exclude updates based on database name. Equivalent to `--replicate-ignore-db`.
- `REPLICATE_DO_TABLE`: Include updates based on table name. Equivalent to `--replicate-do-table`.
- `REPLICATE_IGNORE_TABLE`: Exclude updates based on table name. Equivalent to `--replicate-ignore-table`.
- `REPLICATE_WILD_DO_TABLE`: Include updates based on wildcard pattern matching table name. Equivalent to `--replicate-wild-do-table`.
- `REPLICATE_WILD_IGNORE_TABLE`: Exclude updates based on wildcard pattern matching table name. Equivalent to `--replicate-wild-ignore-table`.
- `REPLICATE_REWRITE_DB`: Perform updates on slave after substituting new name on slave for specified database on master. Equivalent to `--replicate-rewrite-db`.

The precise effects of `REPLICATE_DO_DB` and `REPLICATE_IGNORE_DB` filters are dependent on whether statement-based or row-based replication is in effect. See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#), for more information.

Multiple replication filtering rules can be created in a single `CHANGE REPLICATION FILTER` statement by separating the rules with commas, as shown here:

```
CHANGE REPLICATION FILTER
  REPLICATE_DO_DB = (d1), REPLICATE_IGNORE_DB = (d2);
```

Issuing the statement just shown is equivalent to starting the slave `mysqld` with the options `--replicate-do-db=d1 --replicate-ignore-db=d2`.

On a multi-source replication slave, which uses multiple replication channels to process transaction from different sources, use the `FOR CHANNEL channel_name` clause to set a replication filter on a replication channel:

```
CHANGE REPLICATION FILTER REPLICATE_DO_DB = (d1) FOR CHANNEL channel_1;
```

This enables you to create a channel specific replication filter to filter out selected data from a source. When a `FOR CHANNEL` clause is provided, the replication filter statement acts on that slave replication channel removing any existing replication filter which has the same filter type as the specified replication filters, and replacing them with the specified filter. Filter types not explicitly listed in the statement are not modified. If issued against a slave replication channel which is not configured, the statement fails with an `ER_SLAVE_CONFIGURATION` error. If issued against Group Replication channels, the statement fails with an `ER_SLAVE_CHANNEL_OPERATION_NOT_ALLOWED` error.

On a replication slave with multiple replication channels configured, issuing `CHANGE REPLICATION FILTER` with no `FOR CHANNEL` clause configures the replication filter for every configured slave replication channel, and for the global replication filters. For every filter type, if the filter type is listed in the statement, then any existing filter rules of that type are replaced by the filter rules specified in the most recently issued statement, otherwise the old value of the filter type is retained. For more information see [Section 18.2.5.4, “Replication Channel Based Filters”](#).

If the same filtering rule is specified multiple times, only the *last* such rule is actually used. For example, the two statements shown here have exactly the same effect, because the first `REPLICATE_DO_DB` rule in the first statement is ignored:

```
CHANGE REPLICATION FILTER
  REPLICATE_DO_DB = (db1, db2), REPLICATE_DO_DB = (db3, db4);

CHANGE REPLICATION FILTER
  REPLICATE_DO_DB = (db3, db4);
```

Caution

This behavior differs from that of the `--replicate-*` filter options where specifying the same option multiple times causes the creation of multiple filter rules.

Names of tables and database not containing any special characters need not be quoted. Values used with `REPLICATION_WILD_TABLE` and `REPLICATION_WILD_IGNORE_TABLE` are string expressions, possibly containing (special) wildcard characters, and so must be quoted. This is shown in the following example statements:

```
CHANGE REPLICATION FILTER
  REPLICATE_WILD_DO_TABLE = ('db1.old%');

CHANGE REPLICATION FILTER
  REPLICATE_WILD_IGNORE_TABLE = ('db1.new%', 'db2.new%');
```

Values used with `REPLICATE_REWRITE_DB` represent *pairs* of database names; each such value must be enclosed in parentheses. The following statement rewrites statements occurring on database `db1` on the master to database `db2` on the slave:

```
CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB = ((db1, db2));
```

The statement just shown contains two sets of parentheses, one enclosing the pair of database names, and the other enclosing the entire list. This is perhaps more easily seen in the following example, which creates two `rewrite-db` rules, one rewriting database `dbA` to `dbB`, and one rewriting database `dbC` to `dbD`:

```
CHANGE REPLICATION FILTER
  REPLICATE_REWRITE_DB = ((dbA, dbB), (dbC, dbD));
```

This statement leaves any existing replication filtering rules unchanged; to unset all filters of a given type, set the filter's value to an explicitly empty list, as shown in this example, which removes all existing `REPLICATE_DO_DB` and `REPLICATE_IGNORE_DB` rules:

```
CHANGE REPLICATION FILTER
  REPLICATE_DO_DB = (), REPLICATE_IGNORE_DB = ();
```

Setting a filter to empty in this way removes all existing rules, does not create any new ones, and does not restore any rules set at `mysqld` startup using `--replicate-*` options on the command line or in the configuration file.

Values employed with `REPLICATE_WILD_DO_TABLE` and `REPLICATE_WILD_IGNORE_TABLE` must be in the format `db_name.tbl_name`.

For more information, see [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

13.4.2.3 MASTER_POS_WAIT() Syntax

```
SELECT MASTER_POS_WAIT('master_log_file', master_log_pos [, timeout][, channel])
```

This is actually a function, not a statement. It is used to ensure that the slave has read and executed events up to a given position in the master's binary log. See [Section 12.21, “Miscellaneous Functions”](#), for a full description.

13.4.2.4 RESET SLAVE Syntax

```
RESET SLAVE [ALL] [channel_option]
```

```
channel_option:
  FOR CHANNEL channel
```

`RESET SLAVE` makes the slave forget its replication position in the master's binary log. This statement is meant to be used for a clean start: It clears the master info and relay log info repositories, deletes all the relay log files, and starts a new relay log file. It also resets to 0 the replication delay specified with the `MASTER_DELAY` option to `CHANGE MASTER TO`. `RESET SLAVE` does not change the values of `gtid_executed` or `gtid_purged`. To use `RESET SLAVE`, the slave replication threads must be stopped, so on a running slave use `STOP SLAVE` before issuing `RESET SLAVE`.

Note

All relay log files are deleted, even if they have not been completely executed by the slave SQL thread. (This is a condition likely to exist on a replication slave if you have issued a `STOP SLAVE` statement or if the slave is highly loaded.)

The optional `FOR CHANNEL channel` clause enables you to choose which replication channel the statement applies to. If no clause is set and no extra channels exist, the statement applies to the default channel. Providing a `FOR CHANNEL channel` clause applies the `RESET SLAVE` statement to a specific replication channel. Combining a `FOR CHANNEL channel` clause with the `ALL` option deletes the specified channel. Issuing a `RESET SLAVE ALL` statement without a `FOR CHANNEL channel` clause when multiple replication channels exist deletes *all* replication channels and recreates only the default channel. See [Section 18.2.3, “Replication Channels”](#) for more information.

`RESET SLAVE` does not change any replication connection parameters such as master host, master port, master user, or master password, which are retained in memory. This means that `START SLAVE` can be issued without requiring a `CHANGE MASTER TO` statement following `RESET SLAVE`.

Connection parameters are reset by `RESET SLAVE ALL`. (`RESET SLAVE` followed by a restart of the slave `mysqld` also does this.)

In MySQL 8.0 `RESET SLAVE` causes an implicit commit of an ongoing transaction. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

If the slave SQL thread was in the middle of replicating temporary tables when it was stopped, and `RESET SLAVE` is issued, these replicated temporary tables are deleted on the slave.

Prior to MySQL 5.7.5, `RESET SLAVE` also had the effect of resetting both the heartbeat period (`Slave_heartbeat_period`) and `SSL_VERIFY_SERVER_CERT`. This issue is fixed in MySQL 5.7.5 and later. (Bug #18777899, Bug #18778485)

`RESET SLAVE ALL` clears the `IGNORE_SERVER_IDS` list set by `CHANGE MASTER TO`.

13.4.2.5 SET GLOBAL sql_slave_skip_counter Syntax

```
SET GLOBAL sql_slave_skip_counter = N
```

This statement skips the next *N* events from the master. This is useful for recovering from replication stops caused by a statement.

This statement is valid only when the slave threads are not running. Otherwise, it produces an error.

When using this statement, it is important to understand that the binary log is actually organized as a sequence of groups known as *event groups*. Each event group consists of a sequence of events.

- For transactional tables, an event group corresponds to a transaction.
- For nontransactional tables, an event group corresponds to a single SQL statement.

Note

A single transaction can contain changes to both transactional and nontransactional tables.

When you use `SET GLOBAL sql_slave_skip_counter` to skip events and the result is in the middle of a group, the slave continues to skip events until it reaches the end of the group. Execution then starts with the next event group.

13.4.2.6 START SLAVE Syntax

```
START SLAVE [thread_types] [until_option] [connection_options] [channel_option]
```

```
thread_types:  
  [thread_type [, thread_type] ... ]
```

```
thread_type:
```

```

IO_THREAD | SQL_THREAD

until_option:
  UNTIL { {SQL_BEFORE_GTIDS | SQL_AFTER_GTIDS} = gtid_set
          | MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos
          | RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos
          | SQL_AFTER_MTS_GAPS }

connection_options:
  [USER='user_name'] [PASSWORD='user_pass'] [DEFAULT_AUTH='plugin_name'] [PLUGIN_DIR='plugin_dir']

channel_option:
  FOR CHANNEL channel

gtid_set:
  uuid_set [, uuid_set] ...
  | ''

uuid_set:
  uuid:interval[:interval]...

uuid:
  hhhhhhhh-hhhh-hhhh-hhhh-hhhhhhhhhhhh

h:
  [0-9,A-F]

interval:
  n[-n]

  (n >= 1)

```

`START SLAVE` with no `thread_type` options starts both of the slave threads. The I/O thread reads events from the master server and stores them in the relay log. The SQL thread reads events from the relay log and executes them. `START SLAVE` requires the `REPLICATION_SLAVE_ADMIN` or `SUPER` privilege.

If `START SLAVE` succeeds in starting the slave threads, it returns without any error. However, even in that case, it might be that the slave threads start and then later stop (for example, because they do not manage to connect to the master or read its binary log, or some other problem). `START SLAVE` does not warn you about this. You must check the slave's error log for error messages generated by the slave threads, or check that they are running satisfactorily with `SHOW SLAVE STATUS`.

`START SLAVE` causes an implicit commit of an ongoing transaction. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

`gtid_next` must be set to `AUTOMATIC` before issuing this statement.

The optional `FOR CHANNEL channel` clause enables you to choose which replication channel the statement applies to. If no clause is set and no extra channels exist, the statement applies to the default channel and behaves the same as versions of MySQL prior to 5.7.6. Providing a `FOR CHANNEL channel` clause applies the `START SLAVE` statement to a specific replication channel. If a `START SLAVE` statement does not have a channel defined when using multiple channels, this statement starts the specified threads for all channels. This statement is disallowed for the `group_replication_recovery` channel. See [Section 18.2.3, “Replication Channels”](#) for more information.

MySQL 8.0 supports pluggable user-password authentication with `START SLAVE` with the `USER`, `PASSWORD`, `DEFAULT_AUTH` and `PLUGIN_DIR` options, as described in the following list:

- `USER`: User name. Cannot be set to an empty or null string, or left unset if `PASSWORD` is used.
- `PASSWORD`: Password.
- `DEFAULT_AUTH`: Name of plugin; default is MySQL native authentication.

- `PLUGIN_DIR`: Location of plugin.

You cannot use the `SQL_THREAD` option when specifying any of `USER`, `PASSWORD`, `DEFAULT_AUTH`, or `PLUGIN_DIR`, unless the `IO_THREAD` option is also provided.

See [Section 6.3.10, “Pluggable Authentication”](#), for more information.

If an insecure connection is used with any these options, the server issues the warning `Sending passwords in plain text without SSL/TLS is extremely insecure`.

`START SLAVE ... UNTIL` supports two additional options for use with global transaction identifiers (GTIDs) (see [Section 18.1.3, “Replication with Global Transaction Identifiers”](#)). Each of these takes a set of one or more global transaction identifiers `gtid_set` as an argument (see [GTID Sets](#), for more information).

When no `thread_type` is specified, `START SLAVE UNTIL SQL_BEFORE_GTIDS` causes the slave SQL thread to process transactions until it has reached the *first* transaction whose GTID is listed in the `gtid_set`. `START SLAVE UNTIL SQL_AFTER_GTIDS` causes the slave threads to process all transactions until the *last* transaction in the `gtid_set` has been processed by both threads. In other words, `START SLAVE UNTIL SQL_BEFORE_GTIDS` causes the slave SQL thread to process all transactions occurring before the first GTID in the `gtid_set` is reached, and `START SLAVE UNTIL SQL_AFTER_GTIDS` causes the slave threads to handle all transactions, including those whose GTIDs are found in `gtid_set`, until each has encountered a transaction whose GTID is not part of the set. `SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS` each support the `SQL_THREAD` and `IO_THREAD` options, although using `IO_THREAD` with them currently has no effect.

For example, `START SLAVE SQL_THREAD UNTIL SQL_BEFORE_GTIDS = 3E11FA47-71CA-11E1-9E33-C80AA9429562:11-56` causes the slave SQL thread to process all transactions originating from the master whose `server_uuid` is `3E11FA47-71CA-11E1-9E33-C80AA9429562` until it encounters the transaction having sequence number 11; it then stops without processing this transaction. In other words, all transactions up to and including the transaction with sequence number 10 are processed. Executing `START SLAVE SQL_THREAD UNTIL SQL_AFTER_GTIDS = 3E11FA47-71CA-11E1-9E33-C80AA9429562:11-56`, on the other hand, would cause the slave SQL thread to obtain all transactions just mentioned from the master, including all of the transactions having the sequence numbers 11 through 56, and then to stop without processing any additional transactions; that is, the transaction having sequence number 56 would be the last transaction fetched by the slave SQL thread.

When using a multi-threaded slave, there is a chance of gaps in the sequence of transactions that have been executed from the relay log in the following cases:

- killing the coordinator thread
- after an error occurs in the worker threads
- `mysqld` shuts down unexpectedly

Use the `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` statement to cause a multi-threaded slave's worker threads to only run until no more gaps are found in the relay log, and then to stop. This statement can take an `SQL_THREAD` option, but the effects of the statement remain unchanged. It has no effect on the slave I/O thread (and cannot be used with the `IO_THREAD` option).

Issuing `START SLAVE` on a multi-threaded slave with gaps in the sequence of transactions executed from the relay log generates a warning. In such a situation, the solution is to use `START SLAVE UNTIL SQL_AFTER_MTS_GAPS`, then issue `RESET SLAVE` to remove any remaining relay logs. See [Section 18.4.1.34, “Replication and Transaction Inconsistencies”](#) for more information.

To change a failed multi-threaded slave to single-threaded mode, you can issue the following series of statements, in the order shown:

```
START SLAVE UNTIL SQL_AFTER_MTS_GAPS;

SET @@GLOBAL.slave_parallel_workers = 0;

START SLAVE SQL_THREAD;
```

**Note**

It is possible to view the entire text of a running `START SLAVE ...` statement, including any `USER` or `PASSWORD` values used, in the output of `SHOW PROCESSLIST`. This is also true for the text of a running `CHANGE MASTER TO` statement, including any values it employs for `MASTER_USER` or `MASTER_PASSWORD`.

`START SLAVE` sends an acknowledgment to the user after both the I/O thread and the SQL thread have started. However, the I/O thread may not yet have connected. For this reason, a successful `START SLAVE` causes `SHOW SLAVE STATUS` to show `Slave_SQL_Running=Yes`, but this does not guarantee that `Slave_IO_Running=Yes` (because `Slave_IO_Running=Yes` only if the I/O thread is running *and connected*). For more information, see [Section 13.7.5.34, “SHOW SLAVE STATUS Syntax”](#), and [Section 18.1.7.1, “Checking Replication Status”](#).

You can add `IO_THREAD` and `SQL_THREAD` options to the statement to name which of the threads to start. The `SQL_THREAD` option is disallowed when specifying any of `USER`, `PASSWORD`, `DEFAULT_AUTH`, or `PLUGIN_DIR`, unless the `IO_THREAD` option is also provided.

An `UNTIL` clause (*until_option*, in the preceding grammar) may be added to specify that the slave should start and run until the SQL thread reaches a given point in the master binary log, specified by the `MASTER_LOG_POS` and `MASTER_LOG_FILE` options, or a given point in the slave relay log, indicated with the `RELAY_LOG_POS` and `RELAY_LOG_FILE` options. When the SQL thread reaches the point specified, it stops. If the `SQL_THREAD` option is specified in the statement, it starts only the SQL thread. Otherwise, it starts both slave threads. If the SQL thread is running, the `UNTIL` clause is ignored and a warning is issued. You cannot use an `UNTIL` clause with the `IO_THREAD` option.

It is also possible with `START SLAVE UNTIL` to specify a stop point relative to a given GTID or set of GTIDs using one of the options `SQL_BEFORE_GTIDS` or `SQL_AFTER_GTIDS`, as explained previously in this section. When using one of these options, you can specify `SQL_THREAD`, `IO_THREAD`, both of these, or neither of them. If you specify only `SQL_THREAD`, then only the slave SQL thread is affected by the statement; if only `IO_THREAD` is used, then only the slave I/O is affected. If both `SQL_THREAD` and `IO_THREAD` are used, or if neither of them is used, then both the SQL and I/O threads are affected by the statement.

The `UNTIL` clause is not supported for multi-threaded slaves except when also using `SQL_AFTER_MTS_GAPS`.

For an `UNTIL` clause, you must specify any one of the following:

- *Both* a log file name and a position in that file
- *Either* of `SQL_BEFORE_GTIDS` or `SQL_AFTER_GTIDS`
- `SQL_AFTER_MTS_GAPS`

Do not mix master and relay log options. Do not mix log file options with GTID options.

Any `UNTIL` condition is reset by a subsequent `STOP SLAVE` statement, a `START SLAVE` statement that includes no `UNTIL` clause, or a server restart.

When specifying a log file and position, you can use the `IO_THREAD` option with `START SLAVE ... UNTIL` even though only the SQL thread is affected by this statement. The `IO_THREAD` option is ignored in such cases. The preceding restriction does not apply when using one of the GTID options (`SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS`); the GTID options support both `SQL_THREAD` and `IO_THREAD`, as explained previously in this section.

The `UNTIL` clause can be useful for debugging replication, or to cause replication to proceed until just before the point where you want to avoid having the slave replicate an event. For example, if an unwise `DROP TABLE` statement was executed on the master, you can use `UNTIL` to tell the slave to execute up to that point but no farther. To find what the event is, use `mysqlbinlog` with the master binary log or slave relay log, or by using a `SHOW BINLOG EVENTS` statement.

If you are using `UNTIL` to have the slave process replicated queries in sections, it is recommended that you start the slave with the `--skip-slave-start` option to prevent the SQL thread from running when the slave server starts. It is probably best to use this option in an option file rather than on the command line, so that an unexpected server restart does not cause it to be forgotten.

The `SHOW SLAVE STATUS` statement includes output fields that display the current values of the `UNTIL` condition.

In very old versions of MySQL (before 4.0.5), this statement was called `SLAVE START`. In MySQL 8.0, that syntax produces an error.

13.4.2.7 STOP SLAVE Syntax

```
STOP SLAVE [thread_types]

thread_types:
  [thread_type [, thread_type] ... ]

thread_type: IO_THREAD | SQL_THREAD

channel_option:
  FOR CHANNEL channel
```

Stops the slave threads. `STOP SLAVE` requires the `REPLICATION_SLAVE_ADMIN` or `SUPER` privilege. Recommended best practice is to execute `STOP SLAVE` on the slave before stopping the slave server (see [Section 5.1.12, “The Server Shutdown Process”](#), for more information).

When using the row-based logging format. You should execute `STOP SLAVE` or `STOP SLAVE SQL_THREAD` on the slave prior to shutting down the slave server if you are replicating any tables that use a nontransactional storage engine (see the *Note* later in this section).

Like `START SLAVE`, this statement may be used with the `IO_THREAD` and `SQL_THREAD` options to name the thread or threads to be stopped.

In MySQL 8.0, `STOP SLAVE` causes an implicit commit of an ongoing transaction. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

`gtid_next` must be set to `AUTOMATIC` before issuing this statement.

You can control how long `STOP SLAVE` waits before timing out by setting the `rpl_stop_slave_timeout` system variable. This can be used to avoid deadlocks between `STOP SLAVE` and other slave SQL statements using different client connections to the slave.

Some `CHANGE MASTER TO` statements are allowed while the slave is running, depending on the states of the slave SQL and I/O threads. However, using `STOP SLAVE` prior to executing `CHANGE MASTER TO` in such cases is still supported. See [Section 13.4.2.1, “CHANGE MASTER TO Syntax”](#), and [Section 18.3.8, “Switching Masters During Failover”](#), for more information.

The optional `FOR CHANNEL channel` clause enables you to choose which replication channel the statement applies to. If no clause is set and no extra channels exist, the statement applies to the default channel and behaves the same as versions of MySQL prior to 5.7. Providing a `FOR CHANNEL channel` clause applies the `STOP SLAVE` statement to a specific replication channel. If a `STOP SLAVE` statement does not have a channel defined when using multiple channels, this statement stops the specified threads for all channels. This statement cannot be used with the

`group_replication_recovery` channel. See [Section 18.2.3, “Replication Channels”](#) for more information.

When using statement-based replication: changing the master while it has open temporary tables is potentially unsafe. This is one of the reasons why statement-based replication of temporary tables is not recommended. You can find out whether there are any temporary tables on the slave by checking the value of `Slave_open_temp_tables`; when using statement-based replication, this value should be 0 before executing `CHANGE MASTER TO`. If there are any temporary tables open on the slave, issuing a `CHANGE MASTER TO` statement after issuing a `STOP SLAVE` causes an `ER_WARN_OPEN_TEMP_TABLES_MUST_BE_ZERO` warning.

When using a multi-threaded slave (`slave_parallel_workers` is a nonzero value), any gaps in the sequence of transactions executed from the relay log are closed as part of stopping the worker threads. If the slave is stopped unexpectedly (for example due to an error in a worker thread, or another thread issuing `KILL`) while a `STOP SLAVE` statement is executing, the sequence of executed transactions from the relay log may become inconsistent. See [Section 18.4.1.34, “Replication and Transaction Inconsistencies”](#) for more information.

In MySQL 8.0, `STOP SLAVE` waits until the current replication transaction affecting one or more nontransactional tables has finished executing (if there is any such transaction), or until you issue a `KILL QUERY` or `KILL CONNECTION` statement. (Bug #319, Bug #38205)

13.4.3 SQL Statements for Controlling Group Replication

This section provides information about the statements used for controlling group replication.

13.4.3.1 START GROUP_REPLICATION Syntax

```
START GROUP_REPLICATION
```

Starts group replication. This statement requires the `GROUP_REPLICATION_ADMIN` or `SUPER` privilege.

13.4.3.2 STOP GROUP_REPLICATION Syntax

```
STOP GROUP_REPLICATION
```

Stops group replication. This statement requires the `GROUP_REPLICATION_ADMIN` or `SUPER` privilege.

13.5 Prepared SQL Statement Syntax

MySQL 8.0 provides support for server-side prepared statements. This support takes advantage of the efficient client/server binary protocol. Using prepared statements with placeholders for parameter values has the following benefits:

- Less overhead for parsing the statement each time it is executed. Typically, database applications process large volumes of almost-identical statements, with only changes to literal or variable values in clauses such as `WHERE` for queries and deletes, `SET` for updates, and `VALUES` for inserts.
- Protection against SQL injection attacks. The parameter values can contain unescaped SQL quote and delimiter characters.

Prepared Statements in Application Programs

You can use server-side prepared statements through client programming interfaces, including the [MySQL C API client library](#) or [MySQL Connector/C](#) for C programs, [MySQL Connector/J](#) for Java programs, and [MySQL Connector/Net](#) for programs using .NET technologies. For example, the C API provides a set of function calls that make up its prepared statement API. See [Section 27.7.8, “C API Prepared Statements”](#). Other language interfaces can provide support for prepared statements that use the binary protocol by linking in the C client library, one example being the `mysql_i` extension, available in PHP 5.0 and later.

Prepared Statements in SQL Scripts

An alternative SQL interface to prepared statements is available. This interface is not as efficient as using the binary protocol through a prepared statement API, but requires no programming because it is available directly at the SQL level:

- You can use it when no programming interface is available to you.
- You can use it from any program that can send SQL statements to the server to be executed, such as the `mysql` client program.
- You can use it even if the client is using an old version of the client library, as long as you connect to a server running MySQL 4.1 or higher.

SQL syntax for prepared statements is intended to be used for situations such as these:

- To test how prepared statements work in your application before coding it.
- To use prepared statements when you do not have access to a programming API that supports them.
- To interactively troubleshoot application issues with prepared statements.
- To create a test case that reproduces a problem with prepared statements, so that you can file a bug report.

PREPARE, EXECUTE, and DEALLOCATE PREPARE Statements

SQL syntax for prepared statements is based on three SQL statements:

- `PREPARE` prepares a statement for execution (see [Section 13.5.1, “PREPARE Syntax”](#)).
- `EXECUTE` executes a prepared statement (see [Section 13.5.2, “EXECUTE Syntax”](#)).
- `DEALLOCATE PREPARE` releases a prepared statement (see [Section 13.5.3, “DEALLOCATE PREPARE Syntax”](#)).

The following examples show two equivalent ways of preparing a statement that computes the hypotenuse of a triangle given the lengths of the two sides.

The first example shows how to create a prepared statement by using a string literal to supply the text of the statement:

```
mysql> PREPARE stmt1 FROM 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> SET @a = 3;
mysql> SET @b = 4;
mysql> EXECUTE stmt1 USING @a, @b;
+-----+
| hypotenuse |
+-----+
|          5 |
+-----+
mysql> DEALLOCATE PREPARE stmt1;
```

The second example is similar, but supplies the text of the statement as a user variable:

```
mysql> SET @s = 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
mysql> PREPARE stmt2 FROM @s;
mysql> SET @a = 6;
mysql> SET @b = 8;
mysql> EXECUTE stmt2 USING @a, @b;
+-----+
| hypotenuse |
```

```
+-----+
|          10 |
+-----+
mysql> DEALLOCATE PREPARE stmt2;
```

Here is an additional example that demonstrates how to choose the table on which to perform a query at runtime, by storing the name of the table as a user variable:

```
mysql> USE test;
mysql> CREATE TABLE t1 (a INT NOT NULL);
mysql> INSERT INTO t1 VALUES (4), (8), (11), (32), (80);

mysql> SET @table = 't1';
mysql> SET @s = CONCAT('SELECT * FROM ', @table);

mysql> PREPARE stmt3 FROM @s;
mysql> EXECUTE stmt3;
+-----+
| a |
+-----+
| 4 |
| 8 |
| 11 |
| 32 |
| 80 |
+-----+

mysql> DEALLOCATE PREPARE stmt3;
```

A prepared statement is specific to the session in which it was created. If you terminate a session without deallocating a previously prepared statement, the server deallocates it automatically.

A prepared statement is also global to the session. If you create a prepared statement within a stored routine, it is not deallocated when the stored routine ends.

To guard against too many prepared statements being created simultaneously, set the `max_prepared_stmt_count` system variable. To prevent the use of prepared statements, set the value to 0.

SQL Syntax Allowed in Prepared Statements

The following SQL statements can be used as prepared statements:

```
ALTER TABLE
ALTER USER
ANALYZE TABLE
CACHE INDEX
CALL
CHANGE MASTER
CHECKSUM {TABLE | TABLES}
COMMIT
{CREATE | DROP} INDEX
{CREATE | RENAME | DROP} DATABASE
{CREATE | DROP} TABLE
{CREATE | RENAME | DROP} USER
{CREATE | DROP} VIEW
DELETE
DO
FLUSH {TABLE | TABLES | TABLES WITH READ LOCK | HOSTS | PRIVILEGES
      | LOGS | STATUS | MASTER | SLAVE | DES_KEY_FILE | USER_RESOURCES}
GRANT
INSERT
INSTALL PLUGIN
KILL
LOAD INDEX INTO CACHE
OPTIMIZE TABLE
RENAME TABLE
```

```

REPAIR TABLE
REPLACE
RESET {MASTER | SLAVE | QUERY CACHE}
REVOKE
SELECT
SET
SHOW {WARNINGS | ERRORS}
SHOW BINLOG EVENTS
SHOW CREATE {PROCEDURE | FUNCTION | EVENT | TABLE | VIEW}
SHOW {MASTER | BINARY} LOGS
SHOW {MASTER | SLAVE} STATUS
SLAVE {START | STOP}
TRUNCATE TABLE
UNINSTALL PLUGIN
UPDATE

```

For compliance with the SQL standard, which states that diagnostics statements are not preparable, MySQL does not support the following as prepared statements:

- `SHOW WARNINGS`, `SHOW COUNT(*) WARNINGS`
- `SHOW ERRORS`, `SHOW COUNT(*) ERRORS`
- Statements containing any reference to the `warning_count` or `error_count` system variable.

Other statements are not supported in MySQL 8.0.

Generally, statements not permitted in SQL prepared statements are also not permitted in stored programs. Exceptions are noted in [Section C.1, “Restrictions on Stored Programs”](#).

Metadata changes to tables or views referred to by prepared statements are detected and cause automatic reparation of the statement when it is next executed. For more information, see [Section 8.10.4, “Caching of Prepared Statements and Stored Programs”](#).

Placeholders can be used for the arguments of the `LIMIT` clause when using prepared statements. See [Section 13.2.10, “SELECT Syntax”](#).

In prepared `CALL` statements used with `PREPARE` and `EXECUTE`, placeholder support for `OUT` and `INOUT` parameters is available beginning with MySQL 8.0. See [Section 13.2.1, “CALL Syntax”](#), for an example and a workaround for earlier versions. Placeholders can be used for `IN` parameters regardless of version.

SQL syntax for prepared statements cannot be used in nested fashion. That is, a statement passed to `PREPARE` cannot itself be a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements is distinct from using prepared statement API calls. For example, you cannot use the `mysql_stmt_prepare()` C API function to prepare a `PREPARE`, `EXECUTE`, or `DEALLOCATE PREPARE` statement.

SQL syntax for prepared statements can be used within stored procedures, but not in stored functions or triggers. However, a cursor cannot be used for a dynamic statement that is prepared and executed with `PREPARE` and `EXECUTE`. The statement for a cursor is checked at cursor creation time, so the statement cannot be dynamic.

SQL syntax for prepared statements does not support multi-statements (that is, multiple statements within a single string separated by `;` characters).

Prepared statements use the query cache under the conditions described in [Section 8.10.3.1, “How the Query Cache Operates”](#).

To write C programs that use the `CALL` SQL statement to execute stored procedures that contain prepared statements, the `CLIENT_MULTI_RESULTS` flag must be enabled. This is because each `CALL` returns a result to indicate the call status, in addition to any result sets that might be returned by statements executed within the procedure.

`CLIENT_MULTI_RESULTS` can be enabled when you call `mysql_real_connect()`, either explicitly by passing the `CLIENT_MULTI_RESULTS` flag itself, or implicitly by passing `CLIENT_MULTI_STATEMENTS` (which also enables `CLIENT_MULTI_RESULTS`). For additional information, see [Section 13.2.1, “CALL Syntax”](#).

13.5.1 PREPARE Syntax

```
PREPARE stmt_name FROM preparable_stmt
```

The `PREPARE` statement prepares a SQL statement and assigns it a name, `stmt_name`, by which to refer to the statement later. The prepared statement is executed with `EXECUTE` and released with `DEALLOCATE PREPARE`. For examples, see [Section 13.5, “Prepared SQL Statement Syntax”](#).

Statement names are not case sensitive. `preparable_stmt` is either a string literal or a user variable that contains the text of the SQL statement. The text must represent a single statement, not multiple statements. Within the statement, `?` characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The `?` characters should not be enclosed within quotation marks, even if you intend to bind them to string values. Parameter markers can be used only where data values should appear, not for SQL keywords, identifiers, and so forth.

If a prepared statement with the given name already exists, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name exists.

The scope of a prepared statement is the session within which it is created, which has several implications:

- A prepared statement created in one session is not available to other sessions.
- When a session ends, whether normally or abnormally, its prepared statements no longer exist. If auto-reconnect is enabled, the client is not notified that the connection was lost. For this reason, clients may wish to disable auto-reconnect. See [Section 27.7.19, “Controlling Automatic Reconnection Behavior”](#).
- A prepared statement created within a stored program continues to exist after the program finishes executing and can be executed outside the program later.
- A statement prepared in stored program context cannot refer to stored procedure or function parameters or local variables because they go out of scope when the program ends and would be unavailable were the statement to be executed later outside the program. As a workaround, refer instead to user-defined variables, which also have session scope; see [Section 9.4, “User-Defined Variables”](#).

13.5.2 EXECUTE Syntax

```
EXECUTE stmt_name
  [USING @var_name [, @var_name] ...]
```

After preparing a statement with `PREPARE`, you execute it with an `EXECUTE` statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must supply a `USING` clause that lists user variables containing the values to be bound to the parameters. Parameter values can be supplied only by user variables, and the `USING` clause must name exactly as many variables as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing different variables to it or setting the variables to different values before each execution.

For examples, see [Section 13.5, “Prepared SQL Statement Syntax”](#).

13.5.3 DEALLOCATE PREPARE Syntax

```
{DEALLOCATE | DROP} PREPARE stmt_name
```

To deallocate a prepared statement produced with `PREPARE`, use a `DEALLOCATE PREPARE` statement that refers to the prepared statement name. Attempting to execute a prepared statement after deallocating it results in an error. If too many prepared statements are created and not deallocated by either the `DEALLOCATE PREPARE` statement or the end of the session, you might encounter the upper limit enforced by the `max_prepared_stmt_count` system variable.

For examples, see [Section 13.5, “Prepared SQL Statement Syntax”](#).

13.6 Compound-Statement Syntax

This section describes the syntax for the `BEGIN ... END` compound statement and other statements that can be used in the body of stored programs: Stored procedures and functions, triggers, and events. These objects are defined in terms of SQL code that is stored on the server for later invocation (see [Chapter 23, *Stored Programs and Views*](#)).

A compound statement is a block that can contain other blocks; declarations for variables, condition handlers, and cursors; and flow control constructs such as loops and conditional tests.

13.6.1 BEGIN ... END Compound-Statement Syntax

```
[begin_label:] BEGIN
  [statement_list]
END [end_label]
```

`BEGIN ... END` syntax is used for writing compound statements, which can appear within stored programs (stored procedures and functions, triggers, and events). A compound statement can contain multiple statements, enclosed by the `BEGIN` and `END` keywords. *statement_list* represents a list of one or more statements, each terminated by a semicolon (`;`) statement delimiter. The *statement_list* itself is optional, so the empty compound statement (`BEGIN END`) is legal.

`BEGIN ... END` blocks can be nested.

Use of multiple statements requires that a client is able to send statement strings containing the `;` statement delimiter. In the `mysql` command-line client, this is handled with the `delimiter` command. Changing the `;` end-of-statement delimiter (for example, to `//`) permit `;` to be used in a program body. For an example, see [Section 23.1, “Defining Stored Programs”](#).

A `BEGIN ... END` block can be labeled. See [Section 13.6.2, “Statement Label Syntax”](#).

The optional `[NOT] ATOMIC` clause is not supported. This means that no transactional savepoint is set at the start of the instruction block and the `BEGIN` clause used in this context has no effect on the current transaction.

Note

Within all stored programs, the parser treats `BEGIN [WORK]` as the beginning of a `BEGIN ... END` block. To begin a transaction in this context, use `START TRANSACTION` instead.

13.6.2 Statement Label Syntax

```
[begin_label:] BEGIN
  [statement_list]
END [end_label]
```

```
[begin_label:] LOOP
    statement_list
END LOOP [end_label]

[begin_label:] REPEAT
    statement_list
UNTIL search_condition
END REPEAT [end_label]

[begin_label:] WHILE search_condition DO
    statement_list
END WHILE [end_label]
```

Labels are permitted for `BEGIN ... END` blocks and for the `LOOP`, `REPEAT`, and `WHILE` statements. Label use for those statements follows these rules:

- `begin_label` must be followed by a colon.
- `begin_label` can be given without `end_label`. If `end_label` is present, it must be the same as `begin_label`.
- `end_label` cannot be given without `begin_label`.
- Labels at the same nesting level must be distinct.
- Labels can be up to 16 characters long.

To refer to a label within the labeled construct, use an `ITERATE` or `LEAVE` statement. The following example uses those statements to continue iterating or terminate the loop:

```
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
    labell: LOOP
        SET p1 = p1 + 1;
        IF p1 < 10 THEN ITERATE labell; END IF;
        LEAVE labell;
    END LOOP labell;
END;
```

The scope of a block label does not include the code for handlers declared within the block. For details, see [Section 13.6.7.2, “DECLARE ... HANDLER Syntax”](#).

13.6.3 DECLARE Syntax

The `DECLARE` statement is used to define various items local to a program:

- Local variables. See [Section 13.6.4, “Variables in Stored Programs”](#).
- Conditions and handlers. See [Section 13.6.7, “Condition Handling”](#).
- Cursors. See [Section 13.6.6, “Cursors”](#).

`DECLARE` is permitted only inside a `BEGIN ... END` compound statement and must be at its start, before any other statements.

Declarations must follow a certain order. Cursor declarations must appear before handler declarations. Variable and condition declarations must appear before cursor or handler declarations.

13.6.4 Variables in Stored Programs

System variables and user-defined variables can be used in stored programs, just as they can be used outside stored-program context. In addition, stored programs can use `DECLARE` to define local variables, and stored routines (procedures and functions) can be declared to take parameters that communicate values between the routine and its caller.

- To declare local variables, use the `DECLARE` statement, as described in [Section 13.6.4.1, “Local Variable DECLARE Syntax”](#).
- Variables can be set directly with the `SET` statement. See [Section 13.7.4.1, “SET Syntax for Variable Assignment”](#).
- Results from queries can be retrieved into local variables using `SELECT ... INTO var_list` or by opening a cursor and using `FETCH ... INTO var_list`. See [Section 13.2.10.1, “SELECT ... INTO Syntax”](#), and [Section 13.6.6, “Cursors”](#).

For information about the scope of local variables and how MySQL resolves ambiguous names, see [Section 13.6.4.2, “Local Variable Scope and Resolution”](#).

It is not permitted to assign the value `DEFAULT` to stored procedure or function parameters or stored program local variables (for example with a `SET var_name = DEFAULT` statement). In MySQL 8.0, this results in a syntax error.

13.6.4.1 Local Variable DECLARE Syntax

```
DECLARE var_name [, var_name] ... type [DEFAULT value]
```

This statement declares local variables within stored programs. To provide a default value for a variable, include a `DEFAULT` clause. The value can be specified as an expression; it need not be a constant. If the `DEFAULT` clause is missing, the initial value is `NULL`.

Local variables are treated like stored routine parameters with respect to data type and overflow checking. See [Section 13.1.13, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).

Variable declarations must appear before cursor or handler declarations.

Local variable names are not case sensitive. Permissible characters and quoting rules are the same as for other identifiers, as described in [Section 9.2, “Schema Object Names”](#).

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

For examples of variable declarations, see [Section 13.6.4.2, “Local Variable Scope and Resolution”](#).

13.6.4.2 Local Variable Scope and Resolution

The scope of a local variable is the `BEGIN ... END` block within which it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

Because local variables are in scope only during stored program execution, references to them are not permitted in prepared statements created within a stored program. Prepared statement scope is the current session, not the stored program, so the statement could be executed after the program ends, at which point the variables would no longer be in scope. For example, `SELECT ... INTO local_var` cannot be used as a prepared statement. This restriction also applies to stored procedure and function parameters. See [Section 13.5.1, “PREPARE Syntax”](#).

A local variable should not have the same name as a table column. If an SQL statement, such as a `SELECT ... INTO` statement, contains a reference to a column and a declared local variable with the same name, MySQL currently interprets the reference as the name of a variable. Consider the following procedure definition:

```
CREATE PROCEDURE sp1 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
```

```

DECLARE newname VARCHAR(5);
DECLARE xid INT;

SELECT xname, id INTO newname, xid
  FROM table1 WHERE xname = xname;
SELECT newname;
END;

```

MySQL interprets `xname` in the `SELECT` statement as a reference to the `xname` variable rather than the `xname` column. Consequently, when the procedure `sp1()` is called, the `newname` variable returns the value `'bob'` regardless of the value of the `table1.xname` column.

Similarly, the cursor definition in the following procedure contains a `SELECT` statement that refers to `xname`. MySQL interprets this as a reference to the variable of that name rather than a column reference.

```

CREATE PROCEDURE sp2 (x VARCHAR(5))
BEGIN
  DECLARE xname VARCHAR(5) DEFAULT 'bob';
  DECLARE newname VARCHAR(5);
  DECLARE xid INT;
  DECLARE done TINYINT DEFAULT 0;
  DECLARE cur1 CURSOR FOR SELECT xname, id FROM table1;
  DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = 1;

  OPEN cur1;
  read_loop: LOOP
    FETCH FROM cur1 INTO newname, xid;
    IF done THEN LEAVE read_loop; END IF;
    SELECT newname;
  END LOOP;
  CLOSE cur1;
END;

```

See also [Section C.1, “Restrictions on Stored Programs”](#).

13.6.5 Flow Control Statements

MySQL supports the `IF`, `CASE`, `ITERATE`, `LEAVE LOOP`, `WHILE`, and `REPEAT` constructs for flow control within stored programs. It also supports `RETURN` within stored functions.

Many of these constructs contain other statements, as indicated by the grammar specifications in the following sections. Such constructs may be nested. For example, an `IF` statement might contain a `WHILE` loop, which itself contains a `CASE` statement.

MySQL does not support `FOR` loops.

13.6.5.1 CASE Syntax

```

CASE case_value
  WHEN when_value THEN statement_list
  [WHEN when_value THEN statement_list] ...
  [ELSE statement_list]
END CASE

```

Or:

```

CASE
  WHEN search_condition THEN statement_list
  [WHEN search_condition THEN statement_list] ...
  [ELSE statement_list]
END CASE

```

The `CASE` statement for stored programs implements a complex conditional construct.

**Note**

There is also a *CASE expression*, which differs from the *CASE statement* described here. See [Section 12.4, “Control Flow Functions”](#). The *CASE statement* cannot have an *ELSE NULL* clause, and it is terminated with *END CASE* instead of *END*.

For the first syntax, *case_value* is an expression. This value is compared to the *when_value* expression in each *WHEN* clause until one of them is equal. When an equal *when_value* is found, the corresponding *THEN* clause *statement_list* executes. If no *when_value* is equal, the *ELSE* clause *statement_list* executes, if there is one.

This syntax cannot be used to test for equality with *NULL* because *NULL = NULL* is false. See [Section 3.3.4.6, “Working with NULL Values”](#).

For the second syntax, each *WHEN* clause *search_condition* expression is evaluated until one is true, at which point its corresponding *THEN* clause *statement_list* executes. If no *search_condition* is equal, the *ELSE* clause *statement_list* executes, if there is one.

If no *when_value* or *search_condition* matches the value tested and the *CASE* statement contains no *ELSE* clause, a *Case not found for CASE statement* error results.

Each *statement_list* consists of one or more SQL statements; an empty *statement_list* is not permitted.

To handle situations where no value is matched by any *WHEN* clause, use an *ELSE* containing an empty *BEGIN ... END* block, as shown in this example. (The indentation used here in the *ELSE* clause is for purposes of clarity only, and is not otherwise significant.)

```
DELIMITER |

CREATE PROCEDURE p()
  BEGIN
    DECLARE v INT DEFAULT 1;

    CASE v
      WHEN 2 THEN SELECT v;
      WHEN 3 THEN SELECT 0;
      ELSE
        BEGIN
          END;
        END CASE;
    END;
  |
```

13.6.5.2 IF Syntax

```
IF search_condition THEN statement_list
  [ELSEIF search_condition THEN statement_list] ...
  [ELSE statement_list]
END IF
```

The *IF* statement for stored programs implements a basic conditional construct.

**Note**

There is also an *IF() function*, which differs from the *IF statement* described here. See [Section 12.4, “Control Flow Functions”](#). The *IF* statement can have *THEN*, *ELSE*, and *ELSEIF* clauses, and it is terminated with *END IF*.

If the *search_condition* evaluates to true, the corresponding *THEN* or *ELSEIF* clause *statement_list* executes. If no *search_condition* matches, the *ELSE* clause *statement_list* executes.

Each *statement_list* consists of one or more SQL statements; an empty *statement_list* is not permitted.

An `IF ... END IF` block, like all other flow-control blocks used within stored programs, must be terminated with a semicolon, as shown in this example:

```
DELIMITER //

CREATE FUNCTION SimpleCompare(n INT, m INT)
  RETURNS VARCHAR(20)

  BEGIN
    DECLARE s VARCHAR(20);

    IF n > m THEN SET s = '>';
    ELSEIF n = m THEN SET s = '=';
    ELSE SET s = '<';
    END IF;

    SET s = CONCAT(n, ' ', s, ' ', m);

    RETURN s;
  END //

DELIMITER ;
```

As with other flow-control constructs, `IF ... END IF` blocks may be nested within other flow-control constructs, including other `IF` statements. Each `IF` must be terminated by its own `END IF` followed by a semicolon. You can use indentation to make nested flow-control blocks more easily readable by humans (although this is not required by MySQL), as shown here:

```
DELIMITER //

CREATE FUNCTION VerboseCompare (n INT, m INT)
  RETURNS VARCHAR(50)

  BEGIN
    DECLARE s VARCHAR(50);

    IF n = m THEN SET s = 'equals';
    ELSE
      IF n > m THEN SET s = 'greater';
      ELSE SET s = 'less';
      END IF;

    SET s = CONCAT('is ', s, ' than');
    END IF;

    SET s = CONCAT(n, ' ', s, ' ', m, '.');

    RETURN s;
  END //

DELIMITER ;
```

In this example, the inner `IF` is evaluated only if `n` is not equal to `m`.

13.6.5.3 ITERATE Syntax

```
ITERATE label
```

`ITERATE` can appear only within `LOOP`, `REPEAT`, and `WHILE` statements. `ITERATE` means “start the loop again.”

For an example, see [Section 13.6.5.5, “LOOP Syntax”](#).

13.6.5.4 LEAVE Syntax

```
LEAVE label
```

This statement is used to exit the flow control construct that has the given label. If the label is for the outermost stored program block, `LEAVE` exits the program.

`LEAVE` can be used within `BEGIN ... END` or loop constructs (`LOOP`, `REPEAT`, `WHILE`).

For an example, see [Section 13.6.5.5, “LOOP Syntax”](#).

13.6.5.5 LOOP Syntax

```
[begin_label:] LOOP
  statement_list
END LOOP [end_label]
```

`LOOP` implements a simple loop construct, enabling repeated execution of the statement list, which consists of one or more statements, each terminated by a semicolon (`;`) statement delimiter. The statements within the loop are repeated until the loop is terminated. Usually, this is accomplished with a `LEAVE` statement. Within a stored function, `RETURN` can also be used, which exits the function entirely.

Neglecting to include a loop-termination statement results in an infinite loop.

A `LOOP` statement can be labeled. For the rules regarding label use, see [Section 13.6.2, “Statement Label Syntax”](#).

Example:

```
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
  label1: LOOP
    SET p1 = p1 + 1;
    IF p1 < 10 THEN
      ITERATE label1;
    END IF;
    LEAVE label1;
  END LOOP label1;
  SET @x = p1;
END;
```

13.6.5.6 REPEAT Syntax

```
[begin_label:] REPEAT
  statement_list
UNTIL search_condition
END REPEAT [end_label]
```

The statement list within a `REPEAT` statement is repeated until the *search_condition* expression is true. Thus, a `REPEAT` always enters the loop at least once. *statement_list* consists of one or more statements, each terminated by a semicolon (`;`) statement delimiter.

A `REPEAT` statement can be labeled. For the rules regarding label use, see [Section 13.6.2, “Statement Label Syntax”](#).

Example:

```
mysql> delimiter //

mysql> CREATE PROCEDURE dorepeat(p1 INT)
-> BEGIN
```

```

-> SET @x = 0;
-> REPEAT
->     SET @x = @x + 1;
-> UNTIL @x > p1 END REPEAT;
-> END
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL dorepeat(1000)//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+-----+
| @x    |
+-----+
| 1001  |
+-----+
1 row in set (0.00 sec)

```

13.6.5.7 RETURN Syntax

```
RETURN expr
```

The `RETURN` statement terminates execution of a stored function and returns the value *expr* to the function caller. There must be at least one `RETURN` statement in a stored function. There may be more than one if the function has multiple exit points.

This statement is not used in stored procedures, triggers, or events. The `LEAVE` statement can be used to exit a stored program of those types.

13.6.5.8 WHILE Syntax

```
[begin_label:] WHILE search_condition DO
    statement_list
END WHILE [end_label]
```

The statement list within a `WHILE` statement is repeated as long as the *search_condition* expression is true. *statement_list* consists of one or more SQL statements, each terminated by a semicolon (;) statement delimiter.

A `WHILE` statement can be labeled. For the rules regarding label use, see [Section 13.6.2, “Statement Label Syntax”](#).

Example:

```
CREATE PROCEDURE dowhile()
BEGIN
    DECLARE v1 INT DEFAULT 5;

    WHILE v1 > 0 DO
        ...
        SET v1 = v1 - 1;
    END WHILE;
END;
```

13.6.6 Cursors

MySQL supports cursors inside stored programs. The syntax is as in embedded SQL. Cursors have these properties:

- Asensitive: The server may or may not make a copy of its result table
- Read only: Not updatable

- **Nonscrollable:** Can be traversed only in one direction and cannot skip rows

Cursor declarations must appear before handler declarations and after variable and condition declarations.

Example:

```
CREATE PROCEDURE curdemo()
BEGIN
  DECLARE done INT DEFAULT FALSE;
  DECLARE a CHAR(16);
  DECLARE b, c INT;
  DECLARE cur1 CURSOR FOR SELECT id,data FROM test.t1;
  DECLARE cur2 CURSOR FOR SELECT i FROM test.t2;
  DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = TRUE;

  OPEN cur1;
  OPEN cur2;

  read_loop: LOOP
    FETCH cur1 INTO a, b;
    FETCH cur2 INTO c;
    IF done THEN
      LEAVE read_loop;
    END IF;
    IF b < c THEN
      INSERT INTO test.t3 VALUES (a,b);
    ELSE
      INSERT INTO test.t3 VALUES (a,c);
    END IF;
  END LOOP;

  CLOSE cur1;
  CLOSE cur2;
END;
```

13.6.6.1 Cursor CLOSE Syntax

```
CLOSE cursor_name
```

This statement closes a previously opened cursor. For an example, see [Section 13.6.6, “Cursors”](#).

An error occurs if the cursor is not open.

If not closed explicitly, a cursor is closed at the end of the `BEGIN . . . END` block in which it was declared.

13.6.6.2 Cursor DECLARE Syntax

```
DECLARE cursor_name CURSOR FOR select_statement
```

This statement declares a cursor and associates it with a `SELECT` statement that retrieves the rows to be traversed by the cursor. To fetch the rows later, use a `FETCH` statement. The number of columns retrieved by the `SELECT` statement must match the number of output variables specified in the `FETCH` statement.

The `SELECT` statement cannot have an `INTO` clause.

Cursor declarations must appear before handler declarations and after variable and condition declarations.

A stored program may contain multiple cursor declarations, but each cursor declared in a given block must have a unique name. For an example, see [Section 13.6.6, “Cursors”](#).

For information available through `SHOW` statements, it is possible in many cases to obtain equivalent information by using a cursor with an `INFORMATION_SCHEMA` table.

13.6.6.3 Cursor FETCH Syntax

```
FETCH [[NEXT] FROM] cursor_name INTO var_name [, var_name] ...
```

This statement fetches the next row for the `SELECT` statement associated with the specified cursor (which must be open), and advances the cursor pointer. If a row exists, the fetched columns are stored in the named variables. The number of columns retrieved by the `SELECT` statement must match the number of output variables specified in the `FETCH` statement.

If no more rows are available, a No Data condition occurs with SQLSTATE value `'02000'`. To detect this condition, you can set up a handler for it (or for a `NOT FOUND` condition). For an example, see [Section 13.6.6, “Cursors”](#).

Be aware that another operation, such as a `SELECT` or another `FETCH`, may also cause the handler to execute by raising the same condition. If it is necessary to distinguish which operation raised the condition, place the operation within its own `BEGIN ... END` block so that it can be associated with its own handler.

13.6.6.4 Cursor OPEN Syntax

```
OPEN cursor_name
```

This statement opens a previously declared cursor. For an example, see [Section 13.6.6, “Cursors”](#).

13.6.7 Condition Handling

Conditions may arise during stored program execution that require special handling, such as exiting the current program block or continuing execution. Handlers can be defined for general conditions such as warnings or exceptions, or for specific conditions such as a particular error code. Specific conditions can be assigned names and referred to that way in handlers.

To name a condition, use the `DECLARE ... CONDITION` statement. To declare a handler, use the `DECLARE ... HANDLER` statement. See [Section 13.6.7.1, “DECLARE ... CONDITION Syntax”](#), and [Section 13.6.7.2, “DECLARE ... HANDLER Syntax”](#). For information about how the server chooses handlers when a condition occurs, see [Section 13.6.7.6, “Scope Rules for Handlers”](#).

To raise a condition, use the `SIGNAL` statement. To modify condition information within a condition handler, use `RESIGNAL`. See [Section 13.6.7.1, “DECLARE ... CONDITION Syntax”](#), and [Section 13.6.7.2, “DECLARE ... HANDLER Syntax”](#).

To retrieve information from the diagnostics area, use the `GET DIAGNOSTICS` statement (see [Section 13.6.7.3, “GET DIAGNOSTICS Syntax”](#)). For information about the diagnostics area, see [Section 13.6.7.7, “The MySQL Diagnostics Area”](#).

13.6.7.1 DECLARE ... CONDITION Syntax

```
DECLARE condition_name CONDITION FOR condition_value

condition_value:
  mysql_error_code
  | SQLSTATE [VALUE] sqlstate_value
```

The `DECLARE ... CONDITION` statement declares a named error condition, associating a name with a condition that needs specific handling. The name can be referred to in a subsequent `DECLARE ... HANDLER` statement (see [Section 13.6.7.2, “DECLARE ... HANDLER Syntax”](#)).

Condition declarations must appear before cursor or handler declarations.

The *condition_value* for `DECLARE ... CONDITION` indicates the specific condition or class of conditions to associate with the condition name. It can take the following forms:

- *mysql_error_code*: An integer literal indicating a MySQL error code.

Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see [Section B.3, “Server Error Codes and Messages”](#).

- `SQLSTATE [VALUE] sqlstate_value`: A 5-character string literal indicating an SQLSTATE value.

Do not use SQLSTATE values that begin with '00' because those indicate success rather than an error condition. For a list of SQLSTATE values, see [Section B.3, “Server Error Codes and Messages”](#).

Condition names referred to in `SIGNAL` or use `RESIGNAL` statements must be associated with SQLSTATE values, not MySQL error codes.

Using names for conditions can help make stored program code clearer. For example, this handler applies to attempts to drop a nonexistent table, but that is apparent only if you know that 1051 is the MySQL error code for “unknown table”:

```
DECLARE CONTINUE HANDLER FOR 1051
BEGIN
  -- body of handler
END;
```

By declaring a name for the condition, the purpose of the handler is more readily seen:

```
DECLARE no_such_table CONDITION FOR 1051;
DECLARE CONTINUE HANDLER FOR no_such_table
BEGIN
  -- body of handler
END;
```

Here is a named condition for the same condition, but based on the corresponding SQLSTATE value rather than the MySQL error code:

```
DECLARE no_such_table CONDITION FOR SQLSTATE '42S02';
DECLARE CONTINUE HANDLER FOR no_such_table
BEGIN
  -- body of handler
END;
```

13.6.7.2 DECLARE ... HANDLER Syntax

```
DECLARE handler_action HANDLER
  FOR condition_value [, condition_value] ...
  statement

handler_action:
  CONTINUE
  | EXIT
  | UNDO

condition_value:
  mysql_error_code
  | SQLSTATE [VALUE] sqlstate_value
  | condition_name
  | SQLWARNING
  | NOT FOUND
```

| `SQLEXCEPTION`

The `DECLARE ... HANDLER` statement specifies a handler that deals with one or more conditions. If one of these conditions occurs, the specified *statement* executes. *statement* can be a simple statement such as `SET var_name = value`, or a compound statement written using `BEGIN` and `END` (see [Section 13.6.1, “BEGIN ... END Compound-Statement Syntax”](#)).

Handler declarations must appear after variable or condition declarations.

The *handler_action* value indicates what action the handler takes after execution of the handler statement:

- `CONTINUE`: Execution of the current program continues.
- `EXIT`: Execution terminates for the `BEGIN ... END` compound statement in which the handler is declared. This is true even if the condition occurs in an inner block.
- `UNDO`: Not supported.

The *condition_value* for `DECLARE ... HANDLER` indicates the specific condition or class of conditions that activates the handler. It can take the following forms:

- *mysql_error_code*: An integer literal indicating a MySQL error code, such as 1051 to specify “unknown table”:

```
DECLARE CONTINUE HANDLER FOR 1051
BEGIN
  -- body of handler
END;
```

Do not use MySQL error code 0 because that indicates success rather than an error condition. For a list of MySQL error codes, see [Section B.3, “Server Error Codes and Messages”](#).

- `SQLSTATE [VALUE] sqlstate_value`: A 5-character string literal indicating an SQLSTATE value, such as `'42S01'` to specify “unknown table”:

```
DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
BEGIN
  -- body of handler
END;
```

Do not use SQLSTATE values that begin with `'00'` because those indicate success rather than an error condition. For a list of SQLSTATE values, see [Section B.3, “Server Error Codes and Messages”](#).

- *condition_name*: A condition name previously specified with `DECLARE ... CONDITION`. A condition name can be associated with a MySQL error code or SQLSTATE value. See [Section 13.6.7.1, “DECLARE ... CONDITION Syntax”](#).
- `SQLWARNING`: Shorthand for the class of SQLSTATE values that begin with `'01'`.

```
DECLARE CONTINUE HANDLER FOR SQLWARNING
BEGIN
  -- body of handler
END;
```

- `NOT FOUND`: Shorthand for the class of SQLSTATE values that begin with `'02'`. This is relevant within the context of cursors and is used to control what happens when a cursor reaches the end of a data set. If no more rows are available, a No Data condition occurs with SQLSTATE value `'02000'`. To detect this condition, you can set up a handler for it or for a `NOT FOUND` condition.

```
DECLARE CONTINUE HANDLER FOR NOT FOUND
BEGIN
  -- body of handler
END;
```

For another example, see [Section 13.6.6, “Cursors”](#). The `NOT FOUND` condition also occurs for `SELECT ... INTO var_list` statements that retrieve no rows.

- `SQLEXCEPTION`: Shorthand for the class of `SQLSTATE` values that do not begin with `'00'`, `'01'`, or `'02'`.

```
DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
BEGIN
  -- body of handler
END;
```

For information about how the server chooses handlers when a condition occurs, see [Section 13.6.7.6, “Scope Rules for Handlers”](#).

If a condition occurs for which no handler has been declared, the action taken depends on the condition class:

- For `SQLEXCEPTION` conditions, the stored program terminates at the statement that raised the condition, as if there were an `EXIT` handler. If the program was called by another stored program, the calling program handles the condition using the handler selection rules applied to its own handlers.
- For `SQLWARNING` conditions, the program continues executing, as if there were a `CONTINUE` handler.
- For `NOT FOUND` conditions, if the condition was raised normally, the action is `CONTINUE`. If it was raised by `SIGNAL` or `RESIGNAL`, the action is `EXIT`.

The following example uses a handler for `SQLSTATE '23000'`, which occurs for a duplicate-key error:

```
mysql> CREATE TABLE test.t (s1 INT, PRIMARY KEY (s1));
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter //

mysql> CREATE PROCEDURE handlerdemo ()
-> BEGIN
->   DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
->   SET @x = 1;
->   INSERT INTO test.t VALUES (1);
->   SET @x = 2;
->   INSERT INTO test.t VALUES (1);
->   SET @x = 3;
-> END;
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> CALL handlerdemo();//
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x//
+-----+
| @x    |
+-----+
| 3     |
+-----+
1 row in set (0.00 sec)
```

Notice that `@x` is 3 after the procedure executes, which shows that execution continued to the end of the procedure after the error occurred. If the `DECLARE ... HANDLER` statement had not been

present, MySQL would have taken the default action (`EXIT`) after the second `INSERT` failed due to the `PRIMARY KEY` constraint, and `SELECT @x` would have returned 2.

To ignore a condition, declare a `CONTINUE` handler for it and associate it with an empty block. For example:

```
DECLARE CONTINUE HANDLER FOR SQLWARNING BEGIN END;
```

The scope of a block label does not include the code for handlers declared within the block. Therefore, the statement associated with a handler cannot use `ITERATE` or `LEAVE` to refer to labels for blocks that enclose the handler declaration. Consider the following example, where the `REPEAT` block has a label of `retry`:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 3;
  retry:
  REPEAT
  BEGIN
    DECLARE CONTINUE HANDLER FOR SQLWARNING
    BEGIN
      ITERATE retry;    # illegal
    END;
    IF i < 0 THEN
      LEAVE retry;      # legal
    END IF;
    SET i = i - 1;
  END;
  UNTIL FALSE END REPEAT;
END;
```

The `retry` label is in scope for the `IF` statement within the block. It is not in scope for the `CONTINUE` handler, so the reference there is invalid and results in an error:

```
ERROR 1308 (42000): LEAVE with no matching label: retry
```

To avoid references to outer labels in handlers, use one of these strategies:

- To leave the block, use an `EXIT` handler. If no block cleanup is required, the `BEGIN ... END` handler body can be empty:

```
DECLARE EXIT HANDLER FOR SQLWARNING BEGIN END;
```

Otherwise, put the cleanup statements in the handler body:

```
DECLARE EXIT HANDLER FOR SQLWARNING
BEGIN
  block cleanup statements
END;
```

- To continue execution, set a status variable in a `CONTINUE` handler that can be checked in the enclosing block to determine whether the handler was invoked. The following example uses the variable `done` for this purpose:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE i INT DEFAULT 3;
  DECLARE done INT DEFAULT FALSE;
  retry:
  REPEAT
  BEGIN
    DECLARE CONTINUE HANDLER FOR SQLWARNING
```

```

BEGIN
    SET done = TRUE;
END;
IF done OR i < 0 THEN
    LEAVE retry;
END IF;
SET i = i - 1;
END;
UNTIL FALSE END REPEAT;
END;

```

13.6.7.3 GET DIAGNOSTICS Syntax

```

GET [CURRENT | STACKED] DIAGNOSTICS
{
    statement_information_item
    [, statement_information_item] ...
    | CONDITION condition_number
    condition_information_item
    [, condition_information_item] ...
}

statement_information_item:
    target = statement_information_item_name

condition_information_item:
    target = condition_information_item_name

statement_information_item_name:
    NUMBER
    | ROW_COUNT

condition_information_item_name:
    CLASS_ORIGIN
    | SUBCLASS_ORIGIN
    | RETURNED_SQLSTATE
    | MESSAGE_TEXT
    | MYSQL_ERRNO
    | CONSTRAINT_CATALOG
    | CONSTRAINT_SCHEMA
    | CONSTRAINT_NAME
    | CATALOG_NAME
    | SCHEMA_NAME
    | TABLE_NAME
    | COLUMN_NAME
    | CURSOR_NAME

condition_number, target:
    (see following discussion)

```

SQL statements produce diagnostic information that populates the diagnostics area. The `GET DIAGNOSTICS` statement enables applications to inspect this information. (You can also use `SHOW WARNINGS` or `SHOW ERRORS` to see conditions or errors.)

No special privileges are required to execute `GET DIAGNOSTICS`.

The keyword `CURRENT` means to retrieve information from the current diagnostics area. The keyword `STACKED` means to retrieve information from the second diagnostics area, which is available only if the current context is a condition handler. If neither keyword is given, the default is to use the current diagnostics area.

The `GET DIAGNOSTICS` statement is typically used in a handler within a stored program. It is a MySQL extension that `GET [CURRENT] DIAGNOSTICS` is permitted outside handler context to check the execution of any SQL statement. For example, if you invoke the `mysql` client program, you can enter these statements at the prompt:

```
mysql> DROP TABLE test.no_such_table;
ERROR 1051 (42S02): Unknown table 'test.no_such_table'
mysql> GET DIAGNOSTICS CONDITION 1
-> @p1 = RETURNED_SQLSTATE, @p2 = MESSAGE_TEXT;
mysql> SELECT @p1, @p2;
+-----+-----+
| @p1   | @p2                                     |
+-----+-----+
| 42S02 | Unknown table 'test.no_such_table'    |
+-----+-----+
```

This extension applies only to the current diagnostics area. It does not apply to the second diagnostics area because `GET STACKED DIAGNOSTICS` is permitted only if the current context is a condition handler. If that is not the case, a `GET STACKED DIAGNOSTICS when handler not active` error occurs.

For a description of the diagnostics area, see [Section 13.6.7.7, “The MySQL Diagnostics Area”](#). Briefly, it contains two kinds of information:

- Statement information, such as the number of conditions that occurred or the affected-rows count.
- Condition information, such as the error code and message. If a statement raises multiple conditions, this part of the diagnostics area has a condition area for each one. If a statement raises no conditions, this part of the diagnostics area is empty.

For a statement that produces three conditions, the diagnostics area contains statement and condition information like this:

```
Statement information:
  row count
  ... other statement information items ...
Condition area list:
  Condition area 1:
    error code for condition 1
    error message for condition 1
    ... other condition information items ...
  Condition area 2:
    error code for condition 2:
    error message for condition 2
    ... other condition information items ...
  Condition area 3:
    error code for condition 3
    error message for condition 3
    ... other condition information items ...
```

`GET DIAGNOSTICS` can obtain either statement or condition information, but not both in the same statement:

- To obtain statement information, retrieve the desired statement items into target variables. This instance of `GET DIAGNOSTICS` assigns the number of available conditions and the rows-affected count to the user variables `@p1` and `@p2`:

```
GET DIAGNOSTICS @p1 = NUMBER, @p2 = ROW_COUNT;
```

- To obtain condition information, specify the condition number and retrieve the desired condition items into target variables. This instance of `GET DIAGNOSTICS` assigns the SQLSTATE value and error message to the user variables `@p3` and `@p4`:

```
GET DIAGNOSTICS CONDITION 1
  @p3 = RETURNED_SQLSTATE, @p4 = MESSAGE_TEXT;
```

The retrieval list specifies one or more `target = item_name` assignments, separated by commas. Each assignment names a target variable and either a `statement_information_item_name` or

`condition_information_item_name` designator, depending on whether the statement retrieves statement or condition information.

Valid `target` designators for storing item information can be stored procedure or function parameters, stored program local variables declared with `DECLARE`, or user-defined variables.

Valid `condition_number` designators can be stored procedure or function parameters, stored program local variables declared with `DECLARE`, user-defined variables, system variables, or literals. A character literal may include a `_charset` introducer. A warning occurs if the condition number is not in the range from 1 to the number of condition areas that have information. In this case, the warning is added to the diagnostics area without clearing it.

When a condition occurs, MySQL does not populate all condition items recognized by `GET DIAGNOSTICS`. For example:

```
mysql> GET DIAGNOSTICS CONDITION 1
-> @p5 = SCHEMA_NAME, @p6 = TABLE_NAME;
mysql> SELECT @p5, @p6;
+-----+-----+
| @p5   | @p6   |
+-----+-----+
|       |       |
+-----+-----+
```

In standard SQL, if there are multiple conditions, the first condition relates to the `SQLSTATE` value returned for the previous SQL statement. In MySQL, this is not guaranteed. To get the main error, you cannot do this:

```
GET DIAGNOSTICS CONDITION 1 @errno = MYSQL_ERRNO;
```

Instead, retrieve the condition count first, then use it to specify which condition number to inspect:

```
GET DIAGNOSTICS @cno = NUMBER;
GET DIAGNOSTICS CONDITION @cno @errno = MYSQL_ERRNO;
```

For information about permissible statement and condition information items, and which ones are populated when a condition occurs, see [Diagnostics Area Information Items](#).

Here is an example that uses `GET DIAGNOSTICS` and an exception handler in stored procedure context to assess the outcome of an insert operation. If the insert was successful, the procedure uses `GET DIAGNOSTICS` to get the rows-affected count. This shows that you can use `GET DIAGNOSTICS` multiple times to retrieve information about a statement as long as the current diagnostics area has not been cleared.

```
CREATE PROCEDURE do_insert(value INT)
BEGIN
  -- Declare variables to hold diagnostics area information
  DECLARE code CHAR(5) DEFAULT '00000';
  DECLARE msg TEXT;
  DECLARE rows INT;
  DECLARE result TEXT;
  -- Declare exception handler for failed insert
  DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
  BEGIN
    GET DIAGNOSTICS CONDITION 1
      code = RETURNED_SQLSTATE, msg = MESSAGE_TEXT;
  END;

  -- Perform the insert
  INSERT INTO t1 (int_col) VALUES(value);
  -- Check whether the insert was successful
  IF code = '00000' THEN
```

```

GET DIAGNOSTICS rows = ROW_COUNT;
SET result = CONCAT('insert succeeded, row count = ',rows);
ELSE
SET result = CONCAT('insert failed, error = ',code,', message = ',msg);
END IF;
-- Say what happened
SELECT result;
END;

```

Suppose that `t1.int_col` is an integer column that is declared as `NOT NULL`. The procedure produces these results when invoked to insert non-`NULL` and `NULL` values, respectively:

```

mysql> CALL do_insert(1);
+-----+
| result |
+-----+
| insert succeeded, row count = 1 |
+-----+

mysql> CALL do_insert(NULL);
+-----+
| result |
+-----+
| insert failed, error = 23000, message = Column 'int_col' cannot be null |
+-----+

```

When a condition handler activates, a push to the diagnostics area stack occurs:

- The first (current) diagnostics area becomes the second (stacked) diagnostics area and a new current diagnostics area is created as a copy of it.
- `GET [CURRENT] DIAGNOSTICS` and `GET STACKED DIAGNOSTICS` can be used within the handler to access the contents of the current and stacked diagnostics areas.
- Initially, both diagnostics areas return the same result, so it is possible to get information from the current diagnostics area about the condition that activated the handler, *as long as you execute no statements within the handler that change its current diagnostics area*.
- However, statements executing within the handler can modify the current diagnostics area, clearing and setting its contents according to the normal rules (see [How the Diagnostics Area is Populated](#)).

A more reliable way to obtain information about the handler-activating condition is to use the stacked diagnostics area, which cannot be modified by statements executing within the handler except `RESIGNAL`. For information about when the current diagnostics area is set and cleared, see [Section 13.6.7.7, “The MySQL Diagnostics Area”](#).

The next example shows how `GET STACKED DIAGNOSTICS` can be used within a handler to obtain information about the handled exception, even after the current diagnostics area has been modified by handler statements.

Within a stored procedure `p()`, we attempt to insert two values into a table that contains a `TEXT NOT NULL` column. The first value is a non-`NULL` string and the second is `NULL`. The column prohibits `NULL` values, so the first insert succeeds but the second causes an exception. The procedure includes an exception handler that maps attempts to insert `NULL` into inserts of the empty string:

```

DROP TABLE IF EXISTS t1;
CREATE TABLE t1 (c1 TEXT NOT NULL);
DROP PROCEDURE IF EXISTS p;
delimiter //
CREATE PROCEDURE p ()
BEGIN
-- Declare variables to hold diagnostics area information
DECLARE errcount INT;
DECLARE errno INT;

```

```

DECLARE msg TEXT;
DECLARE EXIT HANDLER FOR SQLEXCEPTION
BEGIN
  -- Here the current DA is nonempty because no prior statements
  -- executing within the handler have cleared it
  GET CURRENT DIAGNOSTICS CONDITION 1
    errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
  SELECT 'current DA before mapped insert' AS op, errno, msg;
  GET STACKED DIAGNOSTICS CONDITION 1
    errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
  SELECT 'stacked DA before mapped insert' AS op, errno, msg;

  -- Map attempted NULL insert to empty string insert
  INSERT INTO t1 (c1) VALUES('');

  -- Here the current DA should be empty (if the INSERT succeeded),
  -- so check whether there are conditions before attempting to
  -- obtain condition information
  GET CURRENT DIAGNOSTICS errcount = NUMBER;
  IF errcount = 0
  THEN
    SELECT 'mapped insert succeeded, current DA is empty' AS op;
  ELSE
    GET CURRENT DIAGNOSTICS CONDITION 1
      errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'current DA after mapped insert' AS op, errno, msg;
  END IF ;
  GET STACKED DIAGNOSTICS CONDITION 1
    errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
  SELECT 'stacked DA after mapped insert' AS op, errno, msg;
END;
INSERT INTO t1 (c1) VALUES('string 1');
INSERT INTO t1 (c1) VALUES(NULL);
END;
//
delimiter ;
CALL p();
SELECT * FROM t1;

```

When the handler activates, a copy of the current diagnostics area is pushed to the diagnostics area stack. The handler first displays the contents of the current and stacked diagnostics areas, which are both the same initially:

```

+-----+-----+-----+
| op                | errno | msg                |
+-----+-----+-----+
| current DA before mapped insert | 1048 | Column 'c1' cannot be null |
+-----+-----+-----+

+-----+-----+-----+
| op                | errno | msg                |
+-----+-----+-----+
| stacked DA before mapped insert | 1048 | Column 'c1' cannot be null |
+-----+-----+-----+

```

Statements executing after the `GET DIAGNOSTICS` statements may reset the current diagnostics area. statements may reset the current diagnostics area. For example, the handler maps the `NULL` insert to an empty-string insert and displays the result. The new insert succeeds and clears the current diagnostics area, but the stacked diagnostics area remains unchanged and still contains information about the condition that activated the handler:

```

+-----+-----+-----+
| op                |        |                    |
+-----+-----+-----+
| mapped insert succeeded, current DA is empty |
+-----+-----+-----+

+-----+-----+-----+
| op                | errno | msg                |
+-----+-----+-----+

```

```
+-----+-----+
| stacked DA after mapped insert | 1048 | Column 'c1' cannot be null |
+-----+-----+
```

When the condition handler ends, its current diagnostics area is popped from the stack and the stacked diagnostics area becomes the current diagnostics area in the stored procedure.

After the procedure returns, the table contains two rows. The empty row results from the attempt to insert `NULL` that was mapped to an empty-string insert:

```
+-----+
| c1 |
+-----+
| string 1 |
| |
+-----+
```

In the preceding example, the first two `GET DIAGNOSTICS` statements within the condition handler that retrieve information from the current and stacked diagnostics areas return the same values. This will not be the case if statements that reset the current diagnostics area execute earlier within the handler. Suppose that `p()` is rewritten to place the `DECLARE` statements within the handler definition rather than preceding it:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    -- Declare variables to hold diagnostics area information
    DECLARE errcount INT;
    DECLARE errno INT;
    DECLARE msg TEXT;
    GET CURRENT DIAGNOSTICS CONDITION 1
      errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'current DA before mapped insert' AS op, errno, msg;
    GET STACKED DIAGNOSTICS CONDITION 1
      errno = MYSQL_ERRNO, msg = MESSAGE_TEXT;
    SELECT 'stacked DA before mapped insert' AS op, errno, msg;
    ...
  END
END
```

In this case, the result is version dependent:

- Before MySQL 5.7.2, `DECLARE` does not change the current diagnostics area, so the first two `GET DIAGNOSTICS` statements return the same result, just as in the original version of `p()`.

In MySQL 5.7.2, work was done to ensure that all nondiagnostic statements populate the diagnostics area, per the SQL standard. `DECLARE` is one of them, so in 5.7.2 and higher, `DECLARE` statements executing at the beginning of the handler clear the current diagnostics area and the `GET DIAGNOSTICS` statements produce different results:

```
+-----+-----+-----+
| op | errno | msg |
+-----+-----+-----+
| current DA before mapped insert | NULL | NULL |
+-----+-----+-----+

+-----+-----+-----+
| op | errno | msg |
+-----+-----+-----+
| stacked DA before mapped insert | 1048 | Column 'c1' cannot be null |
+-----+-----+-----+
```

To avoid this issue within a condition handler when seeking to obtain information about the condition that activated the handler, be sure to access the stacked diagnostics area, not the current diagnostics area.

13.6.7.4 RESIGNAL Syntax

```

RESIGNAL [condition_value]
  [SET signal_information_item
    [, signal_information_item] ...]

condition_value:
  SQLSTATE [VALUE] sqlstate_value
  | condition_name

signal_information_item:
  condition_information_item_name = simple_value_specification

condition_information_item_name:
  CLASS_ORIGIN
  | SUBCLASS_ORIGIN
  | MESSAGE_TEXT
  | MYSQL_ERRNO
  | CONSTRAINT_CATALOG
  | CONSTRAINT_SCHEMA
  | CONSTRAINT_NAME
  | CATALOG_NAME
  | SCHEMA_NAME
  | TABLE_NAME
  | COLUMN_NAME
  | CURSOR_NAME

condition_name, simple_value_specification:
  (see following discussion)

```

RESIGNAL passes on the error condition information that is available during execution of a condition handler within a compound statement inside a stored procedure or function, trigger, or event. **RESIGNAL** may change some or all information before passing it on. **RESIGNAL** is related to **SIGNAL**, but instead of originating a condition as **SIGNAL** does, **RESIGNAL** relays existing condition information, possibly after modifying it.

RESIGNAL makes it possible to both handle an error and return the error information. Otherwise, by executing an SQL statement within the handler, information that caused the handler's activation is destroyed. **RESIGNAL** also can make some procedures shorter if a given handler can handle part of a situation, then pass the condition “up the line” to another handler.

No special privileges are required to execute the **RESIGNAL** statement.

All forms of **RESIGNAL** require that the current context be a condition handler. Otherwise, **RESIGNAL** is illegal and a **RESIGNAL when handler not active** error occurs.

To retrieve information from the diagnostics area, use the **GET DIAGNOSTICS** statement (see [Section 13.6.7.3, “GET DIAGNOSTICS Syntax”](#)). For information about the diagnostics area, see [Section 13.6.7.7, “The MySQL Diagnostics Area”](#).

For *condition_value* and *signal_information_item*, the definitions and rules are the same for **RESIGNAL** as for **SIGNAL**. For example, the *condition_value* can be an **SQLSTATE** value, and the value can indicate errors, warnings, or “not found.” For additional information, see [Section 13.6.7.5, “SIGNAL Syntax”](#).

The **RESIGNAL** statement takes *condition_value* and **SET** clauses, both of which are optional. This leads to several possible uses:

- **RESIGNAL** alone:

```
RESIGNAL;
```

- **RESIGNAL** with new signal information:

```
RESIGNAL SET signal_information_item [, signal_information_item] ...;
```

- **RESIGNAL** with a condition value and possibly new signal information:

```
RESIGNAL condition_value
  [SET signal_information_item [, signal_information_item] ...];
```

These use cases all cause changes to the diagnostics and condition areas:

- A diagnostics area contains one or more condition areas.
- A condition area contains condition information items, such as the `SQLSTATE` value, `MYSQL_ERRNO`, or `MESSAGE_TEXT`.

There is a stack of diagnostics areas. When a handler takes control, it pushes a diagnostics area to the top of the stack, so there are two diagnostics areas during handler execution:

- The first (current) diagnostics area, which starts as a copy of the last diagnostics area, but will be overwritten by the first statement in the handler that changes the current diagnostics area.
- The last (stacked) diagnostics area, which has the condition areas that were set up before the handler took control.

The maximum number of condition areas in a diagnostics area is determined by the value of the `max_error_count` system variable. See [Diagnostics Area-Related System Variables](#).

RESIGNAL Alone

A simple **RESIGNAL** alone means “pass on the error with no change.” It restores the last diagnostics area and makes it the current diagnostics area. That is, it “pops” the diagnostics area stack.

Within a condition handler that catches a condition, one use for **RESIGNAL** alone is to perform some other actions, and then pass on without change the original condition information (the information that existed before entry into the handler).

Example:

```
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL; END IF;
  END;
  DROP TABLE xx;
END//
delimiter ;
SET @error_count = 0;
SET @a = 0;
CALL p();
```

Suppose that the `DROP TABLE xx` statement fails. The diagnostics area stack looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

Then execution enters the **EXIT** handler. It starts by pushing a diagnostics area to the top of the stack, which now looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
DA 2. ERROR 1051 (42S02): Unknown table 'xx'
```

At this point, the contents of the first (current) and second (stacked) diagnostics areas are the same. The first diagnostics area may be modified by statements executing subsequently within the handler.

Usually a procedure statement clears the first diagnostics area. `BEGIN` is an exception, it does not clear, it does nothing. `SET` is not an exception, it clears, performs the operation, and produces a result of “success.” The diagnostics area stack now looks like this:

```
DA 1. ERROR 0000 (00000): Successful operation
DA 2. ERROR 1051 (42S02): Unknown table 'xx'
```

At this point, if `@a = 0`, `RESIGNAL` pops the diagnostics area stack, which now looks like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

And that is what the caller sees.

If `@a` is not 0, the handler simply ends, which means that there is no more use for the current diagnostics area (it has been “handled”), so it can be thrown away, causing the stacked diagnostics area to become the current diagnostics area again. The diagnostics area stack looks like this:

```
DA 1. ERROR 0000 (00000): Successful operation
```

The details make it look complex, but the end result is quite useful: Handlers can execute without destroying information about the condition that caused activation of the handler.

RESIGNAL with New Signal Information

`RESIGNAL` with a `SET` clause provides new signal information, so the statement means “pass on the error with changes”:

```
RESIGNAL SET signal_information_item [, signal_information_item] ...;
```

As with `RESIGNAL` alone, the idea is to pop the diagnostics area stack so that the original information will go out. Unlike `RESIGNAL` alone, anything specified in the `SET` clause changes.

Example:

```
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL SET MYSQL_ERRNO = 5; END IF;
  END;
  DROP TABLE xx;
END//
delimiter ;
SET @error_count = 0;
SET @a = 0;
CALL p();
```

Remember from the previous discussion that `RESIGNAL` alone results in a diagnostics area stack like this:

```
DA 1. ERROR 1051 (42S02): Unknown table 'xx'
```

The `RESIGNAL SET MYSQL_ERRNO = 5` statement results in this stack instead, which is what the caller sees:

```
DA 1. ERROR 5 (42S02): Unknown table 'xx'
```

In other words, it changes the error number, and nothing else.

The `RESIGNAL` statement can change any or all of the signal information items, making the first condition area of the diagnostics area look quite different.

RESIGNAL with a Condition Value and Optional New Signal Information

`RESIGNAL` with a condition value means “push a condition into the current diagnostics area.” If the `SET` clause is present, it also changes the error information.

```
RESIGNAL condition_value
[SET signal_information_item [, signal_information_item] ...];
```

This form of `RESIGNAL` restores the last diagnostics area and makes it the current diagnostics area. That is, it “pops” the diagnostics area stack, which is the same as what a simple `RESIGNAL` alone would do. However, it also changes the diagnostics area depending on the condition value or signal information.

Example:

```
DROP TABLE IF EXISTS xx;
delimiter //
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SET @error_count = @error_count + 1;
    IF @a = 0 THEN RESIGNAL SQLSTATE '45000' SET MYSQL_ERRNO=5; END IF;
  END;
  DROP TABLE xx;
END//
delimiter ;
SET @error_count = 0;
SET @a = 0;
SET @@max_error_count = 2;
CALL p();
SHOW ERRORS;
```

This is similar to the previous example, and the effects are the same, except that if `RESIGNAL` happens, the current condition area looks different at the end. (The reason the condition adds to rather than replaces the existing condition is the use of a condition value.)

The `RESIGNAL` statement includes a condition value (`SQLSTATE '45000'`), so it adds a new condition area, resulting in a diagnostics area stack that looks like this:

```
DA 1. (condition 2) ERROR 1051 (42S02): Unknown table 'xx'
      (condition 1) ERROR 5 (45000) Unknown table 'xx'
```

The result of `CALL p()` and `SHOW ERRORS` for this example is:

```
mysql> CALL p();
ERROR 5 (45000): Unknown table 'xx'
mysql> SHOW ERRORS;
```

Level	Code	Message
Error	1051	Unknown table 'xx'
Error	5	Unknown table 'xx'

RESIGNAL Requires Condition Handler Context

All forms of `RESIGNAL` require that the current context be a condition handler. Otherwise, `RESIGNAL` is illegal and a `RESIGNAL when handler not active` error occurs. For example:

```
mysql> CREATE PROCEDURE p () RESIGNAL;
Query OK, 0 rows affected (0.00 sec)

mysql> CALL p();
ERROR 1645 (0K000): RESIGNAL when handler not active
```

Here is a more difficult example:

```
delimiter //
CREATE FUNCTION f () RETURNS INT
BEGIN
  RESIGNAL;
  RETURN 5;
END//
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION SET @a=f();
  SIGNAL SQLSTATE '55555';
END//
delimiter ;
CALL p();
```

`RESIGNAL` occurs within the stored function `f()`. Although `f()` itself is invoked within the context of the `EXIT` handler, execution within `f()` has its own context, which is not handler context. Thus, `RESIGNAL` within `f()` results in a “handler not active” error.

13.6.7.5 SIGNAL Syntax

```
SIGNAL condition_value
  [SET signal_information_item
  [, signal_information_item] ...]

condition_value:
  SQLSTATE [VALUE] sqlstate_value
  | condition_name

signal_information_item:
  condition_information_item_name = simple_value_specification

condition_information_item_name:
  CLASS_ORIGIN
  | SUBCLASS_ORIGIN
  | MESSAGE_TEXT
  | MYSQL_ERRNO
  | CONSTRAINT_CATALOG
  | CONSTRAINT_SCHEMA
  | CONSTRAINT_NAME
  | CATALOG_NAME
  | SCHEMA_NAME
  | TABLE_NAME
  | COLUMN_NAME
  | CURSOR_NAME

condition_name, simple_value_specification:
```

(see following discussion)

`SIGNAL` is the way to “return” an error. `SIGNAL` provides error information to a handler, to an outer portion of the application, or to the client. Also, it provides control over the error's characteristics (error number, `SQLSTATE` value, message). Without `SIGNAL`, it is necessary to resort to workarounds such as deliberately referring to a nonexistent table to cause a routine to return an error.

No special privileges are required to execute the `SIGNAL` statement.

To retrieve information from the diagnostics area, use the `GET DIAGNOSTICS` statement (see [Section 13.6.7.3, “GET DIAGNOSTICS Syntax”](#)). For information about the diagnostics area, see [Section 13.6.7.7, “The MySQL Diagnostics Area”](#).

The `condition_value` in a `SIGNAL` statement indicates the error value to be returned. It can be an `SQLSTATE` value (a 5-character string literal) or a `condition_name` that refers to a named condition previously defined with `DECLARE ... CONDITION` (see [Section 13.6.7.1, “DECLARE ... CONDITION Syntax”](#)).

An `SQLSTATE` value can indicate errors, warnings, or “not found.” The first two characters of the value indicate its error class, as discussed in [Signal Condition Information Items](#). Some signal values cause statement termination; see [Effect of Signals on Handlers, Cursors, and Statements](#).

The `SQLSTATE` value for a `SIGNAL` statement should not start with '00' because such values indicate success and are not valid for signaling an error. This is true whether the `SQLSTATE` value is specified directly in the `SIGNAL` statement or in a named condition referred to in the statement. If the value is invalid, a `Bad SQLSTATE` error occurs.

To signal a generic `SQLSTATE` value, use '45000', which means “unhandled user-defined exception.”

The `SIGNAL` statement optionally includes a `SET` clause that contains multiple signal items, in a comma-separated list of `condition_information_item_name = simple_value_specification` assignments.

Each `condition_information_item_name` may be specified only once in the `SET` clause. Otherwise, a `Duplicate condition information item` error occurs.

Valid `simple_value_specification` designators can be specified using stored procedure or function parameters, stored program local variables declared with `DECLARE`, user-defined variables, system variables, or literals. A character literal may include a `_charset` introducer.

For information about permissible `condition_information_item_name` values, see [Signal Condition Information Items](#).

The following procedure signals an error or warning depending on the value of `pval`, its input parameter:

```
CREATE PROCEDURE p (pval INT)
BEGIN
  DECLARE specialty CONDITION FOR SQLSTATE '45000';
  IF pval = 0 THEN
    SIGNAL SQLSTATE '01000';
  ELSEIF pval = 1 THEN
    SIGNAL SQLSTATE '45000'
    SET MESSAGE_TEXT = 'An error occurred';
  ELSEIF pval = 2 THEN
    SIGNAL specialty
    SET MESSAGE_TEXT = 'An error occurred';
  ELSE
    SIGNAL SQLSTATE '01000'
    SET MESSAGE_TEXT = 'A warning occurred', MYSQL_ERRNO = 1000;
    SIGNAL SQLSTATE '45000'
    SET MESSAGE_TEXT = 'An error occurred', MYSQL_ERRNO = 1001;
  END IF;
```

```
END;
```

If `pval` is 0, `p()` signals a warning because `SQLSTATE` values that begin with '01' are signals in the warning class. The warning does not terminate the procedure, and can be seen with `SHOW WARNINGS` after the procedure returns.

If `pval` is 1, `p()` signals an error and sets the `MESSAGE_TEXT` condition information item. The error terminates the procedure, and the text is returned with the error information.

If `pval` is 2, the same error is signaled, although the `SQLSTATE` value is specified using a named condition in this case.

If `pval` is anything else, `p()` first signals a warning and sets the message text and error number condition information items. This warning does not terminate the procedure, so execution continues and `p()` then signals an error. The error does terminate the procedure. The message text and error number set by the warning are replaced by the values set by the error, which are returned with the error information.

`SIGNAL` is typically used within stored programs, but it is a MySQL extension that it is permitted outside handler context. For example, if you invoke the `mysql` client program, you can enter any of these statements at the prompt:

```
mysql> SIGNAL SQLSTATE '77777';
mysql> CREATE TRIGGER t_bi BEFORE INSERT ON t
  -> FOR EACH ROW SIGNAL SQLSTATE '77777';
mysql> CREATE EVENT e ON SCHEDULE EVERY 1 SECOND
  -> DO SIGNAL SQLSTATE '77777';
```

`SIGNAL` executes according to the following rules:

If the `SIGNAL` statement indicates a particular `SQLSTATE` value, that value is used to signal the condition specified. Example:

```
CREATE PROCEDURE p (divisor INT)
BEGIN
  IF divisor = 0 THEN
    SIGNAL SQLSTATE '22012';
  END IF;
END;
```

If the `SIGNAL` statement uses a named condition, the condition must be declared in some scope that applies to the `SIGNAL` statement, and must be defined using an `SQLSTATE` value, not a MySQL error number. Example:

```
CREATE PROCEDURE p (divisor INT)
BEGIN
  DECLARE divide_by_zero CONDITION FOR SQLSTATE '22012';
  IF divisor = 0 THEN
    SIGNAL divide_by_zero;
  END IF;
END;
```

If the named condition does not exist in the scope of the `SIGNAL` statement, an `Undefined CONDITION` error occurs.

If `SIGNAL` refers to a named condition that is defined with a MySQL error number rather than an `SQLSTATE` value, a `SIGNAL/RESIGNAL` can only use a `CONDITION` defined with `SQLSTATE` error occurs. The following statements cause that error because the named condition is associated with a MySQL error number:

```
DECLARE no_such_table CONDITION FOR 1051;
```

```
SIGNAL no_such_table;
```

If a condition with a given name is declared multiple times in different scopes, the declaration with the most local scope applies. Consider the following procedure:

```
CREATE PROCEDURE p (divisor INT)
BEGIN
  DECLARE my_error CONDITION FOR SQLSTATE '45000';
  IF divisor = 0 THEN
    BEGIN
      DECLARE my_error CONDITION FOR SQLSTATE '22012';
      SIGNAL my_error;
    END;
  END IF;
  SIGNAL my_error;
END;
```

If `divisor` is 0, the first `SIGNAL` statement executes. The innermost `my_error` condition declaration applies, raising `SQLSTATE '22012'`.

If `divisor` is not 0, the second `SIGNAL` statement executes. The outermost `my_error` condition declaration applies, raising `SQLSTATE '45000'`.

For information about how the server chooses handlers when a condition occurs, see [Section 13.6.7.6, “Scope Rules for Handlers”](#).

Signals can be raised within exception handlers:

```
CREATE PROCEDURE p ()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION
  BEGIN
    SIGNAL SQLSTATE VALUE '99999'
    SET MESSAGE_TEXT = 'An error occurred';
  END;
  DROP TABLE no_such_table;
END;
```

`CALL p()` reaches the `DROP TABLE` statement. There is no table named `no_such_table`, so the error handler is activated. The error handler destroys the original error (“no such table”) and makes a new error with `SQLSTATE '99999'` and message `An error occurred`.

Signal Condition Information Items

The following table lists the names of diagnostics area condition information items that can be set in a `SIGNAL` (or `RESIGNAL`) statement. All items are standard SQL except `MYSQL_ERRNO`, which is a MySQL extension. For more information about these items see [Section 13.6.7.7, “The MySQL Diagnostics Area”](#).

Item Name	Definition
CLASS_ORIGIN	VARCHAR(64)
SUBCLASS_ORIGIN	VARCHAR(64)
CONSTRAINT_CATALOG	VARCHAR(64)
CONSTRAINT_SCHEMA	VARCHAR(64)
CONSTRAINT_NAME	VARCHAR(64)
CATALOG_NAME	VARCHAR(64)
SCHEMA_NAME	VARCHAR(64)
TABLE_NAME	VARCHAR(64)
COLUMN_NAME	VARCHAR(64)
CURSOR_NAME	VARCHAR(64)
MESSAGE_TEXT	VARCHAR(128)
MYSQL_ERRNO	SMALLINT UNSIGNED

The character set for character items is UTF-8.

It is illegal to assign `NULL` to a condition information item in a `SIGNAL` statement.

A `SIGNAL` statement always specifies an `SQLSTATE` value, either directly, or indirectly by referring to a named condition defined with an `SQLSTATE` value. The first two characters of an `SQLSTATE` value are its class, and the class determines the default value for the condition information items:

- Class = '00' (success)

Illegal. `SQLSTATE` values that begin with '00' indicate success and are not valid for `SIGNAL`.

- Class = '01' (warning)

```
MESSAGE_TEXT = 'Unhandled user-defined warning condition';
MYSQL_ERRNO = ER_SIGNAL_WARN
```

- Class = '02' (not found)

```
MESSAGE_TEXT = 'Unhandled user-defined not found condition';
MYSQL_ERRNO = ER_SIGNAL_NOT_FOUND
```

- Class > '02' (exception)

```
MESSAGE_TEXT = 'Unhandled user-defined exception condition';
MYSQL_ERRNO = ER_SIGNAL_EXCEPTION
```

For legal classes, the other condition information items are set as follows:

```
CLASS_ORIGIN = SUBCLASS_ORIGIN = '';
CONSTRAINT_CATALOG = CONSTRAINT_SCHEMA = CONSTRAINT_NAME = '';
CATALOG_NAME = SCHEMA_NAME = TABLE_NAME = COLUMN_NAME = '';
CURSOR_NAME = '';
```

The error values that are accessible after `SIGNAL` executes are the `SQLSTATE` value raised by the `SIGNAL` statement and the `MESSAGE_TEXT` and `MYSQL_ERRNO` items. These values are available from the C API:

- `SQLSTATE` value: Call `mysql_sqlstate()`
- `MYSQL_ERRNO` value: Call `mysql_errno()`
- `MESSAGE_TEXT` value: Call `mysql_error()`

From SQL, the output from `SHOW WARNINGS` and `SHOW ERRORS` indicates the `MYSQL_ERRNO` and `MESSAGE_TEXT` values in the `Code` and `Message` columns.

To retrieve information from the diagnostics area, use the `GET DIAGNOSTICS` statement (see [Section 13.6.7.3, “GET DIAGNOSTICS Syntax”](#)). For information about the diagnostics area, see [Section 13.6.7.7, “The MySQL Diagnostics Area”](#).

Effect of Signals on Handlers, Cursors, and Statements

Signals have different effects on statement execution depending on the signal class. The class determines how severe an error is. MySQL ignores the value of the `sql_mode` system variable; in particular, strict SQL mode does not matter. MySQL also ignores `IGNORE`: The intent of `SIGNAL` is to raise a user-generated error explicitly, so a signal is never ignored.

In the following descriptions, “unhandled” means that no handler for the signaled `SQLSTATE` value has been defined with `DECLARE ... HANDLER`.

- Class = '00' (success)

Illegal. `SQLSTATE` values that begin with '00' indicate success and are not valid for `SIGNAL`.

- Class = '01' (warning)

The value of the `warning_count` system variable goes up. `SHOW WARNINGS` shows the signal. `SQLWARNING` handlers catch the signal. If the signal is unhandled in a function, statements do not end.

- Class = '02' (not found)

`NOT FOUND` handlers catch the signal. There is no effect on cursors. If the signal is unhandled in a function, statements end.

- Class > '02' (exception)

`SQLEXCEPTION` handlers catch the signal. If the signal is unhandled in a function, statements end.

- Class = '40'

Treated as an ordinary exception.

Example:

```
mysql> delimiter //
mysql> CREATE FUNCTION f () RETURNS INT
-> BEGIN
->   SIGNAL SQLSTATE '01234'; -- signal a warning
->   RETURN 5;
-> END//
mysql> delimiter ;
mysql> CREATE TABLE t (s1 INT);
mysql> INSERT INTO t VALUES (f());
```

The result is that a row containing 5 is inserted into table `t`. The warning that is signaled can be viewed with `SHOW WARNINGS`.

13.6.7.6 Scope Rules for Handlers

A stored program may include handlers to be invoked when certain conditions occur within the program. The applicability of each handler depends on its location within the program definition and on the condition or conditions that it handles:

- A handler declared in a `BEGIN ... END` block is in scope only for the SQL statements following the handler declarations in the block. If the handler itself raises a condition, it cannot handle that condition, nor can any other handlers declared in the block. In the following example, handlers `H1` and `H2` are in scope for conditions raised by statements `stmt1` and `stmt2`. But neither `H1` nor `H2` are in scope for conditions raised in the body of `H1` or `H2`.

```
BEGIN -- outer block
  DECLARE EXIT HANDLER FOR ...; -- handler H1
  DECLARE EXIT HANDLER FOR ...; -- handler H2
  stmt1;
  stmt2;
END;
```

- A handler is in scope only for the block in which it is declared, and cannot be activated for conditions occurring outside that block. In the following example, handler `H1` is in scope for `stmt1` in the inner block, but not for `stmt2` in the outer block:

```
BEGIN -- outer block
  BEGIN -- inner block
```

```

DECLARE EXIT HANDLER FOR ...; -- handler H1
    stmt1;
END;
    stmt2;
END;

```

- A handler can be specific or general. A specific handler is for a MySQL error code, `SQLSTATE` value, or condition name. A general handler is for a condition in the `SQLWARNING`, `SQLEXCEPTION`, or `NOT FOUND` class. Condition specificity is related to condition precedence, as described later.

Multiple handlers can be declared in different scopes and with different specificities. For example, there might be a specific MySQL error code handler in an outer block, and a general `SQLWARNING` handler in an inner block. Or there might be handlers for a specific MySQL error code and the general `SQLWARNING` class in the same block.

Whether a handler is activated depends not only on its own scope and condition value, but on what other handlers are present. When a condition occurs in a stored program, the server searches for applicable handlers in the current scope (current `BEGIN ... END` block). If there are no applicable handlers, the search continues outward with the handlers in each successive containing scope (block). When the server finds one or more applicable handlers at a given scope, it chooses among them based on condition precedence:

- A MySQL error code handler takes precedence over an `SQLSTATE` value handler.
- An `SQLSTATE` value handler takes precedence over general `SQLWARNING`, `SQLEXCEPTION`, or `NOT FOUND` handlers.
- An `SQLEXCEPTION` handler takes precedence over an `SQLWARNING` handler.
- It is possible to have several applicable handlers with the same precedence. For example, a statement could generate multiple warnings with different error codes, for each of which an error-specific handler exists. In this case, the choice of which handler the server activates is indeterminate, and may change depending on the circumstances under which the condition occurs.

One implication of the handler selection rules is that if multiple applicable handlers occur in different scopes, handlers with the most local scope take precedence over handlers in outer scopes, even over those for more specific conditions.

If there is no appropriate handler when a condition occurs, the action taken depends on the class of the condition:

- For `SQLEXCEPTION` conditions, the stored program terminates at the statement that raised the condition, as if there were an `EXIT` handler. If the program was called by another stored program, the calling program handles the condition using the handler selection rules applied to its own handlers.
- For `SQLWARNING` conditions, the program continues executing, as if there were a `CONTINUE` handler.
- For `NOT FOUND` conditions, if the condition was raised normally, the action is `CONTINUE`. If it was raised by `SIGNAL` or `RESIGNAL`, the action is `EXIT`.

The following examples demonstrate how MySQL applies the handler selection rules.

This procedure contains two handlers, one for the specific `SQLSTATE` value (`'42S02'`) that occurs for attempts to drop a nonexistent table, and one for the general `SQLEXCEPTION` class:

```

CREATE PROCEDURE p1()
BEGIN
    DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
        SELECT 'SQLSTATE handler was activated' AS msg;
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION

```

```

SELECT 'SQLEXCEPTION handler was activated' AS msg;

DROP TABLE test.t;
END;

```

Both handlers are declared in the same block and have the same scope. However, [SQLSTATE](#) handlers take precedence over [SQLEXCEPTION](#) handlers, so if the table `t` is nonexistent, the `DROP TABLE` statement raises a condition that activates the [SQLSTATE](#) handler:

```

mysql> CALL p1();
+-----+
| msg                |
+-----+
| SQLSTATE handler was activated |
+-----+

```

This procedure contains the same two handlers. But this time, the `DROP TABLE` statement and [SQLEXCEPTION](#) handler are in an inner block relative to the [SQLSTATE](#) handler:

```

CREATE PROCEDURE p2()
BEGIN -- outer block
    DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
        SELECT 'SQLSTATE handler was activated' AS msg;
    BEGIN -- inner block
        DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
            SELECT 'SQLEXCEPTION handler was activated' AS msg;

        DROP TABLE test.t; -- occurs within inner block
    END;
END;

```

In this case, the handler that is more local to where the condition occurs takes precedence. The [SQLEXCEPTION](#) handler activates, even though it is more general than the [SQLSTATE](#) handler:

```

mysql> CALL p2();
+-----+
| msg                |
+-----+
| SQLEXCEPTION handler was activated |
+-----+

```

In this procedure, one of the handlers is declared in a block inner to the scope of the `DROP TABLE` statement:

```

CREATE PROCEDURE p3()
BEGIN -- outer block
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
        SELECT 'SQLEXCEPTION handler was activated' AS msg;
    BEGIN -- inner block
        DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
            SELECT 'SQLSTATE handler was activated' AS msg;
    END;

    DROP TABLE test.t; -- occurs within outer block
END;

```

Only the [SQLEXCEPTION](#) handler applies because the other one is not in scope for the condition raised by the `DROP TABLE`:

```

mysql> CALL p3();
+-----+
| msg                |
+-----+
| SQLEXCEPTION handler was activated |
+-----+

```

In this procedure, both handlers are declared in a block inner to the scope of the `DROP TABLE` statement:

```
CREATE PROCEDURE p4()
BEGIN -- outer block
  BEGIN -- inner block
    DECLARE CONTINUE HANDLER FOR SQLEXCEPTION
      SELECT 'SQLEXCEPTION handler was activated' AS msg;
    DECLARE CONTINUE HANDLER FOR SQLSTATE '42S02'
      SELECT 'SQLSTATE handler was activated' AS msg;
  END;

  DROP TABLE test.t; -- occurs within outer block
END;
```

Neither handler applies because they are not in scope for the `DROP TABLE`. The condition raised by the statement goes unhandled and terminates the procedure with an error:

```
mysql> CALL p4();
ERROR 1051 (42S02): Unknown table 'test.t'
```

13.6.7.7 The MySQL Diagnostics Area

SQL statements produce diagnostic information that populates the diagnostics area. Standard SQL has a diagnostics area stack, containing a diagnostics area for each nested execution context. Standard SQL also supports `GET STACKED DIAGNOSTICS` syntax for referring to the second diagnostics area during condition handler execution. MySQL supports the `STACKED` keyword since MySQL 5.7.

This section describes the structure of the diagnostics area in MySQL, the information items recognized by MySQL, how statements clear and set the diagnostics area, and how diagnostics areas are pushed to and popped from the stack.

Diagnostics Area Structure

The diagnostics area contains two kinds of information:

- Statement information, such as the number of conditions that occurred or the affected-rows count.
- Condition information, such as the error code and message. If a statement raises multiple conditions, this part of the diagnostics area has a condition area for each one. If a statement raises no conditions, this part of the diagnostics area is empty.

For a statement that produces three conditions, the diagnostics area contains statement and condition information like this:

```
Statement information:
  row count
  ... other statement information items ...
Condition area list:
  Condition area 1:
    error code for condition 1
    error message for condition 1
    ... other condition information items ...
  Condition area 2:
    error code for condition 2:
    error message for condition 2
    ... other condition information items ...
  Condition area 3:
    error code for condition 3
    error message for condition 3
    ... other condition information items ...
```

Diagnostics Area Information Items

The diagnostics area contains statement and condition information items. Numeric items are integers. The character set for character items is UTF-8. No item can be `NULL`. If a statement or condition item is not set by a statement that populates the diagnostics area, its value is 0 or the empty string, depending on the item data type.

The statement information part of the diagnostics area contains these items:

- `NUMBER`: An integer indicating the number of condition areas that have information.
- `ROW_COUNT`: An integer indicating the number of rows affected by the statement. `ROW_COUNT` has the same value as the `ROW_COUNT()` function (see [Section 12.14, “Information Functions”](#)).

The condition information part of the diagnostics area contains a condition area for each condition. Condition areas are numbered from 1 to the value of the `NUMBER` statement condition item. If `NUMBER` is 0, there are no condition areas.

Each condition area contains the items in the following list. All items are standard SQL except `MYSQL_ERRNO`, which is a MySQL extension. The definitions apply for conditions generated other than by a signal (that is, by a `SIGNAL` or `RESIGNAL` statement). For nonsignal conditions, MySQL populates only those condition items not described as always empty. The effects of signals on the condition area are described later.

- `CLASS_ORIGIN`: A string containing the class of the `RETURNED_SQLSTATE` value. If the `RETURNED_SQLSTATE` value begins with a class value defined in SQL standards document ISO 9075-2 (section 24.1, `SQLSTATE`), `CLASS_ORIGIN` is `'ISO 9075'`. Otherwise, `CLASS_ORIGIN` is `'MySQL'`.
- `SUBCLASS_ORIGIN`: A string containing the subclass of the `RETURNED_SQLSTATE` value. If `CLASS_ORIGIN` is `'ISO 9075'` or `RETURNED_SQLSTATE` ends with `'000'`, `SUBCLASS_ORIGIN` is `'ISO 9075'`. Otherwise, `SUBCLASS_ORIGIN` is `'MySQL'`.
- `RETURNED_SQLSTATE`: A string that indicates the `SQLSTATE` value for the condition.
- `MESSAGE_TEXT`: A string that indicates the error message for the condition.
- `MYSQL_ERRNO`: An integer that indicates the MySQL error code for the condition.
- `CONSTRAINT_CATALOG`, `CONSTRAINT_SCHEMA`, `CONSTRAINT_NAME`: Strings that indicate the catalog, schema, and name for a violated constraint. They are always empty.
- `CATALOG_NAME`, `SCHEMA_NAME`, `TABLE_NAME`, `COLUMN_NAME`: Strings that indicate the catalog, schema, table, and column related to the condition. They are always empty.
- `CURSOR_NAME`: A string that indicates the cursor name. This is always empty.

For the `RETURNED_SQLSTATE`, `MESSAGE_TEXT`, and `MYSQL_ERRNO` values for particular errors, see [Section B.3, “Server Error Codes and Messages”](#).

If a `SIGNAL` (or `RESIGNAL`) statement populates the diagnostics area, its `SET` clause can assign to any condition information item except `RETURNED_SQLSTATE` any value that is legal for the item data type. `SIGNAL` also sets the `RETURNED_SQLSTATE` value, but not directly in its `SET` clause. That value comes from the `SIGNAL` statement `SQLSTATE` argument.

`SIGNAL` also sets statement information items. It sets `NUMBER` to 1. It sets `ROW_COUNT` to `-1` for errors and 0 otherwise.

How the Diagnostics Area is Populated

Nondiagnostic SQL statements populate the diagnostics area automatically, and its contents can be set explicitly with the `SIGNAL` and `RESIGNAL` statements. The diagnostics area can be examined with `GET`

`DIAGNOSTICS` to extract specific items, or with `SHOW WARNINGS` or `SHOW ERRORS` to see conditions or errors.

SQL statements clear and set the diagnostics area as follows:

- When the server starts executing a statement after parsing it, it clears the diagnostics area for nondiagnostic statements. Diagnostic statements do not clear the diagnostics area (`SHOW WARNINGS`, `SHOW ERRORS`, `GET DIAGNOSTICS`).
- If a statement raises a condition, the diagnostics area is cleared of conditions that belong to earlier statements. The exception is that conditions raised by `GET DIAGNOSTICS` and `RESIGNAL` are added to the diagnostics area without clearing it.

Thus, even a statement that does not normally clear the diagnostics area when it begins executing clears it if the statement raises a condition.

The following example shows the effect of various statements on the diagnostics area, using `SHOW WARNINGS` to display information about conditions stored there.

This `DROP TABLE` statement clears the diagnostics area and populates it when the condition occurs:

```
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected, 1 warning (0.01 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Note  | 1051 | Unknown table 'test.no_such_table'        |
+-----+-----+-----+
1 row in set (0.00 sec)
```

This `SET` statement generates an error, so it clears and populates the diagnostics area:

```
mysql> SET @x = @@x;
ERROR 1193 (HY000): Unknown system variable 'x'

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Error | 1193 | Unknown system variable 'x'                |
+-----+-----+-----+
1 row in set (0.00 sec)
```

The previous `SET` statement produced a single condition, so 1 is the only valid condition number for `GET DIAGNOSTICS` at this point. The following statement uses a condition number of 2, which produces a warning that is added to the diagnostics area without clearing it:

```
mysql> GET DIAGNOSTICS CONDITION 2 @p = MESSAGE_TEXT;
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Error | 1193 | Unknown system variable 'xx'                |
| Error | 1753 | Invalid condition number                    |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

Now there are two conditions in the diagnostics area, so the same `GET DIAGNOSTICS` statement succeeds:

```
mysql> GET DIAGNOSTICS CONDITION 2 @p = MESSAGE_TEXT;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @p;
+-----+
| @p    |
+-----+
| Invalid condition number |
+-----+
1 row in set (0.01 sec)
```

How the Diagnostics Area Stack Works

When a push to the diagnostics area stack occurs, the first (current) diagnostics area becomes the second (stacked) diagnostics area and a new current diagnostics area is created as a copy of it. Diagnostics areas are pushed to and popped from the stack under the following circumstances:

- Execution of a stored program

A push occurs before the program executes and a pop occurs afterward. If the stored program ends while handlers are executing, there can be more than one diagnostics area to pop; this occurs due to an exception for which there are no appropriate handlers or due to `RETURN` in the handler.

Any warning or error conditions occurring during stored program execution then are added to the current diagnostics area, except that, for triggers, only errors are added. When the stored program ends, the caller sees these conditions in its current diagnostics area.

- Execution of a condition handler within a stored program

When a push occurs as a result of condition handler activation, the stacked diagnostics area is the area that was current within the stored program prior to the push. The new now-current diagnostics area is the handler's current diagnostics area. `GET [CURRENT] DIAGNOSTICS` and `GET STACKED DIAGNOSTICS` can be used within the handler to access the contents of the current (handler) and stacked (stored program) diagnostics areas. Initially, they return the same result, but statements executing within the handler modify the current diagnostics area, clearing and setting its contents according to the normal rules (see [How the Diagnostics Area is Populated](#)). The stacked diagnostics area cannot be modified by statements executing within the handler except `RESIGNAL`.

If the handler executes successfully, the current (handler) diagnostics area is popped and the stacked (stored program) diagnostics area again becomes the current diagnostics area. Conditions added to the handler diagnostics area during handler execution are added to the current diagnostics area.

- Execution of `RESIGNAL`

The `RESIGNAL` statement passes on the error condition information that is available during execution of a condition handler within a compound statement inside a stored program. `RESIGNAL` may change some or all information before passing it on, modifying the diagnostics stack as described in [Section 13.6.7.4, "RESIGNAL Syntax"](#).

Diagnostics Area-Related System Variables

Certain system variables control or are related to some aspects of the diagnostics area:

- `max_error_count` controls the number of condition areas in the diagnostics area. If more conditions than this occur, MySQL silently discards information for the excess conditions. (Conditions added by `RESIGNAL` are always added, with older conditions being discarded as necessary to make room.)
- `warning_count` indicates the number of conditions that occurred. This includes errors, warnings, and notes. Normally, `NUMBER` and `warning_count` are the same. However, as the number of conditions generated exceeds `max_error_count`, the value of `warning_count` continues to

rise whereas `NUMBER` remains capped at `max_error_count` because no additional conditions are stored in the diagnostics area.

- `error_count` indicates the number of errors that occurred. This value includes “not found” and exception conditions, but excludes warnings and notes. Like `warning_count`, its value can exceed `max_error_count`.
- If the `sql_notes` system variable is set to 0, notes are not stored and do not increment `warning_count`.

Example: If `max_error_count` is 10, the diagnostics area can contain a maximum of 10 condition areas. Suppose that a statement raises 20 conditions, 12 of which are errors. In that case, the diagnostics area contains the first 10 conditions, `NUMBER` is 10, `warning_count` is 20, and `error_count` is 12.

Changes to the value of `max_error_count` have no effect until the next attempt to modify the diagnostics area. If the diagnostics area contains 10 condition areas and `max_error_count` is set to 5, that has no immediate effect on the size or content of the diagnostics area.

13.7 Database Administration Statements

13.7.1 Account Management Statements

MySQL account information is stored in the tables of the `mysql` database. This database and the access control system are discussed extensively in [Chapter 5, MySQL Server Administration](#), which you should consult for additional details.

Important

Some MySQL releases introduce changes to the structure of the grant tables to add new privileges or features. To make sure that you can take advantage of any new capabilities, update your grant tables to have the current structure whenever you upgrade MySQL. See [Section 4.4.5, “mysql_upgrade — Check and Upgrade MySQL Tables”](#).

When the `read_only` system variable is enabled, account-management statements require the `SUPER` privilege, in addition to any other required privileges. This is because they modify tables in the `mysql` database.

13.7.1.1 ALTER USER Syntax

```
ALTER USER [IF EXISTS]
    user [auth_option] [, user [auth_option]] ...
    [REQUIRE {NONE | tls_option [[AND] tls_option] ...}]
    [WITH resource_option [resource_option] ...]
    [password_option | lock_option] ...

ALTER USER [IF EXISTS]
    USER() IDENTIFIED BY 'auth_string'

ALTER USER [IF EXISTS]
    user DEFAULT ROLE
    {NONE | ALL | role [, role] ...}

user:
    (see Section 6.2.4, “Specifying Account Names”)

auth_option: {
    IDENTIFIED BY 'auth_string'
  | IDENTIFIED WITH auth_plugin
  | IDENTIFIED WITH auth_plugin BY 'auth_string'
  | IDENTIFIED WITH auth_plugin AS 'hash_string'
}
```

```

tls_option: {
  SSL
  | X509
  | CIPHER 'cipher'
  | ISSUER 'issuer'
  | SUBJECT 'subject'
}

resource_option: {
  MAX_QUERIES_PER_HOUR count
  | MAX_UPDATES_PER_HOUR count
  | MAX_CONNECTIONS_PER_HOUR count
  | MAX_USER_CONNECTIONS count
}

password_option: {
  PASSWORD EXPIRE
  | PASSWORD EXPIRE DEFAULT
  | PASSWORD EXPIRE NEVER
  | PASSWORD EXPIRE INTERVAL N DAY
}

lock_option: {
  ACCOUNT LOCK
  | ACCOUNT UNLOCK
}

```

The `ALTER USER` statement modifies MySQL accounts. It enables authentication, SSL/TLS, resource-limit, and password-expiration properties to be modified for existing accounts, and enables account locking and unlocking.

Except for the `DEFAULT ROLE` syntax, `ALTER USER` requires the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql` database. For `DEFAULT ROLE`, `ALTER USER` requires these privileges:

- Setting the default roles for another user requires the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql.default_roles` system table.
- Setting the default roles for yourself requires no special privileges, as long as the roles you want as the default have been granted to you.

When the `read_only` system variable is enabled, `ALTER USER` additionally requires the `SUPER` privilege.

By default, an error occurs if you try to modify a user that does not exist. If the `IF EXISTS` clause is given, the statement produces a warning for each named user that does not exist, rather than an error.

The statement is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named users. If the `IF EXISTS` clause is given, this includes even users that do not exist and were not altered.

If the original statement changes the credentials for a user, the statement written to the binary log specifies the applicable authentication plugin for that user, determined as follows:

- The plugin named in the original statement, if one was specified.
- Otherwise, the plugin associated with the user account if the user exists, or the default authentication plugin if the user does not exist. (If the statement written to the binary log must specify a particular authentication plugin for a user, include it in the original statement.)

If the server adds the default authentication plugin for any users in the statement written to the binary log, it writes a warning to the error log naming those users.

`ALTER USER` modifies the `mysql.user` table row for each affected account according to the options specified in the statement. Unspecified properties retain their current values.

Example 1: Change an account's password and expire it. As a result, the user must connect with the named password and choose a new one at the next connection:

```
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED BY 'new_password' PASSWORD EXPIRE;
```

Example 2: Modify an account to use the `sha256_password` authentication plugin and the given password. Require that a new password be chosen every 180 days:

```
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED WITH sha256_password BY 'new_password'
  PASSWORD EXPIRE INTERVAL 180 DAY;
```

Example 3: Lock or unlock an account:

```
ALTER USER 'jeffrey'@'localhost' ACCOUNT LOCK;
ALTER USER 'jeffrey'@'localhost' ACCOUNT UNLOCK;
```

Example 4: Require an account to connect using SSL and establish a limit of 20 connections per hour:

```
ALTER USER 'jeffrey'@'localhost'
  REQUIRE SSL WITH MAX_CONNECTIONS_PER_HOUR 20;
```

Important

Under some circumstances, `ALTER USER` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see [Section 6.1.2.3, “Passwords and Logging”](#). For similar information about client-side logging, see [Section 4.5.1.3, “mysql Logging”](#).

Each account name uses the format described in [Section 6.2.4, “Specifying Account Names”](#). The host name part of the account name, if omitted, defaults to `'%'`. It is also possible to specify `CURRENT_USER` or `CURRENT_USER()` to refer to the account associated with the current session.

For one syntax only, the account may be specified with the `USER()` function:

```
ALTER USER USER() IDENTIFIED BY 'auth_string';
```

This syntax enables changing your own password without naming your account literally.

For `ALTER USER` syntaxes that permit an `auth_option` value to follow a `user` value, `auth_option` begins with `IDENTIFIED` and indicates how the account authenticates by specifying an account authentication plugin, credentials (password), or both. Each `auth_option` value applies *only* to the user named immediately preceding it.

Following the user specifications, the statement may include options for SSL/TLS, resource-limit, password-expiration, and locking properties. All these options are *global* to the statement and apply to *all* named users.

Example: This statement changes the password for `jeffrey` but leaves that for `jeanne` unchanged. For both accounts, connections are required to use SSL and each account can be used for a maximum of two simultaneous connections:

```
ALTER USER
  'jeffrey'@'localhost' IDENTIFIED BY 'new_password',
  'jeanne'@'localhost'
```

```
REQUIRE SSL WITH MAX_USER_CONNECTIONS 2;
```

In the absence of a particular type of option, the account remains unchanged in that respect. For example, with no locking option, the locking state of the account is not changed.

There are several aspects to the `ALTER USER` statement, described under the following topics in this section:

- [Authentication Options](#)
- [SSL/TLS Options](#)
- [Resource-Limit Options](#)
- [Password-Expiration Options](#)
- [Account-Locking Options](#)
- [Role Options](#)

Authentication Options

An account name may be followed by an authentication option that specifies the account authentication plugin, credentials, or both:

- `auth_plugin` names an authentication plugin. The plugin name can be a quoted string literal or an unquoted name. Plugin names are stored in the `plugin` column of the `mysql.user` table.
- `'auth_string'` or `'hash_string'` specify account credentials, either as cleartext or hashed in the format expected by the authentication plugin, respectively. Credentials are stored in the `authentication_string` column of the `mysql.user` table.

`ALTER USER` permits these `auth_option` syntaxes:

- `IDENTIFIED BY 'auth_string'`

Sets the account authentication plugin to the default plugin, hashes the cleartext `'auth_string'` value, and stores the result in the `mysql.user` account row.

- `IDENTIFIED WITH auth_plugin`

Sets the account authentication plugin to `auth_plugin`, clears the credentials to the empty string (the credentials are associated with the old authentication plugin, not the new one), and stores the result in the `mysql.user` account row.

In addition, the password is marked expired. The user must choose a new one when next connecting.

- `IDENTIFIED WITH auth_plugin BY 'auth_string'`

Sets the account authentication plugin to `auth_plugin`, hashes the cleartext `'auth_string'` value, and stores the result in the `mysql.user` account row.

- `IDENTIFIED WITH auth_plugin AS 'hash_string'`

Sets the account authentication plugin to `auth_plugin`, takes the hashed `'hash_string'` value as is, and stores the result in the `mysql.user` account row. The string is assumed to be already hashed in the format required by the plugin.

The default plugin is `mysql_native_password` unless the `default_authentication_plugin` system variable is set otherwise. For descriptions of each plugin, see [Section 6.5.1, “Authentication Plugins”](#).

Example 1: Specify the password as cleartext; the default plugin is used:

```
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED BY 'mypass';
```

Example 2: Specify the authentication plugin, along with a cleartext password value:

```
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED WITH mysql_native_password
  BY 'mypass';
```

Example 3: Specify the authentication plugin, along with a hashed password value:

```
ALTER USER 'jeffrey'@'localhost'
  IDENTIFIED WITH mysql_native_password
  AS '*6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4';
```

SSL/TLS Options

MySQL can check X509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL with MySQL, see [Section 6.4, “Using Secure Connections”](#).

To specify SSL-related options for a MySQL account, use a `REQUIRE` clause that specifies one or more `tls_option` values.

`ALTER USER` permits these `tls_option` values:

- `NONE`

Indicates that the account has no SSL or X509 requirements. Unencrypted connections are permitted if the user name and password are valid. However, encrypted connections can also be used, at the client's option, if the client has the proper certificate and key files.

A client need specify only the `--ssl-mode=REQUIRED` option to obtain an encrypted connection. The connection attempt fails if SSL is not available.

- `SSL`

Tells the server to permit only encrypted connections for the account.

```
ALTER USER 'jeffrey'@'localhost' REQUIRE SSL;
```

A client need specify only the `--ssl-mode=REQUIRED` option to obtain an encrypted connection. The connection attempt fails if SSL is not available.

- `X509`

Requires that the client must have a valid certificate but the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates. Use of X509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

```
ALTER USER 'jeffrey'@'localhost' REQUIRE X509;
```

The client must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.) This is true for `ISSUER` and `SUBJECT` as well because those `REQUIRE` options imply the requirements of `X509`.

- `ISSUER 'issuer'`

Places the restriction on connection attempts that the client must present a valid X509 certificate issued by CA `'issuer'`. If the client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

Because `ISSUER` implies the requirements of `X509`, the client must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.)

```
ALTER USER 'jeffrey'@'localhost'
  REQUIRE ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL/CN=CA/emailAddress=ca@example.com';
```

- `SUBJECT 'subject'`

Places the restriction on connection attempts that the client must present a valid X509 certificate containing the subject `subject`. If the client presents a certificate that is valid but has a different subject, the server rejects the connection. Use of X509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

Because `SUBJECT` implies the requirements of `X509`, the client must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.)

```
ALTER USER 'jeffrey'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL demo client certificate/
  CN=client/emailAddress=client@example.com';
```

MySQL does a simple string comparison of the `'subject'` value to the value in the certificate, so lettercase and component ordering must be given exactly as present in the certificate.

Note

Regarding `emailAddress`, see the note in the description of `REQUIRE ISSUER`.

- `CIPHER 'cipher'`

Requests a specific cipher method for connections. This option is needed to ensure that ciphers and key lengths of sufficient strength are used. SSL itself can be weak if old algorithms using short encryption keys are used.

```
ALTER USER 'jeffrey'@'localhost' REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The `SUBJECT`, `ISSUER`, and `CIPHER` options can be combined in the `REQUIRE` clause:

```
ALTER USER 'jeffrey'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL demo client certificate/
  CN=client/emailAddress=client@example.com'
  AND ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL/CN=CA/emailAddress=ca@example.com'
  AND CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The order of the options does not matter, but no option can be specified twice. The `AND` keyword is optional between `REQUIRE` options.

Resource-Limit Options

It is possible to place limits on use of server resources by an account, as discussed in [Section 6.3.6, “Setting Account Resource Limits”](#). To do so, use a `WITH` clause that specifies one or more *resource_option* values:

`ALTER USER` permits these *resource_option* values:

- `MAX_QUERIES_PER_HOUR count`, `MAX_UPDATES_PER_HOUR count`, `MAX_CONNECTIONS_PER_HOUR count`

These options restrict the number of queries, updates, and connections to the server permitted to this account during any given one-hour period. (Queries for which results are served from the query cache do not count against the `MAX_QUERIES_PER_HOUR` limit.) If *count* is 0 (the default), this means that there is no limitation for the account.

- `MAX_USER_CONNECTIONS count`

Restricts the maximum number of simultaneous connections to the server by the account. A nonzero *count* specifies the limit for the account explicitly. If *count* is 0 (the default), the server determines the number of simultaneous connections for the account from the global value of the `max_user_connections` system variable. If `max_user_connections` is also zero, there is no limit for the account.

Example:

```
ALTER USER 'jeffrey'@'localhost'
  WITH MAX_QUERIES_PER_HOUR 500 MAX_UPDATES_PER_HOUR 100;
```

If a given resource limit is specified multiple times, the last instance takes precedence.

Password-Expiration Options

`ALTER USER` supports several *password_option* values for password expiration management, to either expire an account password or establish its password expiration *policy*. Policy options do not expire the password; instead, they determine how the server applies automatic expiration to the account (see [Section 6.3.8, “Password Expiration Policy”](#)).

The lifetime of a password is assessed from the date and time it was last changed.

`ALTER USER` permits these *password_option* values:

- `PASSWORD EXPIRE`

Expires the account password.

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
```

- `PASSWORD EXPIRE DEFAULT`

Sets the account so that the global expiration policy applies, as specified by the `default_password_lifetime` system variable.

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
```

- `PASSWORD EXPIRE NEVER`

Disables password expiration for the account so that its password never expires.

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
```

- `PASSWORD EXPIRE INTERVAL N DAY`

Sets the account password lifetime to *N* days. This statement requires the password to be changed every 180 days:

```
ALTER USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 180 DAY;
```

If multiple password-expiration options are specified, the last one takes precedence.

A client session operates in restricted mode if the account password was expired manually or if the password is considered past its lifetime per the automatic expiration policy. In restricted mode, operations performed within the session result in an error until the user establishes a new account password. See [Section 6.3.8, “Password Expiration Policy”](#).

Note

It is possible to “reset” a password by setting it to its current value. As a matter of good policy, it is preferable to choose a different password.

Account-Locking Options

MySQL supports account locking and unlocking using the `ACCOUNT LOCK` and `ACCOUNT UNLOCK` options, which specify the locking state for an account. For additional discussion, see [Section 6.3.12, “User Account Locking”](#).

If multiple account-locking options are specified, the last one takes precedence.

Role Options

`ALTER USER ... DEFAULT ROLE` defines which roles become active when the user connects to the server and authenticates, or when the user executes the `SET ROLE DEFAULT` statement during a session.

`ALTER USER ... DEFAULT ROLE` is alternative syntax for `SET DEFAULT ROLE` (see [Section 13.7.1.9, “SET DEFAULT ROLE Syntax”](#)). However, `ALTER USER` can set the default for only a single user, whereas `SET DEFAULT ROLE` can set the default for multiple users. On the other hand, you can specify `CURRENT_USER` as the user name for the `ALTER USER` statement, whereas you cannot for `SET DEFAULT ROLE`.

Each user account name uses the format described previously.

Each role name uses the format described in [Section 6.2.5, “Specifying Role Names”](#). For example:

```
ALTER USER 'joe'@'10.0.0.1' DEFAULT ROLE administrator, developer;
```

The host name part of the role name, if omitted, defaults to `'%'`.

The clause following the `DEFAULT ROLE` keywords permits these values:

- `NONE`: Set the default to `NONE` (no roles).
- `ALL`: Set the default to all roles granted to the account.
- `role [, role] ...`: Set the default to the named roles, which need not exist or be granted to the account at the time `ALTER USER ... DEFAULT ROLE` is executed.

13.7.1.2 CREATE ROLE Syntax

```
CREATE ROLE [IF NOT EXISTS] role [, role ] ...
```

`CREATE ROLE` creates one or more roles, which are named collections of privileges. To use this statement, you must have the global `CREATE ROLE` or `CREATE USER` privilege.

A role when created is locked, has no password, and is assigned the default authentication plugin.

`CREATE ROLE` either succeeds for all named roles or rolls back and has no effect if any error occurs. By default, an error occurs if you try to create a role that already exists. If the `IF NOT EXISTS` clause is given, the statement produces a warning for each named role that already exists, rather than an error.

The statement is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named roles. If the `IF NOT EXISTS` clause is given, this includes even roles that already exist and were not created.

Each role name uses the format described in [Section 6.2.5, “Specifying Role Names”](#). For example:

```
CREATE ROLE 'administrator', 'developer';
CREATE ROLE 'webapp'@'localhost';
```

The host name part of the role name, if omitted, defaults to `'%'`.

For role usage examples, see [Section 6.3.4, “Using Roles”](#).

13.7.1.3 CREATE USER Syntax

```
CREATE USER [IF NOT EXISTS]
  user [auth_option] [, user [auth_option]] ...
  [REQUIRE {NONE | tls_option [[AND] tls_option] ...}]
  [WITH resource_option [resource_option] ...]
  [password_option | lock_option] ...

user:
  (see Section 6.2.4, “Specifying Account Names”)

auth_option: {
  IDENTIFIED BY 'auth_string'
  | IDENTIFIED BY PASSWORD 'hash_string'
  | IDENTIFIED WITH auth_plugin
  | IDENTIFIED WITH auth_plugin BY 'auth_string'
  | IDENTIFIED WITH auth_plugin AS 'hash_string'
}

tls_option: {
  SSL
  | X509
  | CIPHER 'cipher'
  | ISSUER 'issuer'
  | SUBJECT 'subject'
}

resource_option: {
  MAX_QUERIES_PER_HOUR count
  | MAX_UPDATES_PER_HOUR count
  | MAX_CONNECTIONS_PER_HOUR count
  | MAX_USER_CONNECTIONS count
}

password_option: {
  PASSWORD EXPIRE
  | PASSWORD EXPIRE DEFAULT
  | PASSWORD EXPIRE NEVER
  | PASSWORD EXPIRE INTERVAL N DAY
}
```

```
lock_option: {
  ACCOUNT LOCK
| ACCOUNT UNLOCK
}
```

The `CREATE USER` statement creates new MySQL accounts. It enables authentication, SSL/TLS, resource-limit, and password-expiration properties to be established for new accounts, and controls whether accounts are initially locked or unlocked.

An account when first created has no privileges and a default role of `NONE`.

To use `CREATE USER`, you must have the global `CREATE USER` privilege, or the `INSERT` privilege for the `mysql` database. When the `read_only` system variable is enabled, `CREATE USER` additionally requires the `SUPER` privilege.

`CREATE USER` either succeeds for all named users or rolls back and has no effect if any error occurs. By default, an error occurs if you try to create a user that already exists. If the `IF NOT EXISTS` clause is given, the statement produces a warning for each named user that already exists, rather than an error.

The statement is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named users. If the `IF NOT EXISTS` clause is given, this includes even users that already exist and were not created.

The statement written to the binary log specifies an authentication plugin for each user, determined as follows:

- The plugin named in the original statement, if one was specified.
- Otherwise, the default authentication plugin. In particular, if a user `u1` already exists and uses a nondefault authentication plugin, the statement written to the binary log for `CREATE USER IF NOT EXISTS u1` names the default authentication plugin. (If the statement written to the binary log must specify a nondefault authentication plugin for a user, include it in the original statement.)

If the server adds the default authentication plugin for any nonexisting users in the statement written to the binary log, it writes a warning to the error log naming those users.

For each account, `CREATE USER` creates a new row in the `mysql.user` table. The row reflects the properties specified in the statement. Unspecified properties are set to their default values.

Example 1: Create an account that uses the default authentication plugin and the given password. Mark the password expired so that the user must choose a new one at the first connection to the server:

```
CREATE USER 'jeffrey'@'localhost'
  IDENTIFIED BY 'new_password' PASSWORD EXPIRE;
```

Example 2: Create an account that uses the `sha256_password` authentication plugin and the given password. Require that a new password be chosen every 180 days:

```
CREATE USER 'jeffrey'@'localhost'
  IDENTIFIED WITH sha256_password BY 'new_password'
  PASSWORD EXPIRE INTERVAL 180 DAY;
```

Important

Under some circumstances, `CREATE USER` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that

information. For information about the conditions under which this occurs for the server logs and how to control it, see [Section 6.1.2.3, “Passwords and Logging”](#). For similar information about client-side logging, see [Section 4.5.1.3, “mysql Logging”](#).

For additional information about setting passwords and authentication plugins, see [Section 6.3.7, “Assigning Account Passwords”](#), and [Section 6.3.10, “Pluggable Authentication”](#).

Each account name uses the format described in [Section 6.2.4, “Specifying Account Names”](#). For example:

```
CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
```

The host name part of the account name, if omitted, defaults to `'%'`.

Each `user` value naming an account may be followed by an optional `auth_option` value that specifies how the account authenticates. These values enable account authentication plugins and credentials (passwords) to be specified. Each `auth_option` value applies *only* to the user named immediately preceding it.

Following the user specifications, the statement may include options for SSL/TLS, resource-limit, password-expiration, and locking properties. All these options are *global* to the statement and apply to *all* named users.

Example: This statement creates two accounts, each with the default authentication plugin and named password. For both accounts, connections must be made using a valid X509 certificate and up to 60 queries per hour are permitted. Both accounts are locked initially, so effectively they are placeholders and cannot be used until an administrator unlocks them:

```
CREATE USER
  'jeffrey'@'localhost' IDENTIFIED BY 'new_password1',
  'jeanne'@'localhost' IDENTIFIED BY 'new_password2'
  REQUIRE X509 WITH MAX_QUERIES_PER_HOUR 60
  ACCOUNT LOCK;
```

For omitted options, these default values are used:

- Authentication: The authentication plugin defined by the `default_authentication_plugin` system variable, and empty credentials
- SSL/TLS: `NONE`
- Resource limits: Unlimited
- Password expiration: `PASSWORD EXPIRE DEFAULT`
- Account locking: `ACCOUNT UNLOCK`

There are several aspects to the `CREATE USER` statement, described under the following topics in this section:

- [Authentication Options](#)
- [SSL/TLS Options](#)
- [Resource-Limit Options](#)
- [Password-Expiration Options](#)
- [Account-Locking Options](#)

Authentication Options

An account name may be followed by an authentication option that specifies the account authentication plugin, credentials, or both:

- *auth_plugin* names an authentication plugin. The plugin name can be a quoted string literal or an unquoted name. Plugin names are stored in the `plugin` column of the `mysql.user` table.
- `'auth_string'` or `'hash_string'` specify account credentials, either as cleartext or hashed in the format expected by the authentication plugin, respectively. Credentials are stored in the `authentication_string` column of the `mysql.user` table.

`CREATE USER` permits these *auth_option* syntaxes:

- `IDENTIFIED BY 'auth_string'`

Sets the account authentication plugin to the default plugin, hashes the cleartext `'auth_string'` value, and stores the result in the `mysql.user` account row.

- `IDENTIFIED BY PASSWORD 'hash_string'`

Sets the account authentication plugin to the default plugin, takes the hashed `'hash_string'` value as is, and stores the result in the `mysql.user` account row. The string is assumed to be already hashed in the format required by the plugin.

Note

This syntax is deprecated and will be removed in a future MySQL release.

- `IDENTIFIED WITH auth_plugin`

Sets the account authentication plugin to *auth_plugin*, clears the credentials to the empty string, and stores the result in the `mysql.user` account row.

- `IDENTIFIED WITH auth_plugin BY 'auth_string'`

Sets the account authentication plugin to *auth_plugin*, hashes the cleartext `'auth_string'` value, and stores the result in the `mysql.user` account row.

- `IDENTIFIED WITH auth_plugin AS 'hash_string'`

Sets the account authentication plugin to *auth_plugin*, takes the `'hash_string'` value as is, and stores the result in the `mysql.user` account row. The string is assumed to be already hashed in the format required by the plugin.

The default plugin is `mysql_native_password` unless the `default_authentication_plugin` system variable is set otherwise. For descriptions of each plugin, see [Section 6.5.1, “Authentication Plugins”](#).

Example 1: Specify the password as cleartext; the default plugin is used:

```
CREATE USER 'jeffrey'@'localhost'
  IDENTIFIED BY 'mypass';
```

Example 2: Specify the authentication plugin, along with a cleartext password value:

```
CREATE USER 'jeffrey'@'localhost'
  IDENTIFIED WITH mysql_native_password BY 'mypass';
```

SSL/TLS Options

MySQL can check X509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL/TLS with MySQL, see [Section 6.4, “Using Secure Connections”](#).

To specify SSL/TLS-related options for a MySQL account, use a `REQUIRE` clause that specifies one or more `tls_option` values:

`CREATE USER` permits these `tls_option` values:

- `NONE`

Indicates that the account has no SSL or X509 requirements. Unencrypted connections are permitted if the user name and password are valid. However, encrypted connections can also be used, at the client's option, if the client has the proper certificate and key files.

A client need specify only the `--ssl-mode=REQUIRED` option to obtain an encrypted connection. The connection attempt fails if an encrypted connection cannot be established.

- `SSL`

Tells the server to permit only encrypted connections for the account.

```
CREATE USER 'jeffrey'@'localhost' REQUIRE SSL;
```

A client need specify only the `--ssl-mode=REQUIRED` option to obtain an encrypted connection. The connection attempt fails if an encrypted connection cannot be established.

- `X509`

Requires that the client must have a valid certificate but the exact certificate, issuer, and subject do not matter. The only requirement is that it should be possible to verify its signature with one of the CA certificates. Use of X509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

```
CREATE USER 'jeffrey'@'localhost' REQUIRE X509;
```

The client must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.) This is true for `ISSUER` and `SUBJECT` as well because those `REQUIRE` options imply the requirements of `X509`.

- `ISSUER 'issuer'`

Places the restriction on connection attempts that the client must present a valid X509 certificate issued by CA `'issuer'`. If the client presents a certificate that is valid but has a different issuer, the server rejects the connection. Use of X509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

Because `ISSUER` implies the requirements of `X509`, the client must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.)

```
CREATE USER 'jeffrey'@'localhost'
  REQUIRE ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
  O=MySQL/CN=CA/emailAddress=ca@example.com';
```

- `SUBJECT 'subject'`

Places the restriction on connection attempts that the client must present a valid X509 certificate containing the subject `subject`. If the client presents a certificate that is valid but has a different

subject, the server rejects the connection. Use of X509 certificates always implies encryption, so the `SSL` option is unnecessary in this case.

Because `SUBJECT` implies the requirements of X509, the client must specify the `--ssl-key` and `--ssl-cert` options to connect. (It is recommended but not required that `--ssl-ca` also be specified so that the public certificate provided by the server can be verified.)

```
CREATE USER 'jeffrey'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL demo client certificate/
    CN=client/emailAddress=client@example.com';
```

MySQL does a simple string comparison of the `'subject'` value to the value in the certificate, so lettercase and component ordering must be given exactly as present in the certificate.

Note

Regarding `emailAddress`, see the note in the description of `REQUIRE ISSUER`.

- `CIPHER 'cipher'`

Requests a specific cipher method for encrypting connections. This option is needed to ensure that ciphers and key lengths of sufficient strength are used. Encryption can be weak if old algorithms using short encryption keys are used.

```
CREATE USER 'jeffrey'@'localhost' REQUIRE CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The `SUBJECT`, `ISSUER`, and `CIPHER` options can be combined in the `REQUIRE` clause:

```
CREATE USER 'jeffrey'@'localhost'
  REQUIRE SUBJECT '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL demo client certificate/
    CN=client/emailAddress=client@example.com'
  AND ISSUER '/C=SE/ST=Stockholm/L=Stockholm/
    O=MySQL/CN=CA/emailAddress=ca@example.com'
  AND CIPHER 'EDH-RSA-DES-CBC3-SHA';
```

The order of the options does not matter, but no option can be specified twice. The `AND` keyword is optional between `REQUIRE` options.

Resource-Limit Options

It is possible to place limits on use of server resources by an account, as discussed in [Section 6.3.6, “Setting Account Resource Limits”](#). To do so, use a `WITH` clause that specifies one or more `resource_option` values.

`CREATE USER` permits these `resource_option` values:

- `MAX_QUERIES_PER_HOUR count`, `MAX_UPDATES_PER_HOUR count`, `MAX_CONNECTIONS_PER_HOUR count`

These options restrict the number of queries, updates, and connections to the server permitted to this account during any given one-hour period. (Queries for which results are served from the query cache do not count against the `MAX_QUERIES_PER_HOUR` limit.) If `count` is 0 (the default), this means that there is no limitation for the account.

- `MAX_USER_CONNECTIONS count`

Restricts the maximum number of simultaneous connections to the server by the account. A nonzero `count` specifies the limit for the account explicitly. If `count` is 0 (the default), the server

determines the number of simultaneous connections for the account from the global value of the `max_user_connections` system variable. If `max_user_connections` is also zero, there is no limit for the account.

Example:

```
CREATE USER 'jeffrey'@'localhost'
WITH MAX_QUERIES_PER_HOUR 500 MAX_UPDATES_PER_HOUR 100;
```

If a given resource limit is specified multiple times, the last instance takes precedence.

Password-Expiration Options

`CREATE USER` supports several `password_option` values for password expiration management, to either expire an account password or establish its password expiration *policy*. Policy options do not expire the password; instead, they determine how the server applies automatic expiration to the account (see [Section 6.3.8, “Password Expiration Policy”](#)).

The lifetime of a password is assessed from the date and time it was last changed.

`CREATE USER` permits these `password_option` values:

- `PASSWORD EXPIRE`

Expires the account password.

```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE;
```

- `PASSWORD EXPIRE DEFAULT`

Sets the account so that the global expiration policy applies, as specified by the `default_password_lifetime` system variable.

```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE DEFAULT;
```

- `PASSWORD EXPIRE NEVER`

Disables password expiration for the account so that its password never expires.

```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE NEVER;
```

- `PASSWORD EXPIRE INTERVAL N DAY`

Sets the account password lifetime to *N* days. This statement requires the password to be changed every 180 days:

```
CREATE USER 'jeffrey'@'localhost' PASSWORD EXPIRE INTERVAL 180 DAY;
```

If multiple password-expiration options are specified, the last one takes precedence.

A client session operates in restricted mode if the account password was expired manually or if the password is considered past its lifetime per the automatic expiration policy. In restricted mode, operations performed within the session result in an error until the user establishes a new account password. See [Section 6.3.8, “Password Expiration Policy”](#).

Account-Locking Options

MySQL supports account locking and unlocking using the `ACCOUNT LOCK` and `ACCOUNT UNLOCK` options, which specify the locking state for an account. For additional discussion, see [Section 6.3.12, “User Account Locking”](#).

If multiple account-locking options are specified, the last one takes precedence.

13.7.1.4 DROP ROLE Syntax

```
DROP ROLE [IF EXISTS] role [, role] ...
```

DROP ROLE removes one or more roles (named collections of privileges). To use this statement, you must have the global **DROP ROLE** or **CREATE USER** privilege.

If a role to be dropped is named in the `mandatory_roles` system variable value, it cannot be dropped.

DROP ROLE either succeeds for all named roles or rolls back and has no effect if any error occurs. By default, an error occurs if you try to drop a role that does not exist. If the **IF EXISTS** clause is given, the statement produces a warning for each named role that does not exist, rather than an error.

The statement is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named roles. If the **IF EXISTS** clause is given, this includes even roles that do not exist and were not dropped.

Each role name uses the format described in [Section 6.2.5, “Specifying Role Names”](#). For example:

```
DROP ROLE 'administrator', 'developer';
DROP ROLE 'webapp'@'localhost';
```

The host name part of the role name, if omitted, defaults to `'%'`.

A dropped role is automatically revoked from any user account (or role) to which the role was granted. Within any current session for such an account, its privileges are adjusted for the next statement executed.

13.7.1.5 DROP USER Syntax

```
DROP USER [IF EXISTS] user [, user] ...
```

The **DROP USER** statement removes one or more MySQL accounts and their privileges. It removes privilege rows for the account from all grant tables.

If a user to be dropped is named in the `mandatory_roles` system variable value, it cannot be dropped.

To use **DROP USER**, you must have the global **CREATE USER** privilege, or the **DELETE** privilege for the `mysql` database. When the `read_only` system variable is enabled, **DROP USER** additionally requires the **SUPER** privilege.

DROP USER either succeeds for all named users or rolls back and has no effect if any error occurs. By default, an error occurs if you try to drop a user that does not exist. If the **IF EXISTS** clause is given, the statement produces a warning for each named user that does not exist, rather than an error.

The statement is written to the binary log if it succeeds, but not if it fails; in that case, rollback occurs and no changes are made. A statement written to the binary log includes all named users. If the **IF EXISTS** clause is given, this includes even users that do not exist and were not dropped.

Each account name uses the format described in [Section 6.2.4, “Specifying Account Names”](#). For example:

```
DROP USER 'jeffrey'@'localhost';
```

The host name part of the account name, if omitted, defaults to `'%'`.

Important

`DROP USER` does not automatically close any open user sessions. Rather, in the event that a user with an open session is dropped, the statement does not take effect until that user's session is closed. Once the session is closed, the user is dropped, and that user's next attempt to log in will fail. *This is by design.*

`DROP USER` does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the `DEFINER` attribute names the dropped user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see [Section 23.6, "Access Control for Stored Programs and Views"](#).)

13.7.1.6 GRANT Syntax

```
GRANT
  priv_type [(column_list)]
  [, priv_type [(column_list)]] ...
ON [object_type] priv_level
TO user_or_role [auth_option] [, user_or_role [auth_option]] ...
[REQUIRE {NONE | tls_option [[AND] tls_option] ...}]
[WITH {GRANT OPTION | resource_option} ...]

GRANT PROXY ON user_or_role
  TO user_or_role [, user_or_role] ...
  [WITH GRANT OPTION]

GRANT role [, role] ...
  TO user_or_role [, user_or_role] ...
  [WITH ADMIN OPTION]

object_type: {
  TABLE
  | FUNCTION
  | PROCEDURE
}

priv_level: {
  *
  | *.*
  | db_name.*
  | tbl_name
  | db_name.routine_name
}

user_or_role: {
  user
  | role
}

user:
  (see Section 6.2.4, "Specifying Account Names")

role:
  (see Section 6.2.5, "Specifying Role Names").

auth_option: {
  IDENTIFIED BY 'auth_string'
  | IDENTIFIED BY PASSWORD 'hash_string'
  | IDENTIFIED WITH auth_plugin
  | IDENTIFIED WITH auth_plugin BY 'auth_string'
  | IDENTIFIED WITH auth_plugin AS 'hash_string'
}

tls_option: {
  SSL
  | X509
  | CIPHER 'cipher'
```

```

| ISSUER 'issuer'
| SUBJECT 'subject'
}

resource_option: {
| MAX_QUERIES_PER_HOUR count
| MAX_UPDATES_PER_HOUR count
| MAX_CONNECTIONS_PER_HOUR count
| MAX_USER_CONNECTIONS count
}

```

The `GRANT` statement enables system administrators to grant privileges and roles, which can be granted to user accounts and roles. These syntax restrictions apply:

- `GRANT` cannot mix granting both privileges and roles in the same statement. A given `GRANT` statement must grant either privileges or roles.
- The `ON` clause distinguishes whether the statement grants privileges or roles:
 - With `ON`, the statement grants privileges.
 - Without `ON`, the statement grants roles.
 - It is permitted to assign both privileges and roles to an account, but you must use separate `GRANT` statements, each with syntax appropriate to what is to be granted.

For more information about roles, see [Section 6.3.4, “Using Roles”](#).

To use `GRANT`, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are granting. When the `read_only` system variable is enabled, `GRANT` additionally requires the `SUPER` privilege.

`GRANT` either succeeds for all named users and roles or rolls back and has no effect if any error occurs. The statement is written to the binary log only if it succeeds for all named users and roles.

The `REVOKE` statement is related to `GRANT` and enables administrators to remove account privileges. See [Section 13.7.1.8, “REVOKE Syntax”](#).

Each account name uses the format described in [Section 6.2.4, “Specifying Account Names”](#). Each role name uses the format described in [Section 6.2.5, “Specifying Role Names”](#). For example:

```

GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
GRANT 'role1', 'role2' TO 'user1'@'localhost', 'user2'@'localhost';
GRANT SELECT ON world.* TO 'role3';

```

The host name part of the account or role name, if omitted, defaults to `'%'`.

Normally, a database administrator first uses `CREATE USER` to create an account and define its nonprivilege characteristics such as its password, whether it uses secure connections, and limits on access to server resources, then uses `GRANT` to define its privileges. `ALTER USER` may be used to change the nonprivilege characteristics of existing accounts. For example:

```

CREATE USER 'jeffrey'@'localhost' IDENTIFIED BY 'mypass';
GRANT ALL ON db1.* TO 'jeffrey'@'localhost';
GRANT SELECT ON db2.invoice TO 'jeffrey'@'localhost';
ALTER USER 'jeffrey'@'localhost' WITH MAX_QUERIES_PER_HOUR 90;

```

Note

Examples shown here include no `IDENTIFIED` clause. It is assumed that you establish passwords with `CREATE USER` at account-creation time to avoid creating insecure accounts.

**Note**

If an account named in a `GRANT` statement does not already exist, `GRANT` may create it under the conditions described later in the discussion of the `NO_AUTO_CREATE_USER` SQL mode. It is also possible to use `GRANT` to specify nonprivilege account characteristics such as whether it uses secure connections and limits on access to server resources.

However, use of `GRANT` to create accounts or define nonprivilege characteristics is deprecated. Instead, perform these tasks using `CREATE USER` or `ALTER USER`.

From the `mysql` program, `GRANT` responds with `Query OK, 0 rows affected` when executed successfully. To determine what privileges result from the operation, use `SHOW GRANTS`. See [Section 13.7.5.21, “SHOW GRANTS Syntax”](#).

There are several aspects to the `GRANT` statement, described under the following topics in this section:

- [Object Quoting Guidelines](#)
- [Privileges Supported by MySQL](#)
- [Global Privileges](#)
- [Database Privileges](#)
- [Table Privileges](#)
- [Column Privileges](#)
- [Stored Routine Privileges](#)
- [Proxy User Privileges](#)
- [Granting Roles](#)
- [Account Names and Passwords](#)
- [Implicit Account Creation](#)
- [Other Account Characteristics](#)
- [MySQL and Standard SQL Versions of GRANT](#)

`GRANT` supports host names up to 60 characters long. User names can be up to 32 characters. Database, table, column, and routine names can be up to 64 characters.

**Warning**

Do not attempt to change the permissible length for user names by altering the `mysql.user` table. Doing so results in unpredictable behavior which may even make it impossible for users to log in to the MySQL server. Never alter the structure of tables in the `mysql` database in any manner except by means of the procedure described in [Section 4.4.5, “mysql_upgrade — Check and Upgrade MySQL Tables”](#).

**Important**

Under some circumstances, `GRANT` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the

server logs and how to control it, see [Section 6.1.2.3, “Passwords and Logging”](#). For similar information about client-side logging, see [Section 4.5.1.3, “mysql Logging”](#).

Object Quoting Guidelines

Several objects within `GRANT` statements are subject to quoting, although quoting is optional in many cases: Account, role, database, table, column, and routine names. For example, if a `user_name` or `host_name` value in an account name is legal as an unquoted identifier, you need not quote it. However, quotation marks are necessary to specify a `user_name` string containing special characters (such as `-`), or a `host_name` string containing special characters or wildcard characters (such as `%`); for example, `'test-user'@'%.com'`. Quote the user name and host name separately.

To specify quoted values, quote database, table, column, and routine names as identifiers. Quote user names and host names as identifiers or as strings. Quote passwords as strings. For string-quoting and identifier-quoting guidelines, see [Section 9.1.1, “String Literals”](#), and [Section 9.2, “Schema Object Names”](#).

The `_` and `%` wildcards are permitted when specifying database names in `GRANT` statements that grant privileges at the database level. This means, for example, that if you want to use a `_` character as part of a database name, you should specify it as `_` in the `GRANT` statement, to prevent the user from being able to access additional databases matching the wildcard pattern; for example, `GRANT ... ON `foo_bar`.* TO`

Privileges Supported by MySQL

The following tables summarize the permissible static and dynamic `priv_type` privilege types that can be specified for the `GRANT` and `REVOKE` statements, and the levels at which each privilege can be granted. For additional information about each privilege, see [Section 6.2.1, “Privileges Provided by MySQL”](#). For information about the differences between static and dynamic privileges, see [Section 6.2.2, “Static Versus Dynamic Privileges”](#).

Table 13.3 Permissible Static Privileges for GRANT and REVOKE

Privilege	Meaning and Grantable Levels
<code>ALL [PRIVILEGES]</code>	Grant all privileges at specified access level except <code>GRANT OPTION</code> and <code>PROXY</code> .
<code>ALTER</code>	Enable use of <code>ALTER TABLE</code> . Levels: Global, database, table.
<code>ALTER ROUTINE</code>	Enable stored routines to be altered or dropped. Levels: Global, database, procedure.
<code>CREATE</code>	Enable database and table creation. Levels: Global, database, table.
<code>CREATE ROUTINE</code>	Enable stored routine creation. Levels: Global, database.
<code>CREATE TABLESPACE</code>	Enable tablespaces and log file groups to be created, altered, or dropped. Level: Global.
<code>CREATE TEMPORARY TABLES</code>	Enable use of <code>CREATE TEMPORARY TABLE</code> . Levels: Global, database.
<code>CREATE USER</code>	Enable use of <code>CREATE USER</code> , <code>DROP USER</code> , <code>RENAME USER</code> , and <code>REVOKE ALL PRIVILEGES</code> . Level: Global.
<code>CREATE VIEW</code>	Enable views to be created or altered. Levels: Global, database, table.
<code>DELETE</code>	Enable use of <code>DELETE</code> . Level: Global, database, table.
<code>DROP</code>	Enable databases, tables, and views to be dropped. Levels: Global, database, table.
<code>EVENT</code>	Enable use of events for the Event Scheduler. Levels: Global, database.

Privilege	Meaning and Grantable Levels
EXECUTE	Enable the user to execute stored routines. Levels: Global, database, table.
FILE	Enable the user to cause the server to read or write files. Level: Global.
GRANT OPTION	Enable privileges to be granted to or removed from other accounts. Levels: Global, database, table, procedure, proxy.
INDEX	Enable indexes to be created or dropped. Levels: Global, database, table.
INSERT	Enable use of <code>INSERT</code> . Levels: Global, database, table, column.
LOCK TABLES	Enable use of <code>LOCK TABLES</code> on tables for which you have the <code>SELECT</code> privilege. Levels: Global, database.
PROCESS	Enable the user to see all processes with <code>SHOW PROCESSLIST</code> . Level: Global.
PROXY	Enable user proxying. Level: From user to user.
REFERENCES	Enable foreign key creation. Levels: Global, database, table, column.
RELOAD	Enable use of <code>FLUSH</code> operations. Level: Global.
REPLICATION CLIENT	Enable the user to ask where master or slave servers are. Level: Global.
REPLICATION SLAVE	Enable replication slaves to read binary log events from the master. Level: Global.
SELECT	Enable use of <code>SELECT</code> . Levels: Global, database, table, column.
SHOW DATABASES	Enable <code>SHOW DATABASES</code> to show all databases. Level: Global.
SHOW VIEW	Enable use of <code>SHOW CREATE VIEW</code> . Levels: Global, database, table.
SHUTDOWN	Enable use of <code>mysqladmin shutdown</code> . Level: Global.
SUPER	Enable use of other administrative operations such as <code>CHANGE MASTER TO</code> , <code>KILL</code> , <code>PURGE BINARY LOGS</code> , <code>SET GLOBAL</code> , and <code>mysqladmin debug</code> command. Level: Global.
TRIGGER	Enable trigger operations. Levels: Global, database, table.
UPDATE	Enable use of <code>UPDATE</code> . Levels: Global, database, table, column.
USAGE	Synonym for “no privileges”

Table 13.4 Permissible Dynamic Privileges for GRANT and REVOKE

Privilege	Meaning and Grantable Levels
AUDIT_ADMIN	Enable audit log configuration. Level: Global.
BINLOG_ADMIN	Enable binary log control. Level: Global.
CONNECTION_ADMIN	Enable connection limit/restriction control. Level: Global.
ENCRYPTION_KEY_ADMIN	Enable <code>InnoDB</code> key rotation. Level: Global.
FIREWALL_ADMIN	Enable firewall rule administration, any user. Level: Global.
FIREWALL_USER	Enable firewall rule administration, self. Level: Global.
GROUP_REPLICATION_ADMIN	Enable Group Replication control. Level: Global.
REPLICATION_SLAVE_ADMIN	Enable regular replication control. Level: Global.
ROLE_ADMIN	Enable use of <code>WITH ADMIN OPTION</code> . Level: Global.
SET_USER_ID	Enable setting non-self <code>DEFINER</code> values. Level: Global.
SYSTEM_VARIABLES_ADMIN	Enable modifying or persisting global system variables. Level: Global.
VERSION_TOKEN_ADMIN	Enable use of Version Tokens UDFs. Level: Global.

A trigger is associated with a table. To create or drop a trigger, you must have the `TRIGGER` privilege for the table, not the trigger.

In `GRANT` statements, the `ALL [PRIVILEGES]` or `PROXY` privilege must be named by itself and cannot be specified along with other privileges. `ALL [PRIVILEGES]` stands for all privileges available for the level at which privileges are to be granted except for the `GRANT OPTION` and `PROXY` privileges.

`USAGE` can be specified to create a user that has no privileges, or to specify the `REQUIRE` or `WITH` clauses for an account without changing its existing privileges. (However, use of `GRANT` to define nonprivilege characteristics is deprecated.)

MySQL account information is stored in the tables of the `mysql` database. For additional details, consult [Section 6.2, “The MySQL Access Privilege System”](#), which discusses the `mysql` database and the access control system extensively.

If the grant tables hold privilege rows that contain mixed-case database or table names and the `lower_case_table_names` system variable is set to a nonzero value, `REVOKE` cannot be used to revoke these privileges. It will be necessary to manipulate the grant tables directly. (`GRANT` will not create such rows when `lower_case_table_names` is set, but such rows might have been created prior to setting that variable.)

Privileges can be granted at several levels, depending on the syntax used for the `ON` clause. For `REVOKE`, the same `ON` syntax specifies which privileges to remove.

For the global, database, table, and routine levels, `GRANT ALL` assigns only the privileges that exist at the level you are granting. For example, `GRANT ALL ON db_name.*` is a database-level statement, so it does not grant any global-only privileges such as `FILE`. Granting `ALL` does not assign the `GRANT OPTION` or `PROXY` privilege.

The `object_type` clause, if present, should be specified as `TABLE`, `FUNCTION`, or `PROCEDURE` when the following object is a table, a stored function, or a stored procedure.

The privileges for a database, table, column, or routine are formed additively as the logical `OR` of the privileges at each of the privilege levels. For example, if a user has a global `SELECT` privilege, the privilege cannot be denied by an absence of the privilege at the database, table, or column level. Details of the privilege-checking procedure are presented in [Section 6.2.7, “Access Control, Stage 2: Request Verification”](#).

If you are using table, column, or routine privileges for even one user, the server examines table, column, and routine privileges for all users and this slows down MySQL a bit. Similarly, if you limit the number of queries, updates, or connections for any users, the server must monitor these values.

MySQL enables you to grant privileges on databases or tables that do not exist. For tables, the privileges to be granted must include the `CREATE` privilege. *This behavior is by design*, and is intended to enable the database administrator to prepare user accounts and privileges for databases or tables that are to be created at a later time.

Important

MySQL does not automatically revoke any privileges when you drop a database or table. However, if you drop a routine, any routine-level privileges granted for that routine are revoked.

Global Privileges

Global privileges are administrative or apply to all databases on a given server. To assign global privileges, use `ON *.*` syntax:

```
GRANT ALL ON *.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON *.* TO 'someuser'@'somehost';
```

The `CREATE TABLESPACE`, `CREATE USER`, `FILE`, `PROCESS`, `RELOAD`, `REPLICATION CLIENT`, `REPLICATION SLAVE`, `SHOW DATABASES`, `SHUTDOWN`, and `SUPER` static privileges are administrative and can only be granted globally.

Dynamic privileges are all global and can only be granted globally.

Other privileges can be granted globally or at more specific levels.

The effect of `GRANT OPTION` granted at the global level differs for static and dynamic privileges:

- `GRANT OPTION` granted for any static global privilege applies to all static global privileges.
- `GRANT OPTION` granted for any dynamic privilege applies only to that dynamic privilege.

`GRANT ALL` at the global level grants all static global privileges and all currently registered dynamic privileges. A dynamic privilege registered subsequent to execution of the `GRANT` statement is not granted retroactively to any account.

MySQL stores global privileges in the `mysql.user` table.

Database Privileges

Database privileges apply to all objects in a given database. To assign database-level privileges, use `ON db_name.*` syntax:

```
GRANT ALL ON mydb.* TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.* TO 'someuser'@'somehost';
```

If you use `ON *` syntax (rather than `ON *.*`) and you have selected a default database, privileges are assigned at the database level for the default database. An error occurs if there is no default database.

The `CREATE`, `DROP`, `EVENT`, `GRANT OPTION`, `LOCK TABLES`, and `REFERENCES` privileges can be specified at the database level. Table or routine privileges also can be specified at the database level, in which case they apply to all tables or routines in the database.

MySQL stores database privileges in the `mysql.db` table.

Table Privileges

Table privileges apply to all columns in a given table. To assign table-level privileges, use `ON db_name.tbl_name` syntax:

```
GRANT ALL ON mydb.mytbl TO 'someuser'@'somehost';
GRANT SELECT, INSERT ON mydb.mytbl TO 'someuser'@'somehost';
```

If you specify `tbl_name` rather than `db_name.tbl_name`, the statement applies to `tbl_name` in the default database. An error occurs if there is no default database.

The permissible `priv_type` values at the table level are `ALTER`, `CREATE VIEW`, `CREATE`, `DELETE`, `DROP`, `GRANT OPTION`, `INDEX`, `INSERT`, `REFERENCES`, `SELECT`, `SHOW VIEW`, `TRIGGER`, and `UPDATE`.

Table-level privileges apply to base tables and views. They do not apply to tables created with `CREATE TEMPORARY TABLE`, even if the table names match. For information about `TEMPORARY` table privileges, see [Section 13.1.15.3, “CREATE TEMPORARY TABLE Syntax”](#).

MySQL stores table privileges in the `mysql.tables_priv` table.

Column Privileges

Column privileges apply to single columns in a given table. Each privilege to be granted at the column level must be followed by the column or columns, enclosed within parentheses.

```
GRANT SELECT (col1), INSERT (col1,col2) ON mydb.mytbl TO 'someuser'@'somehost';
```

The permissible *priv_type* values for a column (that is, when you use a *column_list* clause) are [INSERT](#), [REFERENCES](#), [SELECT](#), and [UPDATE](#).

MySQL stores column privileges in the `mysql.columns_priv` table.

Stored Routine Privileges

The [ALTER ROUTINE](#), [CREATE ROUTINE](#), [EXECUTE](#), and [GRANT OPTION](#) privileges apply to stored routines (procedures and functions). They can be granted at the global and database levels. Except for [CREATE ROUTINE](#), these privileges can be granted at the routine level for individual routines.

```
GRANT CREATE ROUTINE ON mydb.* TO 'someuser'@'somehost';
GRANT EXECUTE ON PROCEDURE mydb.myproc TO 'someuser'@'somehost';
```

The permissible *priv_type* values at the routine level are [ALTER ROUTINE](#), [EXECUTE](#), and [GRANT OPTION](#). [CREATE ROUTINE](#) is not a routine-level privilege because you must have this privilege to create a routine in the first place.

MySQL stores routine-level privileges in the `mysql.procs_priv` table.

Proxy User Privileges

The [PROXY](#) privilege enables one user to be a proxy for another. The proxy user impersonates or takes the identity of the proxied user.

```
GRANT PROXY ON 'localuser'@'localhost' TO 'externaluser'@'somehost';
```

When [PROXY](#) is granted, it must be the only privilege named in the [GRANT](#) statement, the [REQUIRE](#) clause cannot be given, and the only permitted [WITH](#) option is [WITH GRANT OPTION](#).

Proxying requires that the proxy user authenticate through a plugin that returns the name of the proxied user to the server when the proxy user connects, and that the proxy user have the [PROXY](#) privilege for the proxied user. For details and examples, see [Section 6.3.11, “Proxy Users”](#).

MySQL stores proxy privileges in the `mysql.proxies_priv` table.

Granting Roles

[GRANT](#) syntax without an [ON](#) clause grants roles rather than individual privileges. A role is a named collection of privileges; see [Section 6.3.4, “Using Roles”](#). For example:

```
GRANT 'role1', 'role2' TO 'user1'@'localhost', 'user2'@'localhost';
```

Each role to be granted must exist, as well as each user account or role to which it is to be granted.

If the [GRANT](#) statement includes the [WITH ADMIN OPTION](#) clause, each named user becomes able to grant the named roles to other users or roles, or revoke them from other users or roles. This includes the ability to use [WITH ADMIN OPTION](#) itself.

It is possible to create circular references with [GRANT](#). For example:

```
CREATE USER 'u1', 'u2';
CREATE ROLE 'r1', 'r2';

GRANT 'u1' TO 'u1'; -- simple loop: u1 -> u1
GRANT 'r1' TO 'r1'; -- simple loop: r1 -> r1

GRANT 'r2' TO 'u2';
GRANT 'u2' TO 'r2'; -- mixed user/role loop: u2 -> r2 -> u2
```

Circular grant references are permitted but add no new privileges or roles to the grantee because a user or role already has its privileges and roles.

Account Names and Passwords

A *user* value in a `GRANT` statement indicates a MySQL account to which the statement applies. To accommodate granting rights to users from arbitrary hosts, MySQL supports specifying the *user* value in the form `'user_name'@'host_name'`.

You can specify wildcards in the host name. For example, `'user_name'@'%.example.com'` applies to *user_name* for any host in the `example.com` domain, and `'user_name'@'192.168.1.%'` applies to *user_name* for any host in the `192.168.1` class C subnet.

The simple form `'user_name'` is a synonym for `'user_name'@'%'`.

MySQL does not support wildcards in user names. To refer to an anonymous user, specify an account with an empty user name with the `GRANT` statement:

```
GRANT ALL ON test.* TO ''@'localhost' ...;
```

In this case, any user who connects from the local host with the correct password for the anonymous user will be permitted access, with the privileges associated with the anonymous-user account.

For additional information about user name and host name values in account names, see [Section 6.2.4, “Specifying Account Names”](#).

Warning

If you permit local anonymous users to connect to the MySQL server, you should also grant privileges to all local users as `'user_name'@'localhost'`. Otherwise, the anonymous user account for `localhost` in the `mysql.user` table is used when named users try to log in to the MySQL server from the local machine. For details, see [Section 6.2.6, “Access Control, Stage 1: Connection Verification”](#).

To determine whether this issue applies to you, execute the following query, which lists any anonymous users:

```
SELECT Host, User FROM mysql.user WHERE User='';
```

To avoid the problem just described, delete the local anonymous user account using this statement:

```
DROP USER ''@'localhost';
```

For `GRANT` syntaxes that permit an *auth_option* value to follow a *user* value, *auth_option* begins with `IDENTIFIED` and indicates how the account authenticates by specifying an account authentication plugin, credentials (password), or both. Syntax of the *auth_option* clause is the same as for the `CREATE USER` statement. For details, see [Section 13.7.1.3, “CREATE USER Syntax”](#).

**Note**

Use of `GRANT` to define account authentication characteristics is deprecated. Instead, establish or change authentication characteristics using `CREATE USER` or `ALTER USER`. This `GRANT` capability will be removed in a future MySQL release.

When `IDENTIFIED` is present and you have the global grant privilege (`GRANT OPTION`), any password specified becomes the new password for the account, even if the account exists and already has a password. Without `IDENTIFIED`, the account password remains unchanged.

Implicit Account Creation

If an account named in a `GRANT` statement does not exist, the action taken depends on the `NO_AUTO_CREATE_USER` SQL mode:

- If `NO_AUTO_CREATE_USER` is not enabled, `GRANT` creates the account. *This is very insecure unless you specify a nonempty password using `IDENTIFIED BY`.*
- If `NO_AUTO_CREATE_USER` is enabled, `GRANT` fails and does not create the account, unless you specify a nonempty password using `IDENTIFIED BY` or name an authentication plugin using `IDENTIFIED WITH`.

If the account already exists, `IDENTIFIED WITH` is prohibited because it is intended only for use when creating new accounts.

Other Account Characteristics

MySQL can check X509 certificate attributes in addition to the usual authentication that is based on the user name and credentials. For background information on the use of SSL with MySQL, see [Section 6.4, “Using Secure Connections”](#).

The optional `REQUIRE` clause specifies SSL-related options for a MySQL account. The syntax is the same as for the `CREATE USER` statement. For details, see [Section 13.7.1.3, “CREATE USER Syntax”](#).

**Note**

Use of `GRANT` to define account SSL characteristics is deprecated. Instead, establish or change SSL characteristics using `CREATE USER` or `ALTER USER`. This `GRANT` capability will be removed in a future MySQL release.

The optional `WITH` clause is used for these purposes:

- To enable a user to grant privileges to other users
- To specify resource limits for a user

The `WITH GRANT OPTION` clause gives the user the ability to give to other users any privileges the user has at the specified privilege level.

To grant the `GRANT OPTION` privilege to an account without otherwise changing its privileges, do this:

```
GRANT USAGE ON *.* TO 'someuser'@'somehost' WITH GRANT OPTION;
```

Be careful to whom you give the `GRANT OPTION` privilege because two users with different privileges may be able to combine privileges!

You cannot grant another user a privilege which you yourself do not have; the `GRANT OPTION` privilege enables you to assign only those privileges which you yourself possess.

Be aware that when you grant a user the `GRANT OPTION` privilege at a particular privilege level, any privileges the user possesses (or may be given in the future) at that level can also be granted by that user to other users. Suppose that you grant a user the `INSERT` privilege on a database. If you then grant the `SELECT` privilege on the database and specify `WITH GRANT OPTION`, that user can give to other users not only the `SELECT` privilege, but also `INSERT`. If you then grant the `UPDATE` privilege to the user on the database, the user can grant `INSERT`, `SELECT`, and `UPDATE`.

For a nonadministrative user, you should not grant the `ALTER` privilege globally or for the `mysql` database. If you do that, the user can try to subvert the privilege system by renaming tables!

For additional information about security risks associated with particular privileges, see [Section 6.2.1, “Privileges Provided by MySQL”](#).

It is possible to place limits on use of server resources by an account, as discussed in [Section 6.3.6, “Setting Account Resource Limits”](#). To do so, use a `WITH` clause that specifies one or more `resource_option` values. Limits not specified retain their current values. The syntax is the same as for the `CREATE USER` statement. For details, see [Section 13.7.1.3, “CREATE USER Syntax”](#).

Note

Use of `GRANT` to define account resource limits is deprecated. Instead, establish or change resource limits using `CREATE USER` or `ALTER USER`. This `GRANT` capability will be removed in a future MySQL release.

MySQL and Standard SQL Versions of GRANT

The biggest differences between the MySQL and standard SQL versions of `GRANT` are:

- MySQL associates privileges with the combination of a host name and user name and not with only a user name.
- Standard SQL does not have global or database-level privileges, nor does it support all the privilege types that MySQL supports.
- MySQL does not support the standard SQL `UNDER` privilege.
- Standard SQL privileges are structured in a hierarchical manner. If you remove a user, all privileges the user has been granted are revoked. This is also true in MySQL if you use `DROP USER`. See [Section 13.7.1.5, “DROP USER Syntax”](#).
- In standard SQL, when you drop a table, all privileges for the table are revoked. In standard SQL, when you revoke a privilege, all privileges that were granted based on that privilege are also revoked. In MySQL, privileges can be dropped with `DROP USER` or `REVOKE` statements.
- In MySQL, it is possible to have the `INSERT` privilege for only some of the columns in a table. In this case, you can still execute `INSERT` statements on the table, provided that you insert values only for those columns for which you have the `INSERT` privilege. The omitted columns are set to their implicit default values if strict SQL mode is not enabled. In strict mode, the statement is rejected if any of the omitted columns have no default value. (Standard SQL requires you to have the `INSERT` privilege on all columns.) For information about strict SQL mode and implicit default values, see [Section 5.1.8, “Server SQL Modes”](#), and [Section 11.7, “Data Type Default Values”](#).

13.7.1.7 RENAME USER Syntax

```
RENAME USER old_user TO new_user
    [, old_user TO new_user] ...
```

The `RENAME USER` statement renames existing MySQL accounts. An error occurs for old accounts that do not exist or new accounts that already exist.

To use `RENAME USER`, you must have the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql` database. When the `read_only` system variable is enabled, `RENAME USER` additionally requires the `SUPER` privilege.

Each account name uses the format described in [Section 6.2.4, “Specifying Account Names”](#). For example:

```
RENAME USER 'jeffrey'@'localhost' TO 'jeff'@'127.0.0.1';
```

The host name part of the account name, if omitted, defaults to `'%'`.

`RENAME USER` causes the privileges held by the old user to be those held by the new user. However, `RENAME USER` does not automatically drop or invalidate databases or objects within them that the old user created. This includes stored programs or views for which the `DEFINER` attribute names the old user. Attempts to access such objects may produce an error if they execute in definer security context. (For information about security context, see [Section 23.6, “Access Control for Stored Programs and Views”](#).)

The privilege changes take effect as indicated in [Section 6.2.8, “When Privilege Changes Take Effect”](#).

13.7.1.8 REVOKE Syntax

```
REVOKE
  priv_type [(column_list)]
  [, priv_type [(column_list)]] ...
ON [object_type] priv_level
FROM user_or_role [, user_or_role] ...

REVOKE ALL [PRIVILEGES], GRANT OPTION
FROM user_or_role [, user_or_role] ...

REVOKE PROXY ON user_or_role
FROM user_or_role [, user_or_role] ...

REVOKE role [, role ] ...
FROM user_or_role [, user_or_role ] ...

user_or_role: {
  user
  | role
}

user:
  (see Section 6.2.4, “Specifying Account Names”)

role:
  (see Section 6.2.5, “Specifying Role Names”.)
```

The `REVOKE` statement enables system administrators to revoke privileges and roles, which can be revoked from user accounts and roles.

For information about roles, see [Section 6.3.4, “Using Roles”](#).

When the `read_only` system variable is enabled, `REVOKE` requires the `SUPER` privilege in addition to any other required privileges described in the following discussion.

`REVOKE` either succeeds for all named users and roles or rolls back and has no effect if any error occurs. The statement is written to the binary log only if it succeeds for all named users and roles.

Each account name uses the format described in [Section 6.2.4, “Specifying Account Names”](#). Each role name uses the format described in [Section 6.2.5, “Specifying Role Names”](#). For example:

```
REVOKE INSERT ON *.* FROM 'jeffrey'@'localhost';
REVOKE 'role1', 'role2' FROM 'user1'@'localhost', 'user2'@'localhost';
REVOKE SELECT ON world.* FROM 'role3';
```

The host name part of the account or role name, if omitted, defaults to `'%'`.

For details on the levels at which privileges exist, the permissible *priv_type*, *priv_level*, and *object_type* values, and the syntax for specifying users and passwords, see [Section 13.7.1.6, “GRANT Syntax”](#)

To use the first `REVOKE` syntax, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are revoking.

To revoke all privileges, use the second syntax, which drops all global, database, table, column, and routine privileges for the named users or roles:

```
REVOKE ALL PRIVILEGES, GRANT OPTION
FROM user_or_role [, user_or_role] ...
```

`REVOKE ALL PRIVILEGES, GRANT OPTION` does not revoke any roles.

To use this `REVOKE` syntax, you must have the global `CREATE USER` privilege, or the `UPDATE` privilege for the `mysql` database.

The syntax for which the `REVOKE` keyword is followed by one or more role names takes a `FROM` clause indicating one or more users or roles from which to revoke the roles.

If a role to be revoked is named in the `mandatory_roles` system variable value, it cannot be revoked.

A revoked role immediately affects any user account from which it was revoked, such that within any current session for the account, its privileges are adjusted for the next statement executed.

Revoking a role revokes the role itself, not the privileges that it represents. If an account is granted a role that includes a given privilege, and is also granted the privilege explicitly or another role that includes the privilege, the account still is granted that privilege after the first role is revoked. For example, if an account is granted two roles that each include `SELECT`, the account still can select after either role is revoked.

`REVOKE ALL ON *.*` (at the global level) revokes all granted static global privileges and all granted dynamic privileges.

User accounts and roles from which privileges and roles are to be revoked must exist, but the roles to be revoked need not be currently granted to them.

`REVOKE` removes privileges, but does not drop `mysql.user` table entries. To remove a user account entirely, use `DROP USER`. See [Section 13.7.1.5, “DROP USER Syntax”](#).

If the grant tables hold privilege rows that contain mixed-case database or table names and the `lower_case_table_names` system variable is set to a nonzero value, `REVOKE` cannot be used to revoke these privileges. It will be necessary to manipulate the grant tables directly. (`GRANT` will not create such rows when `lower_case_table_names` is set, but such rows might have been created prior to setting the variable.)

When successfully executed from the `mysql` program, `REVOKE` responds with `Query OK, 0 rows affected`. To determine what privileges remain after the operation, use `SHOW GRANTS`. See [Section 13.7.5.21, “SHOW GRANTS Syntax”](#).

13.7.1.9 SET DEFAULT ROLE Syntax

```
SET DEFAULT ROLE
{NONE | ALL | role [, role ] ...}
TO user [, user ] ...
```

For each *user* named immediately after the **TO** keyword, this statement defines which roles become active when the user connects to the server and authenticates, or when the user executes the **SET ROLE DEFAULT** statement during a session.

SET DEFAULT ROLE is alternative syntax for **ALTER USER ... DEFAULT ROLE** (see [Section 13.7.1.1, “ALTER USER Syntax”](#)). However, **ALTER USER** can set the default for only a single user, whereas **SET DEFAULT ROLE** can set the default for multiple users. On the other hand, you can specify **CURRENT_USER** as the user name for the **ALTER USER** statement, whereas you cannot for **SET DEFAULT ROLE**.

SET DEFAULT ROLE requires these privileges:

- Setting the default roles for another user requires the global **CREATE USER** privilege, or the **UPDATE** privilege for the `mysql.default_roles` system table.
- Setting the default roles for yourself requires no special privileges, as long as the roles you want as the default have been granted to you.

Each role name uses the format described in [Section 6.2.5, “Specifying Role Names”](#). For example:

```
SET DEFAULT ROLE administrator, developer TO 'joe'@'10.0.0.1';
```

The host name part of the role name, if omitted, defaults to `'%'`.

The clause following the **DEFAULT ROLE** keywords permits these values:

- **NONE**: Set the default to **NONE** (no roles).
- **ALL**: Set the default to all roles granted to the account.
- ***role* [, *role*] ...**: Set the default to the named roles, which need not exist or be granted to the account at the time **SET DEFAULT ROLE** is executed.

Note

SET DEFAULT ROLE and **SET ROLE DEFAULT** are different statements:

- **SET DEFAULT ROLE** defines which account roles to activate by default within account sessions.
- **SET ROLE DEFAULT** sets the active roles within the current session to the current account default roles.

13.7.1.10 SET PASSWORD Syntax

```
SET PASSWORD [FOR user] = password_option

password_option: {
  PASSWORD('auth_string')
  | 'auth_string'
}
```

The **SET PASSWORD** statement assigns a password to a MySQL user account, specified as either a cleartext (unencrypted) or encrypted value:

- `'auth_string'` represents a cleartext password.

- `'hash_string'` represents an encrypted password.

Note

- `SET PASSWORD ... = PASSWORD('auth_string')` syntax is deprecated as of MySQL 5.7.6 and will be removed in a future MySQL release.
- `SET PASSWORD ... = 'auth_string'` syntax is not deprecated, but `ALTER USER` is now the preferred statement for assigning passwords. For example:

```
ALTER USER user IDENTIFIED BY 'auth_string';
```

`SET PASSWORD` can be used with or without an explicitly named user account:

- With a `FOR user` clause, the statement sets the password for the named account, which must exist:

```
SET PASSWORD FOR 'jeffrey'@'localhost' = password_option;
```

In this case, you must have the `UPDATE` privilege for the `mysql` database.

- With no `FOR user` clause, the statement sets the password for the current user:

```
SET PASSWORD = password_option;
```

Any client who connects to the server using a nonanonymous account can change the password for that account. To see which account the server authenticated you as, invoke the `CURRENT_USER()` function:

```
SELECT CURRENT_USER();
```

When the `read_only` system variable is enabled, `SET PASSWORD` requires the `SUPER` privilege in addition to any other required privileges.

If a `FOR user` clause is given, the account name uses the format described in [Section 6.2.4, “Specifying Account Names”](#). The `user` value should be given as `'user_name'@'host_name'`, where `'user_name'` and `'host_name'` are exactly as listed in the `User` and `Host` columns of the account's `mysql.user` table row. The host name part of the account name, if omitted, defaults to `'%'`. For example, to set the password for an account with `User` and `Host` column values of `'bob'` and `'%.example.org'`, write the statement like this:

```
SET PASSWORD FOR 'bob'@'%.example.org' = PASSWORD('auth_string');
```

The password can be specified in these ways:

- Using the `PASSWORD()` function (deprecated as of MySQL 5.7.6)

The `'auth_string'` function argument is the cleartext (unencrypted) password. `PASSWORD()` hashes the password and returns the encrypted password string for storage in the `mysql.user` account row.

The `PASSWORD()` function hashes the password using the hashing method determined by the value of the `old_passwords` system variable value. If `SET PASSWORD` rejects the hashed password value returned by `PASSWORD()` as not being in the correct format, it may be necessary to change `old_passwords` to change the hashing method. For example, if the account uses the `mysql_native_password` plugin, the `old_passwords` value must be 0:

```
SET old_passwords = 0;
SET PASSWORD FOR 'jeffrey'@'localhost' = PASSWORD('mypass');
```

If the `old_passwords` value differs from that required by the authentication plugin, the hashed password value returned by `PASSWORD()` is not acceptable for that plugin, and attempts to set the password produce an error. Permitted `old_passwords` values are described later in this section.

- Using a string without `PASSWORD()`

`SET PASSWORD` interprets the string as a cleartext string and hashes it appropriately for the account authentication plugin before storing it in the `mysql.user` account row.

For more information about setting passwords, see [Section 6.3.7, “Assigning Account Passwords”](#).

The following table shows the permitted values of `old_passwords`, the password hashing method for each value, and which authentication plugins use passwords hashed with each method.

Value	Password Hashing Method	Associated Authentication Plugin
0	MySQL 4.1 native hashing	<code>mysql_native_password</code>
2	SHA-256 hashing	<code>sha256_password</code>

Important

Under some circumstances, `SET PASSWORD` may be recorded in server logs or on the client side in a history file such as `~/.mysql_history`, which means that cleartext passwords may be read by anyone having read access to that information. For information about the conditions under which this occurs for the server logs and how to control it, see [Section 6.1.2.3, “Passwords and Logging”](#). For similar information about client-side logging, see [Section 4.5.1.3, “mysql Logging”](#).

If you are using MySQL Replication, be aware that, currently, a password used by a replication slave as part of a `CHANGE MASTER TO` statement is effectively limited to 32 characters in length; if the password is longer, any excess characters are truncated. This is not due to any limit imposed by the MySQL Server generally, but rather is an issue specific to MySQL Replication. (For more information, see [Bug #43439](#).)

13.7.1.11 SET ROLE Syntax

```
SET ROLE
{
  DEFAULT
| NONE
| ALL
| ALL EXCEPT role [, role ] ...
| role [, role ] ...
}
```

`SET ROLE` modifies the current user's effective privileges within the current session by specifying which of its granted roles are active. Granted roles include those granted explicitly to the user and those named in the `mandatory_roles` system variable value.

Privileges that the user has been granted directly (rather than through roles) remain unaffected by changes to the active roles.

Each role name uses the format described in [Section 6.2.5, “Specifying Role Names”](#). For example:

```
SET ROLE DEFAULT;
SET ROLE 'role1', 'role2';
SET ROLE ALL;
```

```
SET ROLE ALL EXCEPT 'role1', 'role2';
```

The host name part of the role name, if omitted, defaults to `'%'`.

The statement permits these role specifiers:

- **DEFAULT**: Activate the account default roles. Default roles are those specified with `SET DEFAULT ROLE`.

If a user executes `SET ROLE DEFAULT` during a session, an error occurs if any default role cannot be activated (for example, if it does not exist or is not granted to the user). In this case, the current active roles are not changed.

When a user connects to the server and authenticates successfully, the server initializes the session active roles. In this case, the current active roles are those default roles that can be activated. The server writes warnings to its error log for default roles that cannot be activated, but the client receives no warnings. The server determines the roles to activate at connect time as follows:

- If the `activate_all_roles_on_login` system variable is enabled, the server activates all granted roles.
- Otherwise, The server executes `SET ROLE DEFAULT` implicitly.
- **NONE**: Set the active roles to **NONE** (no active roles).
- **ALL**: Activate all roles granted to the account.
- **ALL EXCEPT *role_list***: Activate all roles granted to the account except those named. The named roles need not exist or be granted to the account.
- ***role* [, *role*] ...**: Activate the named roles, which must be granted to the account.

Note

`SET DEFAULT ROLE` and `SET ROLE DEFAULT` are different statements:

- `SET DEFAULT ROLE` defines which account roles to activate by default within account sessions.
- `SET ROLE DEFAULT` sets the active roles within the current session to the current account default roles.

13.7.2 Table Maintenance Statements

13.7.2.1 ANALYZE TABLE Syntax

```
ANALYZE [NO_WRITE_TO_BINLOG | LOCAL]
  TABLE tbl_name [, tbl_name] ...

ANALYZE [NO_WRITE_TO_BINLOG | LOCAL]
  TABLE tbl_name
  UPDATE HISTOGRAM ON col_name [, col_name] ...
  WITH N BUCKETS

ANALYZE [NO_WRITE_TO_BINLOG | LOCAL]
  TABLE tbl_name
  DROP HISTOGRAM ON col_name [, col_name] ...
```

`ANALYZE TABLE` generates table statistics:

- `ANALYZE TABLE` without either `HISTOGRAM` clause performs a key distribution analysis and stores the distribution for the named table or tables. For `MyISAM` tables, `ANALYZE TABLE` for key distribution analysis is equivalent to using `myisamchk --analyze`.

- `ANALYZE TABLE` with the `UPDATE HISTOGRAM` clause generates histogram statistics for the named table columns and stores them in the data dictionary. Only one table name is permitted for this syntax.
- `ANALYZE TABLE` with the `DROP HISTOGRAM` clause removes histogram statistics for the named table columns from the data dictionary. Only one table name is permitted for this syntax.

The `UPDATE HISTOGRAM` and `DROP HISTOGRAM` syntaxes were added in MySQL 8.0.2.

Note

If the `innodb_read_only` system variable is enabled, `ANALYZE TABLE` may fail because it cannot update statistics tables in the data dictionary, which use InnoDB. For `ANALYZE TABLE` operations that update the key distribution, failure may occur even if the operation updates the table itself (for example, if it is a MyISAM table). To obtain the updated distribution statistics, set `information_schema_stats=LATEST`.

This statement requires `SELECT` and `INSERT` privileges for the table.

`ANALYZE TABLE` works with InnoDB, NDB, and MyISAM tables. It does not work with views.

`ANALYZE TABLE` is supported for partitioned tables, and you can use `ALTER TABLE ... ANALYZE PARTITION` to analyze one or more partitions; for more information, see [Section 13.1.7, “ALTER TABLE Syntax”](#), and [Section 22.3.4, “Maintenance of Partitions”](#).

During the analysis, the table is locked with a read lock for InnoDB and MyISAM.

By default, the server writes `ANALYZE TABLE` statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

- [ANALYZE TABLE Output](#)
- [Key Distribution Analysis](#)
- [Histogram Statistics Analysis](#)

ANALYZE TABLE Output

`ANALYZE TABLE` returns a result set with the columns shown in the following table.

Column	Value
Table	The table name
Op	<code>analyze</code> or <code>histogram</code>
Msg_type	<code>status</code> , <code>error</code> , <code>info</code> , <code>note</code> , or <code>warning</code>
Msg_text	An informational message

Key Distribution Analysis

`ANALYZE TABLE` without either `HISTOGRAM` clause performs a key distribution analysis and stores the distribution for the table or tables. Any existing histogram statistics remain unaffected.

If the table has not changed since the last key distribution analysis, the table is not analyzed again.

MySQL uses the stored key distribution to decide the order in which tables should be joined for joins on something other than a constant. In addition, key distributions can be used when deciding which indexes to use for a specific table within a query.

For more information on how key distribution analysis works within InnoDB, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#) and [Section 15.6.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”](#). Also see [Section 15.8.1.7, “Limits on InnoDB Tables”](#). In particular, when you enable the `innodb_stats_persistent` option, you must run `ANALYZE TABLE` after loading substantial data into an InnoDB table, or creating a new index for one.

To check the stored key distribution cardinality, use the `SHOW INDEX` statement or the `INFORMATION_SCHEMA.STATISTICS` table. See [Section 13.7.5.22, “SHOW INDEX Syntax”](#), and [Section 24.21, “The INFORMATION_SCHEMA STATISTICS Table”](#).

Histogram Statistics Analysis

`ANALYZE TABLE` with the `HISTOGRAM` clauses enables management of histogram statistics for table column values. For information about histogram statistics, see [Section 8.9.6, “Optimizer Statistics”](#).

These histogram operations are available:

- `ANALYZE TABLE` with an `UPDATE HISTOGRAM` clause generates histogram statistics for the named table columns and stores them in the data dictionary. Only one table name is permitted for this syntax.

The `WITH N BUCKETS` clause specifies the number of buckets for the histogram. The value of `N` must be an integer in the range from 1 to 1024.

- `ANALYZE TABLE` with a `DROP HISTOGRAM` clause removes histogram statistics for the named table columns from the data dictionary. Only one table name is permitted for this syntax.

Stored histogram management statements affect only the named columns. Consider these statements:

```
ANALYZE TABLE t UPDATE HISTOGRAM ON c1, c2, c3 WITH 10 BUCKETS;
ANALYZE TABLE t UPDATE HISTOGRAM ON c1, c3 WITH 10 BUCKETS;
ANALYZE TABLE t DROP HISTOGRAM ON c2;
```

The first statement updates the histograms for columns `c1`, `c2`, and `c3`, replacing any existing histograms for those columns. The second statement updates the histograms for `c1` and `c3`, leaving the `c2` histogram unaffected. The third statement removes the histogram for `c2`, leaving those for `c1` and `c3` unaffected.

Histogram generation is not supported for encrypted tables (to avoid exposing data in the statistics) or `TEMPORARY` tables.

Histogram generation applies to columns of all data types except geometry types (spatial data) and `JSON`.

Histograms can be generated for stored and virtual generated columns.

Histograms cannot be generated for columns that are covered by single-column unique indexes.

Histogram management statements attempt to perform as much of the requested operation as possible, and report diagnostic messages for the remainder. For example, if an `UPDATE HISTOGRAM` statement names multiple columns, but some of them do not exist or have an unsupported data type, histograms are generated for the other columns, and messages are produced for the invalid columns.

The `histogram_generation_max_mem_size` system variable controls the maximum amount of memory available for histogram generation. The global and session values may be set at runtime. The `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege is required, even for the session value.

For information about memory allocations performed for histogram generation, monitor the Performance Schema `memory/sql/histograms` instrument. See [Section 25.11.15.10, “Memory Summary Tables”](#).

Histograms are affected by these DDL statements:

- `DROP TABLE` removes histograms for columns in the dropped table.
- `DROP DATABASE` removes histograms for any table in the dropped database because the statement drops all tables in the database.
- `RENAME TABLE` does not remove histograms. Instead, it renames histograms for the renamed table to be associated with the new table name.
- `ALTER TABLE` statements that remove or modify a column remove histograms for that column.
- `ALTER TABLE ... CONVERT TO CHARACTER SET` removes histograms for character columns because they are affected by the change of character set. Histograms for noncharacter columns remain unaffected.

13.7.2.2 CHECK TABLE Syntax

```
CHECK TABLE tbl_name [, tbl_name] ... [option] ...

option = {
  FOR UPGRADE
  | QUICK
  | FAST
  | MEDIUM
  | EXTENDED
  | CHANGED
}
```

`CHECK TABLE` checks a table or tables for errors. For `MyISAM` tables, the key statistics are updated as well. `CHECK TABLE` can also check views for problems, such as tables that are referenced in the view definition that no longer exist.

To check a table, you must have some privilege for it.

`CHECK TABLE` works for `InnoDB`, `MyISAM`, `ARCHIVE`, and `CSV` tables.

Before running `CHECK TABLE` on `InnoDB` tables, see [CHECK TABLE Usage Notes for InnoDB Tables](#).

`CHECK TABLE` is supported for partitioned tables, and you can use `ALTER TABLE ... CHECK PARTITION` to check one or more partitions; for more information, see [Section 13.1.7, “ALTER TABLE Syntax”](#), and [Section 22.3.4, “Maintenance of Partitions”](#).

`CHECK TABLE` ignores virtual generated columns that are not indexed.

- [CHECK TABLE Output](#)
- [Checking Version Compatibility](#)
- [Checking Data Consistency](#)
- [CHECK TABLE Usage Notes for InnoDB Tables](#)

CHECK TABLE Output

`CHECK TABLE` returns a result set with the columns shown in the following table.

Column	Value
Table	The table name
Op	Always <code>check</code>

Column	Value
<code>Msg_type</code>	<code>status</code> , <code>error</code> , <code>info</code> , <code>note</code> , or <code>warning</code>
<code>Msg_text</code>	An informational message

The statement might produce many rows of information for each checked table. The last row has a `Msg_type` value of `status` and the `Msg_text` normally should be `OK`. For a `MyISAM` table, if you don't get `OK` or `Table is already up to date`, you should normally run a repair of the table. See [Section 7.6, "MyISAM Table Maintenance and Crash Recovery"](#). `Table is already up to date` means that the storage engine for the table indicated that there was no need to check the table.

Checking Version Compatibility

The `FOR UPGRADE` option checks whether the named tables are compatible with the current version of MySQL. With `FOR UPGRADE`, the server checks each table to determine whether there have been any incompatible changes in any of the table's data types or indexes since the table was created. If not, the check succeeds. Otherwise, if there is a possible incompatibility, the server runs a full check on the table (which might take some time).

Incompatibilities might occur because the storage format for a data type has changed or because its sort order has changed. Our aim is to avoid these changes, but occasionally they are necessary to correct problems that would be worse than an incompatibility between releases.

`FOR UPGRADE` discovers these incompatibilities:

- The indexing order for end-space in `TEXT` columns for `InnoDB` and `MyISAM` tables changed between MySQL 4.1 and 5.0.
- The storage method of the new `DECIMAL` data type changed between MySQL 5.0.3 and 5.0.5.
- Changes are sometimes made to character sets or collations that require table indexes to be rebuilt. For details about such changes, see [Section 2.10.1.1, "Changes Affecting Upgrades to MySQL 8.0"](#). For information about rebuilding tables, see [Section 2.10.3, "Rebuilding or Repairing Tables or Indexes"](#).
- MySQL 8.0 does not support the `YEAR(2)` data type permitted in older versions of MySQL. For tables containing `YEAR(2)` columns, `CHECK TABLE` recommends `REPAIR TABLE`, which converts `YEAR(2)` to `YEAR(4)`.
- Trigger creation time is maintained.
- A table is reported as needing a rebuild if it contains old temporal columns in pre-5.6.4 format (`TIME`, `DATETIME`, and `TIMESTAMP` columns without support for fractional seconds precision) and the `avoid_temporal_upgrade` system variable is disabled. This helps `mysql_upgrade` detect and upgrade tables containing old temporal columns. If `avoid_temporal_upgrade` is enabled, `FOR UPGRADE` ignores the old temporal columns present in the table; consequently, `mysql_upgrade` does not upgrade them.

To check for tables that contain such temporal columns and need a rebuild, disable `avoid_temporal_upgrade` before executing `CHECK TABLE ... FOR UPGRADE`.

Checking Data Consistency

The following table shows the other check options that can be given. These options are passed to the storage engine, which may use or ignore them.

Type	Meaning
<code>QUICK</code>	Do not scan the rows to check for incorrect links. Applies to <code>InnoDB</code> and <code>MyISAM</code> tables and views.

Type	Meaning
FAST	Check only tables that have not been closed properly. Applies only to MyISAM tables and views; ignored for InnoDB .
CHANGED	Check only tables that have been changed since the last check or that have not been closed properly. Applies only to MyISAM tables and views; ignored for InnoDB .
MEDIUM	Scan rows to verify that deleted links are valid. This also calculates a key checksum for the rows and verifies this with a calculated checksum for the keys. Applies only to MyISAM tables and views; ignored for InnoDB .
EXTENDED	Do a full key lookup for all keys for each row. This ensures that the table is 100% consistent, but takes a long time. Applies only to MyISAM tables and views; ignored for InnoDB .

If none of the options [QUICK](#), [MEDIUM](#), or [EXTENDED](#) are specified, the default check type for dynamic-format [MyISAM](#) tables is [MEDIUM](#). This has the same result as running `myisamchk --medium-check tbl_name` on the table. The default check type also is [MEDIUM](#) for static-format [MyISAM](#) tables, unless [CHANGED](#) or [FAST](#) is specified. In that case, the default is [QUICK](#). The row scan is skipped for [CHANGED](#) and [FAST](#) because the rows are very seldom corrupted.

You can combine check options, as in the following example that does a quick check on the table to determine whether it was closed properly:

```
CHECK TABLE test_table FAST QUICK;
```

Note

If [CHECK TABLE](#) finds no problems with a table that is marked as “corrupted” or “not closed properly”, [CHECK TABLE](#) may remove the mark.

If a table is corrupted, the problem is most likely in the indexes and not in the data part. All of the preceding check types check the indexes thoroughly and should thus find most errors.

To check a table that you assume is okay, use no check options or the [QUICK](#) option. The latter should be used when you are in a hurry and can take the very small risk that [QUICK](#) does not find an error in the data file. (In most cases, under normal usage, MySQL should find any error in the data file. If this happens, the table is marked as “corrupted” and cannot be used until it is repaired.)

[FAST](#) and [CHANGED](#) are mostly intended to be used from a script (for example, to be executed from `cron`) to check tables periodically. In most cases, [FAST](#) is to be preferred over [CHANGED](#). (The only case when it is not preferred is when you suspect that you have found a bug in the [MyISAM](#) code.)

[EXTENDED](#) is to be used only after you have run a normal check but still get errors from a table when MySQL tries to update a row or find a row by key. This is very unlikely if a normal check has succeeded.

Use of [CHECK TABLE ... EXTENDED](#) might influence execution plans generated by the query optimizer.

Some problems reported by [CHECK TABLE](#) cannot be corrected automatically:

- `Found row where the auto_increment column has the value 0.`

This means that you have a row in the table where the [AUTO_INCREMENT](#) index column contains the value 0. (It is possible to create a row where the [AUTO_INCREMENT](#) column is 0 by explicitly setting the column to 0 with an [UPDATE](#) statement.)

This is not an error in itself, but could cause trouble if you decide to dump the table and restore it or do an [ALTER TABLE](#) on the table. In this case, the [AUTO_INCREMENT](#) column changes value according to the rules of [AUTO_INCREMENT](#) columns, which could cause problems such as a duplicate-key error.

To get rid of the warning, execute an `UPDATE` statement to set the column to some value other than 0.

CHECK TABLE Usage Notes for InnoDB Tables

The following notes apply to `InnoDB` tables:

- If `CHECK TABLE` encounters a corrupt page, the server exits to prevent error propagation (Bug #10132). If the corruption occurs in a secondary index but table data is readable, running `CHECK TABLE` can still cause a server exit.
- If `CHECK TABLE` encounters a corrupted `DB_TRX_ID` or `DB_ROLL_PTR` field in a clustered index, `CHECK TABLE` can cause `InnoDB` to access an invalid undo log record, resulting in an `MVCC`-related server exit.
- If `CHECK TABLE` encounters errors in `InnoDB` tables or indexes, it reports an error, and usually marks the index and sometimes marks the table as corrupted, preventing further use of the index or table. Such errors include an incorrect number of entries in a secondary index or incorrect links.
- If `CHECK TABLE` finds an incorrect number of entries in a secondary index, it reports an error but does not cause a server exit or prevent access to the file.
- `CHECK TABLE` surveys the index page structure, then surveys each key entry. It does not validate the key pointer to a clustered record or follow the path for `BLOB` pointers.
- When an `InnoDB` table is stored in its own `.ibd` file, the first 3 pages of the `.ibd` file contain header information rather than table or index data. The `CHECK TABLE` statement does not detect inconsistencies that affect only the header data. To verify the entire contents of an `InnoDB .ibd` file, use the `innochecksum` command.
- When running `CHECK TABLE` on large `InnoDB` tables, other threads may be blocked during `CHECK TABLE` execution. To avoid timeouts, the semaphore wait threshold (600 seconds) is extended by 2 hours (7200 seconds) for `CHECK TABLE` operations. If `InnoDB` detects semaphore waits of 240 seconds or more, it starts printing `InnoDB` monitor output to the error log. If a lock request extends beyond the semaphore wait threshold, `InnoDB` aborts the process. To avoid the possibility of a semaphore wait timeout entirely, you can run `CHECK TABLE QUICK` instead of `CHECK TABLE`.
- `CHECK TABLE` functionality for `InnoDB SPATIAL` indexes includes an R-tree validity check and a check to ensure that the R-tree row count matches the clustered index.
- `CHECK TABLE` supports secondary indexes on virtual generated columns. `InnoDB` has support for secondary indexes on virtual generated columns.

13.7.2.3 CHECKSUM TABLE Syntax

```
CHECKSUM TABLE tbl_name [, tbl_name] ... [QUICK | EXTENDED]
```

`CHECKSUM TABLE` reports a `checksum` for the contents of a table. You can use this statement to verify that the contents are the same before and after a backup, rollback, or other operation that is intended to put the data back to a known state.

This statement requires the `SELECT` privilege for the table.

This statement is not supported for views. If you run `CHECKSUM TABLE` against a view, the `Checksum` value is always `NULL`, and a warning is returned.

For a nonexistent table, `CHECKSUM TABLE` returns `NULL` and generates a warning.

During the checksum operation, the table is locked with a read lock for `InnoDB` and `MyISAM`.

Performance Considerations

By default, the entire table is read row by row and the checksum is calculated. For large tables, this could take a long time, thus you would only perform this operation occasionally. This row-by-row calculation is what you get with the `EXTENDED` clause, with `InnoDB` and all other storage engines other than `MyISAM`, and with `MyISAM` tables not created with the `CHECKSUM=1` clause.

For `MyISAM` tables created with the `CHECKSUM=1` clause, `CHECKSUM TABLE` or `CHECKSUM TABLE ... QUICK` returns the “live” table checksum that can be returned very fast. If the table does not meet all these conditions, the `QUICK` method returns `NULL`. See [Section 13.1.15, “CREATE TABLE Syntax”](#) for the syntax of the `CHECKSUM` clause.

The checksum value depends on the table row format. If the row format changes, the checksum also changes. For example, the storage format for temporal types such as `TIME`, `DATETIME`, and `TIMESTAMP` changed in MySQL 5.6 prior to MySQL 5.6.5, so if a 5.5 table is upgraded to MySQL 5.6, the checksum value may change.

Important

If the checksums for two tables are different, then it is almost certain that the tables are different in some way. However, because the hashing function used by `CHECKSUM TABLE` is not guaranteed to be collision-free, there is a slight chance that two tables which are not identical can produce the same checksum.

13.7.2.4 OPTIMIZE TABLE Syntax

```
OPTIMIZE [NO_WRITE_TO_BINLOG | LOCAL]
TABLE tbl_name [, tbl_name] ...
```

`OPTIMIZE TABLE` reorganizes the physical storage of table data and associated index data, to reduce storage space and improve I/O efficiency when accessing the table. The exact changes made to each table depend on the [storage engine](#) used by that table.

Use `OPTIMIZE TABLE` in these cases, depending on the type of table:

- After doing substantial insert, update, or delete operations on an `InnoDB` table that has its own `.ibd` file because it was created with the `innodb_file_per_table` option enabled. The table and indexes are reorganized, and disk space can be reclaimed for use by the operating system.
- After doing substantial insert, update, or delete operations on columns that are part of a `FULLTEXT` index in an `InnoDB` table. Set the configuration option `innodb_optimize_fulltext_only=1` first. To keep the index maintenance period to a reasonable time, set the `innodb_ft_num_word_optimize` option to specify how many words to update in the search index, and run a sequence of `OPTIMIZE TABLE` statements until the search index is fully updated.
- After deleting a large part of a `MyISAM` or `ARCHIVE` table, or making many changes to a `MyISAM` or `ARCHIVE` table with variable-length rows (tables that have `VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT` columns). Deleted rows are maintained in a linked list and subsequent `INSERT` operations reuse old row positions. You can use `OPTIMIZE TABLE` to reclaim the unused space and to defragment the data file. After extensive changes to a table, this statement may also improve performance of statements that use the table, sometimes significantly.

This statement requires `SELECT` and `INSERT` privileges for the table.

`OPTIMIZE TABLE` works for `InnoDB`, `MyISAM`, and `ARCHIVE` tables.

By default, `OPTIMIZE TABLE` does *not* work for tables created using any other storage engine and returns a result indicating this lack of support. You can make `OPTIMIZE TABLE` work for other storage

engines by starting `mysqld` with the `--skip-new` option. In this case, `OPTIMIZE TABLE` is just mapped to `ALTER TABLE`.

This statement does not work with views.

`OPTIMIZE TABLE` is supported for partitioned tables. For information about using this statement with partitioned tables and table partitions, see [Section 22.3.4, “Maintenance of Partitions”](#).

By default, the server writes `OPTIMIZE TABLE` statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

- [OPTIMIZE TABLE Output](#)
- [InnoDB Details](#)
- [MyISAM Details](#)
- [Other Considerations](#)

OPTIMIZE TABLE Output

`OPTIMIZE TABLE` returns a result set with the columns shown in the following table.

Column	Value
Table	The table name
Op	Always <code>optimize</code>
Msg_type	<code>status</code> , <code>error</code> , <code>info</code> , <code>note</code> , or <code>warning</code>
Msg_text	An informational message

`OPTIMIZE TABLE` catches and throws any errors that occur while copying table statistics from the old file to the newly created file. For example, if the user ID of the owner of the `.MYD` or `.MYI` file is different from the user ID of the `mysqld` process, `OPTIMIZE TABLE` generates a "cannot change ownership of the file" error unless `mysqld` is started by the `root` user.

InnoDB Details

For `InnoDB` tables, `OPTIMIZE TABLE` is mapped to `ALTER TABLE ... FORCE`, which rebuilds the table to update index statistics and free unused space in the clustered index. This is displayed in the output of `OPTIMIZE TABLE` when you run it on an `InnoDB` table, as shown here:

```
mysql> OPTIMIZE TABLE foo;
+-----+-----+-----+-----+
| Table   | Op       | Msg_type | Msg_text                                     |
+-----+-----+-----+-----+
| test.foo | optimize | note     | Table does not support optimize, doing recreate + analyze instead |
| test.foo | optimize | status   | OK                                           |
+-----+-----+-----+-----+
```

`OPTIMIZE TABLE` uses [online DDL](#) for regular and partitioned `InnoDB` tables, which reduces downtime for concurrent DML operations. The table rebuild triggered by `OPTIMIZE TABLE` and performed under the cover by `ALTER TABLE ... FORCE` is completed in place. An exclusive table lock is only taken briefly during the prepare phase and the commit phase of the operation. During the prepare phase, metadata is updated and an intermediate table is created. During the commit phase, table metadata changes are committed.

`OPTIMIZE TABLE` rebuilds the table using the table copy method under the following conditions:

- When the `old_alter_table` system variable is enabled.

- When the `mysqld --skip-new` option is enabled.

`OPTIMIZE TABLE` using [online DDL](#) is not supported for [InnoDB](#) tables that contain `FULLTEXT` indexes. The table copy method is used instead.

[InnoDB](#) stores data using a page-allocation method and does not suffer from fragmentation in the same way that legacy storage engines (such as [MyISAM](#)) will. When considering whether or not to run `optimize`, consider the workload of transactions that your server will process:

- Some level of fragmentation is expected. [InnoDB](#) only fills [pages](#) 93% full, to leave room for updates without having to split pages.
- Delete operations might leave gaps that leave pages less filled than desired, which could make it worthwhile to optimize the table.
- Updates to rows usually rewrite the data within the same page, depending on the data type and row format, when sufficient space is available. See [Section 15.9.1.5, “How Compression Works for InnoDB Tables”](#) and [Section 15.10.1, “Overview of InnoDB Row Storage”](#).
- High-concurrency workloads might leave gaps in indexes over time, as [InnoDB](#) retains multiple versions of the same data due through its [MVCC](#) mechanism. See [Section 15.3, “InnoDB Multi-Versioning”](#).

MyISAM Details

For [MyISAM](#) tables, `OPTIMIZE TABLE` works as follows:

1. If the table has deleted or split rows, repair the table.
2. If the index pages are not sorted, sort them.
3. If the table's statistics are not up to date (and the repair could not be accomplished by sorting the index), update them.

Other Considerations

`OPTIMIZE TABLE` is performed online for regular and partitioned [InnoDB](#) tables. Otherwise, MySQL [locks the table](#) during the time `OPTIMIZE TABLE` is running.

`OPTIMIZE TABLE` does not sort R-tree indexes, such as spatial indexes on [POINT](#) columns. (Bug #23578)

13.7.2.5 REPAIR TABLE Syntax

```
REPAIR [NO_WRITE_TO_BINLOG | LOCAL]
TABLE tbl_name [, tbl_name] ...
[QUICK] [EXTENDED] [USE_FRM]
```

`REPAIR TABLE` repairs a possibly corrupted table, for certain storage engines only. For [MyISAM](#) tables, it has the same effect as `myisamchk --recover tbl_name` by default.

This statement requires [SELECT](#) and [INSERT](#) privileges for the table.

`REPAIR TABLE` works for [MyISAM](#), [ARCHIVE](#), and [CSV](#) tables. See [Section 16.2, “The MyISAM Storage Engine”](#), [Section 16.5, “The ARCHIVE Storage Engine”](#), and [Section 16.4, “The CSV Storage Engine”](#). This statement does not work with views.

You can use `ALTER TABLE ... REPAIR PARTITION` to repair one or more partitions; for more information, see [Section 13.1.7, “ALTER TABLE Syntax”](#), and [Section 22.3.4, “Maintenance of Partitions”](#).

Although normally you should never have to run `REPAIR TABLE`, if disaster strikes, this statement is very likely to get back all your data from a `MyISAM` table. If your tables become corrupted often, try to find the reason for it, to eliminate the need to use `REPAIR TABLE`. See [Section B.5.3.3, “What to Do If MySQL Keeps Crashing”](#), and [Section 16.2.4, “MyISAM Table Problems”](#).

Caution

Make a backup of a table before performing a table repair operation; under some circumstances the operation might cause data loss. Possible causes include but are not limited to file system errors. See [Chapter 7, Backup and Recovery](#).

Warning

If the server crashes during a `REPAIR TABLE` operation, it is essential after restarting it that you immediately execute another `REPAIR TABLE` statement for the table before performing any other operations on it. In the worst case, you might have a new clean index file without information about the data file, and then the next operation you perform could overwrite the data file. This is an unlikely but possible scenario that underscores the value of making a backup first.

By default, the server writes `REPAIR TABLE` statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

Important

In the event that a table on the master becomes corrupted and you run `REPAIR TABLE` on it, any resulting changes to the original table are *not* propagated to slaves.

- [REPAIR TABLE Output](#)
- [Table Repair Considerations](#)

REPAIR TABLE Output

`REPAIR TABLE` returns a result set with the columns shown in the following table.

Column	Value
Table	The table name
Op	Always <code>repair</code>
Msg_type	<code>status</code> , <code>error</code> , <code>info</code> , <code>note</code> , or <code>warning</code>
Msg_text	An informational message

The `REPAIR TABLE` statement might produce many rows of information for each repaired table. The last row has a `Msg_type` value of `status` and `Msg_text` normally should be `OK`. For a `MyISAM` table, if you do not get `OK`, you should try repairing it with `myisamchk --safe-recover`. (`REPAIR TABLE` does not implement all the options of `myisamchk`. With `myisamchk --safe-recover`, you can also use options that `REPAIR TABLE` does not support, such as `--max-record-length`.)

`REPAIR TABLE` catches and throws any errors that occur while copying table statistics from the old corrupted file to the newly created file. For example, if the user ID of the owner of the `.MYD` or `.MYI` file is different from the user ID of the `mysqld` process, `REPAIR TABLE` generates a "cannot change ownership of the file" error unless `mysqld` is started by the `root` user.

Table Repair Considerations

If you use the `QUICK` option, `REPAIR TABLE` tries to repair only the index file, and not the data file. This type of repair is like that done by `myisamchk --recover --quick`.

If you use the `EXTENDED` option, MySQL creates the index row by row instead of creating one index at a time with sorting. This type of repair is like that done by `myisamchk --safe-recover`.

The `USE_FRM` option is available for use if the `.MYI` index file is missing or if its header is corrupted. This option tells MySQL not to trust the information in the `.MYI` file header and to re-create it using information from the data dictionary. This kind of repair cannot be done with `myisamchk`.

Caution

Use the `USE_FRM` option *only* if you cannot use regular `REPAIR` modes. Telling the server to ignore the `.MYI` file makes important table metadata stored in the `.MYI` unavailable to the repair process, which can have deleterious consequences:

- The current `AUTO_INCREMENT` value is lost.
- The link to deleted records in the table is lost, which means that free space for deleted records will remain unoccupied thereafter.
- The `.MYI` header indicates whether the table is compressed. If the server ignores this information, it cannot tell that a table is compressed and repair can cause change or loss of table contents. This means that `USE_FRM` should not be used with compressed tables. That should not be necessary, anyway: Compressed tables are read only, so they should not become corrupt.

If `USE_FRM` is *not* used, `REPAIR TABLE` checks the table to see whether an upgrade is required. If so, it performs the upgrade, following the same rules as `CHECK TABLE ... FOR UPGRADE`. See [Section 13.7.2.2, “CHECK TABLE Syntax”](#), for more information.

`REPAIR TABLE` checks the table to see whether an upgrade is required. If so, it performs the upgrade, following the same rules as `CHECK TABLE ... FOR UPGRADE`. See [Section 13.7.2.2, “CHECK TABLE Syntax”](#), for more information.

`REPAIR TABLE` upgrades a table if it contains old temporal columns in pre-5.6.4 format (`TIME`, `DATETIME`, and `TIMESTAMP` columns without support for fractional seconds precision) and the `avoid_temporal_upgrade` system variable is disabled. If `avoid_temporal_upgrade` is enabled, `REPAIR TABLE` ignores the old temporal columns present in the table and does not upgrade them.

To upgrade tables that contain such temporal columns, disable `avoid_temporal_upgrade` before executing `REPAIR TABLE`.

You may be able to increase `REPAIR TABLE` performance by setting certain system variables. See [Section 8.6.3, “Optimizing REPAIR TABLE Statements”](#).

13.7.3 Component, Plugin, and User-Defined Function Statements

13.7.3.1 CREATE FUNCTION Syntax for User-Defined Functions

```
CREATE [AGGREGATE] FUNCTION function_name
  RETURNS {STRING|INTEGER|REAL|DECIMAL}
  SONAME shared_library_name
```

A user-defined function (UDF) is a way to extend MySQL with a new function that works like a native (built-in) MySQL function such as `ABS()` or `CONCAT()`.

function_name is the name that should be used in SQL statements to invoke the function. The `RETURNS` clause indicates the type of the function's return value. `DECIMAL` is a legal value after `RETURNS`, but currently `DECIMAL` functions return string values and should be written like `STRING` functions.

shared_library_name is the base name of the shared library file that contains the code that implements the function. The file must be located in the plugin directory. This directory is given by the value of the `plugin_dir` system variable. For more information, see [Section 28.4.2.5, “UDF Compiling and Installing”](#).

To create a function, you must have the `INSERT` privilege for the `mysql` database. This is necessary because `CREATE FUNCTION` adds a row to the `mysql.func` system table that records the function's name, type, and shared library name. If you do not have this table, you should run the `mysql_upgrade` command to create it. See [Section 4.4.5, “mysql_upgrade — Check and Upgrade MySQL Tables”](#).

As of MySQL 8.0.2, UDFs registered using `CREATE FUNCTION` are listed in the Performance Schema `user_defined_functions` table; see [Section 25.11.16.4, “The user_defined_functions Table”](#).

An active function is one that has been loaded with `CREATE FUNCTION` and not removed with `DROP FUNCTION`. All active functions are reloaded each time the server starts, unless you start `mysqld` with the `--skip-grant-tables` option. In this case, UDF initialization is skipped and UDFs are unavailable.

For instructions on writing user-defined functions, see [Section 28.4.2, “Adding a New User-Defined Function”](#). For the UDF mechanism to work, functions must be written in C or C++ (or another language that can use C calling conventions), your operating system must support dynamic loading and you must have compiled `mysqld` dynamically (not statically).

An `AGGREGATE` function works exactly like a native MySQL aggregate (summary) function such as `SUM` or `COUNT()`. For `AGGREGATE` to work, your `mysql.func` table must contain a `type` column. If your `mysql.func` table does not have this column, you should run the `mysql_upgrade` program to create it (see [Section 4.4.5, “mysql_upgrade — Check and Upgrade MySQL Tables”](#)).

Note

To upgrade the shared library associated with a UDF, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may crash.

13.7.3.2 DROP FUNCTION Syntax

```
DROP FUNCTION function_name
```

This statement drops the user-defined function (UDF) named *function_name*.

To drop a function, you must have the `DELETE` privilege for the `mysql` database. This is because `DROP FUNCTION` removes a row from the `mysql.func` system table that records the function's name, type, and shared library name.

Note

To upgrade the shared library associated with a UDF, issue a `DROP FUNCTION` statement, upgrade the shared library, and then issue a `CREATE FUNCTION` statement. If you upgrade the shared library first and then use `DROP FUNCTION`, the server may crash.

`DROP FUNCTION` is also used to drop stored functions (see [Section 13.1.23, “DROP PROCEDURE and DROP FUNCTION Syntax”](#)).

13.7.3.3 INSTALL COMPONENT Syntax

```
INSTALL COMPONENT component_name [, component_name ] ...
```

This statement installs one or more server components, which become active immediately. A component provides services that are available to the server and other components. (With respect to service use, the server is a component, equal to other components.) `INSTALL COMPONENT` requires the `INSERT` privilege for the `mysql.component` system table.

A loader service handles component installation and uninstallation, and also lists installed components in the `mysql.component` system table, which serves as a registry. For subsequent server restarts, any components listed in `mysql.component` are installed by the loader service during the startup sequence. This occurs even if the server is started with the `--skip-grant-tables` option.

If a component depends on services not present in the registry and you attempt to install the component without also installing the component or components that provide the services it depends on, an error occurs:

```
ERROR 3527 (HY000): Cannot satisfy dependency for service 'component1'
required by component 'component2'.
```

To avoid this, either install all components in the same statement, or install the dependent component after installing any components it depends on.

If any error occurs, the statement fails and has no effect. For example, this happens if a component name is erroneous, a named component does not exist or is already installed, or component initialization fails.

Currently, component names are URNs that begin with `file://` and for which the following file name value contains no directory names and is relative to the directory named by the `plugin_dir` system variable. Component names do not include any platform-dependent file name suffix such as `.so` or `.dll`. These details are subject to change because component name interpretation is itself performed by a service and the component infrastructure makes it possible to replace the default service implementation with alternative implementations.

Example:

```
INSTALL COMPONENT 'file://component1', 'file://component2';
```

For additional information about components, see [Section 5.5, “MySQL Server Components”](#).

13.7.3.4 INSTALL PLUGIN Syntax

```
INSTALL PLUGIN plugin_name SONAME 'shared_library_name'
```

This statement installs a server plugin. It requires the `INSERT` privilege for the `mysql.plugin` system table.

`plugin_name` is the name of the plugin as defined in the plugin descriptor structure contained in the library file (see [Section 28.2.4.2, “Plugin Data Structures”](#)). Plugin names are not case sensitive. For maximal compatibility, plugin names should be limited to ASCII letters, digits, and underscore because they are used in C source files, shell command lines, M4 and Bourne shell scripts, and SQL environments.

`shared_library_name` is the name of the shared library that contains the plugin code. The name includes the file name extension (for example, `libmyplugin.so`, `libmyplugin.dll`, or `libmyplugin.dylib`).

The shared library must be located in the plugin directory (the directory named by the `plugin_dir` system variable). The library must be in the plugin directory itself, not in a subdirectory. By default, `plugin_dir` is the `plugin` directory under the directory named by the `pkglibdir` configuration variable, but it can be changed by setting the value of `plugin_dir` at server startup. For example, set its value in a `my.cnf` file:

```
[mysqld]
plugin_dir=/path/to/plugin/directory
```

If the value of `plugin_dir` is a relative path name, it is taken to be relative to the MySQL base directory (the value of the `basedir` system variable).

`INSTALL PLUGIN` loads and initializes the plugin code to make the plugin available for use. A plugin is initialized by executing its initialization function, which handles any setup that the plugin must perform before it can be used. When the server shuts down, it executes the deinitialization function for each plugin that is loaded so that the plugin has a chance to perform any final cleanup.

`INSTALL PLUGIN` also registers the plugin by adding a line that indicates the plugin name and library file name to the `mysql.plugin` table. At server startup, the server loads and initializes any plugin that is listed in the `mysql.plugin` table. This means that a plugin is installed with `INSTALL PLUGIN` only once, not every time the server starts. Plugin loading at startup does not occur if the server is started with the `--skip-grant-tables` option.

A plugin library can contain multiple plugins. For each of them to be installed, use a separate `INSTALL PLUGIN` statement. Each statement names a different plugin, but all of them specify the same library name.

`INSTALL PLUGIN` causes the server to read option (`my.cnf`) files just as during server startup. This enables the plugin to pick up any relevant options from those files. It is possible to add plugin options to an option file even before loading a plugin (if the `loose` prefix is used). It is also possible to uninstall a plugin, edit `my.cnf`, and install the plugin again. Restarting the plugin this way enables it to the new option values without a server restart.

For options that control individual plugin loading at server startup, see [Section 5.6.2, “Installing and Uninstalling Plugins”](#). If you need to load plugins for a single server startup when the `--skip-grant-tables` option is given (which tells the server not to read system tables), use the `--plugin-load` option. See [Section 5.1.4, “Server Command Options”](#).

To remove a plugin, use the `UNINSTALL PLUGIN` statement.

For additional information about plugin loading, see [Section 5.6.2, “Installing and Uninstalling Plugins”](#).

To see what plugins are installed, use the `SHOW PLUGINS` statement or query the `INFORMATION_SCHEMA.PLUGINS` table.

If you recompile a plugin library and need to reinstall it, you can use either of the following methods:

- Use `UNINSTALL PLUGIN` to uninstall all plugins in the library, install the new plugin library file in the plugin directory, and then use `INSTALL PLUGIN` to install all plugins in the library. This procedure has the advantage that it can be used without stopping the server. However, if the plugin library contains many plugins, you must issue many `INSTALL PLUGIN` and `UNINSTALL PLUGIN` statements.
- Stop the server, install the new plugin library file in the plugin directory, and restart the server.

13.7.3.5 UNINSTALL COMPONENT Syntax

```
UNINSTALL COMPONENT component_name [, component_name ] ...
```

This statement deactivates and uninstalls one or more server components. It requires the `DELETE` privilege for the `mysql.component` system table. `UNINSTALL COMPONENT` is the complement of `INSTALL COMPONENT`.

A loader service also unregisters uninstalled components from the `mysql.component` system table. As a result, they are no longer installed during the startup sequence for subsequent server restarts.

If any error occurs, the statement fails and has no effect. For example, this happens if a component name is erroneous, a named component is not installed, or cannot be uninstalled because other installed components depend on it.

For information about component naming, see [Section 13.7.3.3, “INSTALL COMPONENT Syntax”](#).

Example:

```
UNINSTALL COMPONENT 'file://component2';
```

For additional information about components, see [Section 5.5, “MySQL Server Components”](#).

13.7.3.6 UNINSTALL PLUGIN Syntax

```
UNINSTALL PLUGIN plugin_name
```

This statement removes an installed server plugin. It requires the `DELETE` privilege for the `mysql.plugin` system table. `UNINSTALL PLUGIN` is the complement of `INSTALL PLUGIN`.

plugin_name must be the name of some plugin that is listed in the `mysql.plugin` table. The server executes the plugin's deinitialization function and removes the row for the plugin from the `mysql.plugin` table, so that subsequent server restarts will not load and initialize the plugin. `UNINSTALL PLUGIN` does not remove the plugin's shared library file.

You cannot uninstall a plugin if any table that uses it is open.

Plugin removal has implications for the use of associated tables. For example, if a full-text parser plugin is associated with a `FULLTEXT` index on the table, uninstalling the plugin makes the table unusable. Any attempt to access the table results in an error. The table cannot even be opened, so you cannot drop an index for which the plugin is used. This means that uninstalling a plugin is something to do with care unless you do not care about the table contents. If you are uninstalling a plugin with no intention of reinstalling it later and you care about the table contents, you should dump the table with `mysqldump` and remove the `WITH PARSER` clause from the dumped `CREATE TABLE` statement so that you can reload the table later. If you do not care about the table, `DROP TABLE` can be used even if any plugins associated with the table are missing.

For additional information about plugin loading, see [Section 5.6.2, “Installing and Uninstalling Plugins”](#).

13.7.4 SET Syntax

The `SET` statement has several forms:

- `SET var_name = value` enables you to assign values to variables that affect the operation of the server or clients. See [Section 13.7.4.1, “SET Syntax for Variable Assignment”](#).
- `SET CHARACTER SET` and `SET NAMES` assign values to character set and collation variables associated with the current connection to the server. See [Section 13.7.4.2, “SET CHARACTER SET Syntax”](#), and [Section 13.7.4.3, “SET NAMES Syntax”](#).
- `SET DEFAULT ROLE` and `SET ROLE` set the default role and current role for user accounts. See [Section 13.7.1.9, “SET DEFAULT ROLE Syntax”](#), and [Section 13.7.1.11, “SET ROLE Syntax”](#).

- `SET PASSWORD` assigns account passwords. See [Section 13.7.1.10, “SET PASSWORD Syntax”](#).
- `SET TRANSACTION ISOLATION LEVEL` sets the isolation level for transaction processing. See [Section 13.3.6, “SET TRANSACTION Syntax”](#).

13.7.4.1 SET Syntax for Variable Assignment

```
SET variable_assignment [, variable_assignment] ...

variable_assignment:
    user_var_name = expr
  | param_name = expr
  | local_var_name = expr
  | [GLOBAL | SESSION | PERSIST | PERSIST_ONLY]
    system_var_name = expr
  | [@@global. | @@session. | @@persist. | @@persist_only. | @@]
    system_var_name = expr
```

`SET` syntax for variable assignment enables you to assign values to different types of variables that affect the operation of the server or clients:

- System variables. See [Section 5.1.5, “Server System Variables”](#). System variables also can be set at server startup, as described in [Section 5.1.6, “Using System Variables”](#). (To *display* system variable names and values, use the `SHOW VARIABLES` statement; see [Section 13.7.5.39, “SHOW VARIABLES Syntax”](#).)
- User-defined variables. See [Section 9.4, “User-Defined Variables”](#).
- Stored procedure and function parameters, and stored program local variables. See [Section 13.6.4, “Variables in Stored Programs”](#).

A `SET` statement that assigns variable values is not written to the binary log, so in replication scenarios it affects only the host on which you execute it. To affect all replication hosts, execute the statement on each one.

The following examples illustrate `SET` syntax for setting variables. They use the `=` assignment operator, but the `:=` assignment operator is also permitted for this purpose.

A user variable is written as `@var_name` and is assigned an expression value as follows:

```
SET @var_name = expr;
```

Examples:

```
SET @name = 43;
SET @total_tax = (SELECT SUM(tax) FROM taxable_transactions);
```

As demonstrated by those statements, `expr` can range from simple (a literal value) to more complex (the value returned by a scalar subquery).

`SET` applies to parameters and local variables in the context of the stored object within which they are defined. The following procedure uses the `counter` local variable as a loop counter:

```
CREATE PROCEDURE p()
BEGIN
  DECLARE counter INT DEFAULT 0;
  WHILE counter < 10 DO
    -- ... do work ...
    SET counter = counter + 1;
  END WHILE;
```

```
END;
```

Many system variables are dynamic and can be changed at runtime by using the `SET` statement. For a list, see [Section 5.1.6.2, “Dynamic System Variables”](#). To change a system variable with `SET`, refer to it by name, optionally preceded by a modifier:

- To indicate that a variable is a global variable, precede its name by the `GLOBAL` keyword or the `@@global.` qualifier:

```
SET GLOBAL max_connections = 1000;
SET @@global.max_connections = 1000;
```

The `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege is required to set global variables.

- Another way to set a global variable is to precede its name by the `PERSIST` keyword or the `@@persist.` qualifier:

```
SET PERSIST max_connections = 1000;
SET @@persist.max_connections = 1000;
```

This `SET` syntax enables you to make configuration changes at runtime that also persist across server restarts. Like `SET GLOBAL`, `SET PERSIST` changes the runtime variable value, but also writes the variable setting to an option file named `mysqld-auto.cnf` in the data directory (replacing any existing variable setting if there is one). At startup, the server processes this file after all other option files. The `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege is required to persist global variables.

Note

Management of the `mysqld-auto.cnf` file should be left to the server and not performed manually:

- Removal of the file results in a loss of all persisted settings at the next server startup. (This is permissible if your intent is to reconfigure the server without these settings.) To remove all settings in the file without removing the file itself, use this statement:

```
RESET PERSIST;
```

- Manual changes to the file may result in a parse error at server startup. In this case, the server reports an error and exits. If this issue occurs, start the server with the `persisted_globals_load` system variable disabled or with the `--no-defaults` option. Alternatively, remove the `mysqld-auto.cnf` file, but, as noted previously, removing this file results in a loss of all persisted settings.

A plugin variable can be persisted if the plugin is installed when `SET PERSIST` is executed. Assignment of the persisted plugin variable takes effect for subsequent server restarts if the plugin is still installed. If the plugin is no longer installed, the plugin variable will not exist when the server reads the `mysqld-auto.cnf` file. In this case, the server writes a warning to the error log and continues:

```
currently unknown variable 'var_name'
was read from the persisted config file
```

- The `PERSIST_ONLY` keyword or `@@persist_only.` qualifier is similar to `PERSIST`:

```
SET PERSIST_ONLY back_log = 1000;
SET @@persist_only.back_log = 1000;
```

Like `PERSIST`, `PERSIST_ONLY` writes the variable setting to `mysqld-auto.cnf`. However, unlike `PERSIST`, `PERSIST_ONLY` does not modify the runtime global system variable value, making it suitable for configuring read-only system variables that can be set only at server startup. The `PERSIST_RO_VARIABLES_ADMIN` privilege is required to use `PERSIST_ONLY`.

`PERSIST_ONLY` was added in MySQL 8.0.2.

- To indicate that a variable is a session variable, precede its name by the `SESSION` keyword or either the `@@session.` or `@@` qualifier:

```
SET SESSION sql_mode = 'TRADITIONAL';
SET @@session.sql_mode = 'TRADITIONAL';
SET @@sql_mode = 'TRADITIONAL';
```

Setting a session variable normally requires no special privilege, although there are exceptions that require the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege (such as `sql_log_bin`). A client can change its own session variables, but not those of any other client.

Session-only system variables cannot be persisted. They cannot be set at server startup, so there is no reason to list them in `mysqld-auto.cnf`.

- `LOCAL` and `@@local.` are synonyms for `SESSION` and `@@session..`
- If no modifier is present, `SET` changes the session variable.
- An error occurs under these circumstances:
 - Use of `SET GLOBAL` (or `@@global.`), `SET PERSIST` (or `@@persist.`), or `SET PERSIST_ONLY` (or `@@persist_only.`), when setting a variable that has only a session value:

```
mysql> SET GLOBAL sql_log_bin = ON;
ERROR 1231 (42000): Variable 'sql_log_bin' can't be
set to the value of 'ON'
```

- Omission of `GLOBAL` (or `@@global.`), `PERSIST` (or `@@persist.`), or `PERSIST_ONLY` (or `@@persist_only.`) when setting a variable that has only a global value:

```
mysql> SET max_connections = 1000;
ERROR 1229 (HY000): Variable 'max_connections' is a
GLOBAL variable and should be set with SET GLOBAL
```

- Use of `SET SESSION` (or `@@SESSION.`) when setting a variable that has only a global value:

```
mysql> SET SESSION max_connections = 1000;
ERROR 1229 (HY000): Variable 'max_connections' is a
GLOBAL variable and should be set with SET GLOBAL
```

The preceding modifiers apply only to system variables. An error occurs for attempts to apply them to user-defined variables, stored procedure or function parameters, or stored program local variables.

A `SET` statement can contain multiple variable assignments, separated by commas. This statement assigns values to a user-defined variable and a system variable:

```
SET @x = 1, SESSION sql_mode = '';
```

If you set multiple system variables, the most recent `GLOBAL`, `PERSIST`, `PERSIST_ONLY`, or `SESSION` modifier in the statement is used for following assignments that have no modifier specified.

Examples of multiple-variable assignment:

```
SET GLOBAL sort_buffer_size = 1000000, SESSION sort_buffer_size = 1000000;
SET @@global.sort_buffer_size = 1000000, @@local.sort_buffer_size = 1000000;
SET GLOBAL max_connections = 1000, sort_buffer_size = 1000000;
```

If any variable assignment in a `SET` statement fails, the entire statement fails and no variables are changed, nor is the `mysqld-auto.cnf` file changed.

If you change a session system variable, the value remains in effect within your session until you change the variable to a different value or the session ends. The change has no effect on other sessions.

If you change a global system variable, the value is remembered and used for new sessions until you change the variable to a different value or the server exits. The change is visible to any client that accesses the global variable. However, the change affects the corresponding session variable only for clients that connect after the change. The global variable change does not affect the session variable for any current client sessions (not even the session within which the `SET GLOBAL` statement occurred).

To make a global system variable setting permanent so that it applies across server restarts, modify it with `SET PERSIST` or `PERSIST_ONLY` to record it in the `mysqld-auto.cnf` file. It is also possible to use `SET GLOBAL` and manually modify a `my.cnf` file, but that is more cumbersome, and an error in a manually entered setting might not be discovered until much later. `SET PERSIST` or `PERSIST_ONLY` is more convenient and avoids the possibility of malformed settings.

The Performance Schema `persisted_variables` table provides an SQL interface to the `mysqld-auto.cnf` file, enabling its contents to be inspected at runtime using `SELECT` statements. See [Section 25.11.13.1, “Performance Schema persisted_variables Table”](#).

The Performance Schema `variables_info` table contains information showing when and by which user each system variable was most recently set. See [Section 25.11.13.2, “Performance Schema variables_info Table”](#).

To set a `GLOBAL` value to the compiled-in MySQL default value or a `SESSION` variable to the current corresponding `GLOBAL` value, set the variable to the value `DEFAULT`. For example, the following two statements are identical in setting the session value of `max_join_size` to the current global value:

```
SET @@session.max_join_size=DEFAULT;
SET @@session.max_join_size=@@global.max_join_size;
```

Not all system variables can be set to `DEFAULT`. In such cases, assigning `DEFAULT` results in an error.

With `SET PERSIST` (or `@@persist.`), setting a global variable to `DEFAULT` or to its literal default value assigns the variable its default value and adds a setting for the variable to `mysqld-auto.cnf`. To remove the variable from the file, use `RESET PERSIST`.

An error occurs for attempts to assign `DEFAULT` to user-defined variables, stored procedure or function parameters, or stored program local variables.

To refer to the value of a system variable in expressions, use one of the `@@`-modifiers (except `@@persist.`, which is not permitted in expressions). For example, you can retrieve values in a `SELECT` statement like this:

```
SELECT @@global.sql_mode, @@session.sql_mode, @@sql_mode;
```

For a reference to a system variable in an expression as `@@var_name` (rather than with `@@global.` or `@@session.`), MySQL returns the session value if it exists and the global value otherwise. This differs from `SET @@var_name = expr`, which always refers to the session value.

13.7.4.2 SET CHARACTER SET Syntax

```
SET {CHARACTER SET | CHARSET}
    {'charset_name' | DEFAULT}
```

This statement maps all strings sent between the server and the current client with the given mapping. `SET CHARACTER SET` sets three session system variables: `character_set_client` and `character_set_results` are set to the given character set, and `character_set_connection` to the value of `character_set_database`. See [Section 10.1.4, “Connection Character Sets and Collations”](#).

`charset_name` may be quoted or unquoted.

The default character set mapping can be restored by using the value `DEFAULT`. The default depends on the server configuration.

`ucs2`, `utf16`, and `utf32` cannot be used as a client character set, which means that they do not work for `SET CHARACTER SET`.

13.7.4.3 SET NAMES Syntax

```
SET NAMES {'charset_name'
          [COLLATE 'collation_name'] | DEFAULT}
```

This statement sets the three session system variables `character_set_client`, `character_set_connection`, and `character_set_results` to the given character set. Setting `character_set_connection` to `charset_name` also sets `collation_connection` to the default collation for `charset_name`. See [Section 10.1.4, “Connection Character Sets and Collations”](#).

The optional `COLLATE` clause may be used to specify a collation explicitly. If given, the collation must be one of the permitted collations for `charset_name`.

`charset_name` and `collation_name` may be quoted or unquoted.

The default mapping can be restored by using a value of `DEFAULT`. The default depends on the server configuration.

`ucs2`, `utf16`, and `utf32` cannot be used as a client character set, which means that they do not work for `SET NAMES`.

13.7.5 SHOW Syntax

`SHOW` has many forms that provide information about databases, tables, columns, or status information about the server. This section describes those following:

```
SHOW {BINARY | MASTER} LOGS
SHOW BINLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
SHOW CHARACTER SET [like_or_where]
SHOW COLLATION [like_or_where]
SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [like_or_where]
SHOW CREATE DATABASE db_name
SHOW CREATE EVENT event_name
SHOW CREATE FUNCTION func_name
SHOW CREATE PROCEDURE proc_name
SHOW CREATE TABLE tbl_name
SHOW CREATE TRIGGER trigger_name
SHOW CREATE VIEW view_name
SHOW DATABASES [like_or_where]
SHOW ENGINE engine_name {STATUS | MUTEX}
SHOW [STORAGE] ENGINES
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW EVENTS
SHOW FUNCTION CODE func_name
SHOW FUNCTION STATUS [like_or_where]
```

```

SHOW GRANTS FOR user
SHOW INDEX FROM tbl_name [FROM db_name]
SHOW MASTER STATUS
SHOW OPEN TABLES [FROM db_name] [like_or_where]
SHOW PLUGINS
SHOW PROCEDURE CODE proc_name
SHOW PROCEDURE STATUS [like_or_where]
SHOW PRIVILEGES
SHOW [FULL] PROCESSLIST
SHOW PROFILE [types] [FOR QUERY n] [OFFSET n] [LIMIT n]
SHOW PROFILES
SHOW RELAYLOG EVENTS [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
SHOW SLAVE HOSTS
SHOW SLAVE STATUS [FOR CHANNEL channel]
SHOW [GLOBAL | SESSION] STATUS [like_or_where]
SHOW TABLE STATUS [FROM db_name] [like_or_where]
SHOW [FULL] TABLES [FROM db_name] [like_or_where]
SHOW TRIGGERS [FROM db_name] [like_or_where]
SHOW [GLOBAL | SESSION] VARIABLES [like_or_where]
SHOW WARNINGS [LIMIT [offset,] row_count]

like_or_where:
    LIKE 'pattern'
    | WHERE expr

```

If the syntax for a given `SHOW` statement includes a `LIKE 'pattern'` part, '*pattern*' is a string that can contain the SQL `%` and `_` wildcard characters. The pattern is useful for restricting statement output to matching values.

Several `SHOW` statements also accept a `WHERE` clause that provides more flexibility in specifying which rows to display. See [Section 24.33, "Extensions to SHOW Statements"](#).

Many MySQL APIs (such as PHP) enable you to treat the result returned from a `SHOW` statement as you would a result set from a `SELECT`; see [Chapter 27, Connectors and APIs](#), or your API documentation for more information. In addition, you can work in SQL with results from queries on tables in the `INFORMATION_SCHEMA` database, which you cannot easily do with results from `SHOW` statements. See [Chapter 24, INFORMATION_SCHEMA Tables](#).

13.7.5.1 SHOW BINARY LOGS Syntax

```

SHOW BINARY LOGS
SHOW MASTER LOGS

```

Lists the binary log files on the server. This statement is used as part of the procedure described in [Section 13.4.1.1, "PURGE BINARY LOGS Syntax"](#), that shows how to determine which logs can be purged.

```

mysql> SHOW BINARY LOGS;
+-----+-----+
| Log_name          | File_size |
+-----+-----+
| binlog.000015    | 724935   |
| binlog.000016    | 733481   |
+-----+-----+

```

`SHOW MASTER LOGS` is equivalent to `SHOW BINARY LOGS`.

A user with the `SUPER` or `REPLICATION CLIENT` privilege may execute this statement.

13.7.5.2 SHOW BINLOG EVENTS Syntax

```

SHOW BINLOG EVENTS
  [IN 'log_name' ]
  [FROM pos]

```

```
[LIMIT [offset,] row_count]
```

Shows the events in the binary log. If you do not specify '*log_name*', the first binary log is displayed.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See [Section 13.2.10, “SELECT Syntax”](#).

Note

Issuing a `SHOW BINLOG EVENTS` with no `LIMIT` clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the binary log (which includes all statements executed by the server that modify data). As an alternative to `SHOW BINLOG EVENTS`, use the `mysqlbinlog` utility to save the binary log to a text file for later examination and analysis. See [Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”](#).

Note

Some events relating to the setting of user and system variables are not included in the output from `SHOW BINLOG EVENTS`. To get complete coverage of events within a binary log, use `mysqlbinlog`.

Note

`SHOW BINLOG EVENTS` does *not* work with relay log files. You can use `SHOW RELAYLOG EVENTS` for this purpose.

13.7.5.3 SHOW CHARACTER SET Syntax

```
SHOW CHARACTER SET
  [LIKE 'pattern' | WHERE expr]
```

The `SHOW CHARACTER SET` statement shows all available character sets. The `LIKE` clause, if present, indicates which character set names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 24.33, “Extensions to SHOW Statements”](#). For example:

```
mysql> SHOW CHARACTER SET LIKE 'latin%';
+-----+-----+-----+-----+
| Charset | Description | Default collation | Maxlen |
+-----+-----+-----+-----+
| latin1  | cp1252 West European | latin1_swedish_ci | 1 |
| latin2  | ISO 8859-2 Central European | latin2_general_ci | 1 |
| latin5  | ISO 8859-9 Turkish | latin5_turkish_ci | 1 |
| latin7  | ISO 8859-13 Baltic | latin7_general_ci | 1 |
+-----+-----+-----+-----+
```

The `Maxlen` column shows the maximum number of bytes required to store one character.

The `filename` character set is for internal use only; consequently, `SHOW CHARACTER SET` does not display it.

You can also obtain information about character sets from `INFORMATION_SCHEMA`, which contains a `CHARACTER_SETS` table. See [Section 24.1, “The INFORMATION_SCHEMA CHARACTER_SETS Table”](#).

13.7.5.4 SHOW COLLATION Syntax

```
SHOW COLLATION
  [LIKE 'pattern' | WHERE expr]
```

This statement lists collations supported by the server. By default, the output from `SHOW COLLATION` includes all available collations. The `LIKE` clause, if present, indicates which collation names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 24.33, “Extensions to SHOW Statements”](#). For example:

```
mysql> SHOW COLLATION WHERE Charset = 'latin1';
```

Collation	Charset	Id	Default	Compiled	Sortlen
latin1_german1_ci	latin1	5		Yes	1
latin1_swedish_ci	latin1	8	Yes	Yes	1
latin1_danish_ci	latin1	15		Yes	1
latin1_german2_ci	latin1	31		Yes	2
latin1_bin	latin1	47		Yes	1
latin1_general_ci	latin1	48		Yes	1
latin1_general_cs	latin1	49		Yes	1
latin1_spanish_ci	latin1	94		Yes	1

The `Collation` and `Charset` columns indicate the names of the collation and the character set with which it is associated. `Id` is the collation ID. `Default` indicates whether the collation is the default for its character set. `Compiled` indicates whether the character set is compiled into the server. `Sortlen` is related to the amount of memory required to sort strings expressed in the character set.

To see the default collation for each character set, use the following statement. `Default` is a reserved word, so to use it as an identifier, it must be quoted as such:

```
mysql> SHOW COLLATION WHERE `Default` = 'Yes';
```

Collation	Charset	Id	Default	Compiled	Sortlen
big5_chinese_ci	big5	1	Yes	Yes	1
dec8_swedish_ci	dec8	3	Yes	Yes	1
cp850_general_ci	cp850	4	Yes	Yes	1
hp8_english_ci	hp8	6	Yes	Yes	1
koi8r_general_ci	koi8r	7	Yes	Yes	1
latin1_swedish_ci	latin1	8	Yes	Yes	1

...

You can also obtain information about collations from `INFORMATION_SCHEMA`, which contains a `COLLATIONS` table. See [Section 24.2, “The INFORMATION_SCHEMA COLLATIONS Table”](#).

13.7.5.5 SHOW COLUMNS Syntax

```
SHOW [EXTENDED] [FULL] {COLUMNS | FIELDS}
  {FROM | IN} tbl_name
  [{FROM | IN} db_name]
  [LIKE 'pattern' | WHERE expr]
```

`SHOW COLUMNS` displays information about the columns in a given table. It also works for views. `SHOW COLUMNS` displays information only for those columns for which you have some privilege.

You can use `db_name.tbl_name` as an alternative to the `tbl_name FROM db_name` syntax. In other words, these two statements are equivalent:

```
SHOW COLUMNS FROM mytable FROM mydb;
SHOW COLUMNS FROM mydb.mytable;
```

As of MySQL 8.0.2, the optional `EXTENDED` keyword causes the output to include information about hidden columns that MySQL uses internally and are not accessible by users.

The optional `FULL` keyword causes the output to include the column collation and comments, as well as the privileges you have for each column.

The `LIKE` clause, if present, indicates which column names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 24.33, “Extensions to SHOW Statements”](#).

```
mysql> SHOW COLUMNS FROM City;
```

Field	Type	Null	Key	Default	Extra
ID	int(11)	NO	PRI	NULL	auto_increment
Name	char(35)	NO			
CountryCode	char(3)	NO	MUL		
District	char(20)	NO			
Population	int(11)	NO		0	

The data types may differ from what you expect them to be based on a `CREATE TABLE` statement because MySQL sometimes changes data types when you create or alter a table. The conditions under which this occurs are described in [Section 13.1.15.7, “Silent Column Specification Changes”](#).

`SHOW COLUMNS` displays the following values for each table column:

- `Field`

The column name.

- `Type`

The column data type.

- `Collation`

The collation for nonbinary string columns, or `NULL` for other columns. This value is displayed only if you use the `FULL` keyword.

- `Null`

Column nullability. The value is `YES` if `NULL` values can be stored in the column, `NO` if not.

- `Key`

Whether the column is indexed:

- If `Key` is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, nonunique index.
- If `Key` is `PRI`, the column is a `PRIMARY KEY` or is one of the columns in a multiple-column `PRIMARY KEY`.
- If `Key` is `UNI`, the column is the first column of a `UNIQUE` index. (A `UNIQUE` index permits multiple `NULL` values, but you can tell whether the column permits `NULL` by checking the `Null` field.)
- If `Key` is `MUL`, the column is the first column of a nonunique index in which multiple occurrences of a given value are permitted within the column.

If more than one of the `Key` values applies to a given column of a table, `Key` displays the one with the highest priority, in the order `PRI`, `UNI`, `MUL`.

A `UNIQUE` index may be displayed as `PRI` if it cannot contain `NULL` values and there is no `PRIMARY KEY` in the table. A `UNIQUE` index may display as `MUL` if several columns form a composite `UNIQUE` index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.

- `Default`

The default value for the column. This is `NULL` if the column has an explicit default of `NULL`, or if the column definition includes no `DEFAULT` clause.

- `Extra`

Any additional information that is available about a given column. The value is nonempty in these cases:

- `auto_increment` for columns that have the `AUTO_INCREMENT` attribute
- `on update CURRENT_TIMESTAMP` for `TIMESTAMP` or `DATETIME` columns that have the `ON UPDATE CURRENT_TIMESTAMP` attribute
- `VIRTUAL GENERATED` or `VIRTUAL STORED` for generated columns

- `Privileges`

The privileges you have for the column. This value is displayed only if you use the `FULL` keyword.

- `Comment`

Any comment included in the column definition. This value is displayed only if you use the `FULL` keyword.

You can also obtain information about table columns from `INFORMATION_SCHEMA`, which contains a `COLUMNS` table. See [Section 24.4, “The INFORMATION_SCHEMA COLUMNS Table”](#). The extended information about hidden columns is available only using `SHOW EXTENDED COLUMNS`; it cannot be obtained from the `COLUMNS` table.

You can list a table's columns with the `mysqlshow db_name tbl_name` command.

The `DESCRIBE` statement provides information similar to `SHOW COLUMNS`. See [Section 13.8.1, “DESCRIBE Syntax”](#).

The `SHOW CREATE TABLE`, `SHOW TABLE STATUS`, and `SHOW INDEX` statements also provide information about tables. See [Section 13.7.5, “SHOW Syntax”](#).

13.7.5.6 SHOW CREATE DATABASE Syntax

```
SHOW CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
```

Shows the `CREATE DATABASE` statement that creates the named database. If the `SHOW` statement includes an `IF NOT EXISTS` clause, the output too includes such a clause. `SHOW CREATE SCHEMA` is a synonym for `SHOW CREATE DATABASE`.

```
mysql> SHOW CREATE DATABASE test\G
***** 1. row *****
    Database: test
Create Database: CREATE DATABASE `test`
                  /*!40100 DEFAULT CHARACTER SET utf8mb4 */

mysql> SHOW CREATE SCHEMA test\G
***** 1. row *****
    Database: test
Create Database: CREATE DATABASE `test`
                  /*!40100 DEFAULT CHARACTER SET utf8mb4 */
```

`SHOW CREATE DATABASE` quotes table and column names according to the value of the `sql_quote_show_create` option. See [Section 5.1.5, “Server System Variables”](#).

13.7.5.7 SHOW CREATE EVENT Syntax

```
SHOW CREATE EVENT event_name
```

This statement displays the `CREATE EVENT` statement needed to re-create a given event. It requires the `EVENT` privilege for the database from which the event is to be shown. For example (using the same event `e_daily` defined and then altered in [Section 13.7.5.18, “SHOW EVENTS Syntax”](#)):

```
mysql> SHOW CREATE EVENT test.e_daily\G
***** 1. row *****
      Event: e_daily
      sql_mode:
      time_zone: SYSTEM
      Create Event: CREATE EVENT `e_daily`
                    ON SCHEDULE EVERY 1 DAY
                    STARTS CURRENT_TIMESTAMP + INTERVAL 6 HOUR
                    ON COMPLETION NOT PRESERVE
                    ENABLE
                    COMMENT 'Saves total number of sessions then
                        clears the table each day'
                    DO BEGIN
                        INSERT INTO site_activity.totals (time, total)
                        SELECT CURRENT_TIMESTAMP, COUNT(*)
                        FROM site_activity.sessions;
                        DELETE FROM site_activity.sessions;
                    END
      character_set_client: utf8
      collation_connection: utf8_general_ci
      Database Collation: utf8mb4_0900_ai_ci
```

`character_set_client` is the session value of the `character_set_client` system variable when the event was created. `collation_connection` is the session value of the `collation_connection` system variable when the event was created. `Database Collation` is the collation of the database with which the event is associated.

The output reflects the current status of the event (`ENABLE`) rather than the status with which it was created.

13.7.5.8 SHOW CREATE FUNCTION Syntax

```
SHOW CREATE FUNCTION func_name
```

This statement is similar to `SHOW CREATE PROCEDURE` but for stored functions. See [Section 13.7.5.9, “SHOW CREATE PROCEDURE Syntax”](#).

13.7.5.9 SHOW CREATE PROCEDURE Syntax

```
SHOW CREATE PROCEDURE proc_name
```

This statement is a MySQL extension. It returns the exact string that can be used to re-create the named stored procedure. A similar statement, `SHOW CREATE FUNCTION`, displays information about stored functions (see [Section 13.7.5.8, “SHOW CREATE FUNCTION Syntax”](#)).

To use either statement, you must have the global `SELECT` privilege.

```
mysql> SHOW CREATE PROCEDURE test.simpleproc\G
***** 1. row *****
      Procedure: simpleproc
      sql_mode:
      Create Procedure: CREATE PROCEDURE `simpleproc` (OUT param1 INT)
                        BEGIN
                        SELECT COUNT(*) INTO param1 FROM t;
                        END
      character_set_client: utf8
      collation_connection: utf8_general_ci
```

```

Database Collation: utf8mb4_0900_ai_ci

mysql> SHOW CREATE FUNCTION test.hello\G
***** 1. row *****
      Function: hello
      sql_mode:
      Create Function: CREATE FUNCTION `hello`(s CHAR(20))
                       RETURNS CHAR(50)
                       RETURN CONCAT('Hello, ',s, '!')
character_set_client: utf8
collation_connection: utf8_general_ci
Database Collation: utf8mb4_0900_ai_ci

```

`character_set_client` is the session value of the `character_set_client` system variable when the routine was created. `collation_connection` is the session value of the `collation_connection` system variable when the routine was created. `Database Collation` is the collation of the database with which the routine is associated.

13.7.5.10 SHOW CREATE TABLE Syntax

```
SHOW CREATE TABLE tbl_name
```

Shows the `CREATE TABLE` statement that creates the named table. To use this statement, you must have some privilege for the table. This statement also works with views.

```

mysql> SHOW CREATE TABLE t\G
***** 1. row *****
      Table: t
      Create Table: CREATE TABLE `t` (
        `id` int(11) NOT NULL AUTO_INCREMENT,
        `s` char(60) DEFAULT NULL,
        PRIMARY KEY (`id`)
      ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4

```

`SHOW CREATE TABLE` quotes table and column names according to the value of the `sql_quote_show_create` option. See [Section 5.1.5, “Server System Variables”](#).

13.7.5.11 SHOW CREATE TRIGGER Syntax

```
SHOW CREATE TRIGGER trigger_name
```

This statement shows the `CREATE TRIGGER` statement that creates the named trigger. This statement requires the `TRIGGER` privilege for the table associated with the trigger.

```

mysql> SHOW CREATE TRIGGER ins_sum\G
***** 1. row *****
      Trigger: ins_sum
      sql_mode: STRICT_TRANS_TABLES,NO_ENGINE_SUBSTITUTION
      SQL Original Statement: CREATE DEFINER=`me`@`localhost` TRIGGER ins_sum
                             BEFORE INSERT ON account
                             FOR EACH ROW SET @sum = @sum + NEW.amount
character_set_client: utf8
collation_connection: utf8_general_ci
Database Collation: utf8mb4_0900_ai_ci
Created: 2013-07-09 10:39:34.96

```

`SHOW CREATE TRIGGER` output has the following columns:

- `Trigger`: The trigger name.
- `sql_mode`: The SQL mode in effect when the trigger executes.
- `SQL Original Statement`: The `CREATE TRIGGER` statement that defines the trigger.

- `character_set_client`: The session value of the `character_set_client` system variable when the trigger was created.
- `collation_connection`: The session value of the `collation_connection` system variable when the trigger was created.
- `Database Collation`: The collation of the database with which the trigger is associated.
- `Created`: The date and time when the trigger was created. This is a `TIMESTAMP(2)` value (with a fractional part in hundredths of seconds) for triggers.

You can also obtain information about trigger objects from `INFORMATION_SCHEMA`, which contains a `TRIGGERS` table. See [Section 24.28, “The INFORMATION_SCHEMA TRIGGERS Table”](#).

13.7.5.12 SHOW CREATE USER Syntax

```
SHOW CREATE USER user
```

This statement shows the `CREATE USER` statement that creates the named user. An error occurs if the user does not exist. The statement requires the `SELECT` privilege for the `mysql` database, except to see information for the current user.

To name the account, use the format described in [Section 6.2.4, “Specifying Account Names”](#). The host name part of the account name, if omitted, defaults to `'%'`. It is also possible to specify `CURRENT_USER` or `CURRENT_USER()` to refer to the account associated with the current session.

```
mysql> SHOW CREATE USER 'root'@'localhost'\G
***** 1. row *****
CREATE USER for root@localhost: CREATE USER 'root'@'localhost'
IDENTIFIED WITH 'mysql_native_password'
AS '*2470C0C06DEE42FD1618BB99005ADCA2EC9D1E19'
REQUIRE NONE PASSWORD EXPIRE DEFAULT ACCOUNT UNLOCK
```

The output format is affected by the setting of the `log_built_in_as_identified_by_password` system variable.

To display the privileges granted to an account, use the `SHOW GRANTS` statement. See [Section 13.7.5.21, “SHOW GRANTS Syntax”](#).

13.7.5.13 SHOW CREATE VIEW Syntax

```
SHOW CREATE VIEW view_name
```

This statement shows the `CREATE VIEW` statement that creates the named view.

```
mysql> SHOW CREATE VIEW v\G
***** 1. row *****
View: v
Create View: CREATE ALGORITHM=UNDEFINED
DEFINER='bob'@'localhost'
SQL SECURITY DEFINER VIEW
`v` AS select 1 AS `a`,2 AS `b`
character_set_client: utf8
collation_connection: utf8_general_ci
```

`character_set_client` is the session value of the `character_set_client` system variable when the view was created. `collation_connection` is the session value of the `collation_connection` system variable when the view was created.

Use of `SHOW CREATE VIEW` requires the `SHOW VIEW` privilege, and the `SELECT` privilege for the view in question.

You can also obtain information about view objects from `INFORMATION_SCHEMA`, which contains a `VIEWS` table. See [Section 24.30, “The INFORMATION_SCHEMA VIEWS Table”](#).

MySQL lets you use different `sql_mode` settings to tell the server the type of SQL syntax to support. For example, you might use the `ANSI` SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (`||`), in your queries. If you then create a view that concatenates items, you might worry that changing the `sql_mode` setting to a value different from `ANSI` could cause the view to become invalid. But this is not the case. No matter how you write out a view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a `CONCAT()` function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as coll;
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW CREATE VIEW test.v\G
***** 1. row *****
View: v
Create View: CREATE VIEW "v" AS select concat('a','b') AS "coll"
...
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of `sql_mode` will not affect the results from the view. However an additional consequence is that comments prior to `SELECT` are stripped from the definition by the server.

13.7.5.14 SHOW DATABASES Syntax

```
SHOW {DATABASES | SCHEMAS}
    [LIKE 'pattern' | WHERE expr]
```

`SHOW DATABASES` lists the databases on the MySQL server host. `SHOW SCHEMAS` is a synonym for `SHOW DATABASES`. The `LIKE` clause, if present, indicates which database names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 24.33, “Extensions to SHOW Statements”](#).

You see only those databases for which you have some kind of privilege, unless you have the global `SHOW DATABASES` privilege. You can also get this list using the `mysqlshow` command.

If the server was started with the `--skip-show-database` option, you cannot use this statement at all unless you have the `SHOW DATABASES` privilege.

MySQL implements databases as directories in the data directory, so this statement simply lists directories in that location. However, the output may include names of directories that do not correspond to actual databases.

13.7.5.15 SHOW ENGINE Syntax

```
SHOW ENGINE engine_name {STATUS | MUTEX}
```

`SHOW ENGINE` displays operational information about a storage engine. It requires the `PROCESS` privilege. The statement has these variants:

```
SHOW ENGINE INNODB STATUS
SHOW ENGINE INNODB MUTEX
SHOW ENGINE PERFORMANCE_SCHEMA STATUS
```

`SHOW ENGINE INNODB STATUS` displays extensive information from the standard `InnoDB` Monitor about the state of the `InnoDB` storage engine. For information about the standard monitor and other

InnoDB Monitors that provide information about InnoDB processing, see [Section 15.16, “InnoDB Monitors”](#).

`SHOW ENGINE INNODB MUTEX` displays InnoDB mutex and rw-lock statistics.

Note

InnoDB mutexes and rwlocks can also be monitored using [Performance Schema](#) tables. See [Section 15.15.2, “Monitoring InnoDB Mutex Waits Using Performance Schema”](#).

Mutex statistics collection is configured dynamically using the following options:

- To enable the collection of mutex statistics, run:

```
SET GLOBAL innodb_monitor_enable='latch';
```

- To reset mutex statistics, run:

```
SET GLOBAL innodb_monitor_reset='latch';
```

- To disable the collection of mutex statistics, run:

```
SET GLOBAL innodb_monitor_disable='latch';
```

Collection of mutex statistics for `SHOW ENGINE INNODB MUTEX` can also be enabled by setting `innodb_monitor_enable='all'`, or disabled by setting `innodb_monitor_disable='all'`.

`SHOW ENGINE INNODB MUTEX` output has the following columns:

- Type**

Always InnoDB.

- Name**

For mutexes, the `Name` field reports only the mutex name. For rwlocks, the `Name` field reports the source file where the rwlock is implemented, and the line number in the file where the rwlock is created. The line number is specific to your version of MySQL.

- Status**

The mutex status. This field reports the number of spins, waits, and calls. Statistics for low-level operating system mutexes, which are implemented outside of InnoDB, are not reported.

- `spins` indicates the number of spins.
- `waits` indicates the number of mutex waits.
- `calls` indicates how many times the mutex was requested.

`SHOW ENGINE INNODB MUTEX` skips the `mutexes` and `rw-locks` of `buffer pool` blocks, as the amount of output can be overwhelming on systems with a large buffer pool. (There is one mutex and one rw-lock in each 16K buffer pool block, and there are 65,536 blocks per gigabyte.) `SHOW ENGINE INNODB MUTEX` also does not list any mutexes or rw-locks that have never been waited on (`os_waits=0`). Thus, `SHOW ENGINE INNODB MUTEX` only displays information about mutexes and rw-locks outside of the buffer pool that have caused at least one OS-level `wait`.

Use `SHOW ENGINE PERFORMANCE_SCHEMA STATUS` to inspect the internal operation of the Performance Schema code:

```
mysql> SHOW ENGINE PERFORMANCE_SCHEMA STATUS\G
...
```

```

***** 3. row *****
  Type: performance_schema
  Name: events_waits_history.size
Status: 76
***** 4. row *****
  Type: performance_schema
  Name: events_waits_history.count
Status: 10000
***** 5. row *****
  Type: performance_schema
  Name: events_waits_history.memory
Status: 760000
...
***** 57. row *****
  Type: performance_schema
  Name: performance_schema.memory
Status: 26459600
...

```

This statement is intended to help the DBA understand the effects that different Performance Schema options have on memory requirements.

Name values consist of two parts, which name an internal buffer and a buffer attribute, respectively. Interpret buffer names as follows:

- An internal buffer that is not exposed as a table is named within parentheses. Examples: `(pfs_cond_class).size`, `(pfs_mutex_class).memory`.
- An internal buffer that is exposed as a table in the `performance_schema` database is named after the table, without parentheses. Examples: `events_waits_history.size`, `mutex_instances.count`.
- A value that applies to the Performance Schema as a whole begins with `performance_schema`. Example: `performance_schema.memory`.

Buffer attributes have these meanings:

- `size` is the size of the internal record used by the implementation, such as the size of a row in a table. `size` values cannot be changed.
- `count` is the number of internal records, such as the number of rows in a table. `count` values can be changed using Performance Schema configuration options.
- For a table, `tbl_name.memory` is the product of `size` and `count`. For the Performance Schema as a whole, `performance_schema.memory` is the sum of all the memory used (the sum of all other `memory` values).

In some cases, there is a direct relationship between a Performance Schema configuration parameter and a `SHOW ENGINE` value. For example, `events_waits_history_long.count` corresponds to `performance_schema_events_waits_history_long.size`. In other cases, the relationship is more complex. For example, `events_waits_history.count` corresponds to `performance_schema_events_waits_history_size` (the number of rows per thread) multiplied by `performance_schema_max_thread_instances` (the number of threads).

13.7.5.16 SHOW ENGINES Syntax

```
SHOW [STORAGE] ENGINES
```

`SHOW ENGINES` displays status information about the server's storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is. This information can also be obtained from the `INFORMATION_SCHEMA.ENGINES` table. See [Section 24.7, "The INFORMATION_SCHEMA.ENGINES Table"](#).

```
mysql> SHOW ENGINES\G
```

```

***** 1. row *****
  Engine: InnoDB
  Support: DEFAULT
  Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
  XA: YES
  Savepoints: YES
***** 2. row *****
  Engine: MRG_MYISAM
  Support: YES
  Comment: Collection of identical MyISAM tables
Transactions: NO
  XA: NO
  Savepoints: NO
***** 3. row *****
  Engine: MEMORY
  Support: YES
  Comment: Hash based, stored in memory, useful for temporary tables
Transactions: NO
  XA: NO
  Savepoints: NO
***** 4. row *****
  Engine: BLACKHOLE
  Support: YES
  Comment: /dev/null storage engine (anything you write to it disappears)
Transactions: NO
  XA: NO
  Savepoints: NO
***** 5. row *****
  Engine: MyISAM
  Support: YES
  Comment: MyISAM storage engine
Transactions: NO
  XA: NO
  Savepoints: NO
***** 6. row *****
  Engine: CSV
  Support: YES
  Comment: CSV storage engine
Transactions: NO
  XA: NO
  Savepoints: NO
***** 7. row *****
  Engine: ARCHIVE
  Support: YES
  Comment: Archive storage engine
Transactions: NO
  XA: NO
  Savepoints: NO
***** 8. row *****
  Engine: PERFORMANCE_SCHEMA
  Support: YES
  Comment: Performance Schema
Transactions: NO
  XA: NO
  Savepoints: NO
***** 9. row *****
  Engine: FEDERATED
  Support: YES
  Comment: Federated MySQL storage engine
Transactions: NO
  XA: NO
  Savepoints: NO

```

The output from `SHOW ENGINES` may vary according to the MySQL version used and other factors. The values shown in the `Support` column indicate the server's level of support for the storage engine, as shown in the following table.

Value	Meaning
YES	The engine is supported and is active

Value	Meaning
DEFAULT	Like YES , plus this is the default engine
NO	The engine is not supported
DISABLED	The engine is supported but has been disabled

A value of [NO](#) means that the server was compiled without support for the engine, so it cannot be enabled at runtime.

A value of [DISABLED](#) occurs either because the server was started with an option that disables the engine, or because not all options required to enable it were given. In the latter case, the error log file should contain a reason indicating why the option is disabled. See [Section 5.4.2, “The Error Log”](#).

You might also see [DISABLED](#) for a storage engine if the server was compiled to support it, but was started with a `--skip-engine_name` option.

All MySQL servers support [MyISAM](#) tables. It is not possible to disable [MyISAM](#).

The [Transactions](#), [XA](#), and [Savepoints](#) columns indicate whether the storage engine supports transactions, XA transactions, and savepoints, respectively.

13.7.5.17 SHOW ERRORS Syntax

```
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW COUNT(*) ERRORS
```

[SHOW ERRORS](#) is a diagnostic statement that is similar to [SHOW WARNINGS](#), except that it displays information only for errors, rather than for errors, warnings, and notes.

The [LIMIT](#) clause has the same syntax as for the [SELECT](#) statement. See [Section 13.2.10, “SELECT Syntax”](#).

The [SHOW COUNT\(*\) ERRORS](#) statement displays the number of errors. You can also retrieve this number from the [error_count](#) variable:

```
SHOW COUNT(*) ERRORS;
SELECT @@error_count;
```

[SHOW ERRORS](#) and [error_count](#) apply only to errors, not warnings or notes. In other respects, they are similar to [SHOW WARNINGS](#) and [warning_count](#). In particular, [SHOW ERRORS](#) cannot display information for more than [max_error_count](#) messages, and [error_count](#) can exceed the value of [max_error_count](#) if the number of errors exceeds [max_error_count](#).

For more information, see [Section 13.7.5.40, “SHOW WARNINGS Syntax”](#).

13.7.5.18 SHOW EVENTS Syntax

```
SHOW EVENTS
  [{FROM | IN} schema_name]
  [LIKE 'pattern' | WHERE expr]
```

This statement displays information about Event Manager events. It requires the [EVENT](#) privilege for the database from which the events are to be shown.

In its simplest form, [SHOW EVENTS](#) lists all of the events in the current schema:

```
mysql> SELECT CURRENT_USER(), SCHEMA();
```

```

+-----+-----+
| CURRENT_USER() | SCHEMA() |
+-----+-----+
| jon@ghidora    | myschema  |
+-----+-----+
1 row in set (0.00 sec)

mysql> SHOW EVENTS\G
***** 1. row *****
      Db: myschema
      Name: e_daily
      Definer: jon@ghidora
      Time zone: SYSTEM
      Type: RECURRING
      Execute at: NULL
      Interval value: 10
      Interval field: SECOND
      Starts: 2006-02-09 10:41:23
      Ends: NULL
      Status: ENABLED
      Originator: 0
character_set_client: utf8
collation_connection: utf8_general_ci
Database Collation: utf8mb4_0900_ai_ci

```

To see events for a specific schema, use the `FROM` clause. For example, to see events for the `test` schema, use the following statement:

```
SHOW EVENTS FROM test;
```

The `LIKE` clause, if present, indicates which event names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 24.33, “Extensions to SHOW Statements”](#).

`SHOW EVENTS` output has the following columns:

- **Db:** The schema (database) on which the event is defined.
- **Name:** The name of the event.
- **Time zone:** The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is `SYSTEM`.
- **Definer:** The account of the user who created the event, in `'user_name'@'host_name'` format.
- **Type:** The event repetition type, either `ONE TIME` (transient) or `RECURRING` (repeating).
- **Execute At:** The date and time when a transient event is set to execute. Shown as a `DATETIME` value.

For a recurring event, the value of this column is always `NULL`.

- **Interval Value:** For a recurring event, the number of intervals to wait between event executions.

For a transient event, the value of this column is always `NULL`.

- **Interval Field:** The time units used for the interval which a recurring event waits before repeating.

For a transient event, the value of this column is always `NULL`.

- **Starts:** The start date and time for a recurring event. This is displayed as a `DATETIME` value, and is `NULL` if no start date and time are defined for the event.

For a transient event, this column is always `NULL`.

- **Ends:** The end date and time for a recurring event. This is displayed as a `DATETIME` value, and defaults to `NULL` if no end date and time is defined for the event.

For a transient event, this column is always `NULL`.

- **Status:** The event status. One of `ENABLED`, `DISABLED`, or `SLAVESIDE_DISABLED`.

`SLAVESIDE_DISABLED` indicates that the creation of the event occurred on another MySQL server acting as a replication master and replicated to the current MySQL server which is acting as a slave, but the event is not presently being executed on the slave.

- **Originator:** The server ID of the MySQL server on which the event was created. Defaults to 0.
- `character_set_client` is the session value of the `character_set_client` system variable when the routine was created. `collation_connection` is the session value of the `collation_connection` system variable when the routine was created. `Database Collation` is the collation of the database with which the routine is associated.

For more information about `SLAVE_DISABLED` and the `Originator` column, see [Section 18.4.1.12, “Replication of Invoked Features”](#).

The event action statement is not shown in the output of `SHOW EVENTS`. Use `SHOW CREATE EVENT` or the `INFORMATION_SCHEMA.EVENTS` table.

Times displayed by `SHOW EVENTS` are given in the event time zone, as discussed in [Section 23.4.4, “Event Metadata”](#).

The columns in the output of `SHOW EVENTS` are similar to, but not identical to the columns in the `INFORMATION_SCHEMA.EVENTS` table. See [Section 24.8, “The INFORMATION_SCHEMA EVENTS Table”](#).

13.7.5.19 SHOW FUNCTION CODE Syntax

```
SHOW FUNCTION CODE func_name
```

This statement is similar to `SHOW PROCEDURE CODE` but for stored functions. See [Section 13.7.5.27, “SHOW PROCEDURE CODE Syntax”](#).

13.7.5.20 SHOW FUNCTION STATUS Syntax

```
SHOW FUNCTION STATUS
  [LIKE 'pattern' | WHERE expr]
```

This statement is similar to `SHOW PROCEDURE STATUS` but for stored functions. See [Section 13.7.5.28, “SHOW PROCEDURE STATUS Syntax”](#).

13.7.5.21 SHOW GRANTS Syntax

```
SHOW GRANTS
  [FOR user_or_role
  [USING user [, user] ...]]

user_or_role: {
  user
  | role
}
```

This statement displays the privileges and roles that are assigned to a MySQL user account or role, in the form of `GRANT` statements that must be executed to duplicate the privilege and role assignments.

**Note**

To display nonprivilege information for MySQL accounts, use the `SHOW CREATE USER` statement. See [Section 13.7.5.12, “SHOW CREATE USER Syntax”](#).

`SHOW GRANTS` requires the `SELECT` privilege for the `mysql` database, except to display privileges for the current user. The `USING` clause requires the `SUPER` privilege, except to display information for the current user.

To name the account or role for `SHOW GRANTS`, use the same format as for the `GRANT` statement; for example, `'root'@'localhost'`:

```
mysql> SHOW GRANTS FOR 'root'@'localhost';
+-----+
| Grants for root@localhost |
+-----+
| GRANT ALL PRIVILEGES ON *.* TO 'root'@'localhost' WITH GRANT OPTION |
+-----+
```

The host part, if omitted, defaults to `'%'`. For additional information about specifying account and role names, see [Section 6.2.4, “Specifying Account Names”](#), and [Section 6.2.5, “Specifying Role Names”](#).

To display the privileges granted to the current user (the account that you are using to connect to the server), you can use any of the following statements:

```
SHOW GRANTS;
SHOW GRANTS FOR CURRENT_USER;
SHOW GRANTS FOR CURRENT_USER();
```

If `SHOW GRANTS FOR CURRENT_USER` (or any of the equivalent syntaxes) is used in `DEFINER` context, such as within a stored procedure that executes with `DEFINER` rather than `INVOKER` privileges), the grants displayed are those of the definer and not the invoker.

In MySQL 8.0 compared to previous series, `SHOW GRANTS` no longer displays `ALL PRIVILEGES` in its global-privileges output because the meaning of `ALL PRIVILEGES` at the global level varies depending on which dynamic privileges are defined. Instead, `SHOW GRANTS` explicitly lists each granted global privilege:

```
mysql> SHOW GRANTS FOR 'root'@'localhost';
+-----+
| Grants for root@localhost |
+-----+
| GRANT SELECT, INSERT, UPDATE, DELETE, CREATE, DROP, RELOAD, |
| SHUTDOWN, PROCESS, FILE, REFERENCES, INDEX, ALTER, SHOW DATABASES, |
| SUPER, CREATE TEMPORARY TABLES, LOCK TABLES, EXECUTE, REPLICATION |
| SLAVE, REPLICATION CLIENT, CREATE VIEW, SHOW VIEW, CREATE ROUTINE, |
| ALTER ROUTINE, CREATE USER, EVENT, TRIGGER, CREATE TABLESPACE, |
| CREATE ROLE, DROP ROLE ON *.* TO `root`@`localhost` WITH GRANT |
| OPTION |
| GRANT PROXY ON ''@'' TO 'root'@'localhost' WITH GRANT OPTION |
+-----+
```

Applications that process `SHOW GRANTS` output should be adjusted accordingly.

At the global level, `GRANT OPTION` applies to all granted static global privileges if granted for any of them, but applies individually to granted dynamic privileges. `SHOW GRANTS` displays global privileges this way:

- One line listing all granted static privileges, if there are any, including `WITH GRANT OPTION` if appropriate.
- One line listing all granted dynamic privileges for which `GRANT OPTION` is granted, if there are any, including `WITH GRANT OPTION`.

- One line listing all granted dynamic privileges for which `GRANT OPTION` is not granted, if there are any, without `WITH GRANT OPTION`.

With the optional `USING` clause, `SHOW GRANTS` enables you to examine the privileges associated with roles for the user. Each role named in the `USING` clause must be granted to the user.

The `USING` clause requires the `SUPER` privilege, except to display information for the current user.

Suppose that user `u1` is assigned roles `r1` and `r2`, as follows:

```
CREATE ROLE 'r1', 'r2';
GRANT SELECT ON db1.* TO 'r1';
GRANT INSERT, UPDATE, DELETE ON db1.* TO 'r2';
CREATE USER 'u1'@'localhost' IDENTIFIED BY 'ulpass';
GRANT 'r1', 'r2' TO 'u1'@'localhost';
```

`SHOW GRANTS` without `USING` shows the granted roles:

```
mysql> SHOW GRANTS FOR 'u1'@'localhost';
+-----+
| Grants for u1@localhost |
+-----+
| GRANT USAGE ON *.* TO `u1`@`localhost` |
| GRANT `r1`@`%`,`r2`@`%` TO `u1`@`localhost` |
+-----+
```

Adding a `USING` clause causes the statement to also display the privileges associated with each role named in the clause:

```
mysql> SHOW GRANTS FOR 'u1'@'localhost' USING 'r1';
+-----+
| Grants for u1@localhost |
+-----+
| GRANT USAGE ON *.* TO `u1`@`localhost` |
| GRANT SELECT ON `db1`.* TO `u1`@`localhost` |
| GRANT `r1`@`%`,`r2`@`%` TO `u1`@`localhost` |
+-----+
mysql> SHOW GRANTS FOR 'u1'@'localhost' USING 'r2';
+-----+
| Grants for u1@localhost |
+-----+
| GRANT USAGE ON *.* TO `u1`@`localhost` |
| GRANT INSERT, UPDATE, DELETE ON `db1`.* TO `u1`@`localhost` |
| GRANT `r1`@`%`,`r2`@`%` TO `u1`@`localhost` |
+-----+
mysql> SHOW GRANTS FOR 'u1'@'localhost' USING 'r1', 'r2';
+-----+
| Grants for u1@localhost |
+-----+
| GRANT USAGE ON *.* TO `u1`@`localhost` |
| GRANT SELECT, INSERT, UPDATE, DELETE ON `db1`.* TO `u1`@`localhost` |
| GRANT `r1`@`%`,`r2`@`%` TO `u1`@`localhost` |
+-----+
```

Note

A role granted to an account is not necessarily active. The active roles for an account can differ across and within sessions, depending on the value of the `activate_all_roles_on_login` system variable, the account default roles, and whether `SET ROLE` has been executed within a session.

`SHOW GRANTS` does not display privileges that are available to the named account but are granted to a different account. For example, if an anonymous account exists, the named account might be able to use its privileges, but `SHOW GRANTS` does not display them.

`SHOW GRANTS` displays mandatory roles named in the `mandatory_roles` system variable value as follows:

- `SHOW GRANTS` without a `FOR` clause displays privileges for the current user, and includes mandatory roles.
- `SHOW GRANTS` with a `FOR` clause displays privileges for the named user, and does not include mandatory roles.

This behavior is for the benefit of applications that use the output of `SHOW GRANTS FOR user` to determine which privileges are granted explicitly to the named user. Were that output to include mandatory roles, it would be difficult to distinguish them from roles granted explicitly to the user.

For the current user, applications can determine privileges with or without mandatory roles by using `SHOW GRANTS` or `SHOW GRANTS FOR CURRENT_USER`, respectively.

13.7.5.22 SHOW INDEX Syntax

```
SHOW [EXTENDED] {INDEX | INDEXES | KEYS}
  {FROM | IN} tbl_name
  [{FROM | IN} db_name]
  [WHERE expr]
```

`SHOW INDEX` returns table index information. The format resembles that of the `SQLStatistics` call in ODBC. This statement requires some privilege for any column in the table.

You can use `db_name.tbl_name` as an alternative to the `tbl_name FROM db_name` syntax. These two statements are equivalent:

```
SHOW INDEX FROM mytable FROM mydb;
SHOW INDEX FROM mydb.mytable;
```

As of MySQL 8.0.2, the optional `EXTENDED` keyword causes the output to include information about hidden indexes that MySQL uses internally and are not accessible by users.

The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 24.33, “Extensions to SHOW Statements”](#).

```
mysql> SHOW INDEX FROM City\G
***** 1. row *****
      Table: city
      Non_unique: 0
      Key_name: PRIMARY
      Seq_in_index: 1
      Column_name: ID
      Collation: A
      Cardinality: 4321
      Sub_part: NULL
      Packed: NULL
      Null:
      Index_type: BTREE
      Comment:
      Index_comment:
***** 2. row *****
      Table: city
      Non_unique: 1
      Key_name: CountryCode
      Seq_in_index: 1
      Column_name: CountryCode
      Collation: A
      Cardinality: 4321
      Sub_part: NULL
      Packed: NULL
```

```

Null:
Index_type: BTREE
Comment:
Index_comment:

```

`SHOW INDEX` returns the following fields:

- `Table`

The name of the table.

- `Non_unique`

0 if the index cannot contain duplicates, 1 if it can.

- `Key_name`

The name of the index. If the index is the primary key, the name is always `PRIMARY`.

- `Seq_in_index`

The column sequence number in the index, starting with 1.

- `Column_name`

The column name.

- `Collation`

How the column is sorted in the index. This can have values `A` (ascending), `D` (descending), or `NULL` (not sorted).

- `Cardinality`

An estimate of the number of unique values in the index. To update this number, run `ANALYZE TABLE` or (for `MyISAM` tables) `myisamchk -a`.

`Cardinality` is counted based on statistics stored as integers, so the value is not necessarily exact even for small tables. The higher the cardinality, the greater the chance that MySQL uses the index when doing joins.

- `Sub_part`

The index prefix. That is, the number of indexed characters if the column is only partly indexed, `NULL` if the entire column is indexed.

Note

Prefix limits are measured in bytes, whereas the prefix length in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements is interpreted as number of characters for nonbinary string types (`CHAR`, `VARCHAR`, `TEXT`) and number of bytes for binary string types (`BINARY`, `VARBINARY`, `BLOB`). Take this into account when specifying a prefix length for a nonbinary string column that uses a multibyte character set.

For additional information about index prefixes, see [Section 8.3.4, “Column Indexes”](#), and [Section 13.1.12, “CREATE INDEX Syntax”](#).

- `Packed`

Indicates how the key is packed. `NULL` if it is not.

- `Null`

Contains `YES` if the column may contain `NULL` values and `' '` if not.

- `Index_type`

The index method used (`BTREE`, `FULLTEXT`, `HASH`, `RTREE`).

- `Comment`

Information about the index not described in its own column, such as `disabled` if the index is disabled.

- `Index_comment`

Any comment provided for the index with a `COMMENT` attribute when the index was created.

- `Visible`

Whether the index is visible to the optimizer. See [Section 8.3.11, “Invisible Indexes”](#).

You can also obtain information about table indexes from `INFORMATION_SCHEMA`, which contains a `STATISTICS` table. See [Section 24.21, “The INFORMATION_SCHEMA STATISTICS Table”](#). The extended information about hidden indexes is available only using `SHOW EXTENDED INDEX`; it cannot be obtained from the `STATISTICS` table.

You can list a table's indexes with the `mysqlshow -k db_name tbl_name` command.

13.7.5.23 SHOW MASTER STATUS Syntax

```
SHOW MASTER STATUS
```

This statement provides status information about the binary log files of the master. It requires either the `SUPER` or `REPLICATION CLIENT` privilege.

Example:

```
mysql> SHOW MASTER STATUS\G
***** 1. row *****
      File: master-bin.000002
      Position: 1307
      Binlog_Do_DB: test
      Binlog_Ignore_DB: manual, mysql
      Executed_Gtid_Set: 3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5
1 row in set (0.00 sec)
```

When global transaction IDs are in use, `Executed_Gtid_Set` shows the set of GTIDs for transactions that have been executed on the master. This is the same as the value for the `gtid_executed` system variable on this server, as well as the value for `Executed_Gtid_Set` in the output of `SHOW SLAVE STATUS` on this server.

13.7.5.24 SHOW OPEN TABLES Syntax

```
SHOW OPEN TABLES
  [{FROM | IN} db_name]
  [LIKE 'pattern' | WHERE expr]
```

`SHOW OPEN TABLES` lists the non-`TEMPORARY` tables that are currently open in the table cache. See [Section 8.4.3.1, “How MySQL Opens and Closes Tables”](#). The `FROM` clause, if present, restricts the tables shown to those present in the `db_name` database. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 24.33, “Extensions to SHOW Statements”](#).

`SHOW OPEN TABLES` output has the following columns:

- `Database`

The database containing the table.

- `Table`

The table name.

- `In_use`

The number of table locks or lock requests there are for the table. For example, if one client acquires a lock for a table using `LOCK TABLE t1 WRITE`, `In_use` will be 1. If another client issues `LOCK TABLE t1 WRITE` while the table remains locked, the client will block waiting for the lock, but the lock request causes `In_use` to be 2. If the count is zero, the table is open but not currently being used. `In_use` is also increased by the `HANDLER ... OPEN` statement and decreased by `HANDLER ... CLOSE`.

- `Name_locked`

Whether the table name is locked. Name locking is used for operations such as dropping or renaming tables.

If you have no privileges for a table, it does not show up in the output from `SHOW OPEN TABLES`.

13.7.5.25 SHOW PLUGINS Syntax

```
SHOW PLUGINS
```

`SHOW PLUGINS` displays information about server plugins. Plugin information is also available in the `INFORMATION_SCHEMA.PLUGINS` table. See [Section 24.14, “The INFORMATION_SCHEMA PLUGINS Table”](#).

Example of `SHOW PLUGINS` output:

```
mysql> SHOW PLUGINS\G
***** 1. row *****
  Name: binlog
  Status: ACTIVE
  Type: STORAGE ENGINE
  Library: NULL
  License: GPL
***** 2. row *****
  Name: CSV
  Status: ACTIVE
  Type: STORAGE ENGINE
  Library: NULL
  License: GPL
***** 3. row *****
  Name: MEMORY
  Status: ACTIVE
  Type: STORAGE ENGINE
  Library: NULL
  License: GPL
***** 4. row *****
  Name: MyISAM
  Status: ACTIVE
  Type: STORAGE ENGINE
  Library: NULL
  License: GPL
...
```

`SHOW PLUGINS` output has the following columns:

- **Name:** The name used to refer to the plugin in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`.
- **Status:** The plugin status, one of `ACTIVE`, `INACTIVE`, `DISABLED`, or `DELETED`.
- **Type:** The type of plugin, such as `STORAGE ENGINE`, `INFORMATION_SCHEMA`, or `AUTHENTICATION`.
- **Library:** The name of the plugin shared library file. This is the name used to refer to the plugin file in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`. This file is located in the directory named by the `plugin_dir` system variable. If the library name is `NULL`, the plugin is compiled in and cannot be uninstalled with `UNINSTALL PLUGIN`.
- **License:** How the plugin is licensed; for example, `GPL`.

For plugins installed with `INSTALL PLUGIN`, the `Name` and `Library` values are also registered in the `mysql.plugin` table.

For information about plugin data structures that form the basis of the information displayed by `SHOW PLUGINS`, see [Section 28.2, “The MySQL Plugin API”](#).

13.7.5.26 SHOW PRIVILEGES Syntax

```
SHOW PRIVILEGES
```

`SHOW PRIVILEGES` shows the list of system privileges that the MySQL server supports. The privileges displayed include all static privileges, and all currently registered dynamic privileges.

```
mysql> SHOW PRIVILEGES\G
***** 1. row *****
Privilege: Alter
Context: Tables
Comment: To alter the table
***** 2. row *****
Privilege: Alter routine
Context: Functions,Procedures
Comment: To alter or drop stored functions/procedures
***** 3. row *****
Privilege: Create
Context: Databases,Tables,Indexes
Comment: To create new databases and tables
***** 4. row *****
Privilege: Create routine
Context: Databases
Comment: To use CREATE FUNCTION/PROCEDURE
***** 5. row *****
Privilege: Create temporary tables
Context: Databases
Comment: To use CREATE TEMPORARY TABLE
...
```

Privileges belonging to a specific user are displayed by the `SHOW GRANTS` statement. See [Section 13.7.5.21, “SHOW GRANTS Syntax”](#), for more information.

13.7.5.27 SHOW PROCEDURE CODE Syntax

```
SHOW PROCEDURE CODE proc_name
```

This statement is a MySQL extension that is available only for servers that have been built with debugging support. It displays a representation of the internal implementation of the named stored procedure. A similar statement, `SHOW FUNCTION CODE`, displays information about stored functions (see [Section 13.7.5.19, “SHOW FUNCTION CODE Syntax”](#)).

To use either statement, you must have the global [SELECT](#) privilege.

If the named routine is available, each statement produces a result set. Each row in the result set corresponds to one “instruction” in the routine. The first column is [Pos](#), which is an ordinal number beginning with 0. The second column is [Instruction](#), which contains an SQL statement (usually changed from the original source), or a directive which has meaning only to the stored-routine handler.

```
mysql> DELIMITER //
mysql> CREATE PROCEDURE p1 ()
-> BEGIN
->   DECLARE fanta INT DEFAULT 55;
->   DROP TABLE t2;
->   LOOP
->     INSERT INTO t3 VALUES (fanta);
->   END LOOP;
-> END//
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW PROCEDURE CODE p1//
+-----+
| Pos | Instruction
+-----+
| 0 | set fanta@0 55
| 1 | stmt 9 "DROP TABLE t2"
| 2 | stmt 5 "INSERT INTO t3 VALUES (fanta)"
| 3 | jump 2
+-----+
4 rows in set (0.00 sec)
```

In this example, the nonexecutable [BEGIN](#) and [END](#) statements have disappeared, and for the [DECLARE *variable_name*](#) statement, only the executable part appears (the part where the default is assigned). For each statement that is taken from source, there is a code word [stmt](#) followed by a type (9 means [DROP](#), 5 means [INSERT](#), and so on). The final row contains an instruction [jump 2](#), meaning [GOTO instruction #2](#).

13.7.5.28 SHOW PROCEDURE STATUS Syntax

```
SHOW PROCEDURE STATUS
[LIKE 'pattern' | WHERE expr]
```

This statement is a MySQL extension. It returns characteristics of a stored procedure, such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement, [SHOW FUNCTION STATUS](#), displays information about stored functions (see [Section 13.7.5.20, “SHOW FUNCTION STATUS Syntax”](#)).

The [LIKE](#) clause, if present, indicates which procedure or function names to match. The [WHERE](#) clause can be given to select rows using more general conditions, as discussed in [Section 24.33, “Extensions to SHOW Statements”](#).

```
mysql> SHOW PROCEDURE STATUS LIKE 'sp1'\G
***** 1. row *****
      Db: test
      Name: sp1
      Type: PROCEDURE
      Definer: testuser@localhost
      Modified: 2004-08-03 15:29:37
      Created: 2004-08-03 15:29:37
      Security_type: DEFINER
      Comment:
character_set_client: utf8
collation_connection: utf8_general_ci
      Database Collation: utf8mb4_0900_ai_ci
```

[character_set_client](#) is the session value of the [character_set_client](#) system variable when the routine was created. [collation_connection](#) is the session value of the

`collation_connection` system variable when the routine was created. `Database Collation` is the collation of the database with which the routine is associated.

You can also get information about stored routines from the `ROUTINES` table in `INFORMATION_SCHEMA`. See [Section 24.18, “The INFORMATION_SCHEMA ROUTINES Table”](#).

13.7.5.29 SHOW PROCESSLIST Syntax

```
SHOW [FULL] PROCESSLIST
```

`SHOW PROCESSLIST` shows you which threads are running. You can also get this information from the `INFORMATION_SCHEMA PROCESSLIST` table or the `mysqladmin processlist` command. If you have the `PROCESS` privilege, you can see all threads. Otherwise, you can see only your own threads (that is, threads associated with the MySQL account that you are using). If you do not use the `FULL` keyword, only the first 100 characters of each statement are shown in the `Info` field.

Process information is also available from the `performance_schema.threads` table. However, access to `threads` does not require a mutex and has minimal impact on server performance. `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` have negative performance consequences because they require a mutex. `threads` also shows information about background threads, which `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` do not. This means that `threads` can be used to monitor activity the other thread information sources cannot.

The `SHOW PROCESSLIST` statement is very useful if you get the “too many connections” error message and want to find out what is going on. MySQL reserves one extra connection to be used by accounts that have the `SUPER` privilege, to ensure that administrators should always be able to connect and check the system (assuming that you are not giving this privilege to all your users).

Threads can be killed with the `KILL` statement. See [Section 13.7.6.4, “KILL Syntax”](#).

Here is an example of `SHOW PROCESSLIST` output:

```
mysql> SHOW FULL PROCESSLIST\G
***** 1. row *****
Id: 1
User: system user
Host:
db: NULL
Command: Connect
Time: 1030455
State: Waiting for master to send event
Info: NULL
***** 2. row *****
Id: 2
User: system user
Host:
db: NULL
Command: Connect
Time: 1004
State: Has read all relay log; waiting for the slave
      I/O thread to update it
Info: NULL
***** 3. row *****
Id: 3112
User: replikator
Host: artemis:2204
db: NULL
Command: Binlog Dump
Time: 2144
State: Has sent all binlog to slave; waiting for binlog to be updated
Info: NULL
***** 4. row *****
Id: 3113
User: replikator
```

```

Host: iconnect2:45781
db: NULL
Command: Binlog Dump
Time: 2086
State: Has sent all binlog to slave; waiting for binlog to be updated
Info: NULL
***** 5. row *****
Id: 3123
User: stefan
Host: localhost
db: apollon
Command: Query
Time: 0
State: NULL
Info: SHOW FULL PROCESSLIST
5 rows in set (0.00 sec)

```

The columns produced by `SHOW PROCESSLIST` have the following meanings:

- `Id`

The connection identifier. This is the same type of value displayed in the `ID` column of the `INFORMATION_SCHEMA.PROCESSLIST` table, the `PROCESSLIST_ID` column of the Performance Schema `threads` table, and returned by the `CONNECTION_ID()` function.

- `User`

The MySQL user who issued the statement. If this is `system user`, it refers to a nonclient thread spawned by the server to handle tasks internally. This could be the I/O or SQL thread used on replication slaves or a delayed-row handler. `unauthenticated user` refers to a thread that has become associated with a client connection but for which authentication of the client user has not yet been done. `event_scheduler` refers to the thread that monitors scheduled events. For `system user`, there is no host specified in the `Host` column.

- `Host`

The host name of the client issuing the statement (except for `system user` where there is no host). `SHOW PROCESSLIST` reports the host name for TCP/IP connections in `host_name:client_port` format to make it easier to determine which client is doing what.

- `db`

The default database, if one is selected, otherwise `NULL`.

- `Command`

The type of command the thread is executing. For descriptions for thread commands, see [Section 8.14, “Examining Thread Information”](#). The value of this column corresponds to the `COM_xxx` commands of the client/server protocol and `Com_xxx` status variables. See [Section 5.1.7, “Server Status Variables”](#)

- `Time`

The time in seconds that the thread has been in its current state. For a slave SQL thread, the value is the number of seconds between the timestamp of the last replicated event and the real time of the slave machine. See [Section 18.2.2, “Replication Implementation Details”](#).

- `State`

An action, event, or state that indicates what the thread is doing. Descriptions for `State` values can be found at [Section 8.14, “Examining Thread Information”](#).

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that needs to be investigated.

For the `SHOW PROCESSLIST` statement, the value of `State` is `NULL`.

- [Info](#)

The statement the thread is executing, or `NULL` if it is not executing any statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a `CALL` statement executes a stored procedure that is executing a `SELECT` statement, the `Info` value shows the `SELECT` statement.

13.7.5.30 SHOW PROFILE Syntax

```
SHOW PROFILE [type [, type] ... ]
  [FOR QUERY n]
  [LIMIT row_count [OFFSET offset]]

type:
| ALL
| BLOCK IO
| CONTEXT SWITCHES
| CPU
| IPC
| MEMORY
| PAGE FAULTS
| SOURCE
| SWAPS
```

The `SHOW PROFILE` and `SHOW PROFILES` statements display profiling information that indicates resource usage for statements executed during the course of the current session.

Note

These statements are deprecated and will be removed in a future MySQL release. Use the [Performance Schema](#) instead; see [Section 25.18.1, “Query Profiling Using Performance Schema”](#).

Profiling is controlled by the `profiling` session variable, which has a default value of 0 (`OFF`). Profiling is enabled by setting `profiling` to 1 or `ON`:

```
mysql> SET profiling = 1;
```

`SHOW PROFILES` displays a list of the most recent statements sent to the server. The size of the list is controlled by the `profiling_history_size` session variable, which has a default value of 15. The maximum value is 100. Setting the value to 0 has the practical effect of disabling profiling.

All statements are profiled except `SHOW PROFILE` and `SHOW PROFILES`, so you will find neither of those statements in the profile list. Malformed statements are profiled. For example, `SHOW PROFILING` is an illegal statement, and a syntax error occurs if you try to execute it, but it will show up in the profiling list.

`SHOW PROFILE` displays detailed information about a single statement. Without the `FOR QUERY n` clause, the output pertains to the most recently executed statement. If `FOR QUERY n` is included, `SHOW PROFILE` displays information for statement `n`. The values of `n` correspond to the `Query_ID` values displayed by `SHOW PROFILES`.

The `LIMIT row_count` clause may be given to limit the output to `row_count` rows. If `LIMIT` is given, `OFFSET offset` may be added to begin the output `offset` rows into the full set of rows.

By default, `SHOW PROFILE` displays `Status` and `Duration` columns. The `Status` values are like the `State` values displayed by `SHOW PROCESSLIST`, although there might be some minor differences in interpretation for the two statements for some status values (see [Section 8.14, “Examining Thread Information”](#)).

Optional *type* values may be specified to display specific additional types of information:

- `ALL` displays all information
- `BLOCK IO` displays counts for block input and output operations
- `CONTEXT SWITCHES` displays counts for voluntary and involuntary context switches
- `CPU` displays user and system CPU usage times
- `IPC` displays counts for messages sent and received
- `MEMORY` is not currently implemented
- `PAGE FAULTS` displays counts for major and minor page faults
- `SOURCE` displays the names of functions from the source code, together with the name and line number of the file in which the function occurs
- `SWAPS` displays swap counts

Profiling is enabled per session. When a session ends, its profiling information is lost.

```
mysql> SELECT @@profiling;
+-----+
| @@profiling |
+-----+
|           0 |
+-----+
1 row in set (0.00 sec)

mysql> SET profiling = 1;

| cleaning up       | 0.000005 | 0.000003 | 0.000002 |
+-----+-----+-----+-----+
7 rows in set (0.00 sec)

```

**Note**

Profiling is only partially functional on some architectures. For values that depend on the `getrusage()` system call, `NULL` is returned on systems such as Windows that do not support the call. In addition, profiling is per process and not per thread. This means that activity on threads within the server other than your own may affect the timing information that you see.

You can also get profiling information from the `PROFILING` table in `INFORMATION_SCHEMA`. See [Section 24.16, “The INFORMATION_SCHEMA PROFILING Table”](#). For example, the following queries produce the same result:

```

SHOW PROFILE FOR QUERY 2;

SELECT STATE, FORMAT(DURATION, 6) AS DURATION
FROM INFORMATION_SCHEMA.PROFILING
WHERE QUERY_ID = 2 ORDER BY SEQ;

```

13.7.5.31 SHOW PROFILES Syntax

```
SHOW PROFILES
```

The `SHOW PROFILES` statement, together with `SHOW PROFILE`, displays profiling information that indicates resource usage for statements executed during the course of the current session. For more information, see [Section 13.7.5.30, “SHOW PROFILE Syntax”](#).

**Note**

These statements are deprecated and will be removed in a future MySQL release. Use the Performance Schema instead; see [Chapter 25, MySQL Performance Schema](#).

13.7.5.32 SHOW RELAYLOG EVENTS Syntax

```

SHOW RELAYLOG EVENTS
  [IN 'log_name']
  [FROM pos]
  [LIMIT [offset,] row_count]
  [channel_option]

channel_option:
  FOR CHANNEL channel

```

Shows the events in the relay log of a replication slave. If you do not specify '*log_name*', the first relay log is displayed. This statement has no effect on the master.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See [Section 13.2.10, “SELECT Syntax”](#).

Note

Issuing a `SHOW RELAYLOG EVENTS` with no `LIMIT` clause could start a very time- and resource-consuming process because the server returns to the client the complete contents of the relay log (including all statements modifying data that have been received by the slave).

The optional `FOR CHANNEL channel` clause enables you to choose which replication channel the statement applies to. If no clause is set and no extra channels exist, the statement applies to the default channel. Providing a `FOR CHANNEL channel` clause applies the `SHOW RELAYLOG EVENTS` statement to a specific replication channel.

When using multiple replication channels, if a `SHOW RELAYLOG EVENTS` statement does not have a channel defined using a `FOR CHANNEL channel` clause an error is generated. See [Section 18.2.3, “Replication Channels”](#) for more information.

Note

Some events relating to the setting of user and system variables are not included in the output from `SHOW RELAYLOG EVENTS`. To get complete coverage of events within a relay log, use `mysqlbinlog`.

13.7.5.33 SHOW SLAVE HOSTS Syntax

```
SHOW SLAVE HOSTS
```

Displays a list of replication slaves currently registered with the master.

`SHOW SLAVE HOSTS` should be executed on a server that acts as a replication master. The statement displays information about servers that are or have been connected as replication slaves, with each row of the result corresponding to one slave server, as shown here:

```
mysql> SHOW SLAVE HOSTS;
+-----+-----+-----+-----+-----+
| Server_id | Host      | Port | Master_id | Slave_UUID |
+-----+-----+-----+-----+-----+
| 192168010 | iconnect2 | 3306 | 192168011 | 14cb6624-7f93-11e0-b2c0-c80aa9429562 |
| 1921680101 | athena    | 3306 | 192168011 | 07af4990-f41f-11df-a566-7ac56fdaf645 |
+-----+-----+-----+-----+-----+
```

- **Server_id**: The unique server ID of the slave server, as configured in the slave server's option file, or on the command line with `--server-id=value`.
- **Host**: The host name of the slave server as specified on the slave with the `--report-host` option. This can differ from the machine name as configured in the operating system.
- **User**: The slave server user name as, specified on the slave with the `--report-user` option. Statement output includes this column only if the master server is started with the `--show-slave-auth-info` option.
- **Password**: The slave server password as, specified on the slave with the `--report-password` option. Statement output includes this column only if the master server is started with the `--show-slave-auth-info` option.
- **Port**: The port on the master to which the slave server is listening, as specified on the slave with the `--report-port` option.

A zero in this column means that the slave port (`--report-port`) was not set.

- `Master_id`: The unique server ID of the master server that the slave server is replicating from. This is the server ID of the server on which `SHOW SLAVE HOSTS` is executed, so this same value is listed for each row in the result.
- `Slave_UUID`: The globally unique ID of this slave, as generated on the slave and found in the slave's `auto.cnf` file.

13.7.5.34 SHOW SLAVE STATUS Syntax

```
SHOW SLAVE STATUS [FOR CHANNEL channel]
```

This statement provides status information on essential parameters of the slave threads. It requires either the `SUPER` or `REPLICATION CLIENT` privilege.

`SHOW SLAVE STATUS` is nonblocking. When run concurrently with `STOP SLAVE`, `SHOW SLAVE STATUS` returns without waiting for `STOP SLAVE` to finish shutting down the slave SQL thread or slave I/O thread (or both). This permits use in monitoring and other applications where getting an immediate response from `SHOW SLAVE STATUS` more important than ensuring that it returned the latest data.

If you issue this statement using the `mysql` client, you can use a `\G` statement terminator rather than a semicolon to obtain a more readable vertical layout:

```
mysql> SHOW SLAVE STATUS\G
***** 1. row *****
      Slave_IO_State: Waiting for master to send event
      Master_Host: localhost
      Master_User: root
      Master_Port: 13000

```

The Performance Schema provides tables that expose replication information. This is similar to the information available from the `SHOW SLAVE STATUS` statement, but represented in table form. For details, see [Section 25.11.11, “Performance Schema Replication Tables”](#).

The following list describes the fields returned by `SHOW SLAVE STATUS`. For additional information about interpreting their meanings, see [Section 18.1.7.1, “Checking Replication Status”](#).

- `Slave_IO_State`

A copy of the `State` field of the `SHOW PROCESSLIST` output for the slave I/O thread. This tells you what the thread is doing: trying to connect to the master, waiting for events from the master, reconnecting to the master, and so on. For a listing of possible states, see [Section 8.14.5, “Replication Slave I/O Thread States”](#).

- `Master_Host`

The master host that the slave is connected to.

- `Master_User`

The user name of the account used to connect to the master.

- `Master_Port`

The port used to connect to the master.

- `Connect_Retry`

The number of seconds between connect retries (default 60). This can be set with the `CHANGE MASTER TO` statement.

- `Master_Log_File`

The name of the master binary log file from which the I/O thread is currently reading.

- `Read_Master_Log_Pos`

The position in the current master binary log file up to which the I/O thread has read.

- `Relay_Log_File`

The name of the relay log file from which the SQL thread is currently reading and executing.

- `Relay_Log_Pos`

The position in the current relay log file up to which the SQL thread has read and executed.

- [Relay_Master_Log_File](#)

The name of the master binary log file containing the most recent event executed by the SQL thread.

- [Slave_IO_Running](#)

Whether the I/O thread is started and has connected successfully to the master. Internally, the state of this thread is represented by one of the following three values:

- **MYSQL_SLAVE_NOT_RUN.** The slave I/O thread is not running. For this state, [Slave_IO_Running](#) is `No`.
- **MYSQL_SLAVE_RUN_NOT_CONNECT.** The slave I/O thread is running, but is not connected to a replication master. For this state, [Slave_IO_Running](#) depends on the server version as shown in the following table.

MySQL Version	Slave_IO_Running
4.1 (4.1.13 and earlier); 5.0 (5.0.11 and earlier)	Yes
4.1 (4.1.14 and later); 5.0 (5.0.12 and later)	No
5.1 (5.1.45 and earlier)	No
5.1 (5.1.46 and later); 5.5; 5.6	Connecting

- **MYSQL_SLAVE_RUN_CONNECT.** The slave I/O thread is running, and is connected to a replication master. For this state, [Slave_IO_Running](#) is `Yes`.

The value of the [Slave_running](#) system status variable corresponds with this value.

- [Slave_SQL_Running](#)

Whether the SQL thread is started.

- [Replicate_Do_DB](#), [Replicate_Ignore_DB](#)

The lists of databases that were specified with the `--replicate-do-db` and `--replicate-ignore-db` options, if any.

- [Replicate_Do_Table](#), [Replicate_Ignore_Table](#), [Replicate_Wild_Do_Table](#), [Replicate_Wild_Ignore_Table](#)

The lists of tables that were specified with the `--replicate-do-table`, `--replicate-ignore-table`, `--replicate-wild-do-table`, and `--replicate-wild-ignore-table` options, if any.

- [Last_Errno](#), [Last_Error](#)

These columns are aliases for [Last_SQL_Errno](#) and [Last_SQL_Error](#).

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

Note

When the slave SQL thread receives an error, it reports the error first, then stops the SQL thread. This means that there is a small window of time during which `SHOW SLAVE STATUS` shows a nonzero value for [Last_SQL_Errno](#) even though [Slave_SQL_Running](#) still displays `Yes`.

- [Skip_Counter](#)

The current value of the [sql_slave_skip_counter](#) system variable. See [Section 13.4.2.5, “SET GLOBAL sql_slave_skip_counter Syntax”](#).

- `Exec_Master_Log_Pos`

The position in the current master binary log file to which the SQL thread has read and executed, marking the start of the next transaction or event to be processed. You can use this value with the `CHANGE MASTER TO` statement's `MASTER_LOG_POS` option when starting a new slave from an existing slave, so that the new slave reads from this point. The coordinates given by (`Relay_Master_Log_File`, `Exec_Master_Log_Pos`) in the master's binary log correspond to the coordinates given by (`Relay_Log_File`, `Relay_Log_Pos`) in the relay log.

Inconsistencies in the sequence of transactions from the relay log which have been executed can cause this value to be a “low-water mark”. In other words, transactions appearing before the position are guaranteed to have committed, but transactions after the position may have committed or not. If these gaps need to be corrected, use `START SLAVE UNTIL SQL_AFTER_MTS_GAPS`. See [Section 18.4.1.34, “Replication and Transaction Inconsistencies”](#) for more information.

- `Relay_Log_Space`

The total combined size of all existing relay log files.

- `Until_Condition`, `Until_Log_File`, `Until_Log_Pos`

The values specified in the `UNTIL` clause of the `START SLAVE` statement.

`Until_Condition` has these values:

- `None` if no `UNTIL` clause was specified
- `Master` if the slave is reading until a given position in the master's binary log
- `Relay` if the slave is reading until a given position in its relay log
- `SQL_BEFORE_GTIDS` if the slave SQL thread is processing transactions until it has reached the first transaction whose GTID is listed in the `gtid_set`.
- `SQL_AFTER_GTIDS` if the slave threads are processing all transactions until the last transaction in the `gtid_set` has been processed by both threads.
- `SQL_AFTER_MTS_GAPS` if a multi-threaded slave's SQL threads are running until no more gaps are found in the relay log.

`Until_Log_File` and `Until_Log_Pos` indicate the log file name and position that define the coordinates at which the SQL thread stops executing.

For more information on `UNTIL` clauses, see [Section 13.4.2.6, “START SLAVE Syntax”](#).

- `Master_SSL_Allowed`, `Master_SSL_CA_File`, `Master_SSL_CA_Path`, `Master_SSL_Cert`, `Master_SSL_Cipher`, `Master_SSL_CRL_File`, `Master_SSL_CRL_Path`, `Master_SSL_Key`, `Master_SSL_Verify_Server_Cert`

These fields show the SSL parameters used by the slave to connect to the master, if any.

`Master_SSL_Allowed` has these values:

- `Yes` if an SSL connection to the master is permitted
- `No` if an SSL connection to the master is not permitted
- `Ignored` if an SSL connection is permitted but the slave server does not have SSL support enabled

The values of the other SSL-related fields correspond to the values of the `MASTER_SSL_CA`, `MASTER_SSL_CAPATH`, `MASTER_SSL_CERT`, `MASTER_SSL_CIPHER`, `MASTER_SSL_CRL`,

`MASTER_SSL_CRLPATH`, `MASTER_SSL_KEY`, and `MASTER_SSL_VERIFY_SERVER_CERT` options to the `CHANGE MASTER TO` statement. See [Section 13.4.2.1, “CHANGE MASTER TO Syntax”](#).

- `Seconds_Behind_Master`

This field is an indication of how “late” the slave is:

- When the slave is actively processing updates, this field shows the difference between the current timestamp on the slave and the original timestamp logged on the master for the event currently being processed on the slave.
- When no event is currently being processed on the slave, this value is 0.

In essence, this field measures the time difference in seconds between the slave SQL thread and the slave I/O thread. If the network connection between master and slave is fast, the slave I/O thread is very close to the master, so this field is a good approximation of how late the slave SQL thread is compared to the master. If the network is slow, this is *not* a good approximation; the slave SQL thread may quite often be caught up with the slow-reading slave I/O thread, so `Seconds_Behind_Master` often shows a value of 0, even if the I/O thread is late compared to the master. In other words, *this column is useful only for fast networks*.

This time difference computation works even if the master and slave do not have identical clock times, provided that the difference, computed when the slave I/O thread starts, remains constant from then on. Any changes—including NTP updates—can lead to clock skews that can make calculation of `Seconds_Behind_Master` less reliable.

In MySQL 8.0, this field is `NULL` (undefined or unknown) if the slave SQL thread is not running, or if the SQL thread has consumed all of the relay log and the slave I/O thread is not running. (In older versions of MySQL, this field was `NULL` if the slave SQL thread or the slave I/O thread was not running or was not connected to the master.) If the I/O thread is running but the relay log is exhausted, `Seconds_Behind_Master` is set to 0.

The value of `Seconds_Behind_Master` is based on the timestamps stored in events, which are preserved through replication. This means that if a master M1 is itself a slave of M0, any event from M1's binary log that originates from M0's binary log has M0's timestamp for that event. This enables MySQL to replicate `TIMESTAMP` successfully. However, the problem for `Seconds_Behind_Master` is that if M1 also receives direct updates from clients, the `Seconds_Behind_Master` value randomly fluctuates because sometimes the last event from M1 originates from M0 and sometimes is the result of a direct update on M1.

When using a multi-threaded slave, you should keep in mind that this value is based on `Exec_Master_Log_Pos`, and so may not reflect the position of the most recently committed transaction.

- `Last_IO_Errno`, `Last_IO_Error`

The error number and error message of the most recent error that caused the I/O thread to stop. An error number of 0 and message of the empty string mean “no error.” If the `Last_IO_Error` value is not empty, the error values also appear in the slave's error log.

I/O error information includes a timestamp showing when the most recent I/O thread error occurred. This timestamp uses the format `YYMMDD HH:MM:SS`, and appears in the `Last_IO_Error_Timestamp` column.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

- `Last_SQL_Errno`, `Last_SQL_Error`

The error number and error message of the most recent error that caused the SQL thread to stop. An error number of 0 and message of the empty string mean “no error.” If the `Last_SQL_Error` value is not empty, the error values also appear in the slave's error log.

If the slave is multi-threaded, the SQL thread is the coordinator for worker threads. In this case, the `Last_SQL_Error` field shows exactly what the `Last_Error_Message` column in the Performance Schema `replication_applier_status_by_coordinator` table shows. The field value is modified to suggest that there may be more failures in the other worker threads which can be seen in the `replication_applier_status_by_worker` table that shows each worker thread's status. If that table is not available, the slave error log can be used. The log or the `replication_applier_status_by_worker` table should also be used to learn more about the failure shown by `SHOW SLAVE STATUS` or the coordinator table.

SQL error information includes a timestamp showing when the most recent SQL thread error occurred. This timestamp uses the format `YYMMDD HH:MM:SS`, and appears in the `Last_SQL_Error_Timestamp` column.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

In MySQL 8.0, all error codes and messages displayed in the `Last_SQL_Errno` and `Last_SQL_Error` columns correspond to error values listed in [Section B.3, "Server Error Codes and Messages"](#). This was not always true in previous versions. (Bug #11760365, Bug #52768)

- `Replicate_Ignore_Server_Ids`

In MySQL 8.0, you set a slave to ignore events from 0 or more masters using the `IGNORE_SERVER_IDS` option of the `CHANGE MASTER TO` statement. By default this is blank, and is usually modified only when using a circular or other multi-master replication setup. The message shown for `Replicate_Ignore_Server_Ids` when not blank consists of a comma-delimited list of one or more numbers, indicating the server IDs to be ignored. For example:

```
Replicate_Ignore_Server_Ids: 2, 6, 9
```

Note

`Ignored_server_ids` also shows the server IDs to be ignored, but is a space-delimited list, which is preceded by the total number of server IDs to be ignored. For example, if a `CHANGE MASTER TO` statement containing the `IGNORE_SERVER_IDS = (2,6,9)` option has been issued to tell a slave to ignore masters having the server ID 2, 6, or 9, that information appears as shown here:

```
Ignored_server_ids: 3, 2, 6, 9
```

The first number (in this case 3) shows the number of server IDs being ignored.

`Replicate_Ignore_Server_Ids` filtering is performed by the I/O thread, rather than by the SQL thread, which means that events which are filtered out are not written to the relay log. This differs from the filtering actions taken by server options such `--replicate-do-table`, which apply to the SQL thread.

- `Master_Server_Id`

The `server_id` value from the master.

- `Master_UUID`

The `server_uuid` value from the master.

- `Master_Info_File`

The location of the `master.info` file.

- `SQL_Delay`

The number of seconds that the slave must lag the master.

- `SQL_Remaining_Delay`

When `Slave_SQL_Running_State` is `Waiting until MASTER_DELAY seconds after master executed event`, this field contains the number of delay seconds remaining. At other times, this field is `NULL`.

- `Slave_SQL_Running_State`

The state of the SQL thread (analogous to `Slave_IO_State`). The value is identical to the `State` value of the SQL thread as displayed by `SHOW PROCESSLIST`. [Section 8.14.6, “Replication Slave SQL Thread States”](#), provides a listing of possible states

- `Master_Retry_Count`

The number of times the slave can attempt to reconnect to the master in the event of a lost connection. This value can be set using the `MASTER_RETRY_COUNT` option of the `CHANGE MASTER TO` statement (preferred) or the older `--master-retry-count` server option (still supported for backward compatibility).

- `Master_Bind`

The network interface that the slave is bound to, if any. This is set using the `MASTER_BIND` option for the `CHANGE MASTER TO` statement.

- `Last_IO_Error_Timestamp`

A timestamp in `YYMMDD HH:MM:SS` format that shows when the most recent I/O error took place.

- `Last_SQL_Error_Timestamp`

A timestamp in `YYMMDD HH:MM:SS` format that shows when the last SQL error occurred.

- `Retrieved_Gtid_Set`

The set of global transaction IDs corresponding to all transactions received by this slave. Empty if GTIDs are not in use. See [GTID Sets](#) for more information.

This is the set of all GTIDs that exist or have existed in the relay logs. Each GTID is added as soon as the `Gtid_log_event` is received. This can cause partially transmitted transactions to have their GTIDs included in the set.

When all relay logs are lost due to executing `RESET SLAVE` or `CHANGE MASTER TO`, or due to the effects of the `--relay-log-recovery` option, the set is cleared. When `relay_log_purge = 1`, the newest relay log is always kept, and the set is not cleared.

- `Executed_Gtid_Set`

The set of global transaction IDs written in the binary log. This is the same as the value for the global `gtid_executed` system variable on this server, as well as the value for `Executed_Gtid_Set` in the output of `SHOW MASTER STATUS` on this server. Empty if GTIDs are not in use. See [GTID Sets](#) for more information.

- `Auto_Position`

1 if autopositioning is in use; otherwise 0.

- `Replicate_Rewrite_DB`

The `Replicate_Rewrite_DB` value displays any replication filtering rules that were specified. For example, if the following replication filter rule was set:

```
CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB=((db1,db2), (db3,db4));
```

the `Replicate_Rewrite_DB` value displays:

```
Replicate_Rewrite_DB: (db1,db2),(db3,db4)
```

For more information, see [Section 13.4.2.2, “CHANGE REPLICATION FILTER Syntax”](#).

- `Channel_name`

The replication channel which is being displayed. There is always a default replication channel, and more replication channels can be added. See [Section 18.2.3, “Replication Channels”](#) for more information.

13.7.5.35 SHOW STATUS Syntax

```
SHOW [GLOBAL | SESSION] STATUS
     [LIKE 'pattern' | WHERE expr]
```

`SHOW STATUS` provides server status information (see [Section 5.1.7, “Server Status Variables”](#)). This statement does not require any privilege. It requires only the ability to connect to the server.

Status variable information is also available from these sources:

- Performance Schema tables. See [Section 25.11.14, “Performance Schema Status Variable Tables”](#).
- The `mysqladmin extended-status` command. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

For `SHOW STATUS`, a `LIKE` clause, if present, indicates which variable names to match. A `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 24.33, “Extensions to SHOW Statements”](#).

`SHOW STATUS` accepts an optional `GLOBAL` or `SESSION` variable scope modifier:

- With a `GLOBAL` modifier, the statement displays the global status values. A global status variable may represent status for some aspect of the server itself (for example, `Aborted_connects`), or the aggregated status over all connections to MySQL (for example, `Bytes_received` and `Bytes_sent`). If a variable has no global value, the session value is displayed.
- With a `SESSION` modifier, the statement displays the status variable values for the current connection. If a variable has no session value, the global value is displayed. `LOCAL` is a synonym for `SESSION`.
- If no modifier is present, the default is `SESSION`.

The scope for each status variable is listed at [Section 5.1.7, “Server Status Variables”](#).

Each invocation of the `SHOW STATUS` statement uses an internal temporary table and increments the global `Created_tmp_tables` value.

Partial output is shown here. The list of names and values may differ for your server. The meaning of each variable is given in [Section 5.1.7, “Server Status Variables”](#).

```
mysql> SHOW STATUS;
+-----+-----+
| Variable_name | Value |
+-----+-----+
```

```

+-----+-----+
| Aborted_clients      | 0          |
| Aborted_connects    | 0          |
| Bytes_received       | 155372598  |
| Bytes_sent           | 1176560426 |
| Connections          | 30023      |
| Created_tmp_disk_tables | 0          |
| Created_tmp_tables   | 8340       |
| Created_tmp_files    | 60         |
| ...                  |            |
| Open_tables          | 1          |
| Open_files           | 2          |
| Open_streams         | 0          |
| Opened_tables        | 44600      |
| Questions            | 2026873    |
| ...                  |            |
| Table_locks_immediate | 1920382    |
| Table_locks_waited   | 0          |
| Threads_cached       | 0          |
| Threads_created      | 30022      |
| Threads_connected    | 1          |
| Threads_running      | 1          |
| Uptime               | 80380      |
+-----+-----+

```

With a [LIKE](#) clause, the statement displays only rows for those variables with names that match the pattern:

```

mysql> SHOW STATUS LIKE 'Key%';
+-----+-----+
| Variable_name      | Value      |
+-----+-----+
| Key_blocks_used    | 14955      |
| Key_read_requests  | 96854827  |
| Key_reads          | 162040     |
| Key_write_requests | 7589728    |
| Key_writes         | 3813196   |
+-----+-----+

```

13.7.5.36 SHOW TABLE STATUS Syntax

```

SHOW TABLE STATUS
  [{FROM | IN} db_name]
  [LIKE 'pattern' | WHERE expr]

```

`SHOW TABLE STATUS` works like `SHOW TABLES`, but provides a lot of information about each non-`TEMPORARY` table. You can also get this list using the `mysqlshow --status db_name` command. The `LIKE` clause, if present, indicates which table names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 24.33](#), “[Extensions to SHOW Statements](#)”.

This statement also displays information about views.

`SHOW TABLE STATUS` output has the following columns:

- `Name`

The name of the table.

- `Engine`

The storage engine for the table. See [Chapter 16](#), [Alternative Storage Engines](#).

- `Version`

This field is unused.

- `Row_format`

The row-storage format (`Fixed`, `Dynamic`, `Compressed`, `Redundant`, `Compact`). For `MyISAM` tables, (`Dynamic` corresponds to what `myisamchk -dvv` reports as `Packed`).

- `Rows`

The number of rows. Some storage engines, such as `MyISAM`, store the exact count. For other storage engines, such as `InnoDB`, this value is an approximation, and may vary from the actual value by as much as 40 to 50%. In such cases, use `SELECT COUNT(*)` to obtain an accurate count.

The `Rows` value is `NULL` for tables in the `INFORMATION_SCHEMA` database.

- `Avg_row_length`

The average row length.

- `Data_length`

For `MyISAM`, `Data_length` is the length of the data file, in bytes.

For `InnoDB`, `Data_length` is the approximate amount of memory allocated for the clustered index, in bytes. Specifically, it is the clustered index size, in pages, multiplied by the `InnoDB` page size.

Refer to the notes at the end of this section for information regarding other storage engines.

- `Max_data_length`

For `MyISAM`, `Max_data_length` is maximum length of the data file. This is the total number of bytes of data that can be stored in the table, given the data pointer size used.

Unused for `InnoDB`.

Refer to the notes at the end of this section for information regarding other storage engines.

- `Index_length`

For `MyISAM`, `Index_length` is the length of the index file, in bytes.

For `InnoDB`, `Index_length` is the approximate amount of memory allocated for non-clustered indexes, in bytes. Specifically, it is the sum of non-clustered index sizes, in pages, multiplied by the `InnoDB` page size.

Refer to the notes at the end of this section for information regarding other storage engines.

- `Data_free`

The number of allocated but unused bytes.

This information is also shown for `InnoDB` tables (previously, it was in the `Comment` value). `InnoDB` tables report the free space of the tablespace to which the table belongs. For a table located in the shared tablespace, this is the free space of the shared tablespace. If you are using multiple tablespaces and the table has its own tablespace, the free space is for only that table. Free space means the number of bytes in completely free extents minus a safety margin. Even if free space displays as 0, it may be possible to insert rows as long as new extents need not be allocated.

For partitioned tables, this value is only an estimate and may not be absolutely correct. A more accurate method of obtaining this information in such cases is to query the `INFORMATION_SCHEMA.PARTITIONS` table, as shown in this example:

```
SELECT      SUM(DATA_FREE)
FROM        INFORMATION_SCHEMA.PARTITIONS
```

```
WHERE TABLE_SCHEMA = 'mydb'
AND TABLE_NAME = 'mytable';
```

For more information, see [Section 24.13, “The INFORMATION_SCHEMA PARTITIONS Table”](#).

- [Auto_increment](#)

The next `AUTO_INCREMENT` value.

- [Create_time](#)

When the table was created.

- [Update_time](#)

When the data file was last updated. For some storage engines, this value is `NULL`. For example, [InnoDB](#) stores multiple tables in its [system tablespace](#) and the data file timestamp does not apply. Even with [file-per-table](#) mode with each [InnoDB](#) table in a separate `.ibd` file, [change buffering](#) can delay the write to the data file, so the file modification time is different from the time of the last insert, update, or delete. For [MyISAM](#), the data file timestamp is used; however, on Windows the timestamp is not updated by updates so the value is inaccurate.

- [Check_time](#)

When the table was last checked. Not all storage engines update this time, in which case the value is always `NULL`.

- [Collation](#)

The table's character set and collation.

- [Checksum](#)

The live checksum value (if any).

- [Create_options](#)

Extra options used with `CREATE TABLE`. The original options supplied when `CREATE TABLE` is called are retained and the options reported here may differ from the active table settings and options.

- [Comment](#)

The comment used when creating the table (or information as to why MySQL could not access the table information).

Notes:

- For `MEMORY` tables, the `Data_length`, `Max_data_length`, and `Index_length` values approximate the actual amount of allocated memory. The allocation algorithm reserves memory in large amounts to reduce the number of allocation operations.
- For views, all the fields displayed by `SHOW TABLE STATUS` are `NULL` except that `Name` indicates the view name and `Comment` says `view`.

13.7.5.37 SHOW TABLES Syntax

```
SHOW [EXTENDED] [FULL] TABLES
  [{FROM | IN} db_name]
  [LIKE 'pattern' | WHERE expr]
```

`SHOW TABLES` lists the non-`TEMPORARY` tables in a given database. You can also get this list using the `mysqlshow db_name` command. The `LIKE` clause, if present, indicates which table names to

match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 24.33, “Extensions to SHOW Statements”](#).

Matching performed by the `LIKE` clause is dependent on the setting of the `lower_case_table_names` system variable.

As of MySQL 8.0.2, the optional `EXTENDED` modifier causes `SHOW TABLES` to list hidden tables created by failed `ALTER TABLE` statements. These temporary tables have names beginning with `#sql` and can be dropped using `DROP TABLE`.

This statement also lists any views in the database. The optional `FULL` modifier causes `SHOW TABLES` to display a second output column with values of `BASE TABLE` for a table and `VIEW` for a view.

If you have no privileges for a base table or view, it does not show up in the output from `SHOW TABLES` or `mysqlshow db_name`.

13.7.5.38 SHOW TRIGGERS Syntax

```
SHOW TRIGGERS
  [{FROM | IN} db_name]
  [LIKE 'pattern' | WHERE expr]
```

`SHOW TRIGGERS` lists the triggers currently defined for tables in a database (the default database unless a `FROM` clause is given). This statement returns results only for databases and tables for which you have the `TRIGGER` privilege. The `LIKE` clause, if present, indicates which table names to match (not trigger names) and causes the statement to display triggers for those tables. The `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 24.33, “Extensions to SHOW Statements”](#).

For the trigger `ins_sum` as defined in [Section 23.3, “Using Triggers”](#), the output of this statement is as shown here:

```
mysql> SHOW TRIGGERS LIKE 'acc%'\G
***** 1. row *****
      Trigger: ins_sum
      Event: INSERT
      Table: account
      Statement: SET @sum = @sum + NEW.amount
      Timing: BEFORE
      Created: 2013-07-09 10:39:34.96
      sql_mode: NO_ENGINE_SUBSTITUTION
      Definer: me@localhost
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: utf8mb4_0900_ai_ci
```

`SHOW TRIGGERS` output has the following columns:

- **Trigger:** The trigger name.
- **Event:** The type of operation that causes trigger activation. The value is `'INSERT'`, `'UPDATE'`, or `'DELETE'`.
- **Table:** The table for which the trigger is defined.
- **Statement:** The trigger body; that is, the statement executed when the trigger activates.
- **Timing:** Whether the trigger activates before or after the triggering event. The value is `'BEFORE'` or `'AFTER'`.
- **Created:** The date and time when the trigger was created. This is a `TIMESTAMP(2)` value (with a fractional part in hundredths of seconds) for triggers.
- **sql_mode:** The SQL mode in effect when the trigger executes.

- **Definer**: The account of the user who created the trigger, in `'user_name'@'host_name'` format.
- **character_set_client**: The session value of the `character_set_client` system variable when the trigger was created.
- **collation_connection**: The session value of the `collation_connection` system variable when the trigger was created.
- **Database Collation**: The collation of the database with which the trigger is associated.

You can also obtain information about trigger objects from `INFORMATION_SCHEMA`, which contains a `TRIGGERS` table. See [Section 24.28, “The INFORMATION_SCHEMA TRIGGERS Table”](#).

13.7.5.39 SHOW VARIABLES Syntax

```
SHOW [GLOBAL | SESSION] VARIABLES
     [LIKE 'pattern' | WHERE expr]
```

`SHOW VARIABLES` shows the values of MySQL system variables (see [Section 5.1.5, “Server System Variables”](#)). This statement does not require any privilege. It requires only the ability to connect to the server.

System variable information is also available from these sources:

- Performance Schema tables. See [Section 25.11.13, “Performance Schema System Variable Tables”](#).
- The `mysqladmin variables` command. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

For `SHOW VARIABLES`, a `LIKE` clause, if present, indicates which variable names to match. A `WHERE` clause can be given to select rows using more general conditions, as discussed in [Section 24.33, “Extensions to SHOW Statements”](#).

`SHOW VARIABLES` accepts an optional `GLOBAL` or `SESSION` variable scope modifier:

- With a `GLOBAL` modifier, the statement displays global system variable values. These are the values used to initialize the corresponding session variables for new connections to MySQL. If a variable has no global value, no value is displayed.
- With a `SESSION` modifier, the statement displays the system variable values that are in effect for the current connection. If a variable has no session value, the global value is displayed. `LOCAL` is a synonym for `SESSION`.
- If no modifier is present, the default is `SESSION`.

The scope for each system variable is listed at [Section 5.1.5, “Server System Variables”](#).

`SHOW VARIABLES` is subject to a version-dependent display-width limit. For variables with very long values that are not completely displayed, use `SELECT` as a workaround. For example:

```
SELECT @@GLOBAL.innodb_data_file_path;
```

Most system variables can be set at server startup (read-only variables such as `version_comment` are exceptions). Many can be changed at runtime with the `SET` statement. See [Section 5.1.6, “Using System Variables”](#), and [Section 13.7.4.1, “SET Syntax for Variable Assignment”](#).

Partial output is shown here. The list of names and values may differ for your server. [Section 5.1.5, “Server System Variables”](#), describes the meaning of each variable, and [Section 5.1.1, “Configuring the Server”](#), provides information about tuning them.

```
mysql> SHOW VARIABLES;
```

Variable_name	Value
auto_increment_increment	1

warning_count	0

With a [LIKE](#) clause, the statement displays only rows for those variables with names that match the pattern. To obtain the row for a specific variable, use a [LIKE](#) clause as shown:

```
SHOW VARIABLES LIKE 'max_join_size';
SHOW SESSION VARIABLES LIKE 'max_join_size';
```

To get a list of variables whose name match a pattern, use the [%](#) wildcard character in a [LIKE](#) clause:

```
SHOW VARIABLES LIKE '%size%';
SHOW GLOBAL VARIABLES LIKE '%size%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because [_](#) is a wildcard that matches any single character, you should escape it as [_](#) to match it literally. In practice, this is rarely necessary.

13.7.5.40 SHOW WARNINGS Syntax

```
SHOW WARNINGS [LIMIT [offset,] row_count]
SHOW COUNT(*) WARNINGS
```

`SHOW WARNINGS` is a diagnostic statement that displays information about the conditions (errors, warnings, and notes) resulting from executing a statement in the current session. Warnings are generated for DML statements such as `INSERT`, `UPDATE`, and `LOAD DATA INFILE` as well as DDL statements such as `CREATE TABLE` and `ALTER TABLE`.

The `LIMIT` clause has the same syntax as for the `SELECT` statement. See [Section 13.2.10, “SELECT Syntax”](#).

`SHOW WARNINGS` is also used following `EXPLAIN`, to display the extended information generated by `EXPLAIN`. See [Section 8.8.3, “Extended EXPLAIN Output Format”](#).

`SHOW WARNINGS` displays information about the conditions resulting from execution of the most recent nondiagnostic statement in the current session. If the most recent statement resulted in an error during parsing, `SHOW WARNINGS` shows the resulting conditions, regardless of statement type (diagnostic or nondiagnostic).

The `SHOW COUNT(*) WARNINGS` diagnostic statement displays the total number of errors, warnings, and notes. You can also retrieve this number from the `warning_count` system variable:

```
SHOW COUNT(*) WARNINGS;
SELECT @@warning_count;
```

A difference in these statements is that the first is a diagnostic statement that does not clear the message list. The second, because it is a `SELECT` statement is considered nondiagnostic and does clear the message list.

A related diagnostic statement, `SHOW ERRORS`, shows only error conditions (it excludes warnings and notes), and `SHOW COUNT(*) ERRORS` statement displays the total number of errors. See [Section 13.7.5.17, “SHOW ERRORS Syntax”](#). `GET DIAGNOSTICS` can be used to examine information for individual conditions. See [Section 13.6.7.3, “GET DIAGNOSTICS Syntax”](#).

Here is a simple example that shows data-conversion warnings for `INSERT`:

```
mysql> CREATE TABLE t1 (a TINYINT NOT NULL, b CHAR(4));
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t1 VALUES(10,'mysql'), (NULL,'test'), (300,'xyz');
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 3

mysql> SHOW WARNINGS\G
***** 1. row *****
Level: Warning
Code: 1265
Message: Data truncated for column 'b' at row 1
***** 2. row *****
Level: Warning
Code: 1048
Message: Column 'a' cannot be null
***** 3. row *****
Level: Warning
Code: 1264
Message: Out of range value for column 'a' at row 3
3 rows in set (0.00 sec)
```

The `max_error_count` system variable controls the maximum number of error, warning, and note messages for which the server stores information, and thus the number of messages that `SHOW WARNINGS` displays. To change the number of messages the server can store, change the value of `max_error_count`.

`max_error_count` controls only how many messages are stored, not how many are counted. The value of `warning_count` is not limited by `max_error_count`, even if the number of messages generated exceeds `max_error_count`. The following example demonstrates this. The `ALTER TABLE` statement produces three warning messages (strict SQL mode is disabled for the example to prevent an error from occurring after a single conversion issue). Only one message is stored and displayed because `max_error_count` has been set to 1, but all three are counted (as shown by the value of `warning_count`):

```
mysql> SHOW VARIABLES LIKE 'max_error_count';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| max_error_count | 1024 |
+-----+-----+
1 row in set (0.00 sec)

mysql> SET max_error_count=1, sql_mode = '';
Query OK, 0 rows affected (0.00 sec)

mysql> ALTER TABLE t1 MODIFY b CHAR;
Query OK, 3 rows affected, 3 warnings (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 3

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 1263 | Data truncated for column 'b' at row 1 |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT @@warning_count;
+-----+
| @@warning_count |
+-----+
| 3 |
+-----+
1 row in set (0.01 sec)
```

To disable message storage, set `max_error_count` to 0. In this case, `warning_count` still indicates how many warnings occurred, but messages are not stored and cannot be displayed.

The `sql_notes` system variable controls whether note messages increment `warning_count` and whether the server stores them. By default, `sql_notes` is 1, but if set to 0, notes do not increment `warning_count` and the server does not store them:

```
mysql> SET sql_notes = 1;
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected, 1 warning (0.00 sec)
mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Note | 1051 | Unknown table 'test.no_such_table' |
+-----+-----+-----+
1 row in set (0.00 sec)

mysql> SET sql_notes = 0;
mysql> DROP TABLE IF EXISTS test.no_such_table;
Query OK, 0 rows affected (0.00 sec)
mysql> SHOW WARNINGS;
Empty set (0.00 sec)
```

The MySQL server sends to each client a count indicating the total number of errors, warnings, and notes resulting from the most recent statement executed by that client. From the C API, this value can be obtained by calling `mysql_warning_count()`. See [Section 27.7.7.80, “mysql_warning_count\(\)”](#).

In the `mysql` client, you can enable and disable automatic warnings display using the `warnings` and `nowarning` commands, respectively, or their shortcuts, `\W` and `\w` (see [Section 4.5.1.2, “mysql Commands”](#)). For example:

```
mysql> \W
Show warnings enabled.
mysql> SELECT 1/0;
+-----+
| 1/0 |
+-----+
| NULL |
+-----+
1 row in set, 1 warning (0.03 sec)

Warning (Code 1365): Division by 0
mysql> \w
Show warnings disabled.
```

13.7.6 Other Administrative Statements

13.7.6.1 BINLOG Syntax

```
BINLOG 'str'
```

`BINLOG` is an internal-use statement. It is generated by the `mysqlbinlog` program as the printable representation of certain events in binary log files. (See [Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”](#).) The '*str*' value is a base 64-encoded string that the server decodes to determine the data change indicated by the corresponding event. This statement requires the `BINLOG_ADMIN` or `SUPER` privilege.

This statement can execute only format description events and row events.

13.7.6.2 CACHE INDEX Syntax

```
CACHE INDEX
  tbl_index_list [, tbl_index_list] ...
  [PARTITION (partition_list | ALL)]
  IN key_cache_name

tbl_index_list:
  tbl_name [[INDEX|KEY] (index_name [, index_name] ...)]

partition_list:
  partition_name [, partition_name] [, ...]
```

The `CACHE INDEX` statement assigns table indexes to a specific key cache. It is used only for `MyISAM` tables. After the indexes have been assigned, they can be preloaded into the cache if desired with `LOAD INDEX INTO CACHE`.

The following statement assigns indexes from the tables `t1`, `t2`, and `t3` to the key cache named `hot_cache`:

```
mysql> CACHE INDEX t1, t2, t3 IN hot_cache;
+-----+-----+-----+-----+
| Table | Op           | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.t1 | assign_to_keycache | status   | OK       |
| test.t2 | assign_to_keycache | status   | OK       |
| test.t3 | assign_to_keycache | status   | OK       |
+-----+-----+-----+-----+
```

The syntax of `CACHE INDEX` enables you to specify that only particular indexes from a table should be assigned to the cache. The current implementation assigns all the table's indexes to the cache, so there is no reason to specify anything other than the table name.

The key cache referred to in a `CACHE INDEX` statement can be created by setting its size with a parameter setting statement or in the server parameter settings. For example:

```
mysql> SET GLOBAL keycache1.key_buffer_size=128*1024;
```

Key cache parameters can be accessed as members of a structured system variable. See [Section 5.1.6.1, “Structured System Variables”](#).

A key cache must exist before you can assign indexes to it:

```
mysql> CACHE INDEX t1 IN non_existent_cache;
ERROR 1284 (HY000): Unknown key cache 'non_existent_cache'
```

By default, table indexes are assigned to the main (default) key cache created at the server startup. When a key cache is destroyed, all indexes assigned to it become assigned to the default key cache again.

Index assignment affects the server globally: If one client assigns an index to a given cache, this cache is used for all queries involving the index, no matter which client issues the queries.

In MySQL 8.0, this statement is also supported for partitioned `MyISAM` tables. You can assign one or more indexes for one, several, or all partitions to a given key cache. For example, you can do the following:

```
CREATE TABLE pt (c1 INT, c2 VARCHAR(50), INDEX i(c1))
ENGINE=MyISAM
PARTITION BY HASH(c1)
PARTITIONS 4;

SET GLOBAL kc_fast.key_buffer_size = 128 * 1024;
SET GLOBAL kc_slow.key_buffer_size = 128 * 1024;

CACHE INDEX pt PARTITION (p0) IN kc_fast;
CACHE INDEX pt PARTITION (p1, p3) IN kc_slow;
```

The previous set of statements performs the following actions:

- Creates a partitioned table with 4 partitions; these partitions are automatically named `p0`, ..., `p3`; this table has an index named `i` on column `c1`.
- Creates 2 key caches named `kc_fast` and `kc_slow`
- Assigns the index for partition `p0` to the `kc_fast` key cache and the index for partitions `p1` and `p3` to the `kc_slow` key cache; the index for the remaining partition (`p2`) uses the server's default key cache.

If you wish instead to assign the indexes for all partitions in table `pt` to a single key cache named `kc_all`, you can use either one of the following 2 statements:

```
CACHE INDEX pt PARTITION (ALL) IN kc_all;

CACHE INDEX pt IN kc_all;
```

The two statements just shown are equivalent, and issuing either one of them has exactly the same effect. In other words, if you wish to assign indexes for all partitions of a partitioned table to the same key cache, then the `PARTITION (ALL)` clause is optional.

When assigning indexes for multiple partitions to a key cache, the partitions do not have to be contiguous, and you are not required to list their names in any particular order. Indexes for any partitions that are not explicitly assigned to a key cache automatically use the server's default key cache.

In MySQL 8.0, index preloading is also supported for partitioned `MyISAM` tables. For more information, see [Section 13.7.6.5, “LOAD INDEX INTO CACHE Syntax”](#).

13.7.6.3 FLUSH Syntax

```
FLUSH [NO_WRITE_TO_BINLOG | LOCAL]
      flush_option [, flush_option] ...
```

The `FLUSH` statement has several variant forms that clear or reload various internal caches, flush tables, or acquire locks. To execute `FLUSH`, you must have the `RELOAD` privilege. Specific flush options might require additional privileges, as described later.

By default, the server writes `FLUSH` statements to the binary log so that they replicate to replication slaves. To suppress logging, specify the optional `NO_WRITE_TO_BINLOG` keyword or its alias `LOCAL`.

Note

`FLUSH LOGS`, `FLUSH TABLES WITH READ LOCK` (with or without a table list), and `FLUSH TABLES tbl_name ... FOR EXPORT` are not written to the binary log in any case because they would cause problems if replicated to a slave.

Sending a `SIGHUP` signal to the server causes several flush operations to occur that are similar to various forms of the `FLUSH` statement. See [Section 5.1.11, “Server Response to Signals”](#).

The `FLUSH` statement causes an implicit commit. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

The `RESET` statement is similar to `FLUSH`. See [Section 13.7.6.6, “RESET Syntax”](#), for information about using the `RESET` statement with replication.

flush_option can be any of the following items.

- `DES_KEY_FILE`

Reloads the DES keys from the file that was specified with the `--des-key-file` option at server startup time.

- `HOSTS`

Empties the host cache. You should flush the host cache if some of your hosts change IP address or if the error message `Host 'host_name' is blocked` occurs. (See [Section B.5.2.5, “Host 'host_name' is blocked”](#).) When more than `max_connect_errors` errors occur successively for a given host while connecting to the MySQL server, MySQL assumes that something is wrong and blocks the host from further connection requests. Flushing the host cache enables further connection attempts from the host. The default value of `max_connect_errors` is 100. To avoid this error message, start the server with `max_connect_errors` set to a large value.

- `[log_type] LOGS | RELAY LOGS [channel_option]`

With no *log_type* option, `FLUSH LOGS` closes and reopens all log files. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file.

`FLUSH LOGS` has no effect on tables used for the general query log or for the slow query log (see [Section 5.4.1, “Selecting General Query and Slow Query Log Output Destinations”](#)).

With a *log_type* option, only the specified log type is flushed. These *log_type* options are permitted:

- `BINARY` closes and reopens the binary log files. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file.

- `ENGINE` closes and reopens any flushable logs for installed storage engines. This causes `InnoDB` to flush its logs to disk.
- `ERROR` closes and reopens the error log file.
- `GENERAL` closes and reopens the general query log file.
- `RELAY` closes and reopens the relay log files. If binary logging is enabled, the sequence number of the binary log file is incremented by one relative to the previous file.

The `FOR CHANNEL channel` clause enables you to choose which replication channel to apply a `FLUSH RELAY LOGS` statement to. If no clause is set and no extra replication channels exist, the statement applies to the default channel and behaves the same as versions of MySQL prior to 5.7.6. If multiple replication channels exist and no clause is set, *all* replication channels are flushed. Execute a `FLUSH RELAY LOGS FOR CHANNEL channel` statement to flush a specific replication channel's relay log. See [Section 18.2.3, “Replication Channels”](#) for more information.

Note

The `FOR CHANNEL channel` clause can only be used with the `RELAY LOGS log_type`.

- `SLOW` closes and reopens the slow query log file.
- `OPTIMIZER_COSTS`

Rereads the cost model tables so that the optimizer starts using the current cost estimates stored in them. The server writes a warning to the error log for any unrecognized entries. (For information about these tables, see [Section 8.9.5, “The Optimizer Cost Model”](#).) This operation affects only sessions that begin subsequent to the flush. Existing sessions continue to use the cost estimates that were current when they began.

- `PRIVILEGES`

Reloads the privileges from the grant tables in the `mysql` database.

The `FLUSH PRIVILEGES` statement reads the `global_grants` table for dynamic privilege assignments and registers any unregistered privileges found there.

The server caches information in memory as a result of `GRANT`, `CREATE USER`, `CREATE SERVER`, and `INSTALL PLUGIN` statements. This memory is not released by the corresponding `REVOKE`, `DROP USER`, `DROP SERVER`, and `UNINSTALL PLUGIN` statements, so for a server that executes many instances of the statements that cause caching, there will be an increase in memory use. This cached memory can be freed with `FLUSH PRIVILEGES`.

- `QUERY CACHE`

Defragment the query cache to better utilize its memory. `FLUSH QUERY CACHE` does not remove any queries from the cache, unlike `FLUSH TABLES` or `RESET QUERY CACHE`.

- `STATUS`

This option adds the session status from all active sessions to the global status variables, resets the status of all active sessions, and resets account, host, and user status values aggregated from disconnected sessions. This is something that may be of use when debugging a query. See [Section 1.7, “How to Report Bugs or Problems”](#).

- `TABLES`

`FLUSH TABLES` flushes tables, and, depending on the variant used, acquires locks. The permitted syntax is discussed later in this section.

- `USER_RESOURCES`

Resets all per-hour user resources to zero. This enables clients that have reached their hourly connection, query, or update limits to resume activity immediately. `FLUSH USER_RESOURCES` does not apply to the limit on maximum simultaneous connections. See [Section 6.3.6, “Setting Account Resource Limits”](#).

The `mysqladmin` utility provides a command-line interface to some flush operations, using commands such as `flush-hosts`, `flush-logs`, `flush-privileges`, `flush-status`, and `flush-tables`. See [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#).

Note

It is not possible to issue `FLUSH` statements within stored functions or triggers. However, you may use `FLUSH` in stored procedures, so long as these are not called from stored functions or triggers. See [Section C.1, “Restrictions on Stored Programs”](#).

FLUSH TABLES Syntax

`FLUSH TABLES` has several forms, described following. If any variant of the `TABLES` option is used in a `FLUSH` statement, it must be the only option used. `FLUSH TABLE` is a synonym for `FLUSH TABLES`.

- `FLUSH TABLES`

Closes all open tables, forces all tables in use to be closed, and flushes the query cache. `FLUSH TABLES` also removes all query results from the query cache, like the `RESET QUERY CACHE` statement.

In MySQL 8.0, `FLUSH TABLES` is not permitted when there is an active `LOCK TABLES ... READ`. To flush and lock tables, use `FLUSH TABLES tbl_name ... WITH READ LOCK` instead.

- `FLUSH TABLES tbl_name [, tbl_name] ...`

With a list of one or more comma-separated table names, this statement is like `FLUSH TABLES` with no names except that the server flushes only the named tables. No error occurs if a named table does not exist.

- `FLUSH TABLES WITH READ LOCK`

Closes all open tables and locks all tables for all databases with a global read lock. This is a very convenient way to get backups if you have a file system such as Veritas or ZFS that can take snapshots in time. Use `UNLOCK TABLES` to release the lock.

`FLUSH TABLES WITH READ LOCK` acquires a global read lock and not table locks, so it is not subject to the same behavior as `LOCK TABLES` and `UNLOCK TABLES` with respect to table locking and implicit commits:

- `UNLOCK TABLES` implicitly commits any active transaction only if any tables currently have been locked with `LOCK TABLES`. The commit does not occur for `UNLOCK TABLES` following `FLUSH TABLES WITH READ LOCK` because the latter statement does not acquire table locks.
- Beginning a transaction causes table locks acquired with `LOCK TABLES` to be released, as though you had executed `UNLOCK TABLES`. Beginning a transaction does not release a global read lock acquired with `FLUSH TABLES WITH READ LOCK`.

`FLUSH TABLES WITH READ LOCK` does not prevent the server from inserting rows into the log tables (see [Section 5.4.1, “Selecting General Query and Slow Query Log Output Destinations”](#)).

`FLUSH TABLES WITH READ LOCK` is not compatible with XA transactions.

- `FLUSH TABLES tbl_name [, tbl_name] ... WITH READ LOCK`

This statement flushes and acquires read locks for the named tables. The statement first acquires exclusive metadata locks for the tables, so it waits for transactions that have those tables open to complete. Then the statement flushes the tables from the table cache, reopens the tables, acquires table locks (like `LOCK TABLES ... READ`), and downgrades the metadata locks from exclusive to shared. After the statement acquires locks and downgrades the metadata locks, other sessions can read but not modify the tables.

Because this statement acquires table locks, you must have the `LOCK TABLES` privilege for each table, in addition to the `RELOAD` privilege that is required to use any `FLUSH` statement.

This statement applies only to existing base tables. If a name refers to a base table, that table is used. If it refers to a `TEMPORARY` table, it is ignored. If a name applies to a view, an `ER_WRONG_OBJECT` error occurs. Otherwise, an `ER_NO_SUCH_TABLE` error occurs.

Use `UNLOCK TABLES` to release the locks, `LOCK TABLES` to release the locks and acquire other locks, or `START TRANSACTION` to release the locks and begin a new transaction.

This variant of `FLUSH` enables tables to be flushed and locked in a single operation. It provides a workaround for the restriction in MySQL 8.0 that `FLUSH TABLES` is not permitted when there is an active `LOCK TABLES ... READ`.

This statement does not perform an implicit `UNLOCK TABLES`, so an error results if you use the statement while there is any active `LOCK TABLES` or use it a second time without first releasing the locks acquired.

If a flushed table was opened with `HANDLER`, the handler is implicitly flushed and loses its position.

- `FLUSH TABLES tbl_name [, tbl_name] ... FOR EXPORT`

This `FLUSH TABLES` variant applies to `InnoDB` tables. It ensures that changes to the named tables have been flushed to disk so that binary table copies can be made while the server is running.

The statement works like this:

1. It acquires shared metadata locks for the named tables. The statement blocks as long as other sessions have active transactions that have modified those tables or hold table locks for them. When the locks have been acquired, the statement blocks transactions that attempt to update the tables while permitting read-only operations to continue.
2. It checks whether all storage engines for the tables support `FOR EXPORT`. If any do not, an `ER_ILLEGAL HA` error occurs and the statement fails.
3. The statement notifies the storage engine for each table to make the table ready for export. The storage engine must ensure that any pending changes are written to disk.
4. The statement puts the session in lock-tables mode so that the metadata locks acquired earlier are not released when the `FOR EXPORT` statement completes.

The `FLUSH TABLES ... FOR EXPORT` statement requires that you have the `SELECT` privilege for each table. Because this statement acquires table locks, you must also have the `LOCK TABLES` privilege for each table, in addition to the `RELOAD` privilege that is required to use any `FLUSH` statement.

This statement applies only to existing base tables. If a name refers to a base table, that table is used. If it refers to a `TEMPORARY` table, it is ignored. If a name applies to a view, an `ER_WRONG_OBJECT` error occurs. Otherwise, an `ER_NO_SUCH_TABLE` error occurs.

`InnoDB` supports `FOR EXPORT` for tables that have their own `.ibd` file (that is, tables that were created with the `innodb_file_per_table` setting enabled). `InnoDB` ensures when notified by the `FOR EXPORT` statement that any changes have been flushed to disk. This permits a binary copy

of table contents to be made while the `FOR EXPORT` statement is in effect because the `.ibd` file is transaction consistent and can be copied while the server is running. `FOR EXPORT` does not apply to `InnoDB` system tablespace files, or to `InnoDB` tables that have any `FULLTEXT` indexes.

`FLUSH TABLES ... FOR EXPORT` is supported for partitioned `InnoDB` tables.

When notified by `FOR EXPORT`, `InnoDB` writes to disk certain kinds of data that is normally held in memory or in separate disk buffers outside the tablespace files. For each table, `InnoDB` also produces a file named `table_name.cfg` in the same database directory as the table. The `.cfg` file contains metadata needed to reimport the tablespace files later, into the same or different server.

When the `FOR EXPORT` statement completes, `InnoDB` will have flushed all `dirty pages` to the table data files. Any `change buffer` entries are merged prior to flushing. At this point, the tables are locked and quiescent: The tables are in a transactionally consistent state on disk and you can copy the `.ibd` tablespace files along with the corresponding `.cfg` files to get a consistent snapshot of those tables.

For the procedure to reimport the copied table data into a MySQL instance, see [Section 15.7.6, “Copying File-Per-Table Tablespaces to Another Instance”](#).

After you are done with the tables, use `UNLOCK TABLES` to release the locks, `LOCK TABLES` to release the locks and acquire other locks, or `START TRANSACTION` to release the locks and begin a new transaction.

While any of these statements is in effect within the session, attempts to use `FLUSH TABLES ... FOR EXPORT` produce an error:

```
FLUSH TABLES ... WITH READ LOCK
FLUSH TABLES ... FOR EXPORT
LOCK TABLES ... READ
LOCK TABLES ... WRITE
```

While `FLUSH TABLES ... FOR EXPORT` is in effect within the session, attempts to use any of these statements produce an error:

```
FLUSH TABLES WITH READ LOCK
FLUSH TABLES ... WITH READ LOCK
FLUSH TABLES ... FOR EXPORT
```

13.7.6.4 KILL Syntax

```
KILL [CONNECTION | QUERY] processlist_id
```

Each connection to `mysqld` runs in a separate thread. You can kill a thread with the `KILL processlist_id` statement.

Thread `processlist` identifiers can be determined from the `ID` column of the `INFORMATION_SCHEMA.PROCESSLIST` table, the `Id` column of `SHOW PROCESSLIST` output, and the `PROCESSLIST_ID` column of the Performance Schema `threads` table. The value for the current thread is returned by the `CONNECTION_ID()` function.

`KILL` permits an optional `CONNECTION` or `QUERY` modifier:

- `KILL CONNECTION` is the same as `KILL` with no modifier: It terminates the connection associated with the given `processlist_id`, after terminating any statement the connection is executing.
- `KILL QUERY` terminates the statement the connection is currently executing, but leaves the connection itself intact.

If you have the `PROCESS` privilege, you can see all threads. If you have the `SUPER` privilege, you can kill all threads and statements. Otherwise, you can see and kill only your own threads and statements.

You can also use the `mysqladmin processlist` and `mysqladmin kill` commands to examine and kill threads.

When you use `KILL`, a thread-specific kill flag is set for the thread. In most cases, it might take some time for the thread to die because the kill flag is checked only at specific intervals:

- During `SELECT` operations, for `ORDER BY` and `GROUP BY` loops, the flag is checked after reading a block of rows. If the kill flag is set, the statement is aborted.
- `ALTER TABLE` operations that make a table copy check the kill flag periodically for each few copied rows read from the original table. If the kill flag was set, the statement is aborted and the temporary table is deleted.

The `KILL` statement returns without waiting for confirmation, but the kill flag check aborts the operation within a reasonably small amount of time. Aborting the operation to perform any necessary cleanup also takes some time.

- During `UPDATE` or `DELETE` operations, the kill flag is checked after each block read and after each updated or deleted row. If the kill flag is set, the statement is aborted. If you are not using transactions, the changes are not rolled back.
- `GET_LOCK()` aborts and returns `NULL`.
- If the thread is in the table lock handler (state: `Locked`), the table lock is quickly aborted.
- If the thread is waiting for free disk space in a write call, the write is aborted with a “disk full” error message.

Warning

Killing a `REPAIR TABLE` or `OPTIMIZE TABLE` operation on a `MyISAM` table results in a table that is corrupted and unusable. Any reads or writes to such a table fail until you optimize or repair it again (without interruption).

13.7.6.5 LOAD INDEX INTO CACHE Syntax

```
LOAD INDEX INTO CACHE
  tbl_index_list [, tbl_index_list] ...

tbl_index_list:
  tbl_name
  [PARTITION (partition_list | ALL)]
  [[INDEX|KEY] (index_name[, index_name] ...)]
  [IGNORE LEAVES]

partition_list:
  partition_name[, partition_name][, ...]
```

The `LOAD INDEX INTO CACHE` statement preloads a table index into the key cache to which it has been assigned by an explicit `CACHE INDEX` statement, or into the default key cache otherwise.

`LOAD INDEX INTO CACHE` is used only for `MyISAM` tables. In MySQL 8.0, it is also supported for partitioned `MyISAM` tables; in addition, indexes on partitioned tables can be preloaded for one, several, or all partitions.

The `IGNORE LEAVES` modifier causes only blocks for the nonleaf nodes of the index to be preloaded.

`IGNORE LEAVES` is also supported for partitioned `MyISAM` tables.

The following statement preloads nodes (index blocks) of indexes for the tables `t1` and `t2`:

```
mysql> LOAD INDEX INTO CACHE t1, t2 IGNORE LEAVES;
+-----+-----+-----+-----+-----+
```

Table	Op	Msg_type	Msg_text
test.t1	preload_keys	status	OK
test.t2	preload_keys	status	OK

This statement preloads all index blocks from `t1`. It preloads only blocks for the nonleaf nodes from `t2`.

The syntax of `LOAD INDEX INTO CACHE` enables you to specify that only particular indexes from a table should be preloaded. The current implementation preloads all the table's indexes into the cache, so there is no reason to specify anything other than the table name.

It is possible to preload indexes on specific partitions of partitioned `MyISAM` tables. For example, of the following 2 statements, the first preloads indexes for partition `p0` of a partitioned table `pt`, while the second preloads the indexes for partitions `p1` and `p3` of the same table:

```
LOAD INDEX INTO CACHE pt PARTITION (p0);
LOAD INDEX INTO CACHE pt PARTITION (p1, p3);
```

To preload the indexes for all partitions in table `pt`, you can use either one of the following 2 statements:

```
LOAD INDEX INTO CACHE pt PARTITION (ALL);
LOAD INDEX INTO CACHE pt;
```

The two statements just shown are equivalent, and issuing either one of them has exactly the same effect. In other words, if you wish to preload indexes for all partitions of a partitioned table, then the `PARTITION (ALL)` clause is optional.

When preloading indexes for multiple partitions, the partitions do not have to be contiguous, and you are not required to list their names in any particular order.

`LOAD INDEX INTO CACHE ... IGNORE LEAVES` fails unless all indexes in a table have the same block size. You can determine index block sizes for a table by using `myisamchk -dv` and checking the `Blocksize` column.

13.7.6.6 RESET Syntax

```
RESET reset_option [, reset_option] ...
```

The `RESET` statement is used to clear the state of various server operations. You must have the `RELOAD` privilege to execute `RESET`.

For information about the `RESET PERSIST` statement that removes persisted global system variables, see [Section 13.7.6.7, “RESET PERSIST Syntax”](#).

`RESET` acts as a stronger version of the `FLUSH` statement. See [Section 13.7.6.3, “FLUSH Syntax”](#).

The `RESET` statement causes an implicit commit. See [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

`reset_option` can be any of the following:

- `MASTER`

Deletes all binary logs listed in the index file, resets the binary log index file to be empty, and creates a new binary log file.

- `QUERY CACHE`

Removes all query results from the query cache.

- `SLAVE`

Makes the slave forget its replication position in the master binary logs. Also resets the relay log by deleting any existing relay log files and beginning a new one.

13.7.6.7 RESET PERSIST Syntax

```
RESET PERSIST [[IF EXISTS] system_var_name]
```

`RESET PERSIST` is used to remove persisted global system variable settings from the `mysqld-auto.cnf` file. This statement requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege. Removing a persisted system variable causes the variable no longer to be initialized from `mysqld-auto.cnf` at server startup.

For information about persisted system variables, see [Section 5.1.6, “Using System Variables”](#). For information about `RESET` statement variants that clear the state of other server operations, see [Section 13.7.6.6, “RESET Syntax”](#).

Depending on whether the variable name and `IF EXISTS` clauses are present, the statement has these forms:

- `RESET PERSIST`

This statement removes all persisted variables from `mysqld-auto.cnf`.

- `RESET PERSIST system_var_name`

This statement removes the named persisted variable from `mysqld-auto.cnf`. This includes plugin system variables, even if the plugin is not currently installed. If the variable is not present in the file, an error occurs.

- `RESET PERSIST IF EXISTS system_var_name`

This statement removes the named persisted variable from `mysqld-auto.cnf`. This includes plugin system variables, even if the plugin is not currently installed. If the variable is not present in the file, a warning is generated.

`RESET PERSIST` is not affected by the value of the `persisted_globals_load` system variable.

`RESET PERSIST` affects the contents of the Performance Schema `persisted_variables` table because the table contents correspond to the contents of the `mysqld-auto.cnf` file.

`RESET PERSIST` has no effect on the contents of the Performance Schema `variables_info` table.

13.7.6.8 SHUTDOWN Syntax

```
SHUTDOWN
```

This statement stops the MySQL server. It requires the `SHUTDOWN` privilege.

`SHUTDOWN` provides an SQL-level interface to the same functionality available using the `mysqladmin shutdown` command.

13.8 Utility Statements

13.8.1 DESCRIBE Syntax

The `DESCRIBE` and `EXPLAIN` statements are synonyms, used either to obtain information about table structure or query execution plans. For more information, see [Section 13.7.5.5, “SHOW COLUMNS Syntax”](#), and [Section 13.8.2, “EXPLAIN Syntax”](#).

13.8.2 EXPLAIN Syntax

```
{EXPLAIN | DESCRIBE | DESC}
    tbl_name [col_name | wild]

{EXPLAIN | DESCRIBE | DESC}
    [explain_type]
    {explainable_stmt | FOR CONNECTION connection_id}

explain_type: {
    EXTENDED
  | PARTITIONS
  | FORMAT = format_name
}

format_name: {
    TRADITIONAL
  | JSON
}

explainable_stmt: {
    SELECT statement
  | DELETE statement
  | INSERT statement
  | REPLACE statement
  | UPDATE statement
}
```

The `DESCRIBE` and `EXPLAIN` statements are synonyms. In practice, the `DESCRIBE` keyword is more often used to obtain information about table structure, whereas `EXPLAIN` is used to obtain a query execution plan (that is, an explanation of how MySQL would execute a query).

The following discussion uses the `DESCRIBE` and `EXPLAIN` keywords in accordance with those uses, but the MySQL parser treats them as completely synonymous.

- [Obtaining Table Structure Information](#)
- [Obtaining Execution Plan Information](#)

Obtaining Table Structure Information

`DESCRIBE` provides information about the columns in a table:

```
mysql> DESCRIBE City;
+-----+-----+-----+-----+-----+-----+
| Field      | Type      | Null | Key | Default | Extra          |
+-----+-----+-----+-----+-----+-----+
| Id         | int(11)   | NO   | PRI | NULL    | auto_increment |
| Name      | char(35)  | NO   |     |         |                |
| Country   | char(3)   | NO   | UNI |         |                |
| District  | char(20)  | YES  | MUL |         |                |
| Population | int(11)   | NO   |     | 0       |                |
+-----+-----+-----+-----+-----+-----+
```

`DESCRIBE` is a shortcut for `SHOW COLUMNS`. These statements also display information for views. The description for `SHOW COLUMNS` provides more information about the output columns. See [Section 13.7.5.5, “SHOW COLUMNS Syntax”](#).

By default, `DESCRIBE` displays information about all columns in the table. `col_name`, if given, is the name of a column in the table. In this case, the statement displays information only for the named column. `wild`, if given, is a pattern string. It can contain the SQL `%` and `_` wildcard characters. In this case, the statement displays output only for the columns with names matching the string. There is no need to enclose the string within quotation marks unless it contains spaces or other special characters.

The `DESCRIBE` statement is provided for compatibility with Oracle.

The `SHOW CREATE TABLE`, `SHOW TABLE STATUS`, and `SHOW INDEX` statements also provide information about tables. See [Section 13.7.5, “SHOW Syntax”](#).

Obtaining Execution Plan Information

The `EXPLAIN` statement provides information about how MySQL executes statements:

- `EXPLAIN` works with `SELECT`, `DELETE`, `INSERT`, `REPLACE`, and `UPDATE` statements.
- When `EXPLAIN` is used with an explainable statement, MySQL displays information from the optimizer about the statement execution plan. That is, MySQL explains how it would process the statement, including information about how tables are joined and in which order. For information about using `EXPLAIN` to obtain execution plan information, see [Section 8.8.2, “EXPLAIN Output Format”](#).
- When `EXPLAIN` is used with `FOR CONNECTION connection_id` rather than an explainable statement, it displays the execution plan for the statement executing in the named connection. See [Section 8.8.4, “Obtaining Execution Plan Information for a Named Connection”](#).
- For `SELECT` statements, `EXPLAIN` produces additional execution plan information. See [Section 8.8.3, “Extended EXPLAIN Output Format”](#).

Note

In older MySQL releases, extended information was produced using `EXPLAIN EXTENDED`. That syntax is still recognized for backward compatibility but extended output is now enabled by default, so the `EXTENDED` keyword is superfluous and deprecated. Its use results in a warning, and it will be removed from `EXPLAIN` syntax in a future MySQL release.

- `EXPLAIN` is useful for examining queries involving partitioned tables. See [Section 22.3.5, “Obtaining Information About Partitions”](#).

Note

In older MySQL releases, partition information was produced using `EXPLAIN PARTITIONS`. That syntax is still recognized for backward compatibility but partition output is now enabled by default, so the `PARTITIONS` keyword is superfluous and deprecated. Its use results in a warning, and it will be removed from `EXPLAIN` syntax in a future MySQL release.

- The `FORMAT` option can be used to select the output format. `TRADITIONAL` presents the output in tabular format. This is the default if no `FORMAT` option is present. `JSON` format displays the information in JSON format.

`EXPLAIN` requires the `SELECT` privilege for any tables or views accessed, including any underlying tables of views. For views, `EXPLAIN` also requires the `SHOW VIEW` privilege.

With the help of `EXPLAIN`, you can see where you should add indexes to tables so that the statement executes faster by using indexes to find rows. You can also use `EXPLAIN` to check whether the optimizer joins the tables in an optimal order. To give a hint to the optimizer to use a join order corresponding to the order in which the tables are named in a `SELECT` statement, begin the statement with `SELECT STRAIGHT_JOIN` rather than just `SELECT`. (See [Section 13.2.10, “SELECT Syntax”](#).)

The optimizer trace may sometimes provide information complementary to that of `EXPLAIN`. However, the optimizer trace format and content are subject to change between versions. For details, see [MySQL Internals: Tracing the Optimizer](#).

If you have a problem with indexes not being used when you believe that they should be, run `ANALYZE TABLE` to update table statistics, such as cardinality of keys, that can affect the choices the optimizer makes. See [Section 13.7.2.1, “ANALYZE TABLE Syntax”](#).

**Note**

MySQL Workbench has a Visual Explain capability that provides a visual representation of [EXPLAIN](#) output. See [Tutorial: Using Visual Explain to Improve Query Performance](#).

13.8.3 HELP Syntax

```
HELP 'search_string'
```

The [HELP](#) statement returns online information from the MySQL Reference manual. Its proper operation requires that the help tables in the `mysql` database be initialized with help topic information (see [Section 5.1.10, “Server-Side Help”](#)).

The [HELP](#) statement searches the help tables for the given search string and displays the result of the search. The search string is not case sensitive.

The search string can contain the wildcard characters `%` and `_`. These have the same meaning as for pattern-matching operations performed with the [LIKE](#) operator. For example, `HELP 'rep%'` returns a list of topics that begin with `rep`.

The [HELP](#) statement understands several types of search strings:

- At the most general level, use `contents` to retrieve a list of the top-level help categories:

```
HELP 'contents'
```

- For a list of topics in a given help category, such as `Data Types`, use the category name:

```
HELP 'data types'
```

- For help on a specific help topic, such as the `ASCII()` function or the `CREATE TABLE` statement, use the associated keyword or keywords:

```
HELP 'ascii'
HELP 'create table'
```

In other words, the search string matches a category, many topics, or a single topic. You cannot necessarily tell in advance whether a given search string will return a list of items or the help information for a single help topic. However, you can tell what kind of response [HELP](#) returned by examining the number of rows and columns in the result set.

The following descriptions indicate the forms that the result set can take. Output for the example statements is shown using the familiar “tabular” or “vertical” format that you see when using the `mysql` client, but note that `mysql` itself reformats [HELP](#) result sets in a different way.

- Empty result set

No match could be found for the search string.

- Result set containing a single row with three columns

This means that the search string yielded a hit for the help topic. The result has three columns:

- `name`: The topic name.
- `description`: Descriptive help text for the topic.
- `example`: Usage example or examples. This column might be blank.

Example: `HELP 'replace'`

Yields:

```
name: REPLACE
description: Syntax:
REPLACE(str,from_str,to_str)

Returns the string str with all occurrences of the string from_str
replaced by the string to_str. REPLACE() performs a case-sensitive
match when searching for from_str.
example: mysql> SELECT REPLACE('www.mysql.com', 'w', 'Ww');
-> 'WwWwWw.mysql.com'
```

- Result set containing multiple rows with two columns

This means that the search string matched many help topics. The result set indicates the help topic names:

- `name`: The help topic name.
- `is_it_category`: `Y` if the name represents a help category, `N` if it does not. If it does not, the `name` value when specified as the argument to the `HELP` statement should yield a single-row result set containing a description for the named item.

Example: `HELP 'status'`

Yields:

name	is_it_category
SHOW	N
SHOW ENGINE	N
SHOW MASTER STATUS	N
SHOW PROCEDURE STATUS	N
SHOW SLAVE STATUS	N
SHOW STATUS	N
SHOW TABLE STATUS	N

- Result set containing multiple rows with three columns

This means the search string matches a category. The result set contains category entries:

- `source_category_name`: The help category name.
- `name`: The category or topic name
- `is_it_category`: `Y` if the name represents a help category, `N` if it does not. If it does not, the `name` value when specified as the argument to the `HELP` statement should yield a single-row result set containing a description for the named item.

Example: `HELP 'functions'`

Yields:

source_category_name	name	is_it_category
Functions	CREATE FUNCTION	N
Functions	DROP FUNCTION	N
Functions	Bit Functions	Y
Functions	Comparison operators	Y
Functions	Control flow functions	Y

Functions	Date and Time Functions	Y
Functions	Encryption Functions	Y
Functions	Information Functions	Y
Functions	Logical operators	Y
Functions	Miscellaneous Functions	Y
Functions	Numeric Functions	Y
Functions	String Functions	Y

13.8.4 USE Syntax

USE *db_name*

The `USE db_name` statement tells MySQL to use the *db_name* database as the default (current) database for subsequent statements. The database remains the default until the end of the session or another `USE` statement is issued:

```
USE db1;
SELECT COUNT(*) FROM mytable; # selects from db1.mytable
USE db2;
SELECT COUNT(*) FROM mytable; # selects from db2.mytable
```

Making a particular database the default by means of the `USE` statement does not preclude you from accessing tables in other databases. The following example accesses the `author` table from the `db1` database and the `editor` table from the `db2` database:

```
USE db1;
SELECT author_name,editor_name FROM author,db2.editor
WHERE author.editor_id = db2.editor.editor_id;
```

Chapter 14 MySQL Data Dictionary

Table of Contents

14.1 Data Dictionary Schema	1953
14.2 Removal of File-based Metadata Storage	1954
14.3 Transactional Storage of Dictionary Data	1954
14.4 Dictionary Object Cache	1954
14.5 INFORMATION_SCHEMA and Data Dictionary Integration	1955
14.6 Data Dictionary Usage Differences	1956
14.7 Data Dictionary Limitations	1958

MySQL Server now incorporates a transactional data dictionary that stores information about database objects. In previous MySQL releases, dictionary data was stored in metadata files and nontransactional tables.

This chapter describes the main features, benefits, usage differences, and limitations of the data dictionary. For other implications of the data dictionary feature, refer to the “Data Dictionary Notes” section in the [MySQL 8.0 Release Notes](#).

In MySQL 8.0.0 and MySQL 8.0.1, the [InnoDB](#) storage engine uses its own storage engine-specific data dictionary. As of MySQL 8.0.2, [InnoDB](#) uses the MySQL data dictionary.

Benefits of the MySQL data dictionary include:

- Simplicity of a centralized data dictionary schema that uniformly stores dictionary data. See [Section 14.1, “Data Dictionary Schema”](#).
- Removal of file-based metadata storage. See [Section 14.2, “Removal of File-based Metadata Storage”](#).
- Transactional, crash-safe storage of dictionary data. See [Section 14.3, “Transactional Storage of Dictionary Data”](#).
- Uniform and centralized caching for dictionary objects. See [Section 14.4, “Dictionary Object Cache”](#).
- A simpler and improved implementation for some [INFORMATION_SCHEMA](#) tables. See [Section 14.5, “INFORMATION_SCHEMA and Data Dictionary Integration”](#).

Important

A data dictionary-enabled server entails some general operational differences compared to a server that does not have a data dictionary; see [Section 14.6, “Data Dictionary Usage Differences”](#). Also, for upgrades to MySQL 8.0, the upgrade procedure differs somewhat from previous MySQL releases and requires that you verify the upgrade readiness of your installation by checking specific prerequisites. For more information, see [Section 2.10.1, “Upgrading MySQL”](#), particularly [Verifying Upgrade Prerequisites for Your MySQL 5.7 Installation](#).

14.1 Data Dictionary Schema

Data dictionary tables are invisible and cannot be accessed directly. However, MySQL supports access to data stored in data dictionary tables through [INFORMATION_SCHEMA](#) tables and [SHOW](#) statements. For an overview of the tables that comprise the data dictionary, see [Data Dictionary Tables](#).

MySQL system tables still exist in MySQL 8.0 and can be viewed by issuing a [SHOW TABLES](#) statement on the `mysql` system database. Generally, the difference between MySQL system tables and data dictionary tables is that system tables contain auxiliary data such as time zone and help

information, whereas data dictionary tables contain data required to execute SQL queries. MySQL system tables and data dictionary tables also differ in how they are upgraded. Upgrading MySQL system tables requires running `mysql_upgrade`. Data dictionary upgrades are managed by the MySQL server.

14.2 Removal of File-based Metadata Storage

In previous MySQL releases, dictionary data was partially stored in metadata files. Issues with file-based metadata storage included expensive file scans, susceptibility to file system-related bugs, complex code for handling of replication and crash recovery failure states, and a lack of extensibility that made it difficult to add metadata for new features and relational objects.

The metadata files listed below are removed from MySQL. Unless otherwise noted, data previously stored in metadata files is now stored in data dictionary tables.

- `.frm` files: Table metadata files. With the removal of `.frm` files:
 - The 64KB table definition size limit imposed by the `.frm` file structure is removed.
 - the `INFORMATION_SCHEMA.TABLES.VERSION` column now reports a hardcoded value of `10`, which is the last `frm` file version used in MySQL 5.7.
- `.par` files: Partition definition files. `.par` files were removed in MySQL 5.7.6 with the introduction of native partitioning for `InnoDB` tables.
- `.TRN` files: Trigger namespace files.
- `.TRG` files: Trigger parameter files.
- `.isl` files: `InnoDB` Symbolic Link files containing the location of `file-per-table` tablespace files created outside of the MySQL data directory.
- `db.opt` files: Database configuration files. These files, one per database directory, contained database default character set attributes.

14.3 Transactional Storage of Dictionary Data

The data dictionary schema stores dictionary data in transactional (`InnoDB`) tables. Data dictionary tables are located in the `mysql` database together with non-data dictionary system tables.

As of MySQL 8.0.2, data dictionary tables are created in a single `InnoDB` tablespace named `mysql.ibd` in the MySQL data directory. The `mysql.ibd` tablespace file must reside in the MySQL data directory and its name cannot be modified or used by another tablespace. Previously, these tables were created in individual tablespace files in the `mysql` database directory.

Dictionary data is protected by the same commit, rollback, and crash-recovery capabilities that protect user data stored in `InnoDB` tables.

14.4 Dictionary Object Cache

The dictionary object cache is a shared global cache that stores previously accessed data dictionary objects in memory to enable object reuse and minimize disk I/O. Similar to other cache mechanisms used by MySQL, the dictionary object cache uses an `LRU`-based eviction strategy to evict least recently used objects from memory.

The dictionary object cache comprises cache partitions that store different object types. Some cache partition size limits are configurable, whereas others are hardcoded.

- **tablespace definition cache partition:** Stores tablespace definition objects. The `tablespace_definition_cache` option sets a limit for the number of tablespace definition objects that can be stored in the dictionary object cache. The default value is `256`.

- **schema definition cache partition:** Stores schema definition objects. The `schema_definition_cache` option sets a limit for the number of schema definition objects that can be stored in the dictionary object cache. The default value is 256.
- **table definition cache partition:** Stores table definition objects. The object limit is set to the value of `max_connections`, which has a default value of 151.

The table definition cache partition exists in parallel with the table definition cache that is configured using the `table_definition_cache` configuration option. Both caches store table definitions but serve different parts of the MySQL server. Objects in one cache have no dependence on the existence of objects in the other.

- **stored program definition cache partition:** Stores stored program definition objects. The `stored_program_definition_cache` option sets a limit for the number of stored program definition objects that can be stored in the dictionary object cache. The default value is 256.

The stored program definition cache partition exists in parallel with the stored procedure and stored function caches that are configured using the `stored_program_cache` option.

The `stored_program_cache` option sets a soft upper limit for the number of cached stored procedures or functions per connection, and the limit is checked each time a connection executes a stored procedure or function. The stored program definition cache partition, on the other hand, is a shared cache that stores stored program definition objects for other purposes. The existence of objects in the stored program definition cache partition has no dependence on the existence of objects in the stored procedure cache or stored function cache, and vice versa.

- **character set definition cache partition:** Stores character set definition objects and has a hardcoded object limit of 256.
- **collation definition cache partition:** Stores collation definition objects and has a hardcoded object limit of 256.

For information about valid values for dictionary object cache configuration options, refer to [Section 5.1.5, “Server System Variables”](#).

14.5 INFORMATION_SCHEMA and Data Dictionary Integration

With the introduction of the data dictionary, the following `INFORMATION_SCHEMA` tables are implemented as views on data dictionary tables:

- `CHARACTER_SETS`
- `COLLATIONS`
- `COLLATION_CHARACTER_SET_APPLICABILITY`
- `COLUMNS`
- `EVENTS`
- `KEY_COLUMN_USAGE`
- `PARAMETERS`
- `ROUTINES`
- `SCHEMATA`
- `STATISTICS`
- `ST_SPATIAL_REFERENCE_SYSTEMS`
- `TABLES`

- [TABLE_CONSTRAINTS](#)
- [TRIGGERS](#)
- [VIEWS](#)

Queries on those tables are now more efficient because they obtain information from data dictionary tables rather than by other, slower means. In particular, for each [INFORMATION_SCHEMA](#) table that is a view on data dictionary tables:

- The server no longer must create a temporary table for each query of the [INFORMATION_SCHEMA](#) table.
- When the underlying data dictionary tables store values previously obtained by directory scans (for example, to enumerate database names or table names within databases) or file-opening operations (for example, to read information from `.frm` files), [INFORMATION_SCHEMA](#) queries for those values now use table lookups instead. (Additionally, even for a non-view [INFORMATION_SCHEMA](#) table, values such as database and table names are retrieved by lookups from the data dictionary and do not require directory or file scans.)
- Indexes on the underlying data dictionary tables permit the optimizer to construct efficient query execution plans, something not true for the previous implementation that processed the [INFORMATION_SCHEMA](#) table using a temporary table per query.

The preceding improvements also apply to [SHOW](#) statements that display information corresponding to the [INFORMATION_SCHEMA](#) tables that are views on data dictionary tables. For example, [SHOW DATABASES](#) displays the same information as the [SCHEMATA](#) table.

In addition to the introduction of views on data dictionary tables, table metadata contained in the [STATISTICS](#) and [TABLES](#) tables is now cached to improve [INFORMATION_SCHEMA](#) query performance. Caching of table metadata is controlled by the `information_schema_stats` configuration option, which is set to `CACHED` by default. Cached table metadata is updated by issuing an [ANALYZE TABLE](#) statement.

`information_schema_stats` can be set to `LATEST` to have [INFORMATION_SCHEMA](#) queries retrieve the latest metadata directly from the storage engine, which is not as fast as retrieving cached table metadata.

For more information, see [Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”](#).

14.6 Data Dictionary Usage Differences

Use of a data dictionary-enabled MySQL server entails some operational differences compared to a server that does not have a data dictionary:

- Previously, enabling the `innodb_read_only` system variable prevented creating and dropping tables only for the `InnoDB` storage. As of MySQL 8.0, enabling `innodb_read_only` prevents these operations for all storage engines. Table creation and drop operations for any storage engine modify data dictionary tables in the `mysql` system database, but those tables use the `InnoDB` storage engine and cannot be modified when `innodb_read_only` is enabled. The same principle applies to other table operations that require modifying data dictionary tables. Examples:
 - [ANALYZE TABLE](#) fails because it updates table statistics, which are stored in the data dictionary.
 - [ALTER TABLE *tbl_name* ENGINE=*engine_name*](#) fails because it updates the storage engine designation, which is stored in the data dictionary.

Note

Enabling `innodb_read_only` also has important implications for non-data dictionary tables in the `mysql` system database. For details, see the

description of `innodb_read_only` in [Section 15.13, “InnoDB Startup Options and System Variables”](#)

- Previously, tables in the `mysql` system database were visible to DML and DDL statements. As of MySQL 8.0, data dictionary tables are invisible and cannot be modified or queried directly. However, in most cases there are corresponding `INFORMATION_SCHEMA` tables that can be queried instead. This enables the underlying data dictionary tables to be changed as server development proceeds, while maintaining a stable `INFORMATION_SCHEMA` interface for application use.
- `INFORMATION_SCHEMA` tables in MySQL 8.0 are closely tied to the data dictionary, resulting in several usage differences:
 - Previously, `INFORMATION_SCHEMA` queries for table statistics in the `STATISTICS` and `TABLES` tables retrieved statistics directly from storage engines. As of MySQL 8.0, the default is to use cached table statistics, which is more efficient. However, when the server starts, the cached statistics are `NULL` and are not updated for a given table until `ANALYZE TABLE` is run. Also, the statistics go out of date to the extent that the table is modified thereafter. To use the latest table statistics obtained from storage engines (the pre-8.0 behavior), change the `information_schema_stats` system variable from `CACHED` to `LATEST`. For more information, see [Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”](#).
 - Several `INFORMATION_SCHEMA` tables are views on data dictionary tables, which enables the optimizer to use indexes on those underlying tables. Consequently, depending on optimizer choices, the row order of results for `INFORMATION_SCHEMA` queries might differ from previous results. If a query result must have specific row ordering characteristics, include an `ORDER BY` clause.
 - `mysqldump` and `mysqlpump` no longer dump the `INFORMATION_SCHEMA` database, even if explicitly named on the command line.
 - `CREATE TABLE dst_tbl LIKE src_tbl` requires that `src_tbl` be a base table and fails if it is an `INFORMATION_SCHEMA` table that is a view on data dictionary tables.
 - Previously, result set headers of columns selected from `INFORMATION_SCHEMA` tables used the capitalization specified in the query. This query produces a result set with a header of `table_name`:

```
SELECT table_name FROM INFORMATION_SCHEMA.TABLES;
```

As of MySQL 8.0, these headers are capitalized; the preceding query produces a result set with a header of `TABLE_NAME`. If necessary, a column alias can be used to achieve a different lettercase. For example:

```
SELECT table_name AS 'table_name' FROM INFORMATION_SCHEMA.TABLES;
```

- The data directory affects how `mysqldump` and `mysqlpump` dump information from the `mysql` system database:
 - Previously, it was possible to dump all tables in the `mysql` system database. As of MySQL 8.0, `mysqldump` and `mysqlpump` dump only non-data dictionary tables in that database.
 - Previously, the `--routines` and `--events` options were not required to include stored routines and events when using the `--all-databases` option: The dump included the `mysql` system database, and therefore also the `proc` and `event` tables containing stored routine and event definitions. As of MySQL 8.0, the `event` and `proc` tables are not used. Definitions for the corresponding objects are stored in data dictionary tables, but those tables are not dumped. To include stored routines and events in a dump made using `--all-databases`, use the `--routines` and `--events` options explicitly.

- Previously, the `--routines` option required the `SELECT` privilege for the `proc` table. As of MySQL 8.0, that table is not used; `--routines` requires the global `SELECT` privilege instead.
- Previously, it was possible to dump stored routine and event definitions together with their creation and modification timestamps, by dumping the `proc` and `event` tables. As of MySQL 8.0, those tables are not used, so it is not possible to dump timestamps.
- Previously, creating a stored routine that contains illegal characters produced a warning. As of MySQL 8.0, this is an error.

14.7 Data Dictionary Limitations

This section describes temporary limitations introduced with the MySQL data dictionary.

- Manual creation of database directories under the data directory (for example, with `mkdir`) is unsupported. Manually created database directories are not recognized by the MySQL Server.
- Moving data stored in `MyISAM` tables by copying and moving `MyISAM` data files is unsupported. Tables moved using this method are not discovered by the server.
- Simple backup and restore of individual `MyISAM` tables using copied data files is unsupported.
- `TRUNCATE TABLE`, which is mapped to `DROP TABLE` and `CREATE TABLE` in MySQL 8.0, is temporarily non-atomic. A server exit during a `TRUNCATE TABLE` operation can result in a dropped table. It may also result in orphaned foreign key entries in the `InnoDB SYS_FOREIGN` and `SYS_FOREIGN_COLS` dictionary tables if the table contains foreign key constraints.
- DDL operations take longer due to writing to storage, undo logs, and redo logs instead of `.frm` files.
- The period of time during which DDL operations are vulnerable to a server exit is longer due to writing to storage, undo logs, and redo logs instead of `.frm` files. The minimal risk introduced by this limitation is mostly applicable to restore operations and other operations that load numerous new tables.
- With the removal of `.isl` files in MySQL 8.0, offline relocation of `file-per-table` tablespaces created outside of the MySQL data directory is not supported.
- If MySQL exits in the middle of an `ALTER TABLE` operation on an `InnoDB` table, you may be left with an orphan intermediate or temporary table. Removing orphan intermediate and temporary tables is unsupported.

15.1 Introduction to InnoDB

InnoDB is a general-purpose storage engine that balances high reliability and high performance. In MySQL 8.0, **InnoDB** is the default MySQL storage engine. Unless you have configured a different default storage engine, issuing a `CREATE TABLE` statement without an `ENGINE=` clause creates an **InnoDB** table.

Key Advantages of InnoDB

Key advantages of **InnoDB** include:

- Its **DML** operations follow the **ACID** model, with **transactions** featuring **commit**, **rollback**, and **crash-recovery** capabilities to protect user data. See [Section 15.2, “InnoDB and the ACID Model”](#) for more information.
- Row-level **locking** and Oracle-style **consistent reads** increase multi-user concurrency and performance. See [Section 15.5, “InnoDB Locking and Transaction Model”](#) for more information.
- **InnoDB** tables arrange your data on disk to optimize queries based on **primary keys**. Each **InnoDB** table has a primary key index called the **clustered index** that organizes the data to minimize I/O for primary key lookups. See [Section 15.8.2.1, “Clustered and Secondary Indexes”](#) for more information.
- To maintain data **integrity**, **InnoDB** supports **FOREIGN KEY** constraints. With foreign keys, inserts, updates, and deletes are checked to ensure they do not result in inconsistencies across different tables. See [Section 15.8.1.6, “InnoDB and FOREIGN KEY Constraints”](#) for more information.

Table 15.1 InnoDB Storage Engine Features

Storage limits	64TB	Transactions	Yes	Locking granularity	Row
MVCC	Yes	Geospatial data type support	Yes	Geospatial indexing support	Yes ^a
B-tree indexes	Yes	T-tree indexes	No	Hash indexes	No ^b
Full-text search indexes	Yes ^c	Clustered indexes	Yes	Data caches	Yes
Index caches	Yes	Compressed data	Yes ^d	Encrypted data^e	Yes
Cluster database support	No	Replication support^f	Yes	Foreign key support	Yes
Backup / point-in-time recovery^g	Yes	Query cache support	Yes	Update statistics for data dictionary	Yes

^aInnoDB support for geospatial indexing is available in MySQL 5.7.5 and later.

^bInnoDB utilizes hash indexes internally for its Adaptive Hash Index feature.

^cInnoDB support for FULLTEXT indexes is available in MySQL 5.6.4 and later.

^dCompressed InnoDB tables require the InnoDB Barracuda file format.

^eImplemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and later.

^fImplemented in the server, rather than in the storage engine.

^gImplemented in the server, rather than in the storage engine.

To compare the features of **InnoDB** with other storage engines provided with MySQL, see the *Storage Engine Features* table in [Chapter 16, Alternative Storage Engines](#).

InnoDB Enhancements and New Features

For information about **InnoDB** enhancements and new features in MySQL 8.0, refer to:

- The [InnoDB](#) enhancements list in [Section 1.4, “What Is New in MySQL 8.0”](#).
- The [Release Notes](#).

Additional InnoDB Information and Resources

- For [InnoDB](#)-related terms and definitions, see [MySQL Glossary](#).
- For a forum dedicated to the [InnoDB](#) storage engine, see [MySQL Forums::InnoDB](#).
- [InnoDB](#) is published under the same GNU GPL License Version 2 (of June 1991) as MySQL. For more information on MySQL licensing, see <http://www.mysql.com/company/legal/licensing/>.

15.1.1 Benefits of Using InnoDB Tables

If you use [MyISAM](#) tables but are not committed to them for technical reasons, you may find [InnoDB](#) tables beneficial for the following reasons:

- If your server crashes because of a hardware or software issue, regardless of what was happening in the database at the time, you don't need to do anything special after restarting the database. [InnoDB crash recovery](#) automatically finalizes any changes that were committed before the time of the crash, and undoes any changes that were in process but not committed. Just restart and continue where you left off.
- The [InnoDB](#) storage engine maintains its own [buffer pool](#) that caches table and index data in main memory as data is accessed. Frequently used data is processed directly from memory. This cache applies to many types of information and speeds up processing. On dedicated database servers, up to 80% of physical memory is often assigned to the [InnoDB](#) buffer pool.
- If you split up related data into different tables, you can set up [foreign keys](#) that enforce [referential integrity](#). Update or delete data, and the related data in other tables is updated or deleted automatically. Try to insert data into a secondary table without corresponding data in the primary table, and the bad data gets kicked out automatically.
- If data becomes corrupted on disk or in memory, a [checksum](#) mechanism alerts you to the bogus data before you use it.
- When you design your database with appropriate [primary key](#) columns for each table, operations involving those columns are automatically optimized. It is very fast to reference the primary key columns in [WHERE](#) clauses, [ORDER BY](#) clauses, [GROUP BY](#) clauses, and [join](#) operations.
- Inserts, updates, and deletes are optimized by an automatic mechanism called [change buffering](#). [InnoDB](#) not only allows concurrent read and write access to the same table, it caches changed data to streamline disk I/O.
- Performance benefits are not limited to giant tables with long-running queries. When the same rows are accessed over and over from a table, a feature called the [Adaptive Hash Index](#) takes over to make these lookups even faster, as if they came out of a hash table.
- You can compress tables and associated indexes.
- You can create and drop indexes with much less impact on performance and availability.
- Truncating a [file-per-table](#) tablespace is very fast, and can free up disk space for the operating system to reuse, rather than freeing up space within the [system tablespace](#) that only [InnoDB](#) could reuse.
- The storage layout for table data is more efficient for [BLOB](#) and long text fields, with the [DYNAMIC](#) row format.
- You can monitor the internal workings of the storage engine by querying [INFORMATION_SCHEMA](#) tables.

- You can monitor the performance details of the storage engine by querying [Performance Schema](#) tables.
- You can freely mix [InnoDB](#) tables with tables from other MySQL storage engines, even within the same statement. For example, you can use a [join](#) operation to combine data from [InnoDB](#) and [MEMORY](#) tables in a single query.
- [InnoDB](#) has been designed for CPU efficiency and maximum performance when processing large data volumes.
- [InnoDB](#) tables can handle large quantities of data, even on operating systems where file size is limited to 2GB.

For [InnoDB](#)-specific tuning techniques you can apply in your application code, see [Section 8.5, “Optimizing for InnoDB Tables”](#).

15.1.2 Best Practices for InnoDB Tables

This section describes best practices when using [InnoDB](#) tables.

- Specifying a [primary key](#) for every table using the most frequently queried column or columns, or an [auto-increment](#) value if there is no obvious primary key.
- Using [joins](#) wherever data is pulled from multiple tables based on identical ID values from those tables. For fast join performance, define [foreign keys](#) on the join columns, and declare those columns with the same data type in each table. Adding foreign keys ensures that referenced columns are indexed, which can improve performance. Foreign keys also propagate deletes or updates to all affected tables, and prevent insertion of data in a child table if the corresponding IDs are not present in the parent table.
- Turning off [autocommit](#). Committing hundreds of times a second puts a cap on performance (limited by the write speed of your storage device).
- Grouping sets of related [DML](#) operations into [transactions](#), by bracketing them with [START TRANSACTION](#) and [COMMIT](#) statements. While you don't want to commit too often, you also don't want to issue huge batches of [INSERT](#), [UPDATE](#), or [DELETE](#) statements that run for hours without committing.
- Not using [LOCK TABLES](#) statements. [InnoDB](#) can handle multiple sessions all reading and writing to the same table at once, without sacrificing reliability or high performance. To get exclusive write access to a set of rows, use the [SELECT ... FOR UPDATE](#) syntax to lock just the rows you intend to update.
- Enabling the [innodb_file_per_table](#) option to put the data and indexes for individual tables into separate files, instead of in a single giant [system tablespace](#). This setting is required to use some of the other features, such as table [compression](#) and fast [truncation](#).

The [innodb_file_per_table](#) option is enabled by default as of MySQL 5.6.6.

- Evaluating whether your data and access patterns benefit from the [InnoDB](#) table [compression](#) feature ([ROW_FORMAT=COMPRESSED](#)) on the [CREATE TABLE](#) statement. You can compress [InnoDB](#) tables without sacrificing read/write capability.
- Running your server with the option [--sql_mode=NO_ENGINE_SUBSTITUTION](#) to prevent tables being created with a different storage engine if there is an issue with the engine specified in the [ENGINE=](#) clause of [CREATE TABLE](#).

15.1.3 Verifying that InnoDB is the Default Storage Engine

To verify that [InnoDB](#) is the default storage engine, issue the [SHOW ENGINES](#) command to view the different MySQL storage engines. Look for [DEFAULT](#) in the [InnoDB](#) line. Alternatively, query the [INFORMATION_SCHEMA ENGINES](#) table.

15.1.4 Testing and Benchmarking with InnoDB

If [InnoDB](#) is not your default storage engine, you can determine if your database server or applications work correctly with [InnoDB](#) by restarting the server with `--default-storage-engine=InnoDB` defined on the command line or with `default-storage-engine=innodb` defined in the `[mysqld]` section of the `my.cnf` configuration file.

Since changing the default storage engine only affects new tables as they are created, run all your application installation and setup steps to confirm that everything installs properly. Then exercise all the application features to make sure all the data loading, editing, and querying features work. If a table relies on some [MyISAM](#)-specific feature, you'll receive an error; add the `ENGINE=MyISAM` clause to the `CREATE TABLE` statement to avoid the error.

If you did not make a deliberate decision about the storage engine, and you just want to preview how certain tables work when they're created under [InnoDB](#), issue the command `ALTER TABLE table_name ENGINE=InnoDB;` for each table. Or, to run test queries and other statements without disturbing the original table, make a copy like so:

```
CREATE TABLE InnoDB_Table (...) ENGINE=InnoDB AS SELECT * FROM MyISAM_Table;
```

To get a true idea of the performance with a full application under a realistic workload, install the latest MySQL server and run benchmarks.

Test the full application lifecycle, from installation, through heavy usage, and server restart. Kill the server process while the database is busy to simulate a power failure, and verify that the data is recovered successfully when you restart the server.

Test any replication configurations, especially if you use different MySQL versions and options on the master and the slaves.

15.2 InnoDB and the ACID Model

The [ACID](#) model is a set of database design principles that emphasize aspects of reliability that are important for business data and mission-critical applications. MySQL includes components such as the [InnoDB](#) storage engine that adhere closely to the ACID model, so that data is not corrupted and results are not distorted by exceptional conditions such as software crashes and hardware malfunctions. When you rely on ACID-compliant features, you do not need to reinvent the wheel of consistency checking and crash recovery mechanisms. In cases where you have additional software safeguards, ultra-reliable hardware, or an application that can tolerate a small amount of data loss or inconsistency, you can adjust MySQL settings to trade some of the ACID reliability for greater performance or throughput.

The following sections discuss how MySQL features, in particular the [InnoDB](#) storage engine, interact with the categories of the ACID model:

- **A**: atomicity.
- **C**: consistency.
- **I**: isolation.
- **D**: durability.

Atomicity

The **atomicity** aspect of the ACID model mainly involves [InnoDB transactions](#). Related MySQL features include:

- Autocommit setting.
- [COMMIT](#) statement.
- [ROLLBACK](#) statement.
- Operational data from the [INFORMATION_SCHEMA](#) tables.

Consistency

The **consistency** aspect of the ACID model mainly involves internal [InnoDB](#) processing to protect data from crashes. Related MySQL features include:

- [InnoDB doublewrite buffer](#).
- [InnoDB crash recovery](#).

Isolation

The **isolation** aspect of the ACID model mainly involves [InnoDB transactions](#), in particular the [isolation level](#) that applies to each transaction. Related MySQL features include:

- [Autocommit](#) setting.
- [SET ISOLATION LEVEL](#) statement.
- The low-level details of [InnoDB locking](#). During performance tuning, you see these details through [INFORMATION_SCHEMA](#) tables.

Durability

The **durability** aspect of the ACID model involves MySQL software features interacting with your particular hardware configuration. Because of the many possibilities depending on the capabilities of your CPU, network, and storage devices, this aspect is the most complicated to provide concrete guidelines for. (And those guidelines might take the form of buy “new hardware”.) Related MySQL features include:

- [InnoDB doublewrite buffer](#), turned on and off by the `innodb_doublewrite` configuration option.
- Configuration option `innodb_flush_log_at_trx_commit`.
- Configuration option `sync_binlog`.
- Configuration option `innodb_file_per_table`.
- Write buffer in a storage device, such as a disk drive, SSD, or RAID array.
- Battery-backed cache in a storage device.
- The operating system used to run MySQL, in particular its support for the `fsync()` system call.
- Uninterruptible power supply (UPS) protecting the electrical power to all computer servers and storage devices that run MySQL servers and store MySQL data.
- Your backup strategy, such as frequency and types of backups, and backup retention periods.
- For distributed or hosted data applications, the particular characteristics of the data centers where the hardware for the MySQL servers is located, and network connections between the data centers.

15.3 InnoDB Multi-Versioning

InnoDB is a [multi-versioned storage engine](#): it keeps information about old versions of changed rows, to support transactional features such as concurrency and [rollback](#). This information is stored in the tablespace in a data structure called a [rollback segment](#) (after an analogous data structure in Oracle). InnoDB uses the information in the rollback segment to perform the undo operations needed in a transaction rollback. It also uses the information to build earlier versions of a row for a [consistent read](#).

Internally, InnoDB adds three fields to each row stored in the database. A 6-byte `DB_TRX_ID` field indicates the transaction identifier for the last transaction that inserted or updated the row. Also, a deletion is treated internally as an update where a special bit in the row is set to mark it as deleted. Each row also contains a 7-byte `DB_ROLL_PTR` field called the roll pointer. The roll pointer points to an undo log record written to the rollback segment. If the row was updated, the undo log record contains the information necessary to rebuild the content of the row before it was updated. A 6-byte `DB_ROW_ID` field contains a row ID that increases monotonically as new rows are inserted. If InnoDB generates a clustered index automatically, the index contains row ID values. Otherwise, the `DB_ROW_ID` column does not appear in any index.

Undo logs in the rollback segment are divided into insert and update undo logs. Insert undo logs are needed only in transaction rollback and can be discarded as soon as the transaction commits. Update undo logs are used also in consistent reads, but they can be discarded only after there is no transaction present for which InnoDB has assigned a snapshot that in a consistent read could need the information in the update undo log to build an earlier version of a database row.

Commit your transactions regularly, including those transactions that issue only consistent reads. Otherwise, InnoDB cannot discard data from the update undo logs, and the rollback segment may grow too big, filling up your tablespace.

The physical size of an undo log record in the rollback segment is typically smaller than the corresponding inserted or updated row. You can use this information to calculate the space needed for your rollback segment.

In the InnoDB multi-versioning scheme, a row is not physically removed from the database immediately when you delete it with an SQL statement. InnoDB only physically removes the corresponding row and its index records when it discards the update undo log record written for the deletion. This removal operation is called a [purge](#), and it is quite fast, usually taking the same order of time as the SQL statement that did the deletion.

If you insert and delete rows in smallish batches at about the same rate in the table, the purge thread can start to lag behind and the table can grow bigger and bigger because of all the “dead” rows, making everything disk-bound and very slow. In such a case, throttle new row operations, and allocate more resources to the purge thread by tuning the `innodb_max_purge_lag` system variable. See [Section 15.13, “InnoDB Startup Options and System Variables”](#) for more information.

Multi-Versioning and Secondary Indexes

InnoDB multiversion concurrency control (MVCC) treats secondary indexes differently than clustered indexes. Records in a clustered index are updated in-place, and their hidden system columns point undo log entries from which earlier versions of records can be reconstructed. Unlike clustered index records, secondary index records do not contain hidden system columns nor are they updated in-place.

When a secondary index column is updated, old secondary index records are delete-marked, new records are inserted, and delete-marked records are eventually purged. When a secondary index record is delete-marked or the secondary index page is updated by a newer transaction, InnoDB looks up the database record in the clustered index. In the clustered index, the record's `DB_TRX_ID` is checked, and the correct version of the record is retrieved from the undo log if the record was modified after the reading transaction was initiated.

If a secondary index record is marked for deletion or the secondary index page is updated by a newer transaction, the [covering index](#) technique is not used. Instead of returning values from the index structure, InnoDB looks up the record in the clustered index.

However, if the [index condition pushdown \(ICP\)](#) optimization is enabled, and parts of the `WHERE` condition can be evaluated using only fields from the index, the MySQL server still pushes this part of the `WHERE` condition down to the storage engine where it is evaluated using the index. If no matching records are found, the clustered index lookup is avoided. If matching records are found, even among delete-marked records, [InnoDB](#) looks up the record in the clustered index.

15.4 InnoDB Architecture

This section provides an introduction to the major components of the [InnoDB](#) storage engine architecture.

15.4.1 Buffer Pool

The buffer pool is an area in main memory where [InnoDB](#) caches table and index data as data is accessed. The buffer pool allows frequently used data to be processed directly from memory, which speeds up processing. On dedicated database servers, up to 80% of physical memory is often assigned to the [InnoDB](#) buffer pool.

For efficiency of high-volume read operations, the buffer pool is divided into [pages](#) that can potentially hold multiple rows. For efficiency of cache management, the buffer pool is implemented as a linked list of pages; data that is rarely used is aged out of the cache, using a variation of the [LRU](#) algorithm.

For more information, see [Section 15.6.3.1, “The InnoDB Buffer Pool”](#), and [Section 15.6.3, “InnoDB Buffer Pool Configuration”](#).

15.4.2 Change Buffer

The change buffer is a special data structure that caches changes to [secondary index](#) pages when affected pages are not in the [buffer pool](#). The buffered changes, which may result from `INSERT`, `UPDATE`, or `DELETE` operations (DML), are merged later when the pages are loaded into the buffer pool by other read operations.

Unlike [clustered indexes](#), secondary indexes are usually non-unique, and inserts into secondary indexes happen in a relatively random order. Similarly, deletes and updates may affect secondary index pages that are not adjacently located in an index tree. Merging cached changes at a later time, when affected pages are read into the buffer pool by other operations, avoids substantial random access I/O that would be required to read-in secondary index pages from disk.

Periodically, the purge operation that runs when the system is mostly idle, or during a slow shutdown, writes the updated index pages to disk. The purge operation can write disk blocks for a series of index values more efficiently than if each value were written to disk immediately.

Change buffer merging may take several hours when there are numerous secondary indexes to update and many affected rows. During this time, disk I/O is increased, which can cause a significant slowdown for disk-bound queries. Change buffer merging may also continue to occur after a transaction is committed. In fact, change buffer merging may continue to occur after a server shutdown and restart (see [Section 15.20.2, “Forcing InnoDB Recovery”](#) for more information).

In memory, the change buffer occupies part of the [InnoDB](#) buffer pool. On disk, the change buffer is part of the system tablespace, so that index changes remain buffered across database restarts.

The type of data cached in the change buffer is governed by the `innodb_change_buffering` configuration option. For more information, see [Section 15.6.4, “Configuring InnoDB Change Buffering”](#). You can also configure the maximum change buffer size. For more information, see [Section 15.6.4.1, “Configuring the Change Buffer Maximum Size”](#).

Change buffering is not supported for a secondary index if the index contains a descending index column or if the primary key includes a descending index column.

Monitoring the Change Buffer

The following options are available for change buffer monitoring:

- [InnoDB Standard Monitor](#) output includes status information for the change buffer. To view monitor data, issue the `SHOW ENGINE INNODB STATUS` command.

```
mysql> SHOW ENGINE INNODB STATUS\G
```

Change buffer status information is located under the [INSERT BUFFER AND ADAPTIVE HASH INDEX](#) heading and appears similar to the following:

```
-----
INSERT BUFFER AND ADAPTIVE HASH INDEX
-----
Ibuf: size 1, free list len 0, seg size 2, 0 merges
merged operations:
  insert 0, delete mark 0, delete 0
discarded operations:
  insert 0, delete mark 0, delete 0
Hash table size 4425293, used cells 32, node heap has 1 buffer(s)
13577.57 hash searches/s, 202.47 non-hash searches/s
```

For more information, see [Section 15.16.3, “InnoDB Standard Monitor and Lock Monitor Output”](#).

- The [INFORMATION_SCHEMA.INNODB_METRICS](#) table provides most of the data points found in [InnoDB Standard Monitor](#) output, plus other data points. To view change buffer metrics and a description of each, issue the following query:

```
mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME LIKE '%ibuf%'\G
```

For [INNODB_METRICS](#) table usage information, see [Section 15.14.6, “InnoDB INFORMATION_SCHEMA Metrics Table”](#).

- The [INFORMATION_SCHEMA.INNODB_BUFFER_PAGE](#) table provides metadata about each page in the buffer pool, including change buffer index and change buffer bitmap pages. Change buffer pages are identified by [PAGE_TYPE](#). [IBUF_INDEX](#) is the page type for change buffer index pages, and [IBUF_BITMAP](#) is the page type for change buffer bitmap pages.

Warning

Querying the [INNODB_BUFFER_PAGE](#) table can introduce significant performance overhead. To avoid impacting performance, reproduce the issue you want to investigate on a test instance and run your queries on the test instance.

For example, you can query the [INNODB_BUFFER_PAGE](#) table to determine the approximate number of [IBUF_INDEX](#) and [IBUF_BITMAP](#) pages as a percentage of total buffer pool pages.

```
SELECT
  (SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
   WHERE PAGE_TYPE LIKE 'IBUF%'
  ) AS change_buffer_pages,
  (
    SELECT COUNT(*)
    FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
  ) AS total_pages,
  (
    SELECT ((change_buffer_pages/total_pages)*100)
  ) AS change_buffer_page_percentage;
+-----+-----+-----+
| change_buffer_pages | total_pages | change_buffer_page_percentage |
+-----+-----+-----+
|                25 |          8192 |                0.3052 |
+-----+-----+-----+
```

For information about other data provided by the `INNODB_BUFFER_PAGE` table, see [Section 24.31.1, “The INFORMATION_SCHEMA INNODB_BUFFER_PAGE Table”](#). For related usage information, see [Section 15.14.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”](#).

- [Performance Schema](#) provides change buffer mutex wait instrumentation for advanced performance monitoring. To view change buffer instrumentation, issue the following query:

```
mysql> SELECT * FROM performance_schema.setup_instruments
WHERE NAME LIKE '%wait/synch/mutex/innodb/ibuf%';
```

NAME	ENABLED	TIMED
wait/synch/mutex/innodb/ibuf_bitmap_mutex	YES	YES
wait/synch/mutex/innodb/ibuf_mutex	YES	YES
wait/synch/mutex/innodb/ibuf_pessimistic_insert_mutex	YES	YES

For information about monitoring `InnoDB` mutex waits, see [Section 15.15.2, “Monitoring InnoDB Mutex Waits Using Performance Schema”](#).

15.4.3 Adaptive Hash Index

The [adaptive hash index](#) (AHI) lets `InnoDB` perform more like an in-memory database on systems with appropriate combinations of workload and ample memory for the [buffer pool](#), without sacrificing any transactional features or reliability. This feature is enabled by the `innodb_adaptive_hash_index` option, or turned off by `--skip-innodb_adaptive_hash_index` at server startup.

Based on the observed pattern of searches, MySQL builds a hash index using a prefix of the index key. The prefix of the key can be any length, and it may be that only some of the values in the B-tree appear in the hash index. Hash indexes are built on demand for those pages of the index that are often accessed.

If a table fits almost entirely in main memory, a hash index can speed up queries by enabling direct lookup of any element, turning the index value into a sort of pointer. `InnoDB` has a mechanism that monitors index searches. If `InnoDB` notices that queries could benefit from building a hash index, it does so automatically.

With some [workloads](#), the speedup from hash index lookups greatly outweighs the extra work to monitor index lookups and maintain the hash index structure. Sometimes, the read/write lock that guards access to the adaptive hash index can become a source of contention under heavy workloads, such as multiple concurrent joins. Queries with `LIKE` operators and `%` wildcards also tend not to benefit from the AHI. For workloads where the adaptive hash index is not needed, turning it off reduces unnecessary performance overhead. Because it is difficult to predict in advance whether this feature is appropriate for a particular system, consider running benchmarks with it both enabled and disabled, using a realistic workload. The architectural changes in MySQL 5.6 and higher make more workloads suitable for disabling the adaptive hash index than in earlier releases, although it is still enabled by default.

The adaptive hash index search system is partitioned. Each index is bound to a specific partition, and each partition is protected by a separate latch. Partitioning is controlled by the `innodb_adaptive_hash_index_parts` configuration option. The `innodb_adaptive_hash_index_parts` option is set to 8 by default. The maximum setting is 512.

The hash index is always built based on an existing [B-tree](#) index on the table. `InnoDB` can build a hash index on a prefix of any length of the key defined for the B-tree, depending on the pattern of searches that `InnoDB` observes for the B-tree index. A hash index can be partial, covering only those pages of the index that are often accessed.

You can monitor the use of the adaptive hash index and the contention for its use in the [SEMAPHORES](#) section of the output of the `SHOW ENGINE INNODB STATUS` command. If you see many threads

waiting on an RW-latch created in `btr0sea.c`, then it might be useful to disable adaptive hash indexing.

For more information about the performance characteristics of hash indexes, see [Section 8.3.8, “Comparison of B-Tree and Hash Indexes”](#).

15.4.4 Redo Log Buffer

The redo log buffer is the memory area that holds data to be written to the [redo log](#). Redo log buffer size is defined by the `innodb_log_buffer_size` configuration option. The redo log buffer is periodically flushed to the log file on disk. A large redo log buffer enables large transactions to run without the need to write redo log to disk before the transactions commit. Thus, if you have transactions that update, insert, or delete many rows, making the log buffer larger saves disk I/O.

The `innodb_flush_log_at_trx_commit` option controls how the contents of the redo log buffer are written to the log file. The `innodb_flush_log_at_timeout` option controls redo log flushing frequency.

15.4.5 System Tablespace

The [InnoDB](#) system tablespace contains the [InnoDB](#) data dictionary (metadata for [InnoDB](#)-related objects) and is the storage area for the doublewrite buffer, the change buffer, and undo logs. The system tablespace also contains table and index data for any user-created tables that are created in the system tablespace. The system tablespace is considered a shared tablespace since it is shared by multiple tables.

The system tablespace is represented by one or more data files. By default, one system data file, named `ibdata1`, is created in the MySQL `data` directory. The size and number of system data files is controlled by the `innodb_data_file_path` startup option.

For related information, see [Section 15.6.1, “InnoDB Startup Configuration”](#), and [Section 15.7.1, “Resizing the InnoDB System Tablespace”](#).

15.4.6 Doublewrite Buffer

The doublewrite buffer is a storage area located in the system tablespace where [InnoDB](#) writes pages that are flushed from the [InnoDB](#) buffer pool, before the pages are written to their proper positions in the data file. Only after flushing and writing pages to the doublewrite buffer, does [InnoDB](#) write pages to their proper positions. If there is an operating system, storage subsystem, or `mysqld` process crash in the middle of a page write, [InnoDB](#) can later find a good copy of the page from the doublewrite buffer during crash recovery.

Although data is always written twice, the doublewrite buffer does not require twice as much I/O overhead or twice as many I/O operations. Data is written to the doublewrite buffer itself as a large sequential chunk, with a single `fsync()` call to the operating system.

The doublewrite buffer is enabled by default in most cases. To disable the doublewrite buffer, set `innodb_doublewrite` to 0.

If system tablespace files (“ibdata files”) are located on Fusion-io devices that support atomic writes, doublewrite buffering is automatically disabled and Fusion-io atomic writes are used for all data files. Because the doublewrite buffer setting is global, doublewrite buffering is also disabled for data files residing on non-Fusion-io hardware. This feature is only supported on Fusion-io hardware and is only enabled for Fusion-io NVMFS on Linux. To take full advantage of this feature, an `innodb_flush_method` setting of `O_DIRECT` is recommended.

15.4.7 Undo Logs

An undo log is a collection of undo log records associated with a single transaction. An undo log record contains information about how to undo the latest change by a transaction to a [clustered index](#)

record. If another transaction needs to see the original data (as part of a consistent read operation), the unmodified data is retrieved from the undo log records. Undo logs exist within [undo log segments](#), which are contained within [rollback segments](#). Rollback segments reside in the [system tablespace](#), [temporary tablespace](#), and [undo tablespaces](#). For more information about undo tablespaces, see [Section 15.7.7, “Storing InnoDB Undo Logs in Separate Tablespaces”](#). For information about multi-versioning, see [Section 15.3, “InnoDB Multi-Versioning”](#).

Prior to MySQL 8.0.2, [InnoDB](#) supports a maximum of 128 rollback segments. As of MySQL 8.0.2, the system tablespace, temporary tablespace, and each undo tablespace individually support a maximum of 128 rollback segments. The `innodb_rollback_segments` configuration option defines the number of rollback segments. Each rollback segment supports up to 1023 concurrent data-modifying transactions.

15.4.8 File-Per-Table Tablespaces

A file-per-table tablespace is a single-table tablespace that is created in its own data file rather than in the system tablespace. Tables are created in file-per-table tablespaces when the `innodb_file_per_table` option is enabled. Otherwise, [InnoDB](#) tables are created in the system tablespace. Each file-per-table tablespace is represented by a single `.ibd` data file, which is created in the database directory by default.

File per-table tablespaces support [DYNAMIC](#) and [COMPRESSED](#) row formats which support features such as off-page storage for variable length data and table compression. For information about these features, and about other advantages of file-per-table tablespaces, see [Section 15.7.4, “InnoDB File-Per-Table Tablespaces”](#).

15.4.9 General Tablespaces

A shared [InnoDB](#) tablespace created using `CREATE TABLESPACE` syntax. General tablespaces can be created outside of the MySQL data directory, are capable of holding multiple tables, and support tables of all row formats.

Tables are added to a general tablespace using `CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name` or `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` syntax.

For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

15.4.10 Undo Tablespace

An undo tablespace comprises one or more files that contain [undo logs](#). An undo tablespace is created when the `innodb_undo_tablespaces` configuration option is set to a non-zero value. For more information, see [Section 15.7.7, “Storing InnoDB Undo Logs in Separate Tablespaces”](#).

15.4.11 Temporary Tablespace

The temporary tablespace is used for non-compressed [InnoDB](#) temporary tables and related objects. The `innodb_temp_data_file_path` configuration option defines a relative path for the temporary tablespace data file. If `innodb_temp_data_file_path` is not defined, a single auto-extending 12MB data file named `ibtmp1` is created in the data directory. The temporary tablespace is recreated on each server start and receives a dynamically generated space ID, which helps avoid conflicts with existing space IDs. The temporary tablespace cannot reside on a raw device. Startup is refused if the temporary tablespace cannot be created.

The temporary tablespace is removed on normal shutdown or on an aborted initialization. The temporary tablespace is not removed when a crash occurs. In this case, the database administrator may remove the temporary tablespace manually or restart the server with the same configuration, which removes and recreates the temporary tablespace.

15.4.11.1 Temporary Table Undo Logs

Temporary table undo logs are used for temporary tables and related objects. This type of [undo log](#) is not a redo log, as temporary tables are not recovered during crash recovery and do not require redo logs. Temporary table undo logs are, however, used for rollback while the server is running. This special type of non-redo undo log benefits performance by avoiding redo logging I/O for temporary tables and related objects. Temporary table undo logs reside in the temporary tablespace.

Prior to MySQL 8.0.2, 32 [rollback segments](#) are assigned for temporary table [undo logs](#) for transactions that modify temporary tables and related objects. As of MySQL 8.0.2, the [innodb_rollback_segments](#) configuration option defines the number of rollback segments used by the temporary tablespace.

15.4.12 Redo Log

The redo log is a disk-based data structure used during crash recovery to correct data written by incomplete transactions. During normal operations, the redo log encodes requests to change [InnoDB](#) table data that result from SQL statements or low-level API calls. Modifications that did not finish updating the data files before an unexpected shutdown are replayed automatically during initialization, and before the connections are accepted. For information about the role of the redo log in crash recovery, see [Section 15.17.2, “InnoDB Recovery”](#).

By default, the redo log is physically represented on disk as a set of files, named [ib_logfile0](#) and [ib_logfile1](#). MySQL writes to the redo log files in a circular fashion. Data in the redo log is encoded in terms of records affected; this data is collectively referred to as redo. The passage of data through the redo log is represented by an ever-increasing [LSN](#) value.

For related information, see:

- [Section 15.6.1, “InnoDB Startup Configuration”](#)
- [Section 8.5.4, “Optimizing InnoDB Redo Logging”](#)
- [Section 15.7.2, “Changing the Number or Size of InnoDB Redo Log Files”](#)
- [InnoDB Crash Recovery](#)

15.4.12.1 Group Commit for Redo Log Flushing

[InnoDB](#), like any other [ACID](#)-compliant database engine, flushes the [redo log](#) of a transaction before it is committed. [InnoDB](#) uses [group commit](#) functionality to group multiple such flush requests together to avoid one flush for each commit. With group commit, [InnoDB](#) issues a single write to the log file to perform the commit action for multiple user transactions that commit at about the same time, significantly improving throughput.

For more information about performance of [COMMIT](#) and other transactional operations, see [Section 8.5.2, “Optimizing InnoDB Transaction Management”](#).

15.5 InnoDB Locking and Transaction Model

To implement a large-scale, busy, or highly reliable database application, to port substantial code from a different database system, or to tune MySQL performance, it is important to understand [InnoDB](#) locking and the [InnoDB](#) transaction model.

This section discusses several topics related to [InnoDB](#) locking and the [InnoDB](#) transaction model with which you should be familiar.

- [Section 15.5.1, “InnoDB Locking”](#) describes lock types used by [InnoDB](#).

- [Section 15.5.2, “InnoDB Transaction Model”](#) describes transaction isolation levels and the locking strategies used by each. It also discusses the use of `autocommit`, consistent non-locking reads, and locking reads.
- [Section 15.5.3, “Locks Set by Different SQL Statements in InnoDB”](#) discusses specific types of locks set in `InnoDB` for various statements.
- [Section 15.5.4, “Phantom Rows”](#) describes how `InnoDB` uses next-key locking to avoid phantom rows.
- [Section 15.5.5, “Deadlocks in InnoDB”](#) provides a deadlock example, discusses deadlock detection and rollback, and provides tips for minimizing and handling deadlocks in `InnoDB`.

15.5.1 InnoDB Locking

This section describes lock types used by `InnoDB`.

- [Shared and Exclusive Locks](#)
- [Intention Locks](#)
- [Record Locks](#)
- [Gap Locks](#)
- [Next-Key Locks](#)
- [Insert Intention Locks](#)
- [AUTO-INC Locks](#)
- [Predicate Locks for Spatial Indexes](#)

Shared and Exclusive Locks

`InnoDB` implements standard row-level locking where there are two types of locks, [shared \(*S*\) locks](#) and [exclusive \(*X*\) locks](#).

- A [shared \(*S*\) lock](#) permits the transaction that holds the lock to read a row.
- An [exclusive \(*X*\) lock](#) permits the transaction that holds the lock to update or delete a row.

If transaction `T1` holds a shared (*S*) lock on row `r`, then requests from some distinct transaction `T2` for a lock on row `r` are handled as follows:

- A request by `T2` for an *S* lock can be granted immediately. As a result, both `T1` and `T2` hold an *S* lock on `r`.
- A request by `T2` for an *X* lock cannot be granted immediately.

If a transaction `T1` holds an exclusive (*X*) lock on row `r`, a request from some distinct transaction `T2` for a lock of either type on `r` cannot be granted immediately. Instead, transaction `T2` has to wait for transaction `T1` to release its lock on row `r`.

Intention Locks

`InnoDB` supports *multiple granularity locking* which permits coexistence of row-level locks and locks on entire tables. To make locking at multiple granularity levels practical, additional types of locks called [intention locks](#) are used. Intention locks are table-level locks in `InnoDB` that indicate which type of lock (shared or exclusive) a transaction requires later for a row in that table. There are two types of intention locks used in `InnoDB` (assume that transaction `T` has requested a lock of the indicated type on table `t`):

- **Intention shared** (*IS*): Transaction *T* intends to set *S* locks on individual rows in table *t*.
- **Intention exclusive** (*IX*): Transaction *T* intends to set *X* locks on those rows.

For example, `SELECT ... FOR SHARE` sets an *IS* lock and `SELECT ... FOR UPDATE` sets an *IX* lock.

The intention locking protocol is as follows:

- Before a transaction can acquire an *S* lock on a row in table *t*, it must first acquire an *IS* or stronger lock on *t*.
- Before a transaction can acquire an *X* lock on a row, it must first acquire an *IX* lock on *t*.

These rules can be conveniently summarized by means of the following *lock type compatibility matrix*.

	<i>X</i>	<i>IX</i>	<i>S</i>	<i>IS</i>
<i>X</i>	Conflict	Conflict	Conflict	Conflict
<i>IX</i>	Conflict	Compatible	Conflict	Compatible
<i>S</i>	Conflict	Conflict	Compatible	Compatible
<i>IS</i>	Conflict	Compatible	Compatible	Compatible

A lock is granted to a requesting transaction if it is compatible with existing locks, but not if it conflicts with existing locks. A transaction waits until the conflicting existing lock is released. If a lock request conflicts with an existing lock and cannot be granted because it would cause **deadlock**, an error occurs.

Thus, intention locks do not block anything except full table requests (for example, `LOCK TABLES ... WRITE`). The main purpose of *IX* and *IS* locks is to show that someone is locking a row, or going to lock a row in the table.

Transaction data for an intention lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and `InnoDB monitor` output:

```
TABLE LOCK table `test`.`t` trx id 10080 lock mode IX
```

Record Locks

A record lock is a lock on an index record. For example, `SELECT c1 FROM t WHERE c1 = 10 FOR UPDATE;` prevents any other transaction from inserting, updating, or deleting rows where the value of `t.c1` is 10.

Record locks always lock index records, even if a table is defined with no indexes. For such cases, `InnoDB` creates a hidden clustered index and uses this index for record locking. See [Section 15.8.2.1, “Clustered and Secondary Indexes”](#).

Transaction data for a record lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and `InnoDB monitor` output:

```
RECORD LOCKS space id 58 page no 3 n bits 72 index `PRIMARY` of table `test`.`t`
trx id 10078 lock_mode X locks rec but not gap
Record lock, heap no 2 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
0: len 4; hex 8000000a; asc      ;;
1: len 6; hex 00000000274f; asc  'O;;
2: len 7; hex b60000019d0110; asc      ;;
```

Gap Locks

A gap lock is a lock on a gap between index records, or a lock on the gap before the first or after the last index record. For example, `SELECT c1 FROM t WHERE c1 BETWEEN 10 and 20 FOR`

`UPDATE`; prevents other transactions from inserting a value of 15 into column `t.c1`, whether or not there was already any such value in the column, because the gaps between all existing values in the range are locked.

A gap might span a single index value, multiple index values, or even be empty.

Gap locks are part of the tradeoff between performance and concurrency, and are used in some transaction isolation levels and not others.

Gap locking is not needed for statements that lock rows using a unique index to search for a unique row. (This does not include the case that the search condition includes only some columns of a multiple-column unique index; in that case, gap locking does occur.) For example, if the `id` column has a unique index, the following statement uses only an index-record lock for the row having `id` value 100 and it does not matter whether other sessions insert rows in the preceding gap:

```
SELECT * FROM child WHERE id = 100;
```

If `id` is not indexed or has a nonunique index, the statement does lock the preceding gap.

It is also worth noting here that conflicting locks can be held on a gap by different transactions. For example, transaction A can hold a shared gap lock (gap S-lock) on a gap while transaction B holds an exclusive gap lock (gap X-lock) on the same gap. The reason conflicting gap locks are allowed is that if a record is purged from an index, the gap locks held on the record by different transactions must be merged.

Gap locks in InnoDB are “purely inhibitive”, which means they only stop other transactions from inserting to the gap. They do not prevent different transactions from taking gap locks on the same gap. Thus, a gap X-lock has the same effect as a gap S-lock.

Gap locking can be disabled explicitly. This occurs if you change the transaction isolation level to `READ COMMITTED`. Under these circumstances, gap locking is disabled for searches and index scans and is used only for foreign-key constraint checking and duplicate-key checking.

There are also other effects of using the `READ COMMITTED` isolation level. Record locks for nonmatching rows are released after MySQL has evaluated the `WHERE` condition. For `UPDATE` statements, InnoDB does a “semi-consistent” read, such that it returns the latest committed version to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`.

Next-Key Locks

A next-key lock is a combination of a record lock on the index record and a gap lock on the gap before the index record.

InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. A next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record `R` in an index, another session cannot insert a new index record in the gap immediately before `R` in the index order.

Suppose that an index contains the values 10, 11, 13, and 20. The possible next-key locks for this index cover the following intervals, where a round bracket denotes exclusion of the interval endpoint and a square bracket denotes inclusion of the endpoint:

```
(negative infinity, 10]
(10, 11]
(11, 13]
(13, 20]
(20, positive infinity)
```

For the last interval, the next-key lock locks the gap above the largest value in the index and the “supremum” pseudo-record having a value higher than any value actually in the index. The supremum is not a real index record, so, in effect, this next-key lock locks only the gap following the largest index value.

By default, InnoDB operates in `REPEATABLE READ` transaction isolation level. In this case, InnoDB uses next-key locks for searches and index scans, which prevents phantom rows (see [Section 15.5.4, “Phantom Rows”](#)).

Transaction data for a next-key lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and `InnoDB monitor` output:

```
RECORD LOCKS space id 58 page no 3 n bits 72 index `PRIMARY` of table `test`.`t`
trx id 10080 lock_mode X
Record lock, heap no 1 PHYSICAL RECORD: n_fields 1; compact format; info bits 0
 0: len 8; hex 73757072656d756d; asc supremum;;

Record lock, heap no 2 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
 0: len 4; hex 8000000a; asc      ;;
 1: len 6; hex 00000000274f; asc      'O';
 2: len 7; hex b60000019d0110; asc      ;;
```

Insert Intention Locks

An insert intention lock is a type of gap lock set by `INSERT` operations prior to row insertion. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6, respectively, each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are nonconflicting.

The following example demonstrates a transaction taking an insert intention lock prior to obtaining an exclusive lock on the inserted record. The example involves two clients, A and B.

Client A creates a table containing two index records (90 and 102) and then starts a transaction that places an exclusive lock on index records with an ID greater than 100. The exclusive lock includes a gap lock before record 102:

```
mysql> CREATE TABLE child (id int(11) NOT NULL, PRIMARY KEY(id)) ENGINE=InnoDB;
mysql> INSERT INTO child (id) values (90),(102);

mysql> START TRANSACTION;
mysql> SELECT * FROM child WHERE id > 100 FOR UPDATE;
+-----+
| id   |
+-----+
| 102 |
+-----+
```

Client B begins a transaction to insert a record into the gap. The transaction takes an insert intention lock while it waits to obtain an exclusive lock.

```
mysql> START TRANSACTION;
mysql> INSERT INTO child (id) VALUES (101);
```

Transaction data for an insert intention lock appears similar to the following in `SHOW ENGINE INNODB STATUS` and `InnoDB monitor` output:

```
RECORD LOCKS space id 31 page no 3 n bits 72 index `PRIMARY` of table `test`.`child`
trx id 8731 lock_mode X locks gap before rec insert intention waiting
Record lock, heap no 3 PHYSICAL RECORD: n_fields 3; compact format; info bits 0
 0: len 4; hex 80000066; asc      f;;
 1: len 6; hex 000000002215; asc      "  ;;
```

```
2: len 7; hex 9000000172011c; asc r ; ;...
```

AUTO-INC Locks

An `AUTO-INC` lock is a special table-level lock taken by transactions inserting into tables with `AUTO_INCREMENT` columns. In the simplest case, if one transaction is inserting values into the table, any other transactions must wait to do their own inserts into that table, so that rows inserted by the first transaction receive consecutive primary key values.

The `innodb_autoinc_lock_mode` configuration option controls the algorithm used for auto-increment locking. It allows you to choose how to trade off between predictable sequences of auto-increment values and maximum concurrency for insert operations.

For more information, see [Section 15.8.1.5, “AUTO_INCREMENT Handling in InnoDB”](#).

Predicate Locks for Spatial Indexes

InnoDB supports `SPATIAL` indexing of columns containing spatial columns (see [Section 11.5.8, “Optimizing Spatial Analysis”](#)).

To handle locking for operations involving `SPATIAL` indexes, next-key locking does not work well to support `REPEATABLE READ` or `SERIALIZABLE` transaction isolation levels. There is no absolute ordering concept in multidimensional data, so it is not clear which is the “next” key.

To enable support of isolation levels for tables with `SPATIAL` indexes, InnoDB uses predicate locks. A `SPATIAL` index contains minimum bounding rectangle (MBR) values, so InnoDB enforces consistent read on the index by setting a predicate lock on the MBR value used for a query. Other transactions cannot insert or modify a row that would match the query condition.

15.5.2 InnoDB Transaction Model

In the InnoDB transaction model, the goal is to combine the best properties of a [multi-versioning](#) database with traditional two-phase locking. InnoDB performs locking at the row level and runs queries as nonlocking [consistent reads](#) by default, in the style of Oracle. The lock information in InnoDB is stored space-efficiently so that lock escalation is not needed. Typically, several users are permitted to lock every row in InnoDB tables, or any random subset of the rows, without causing InnoDB memory exhaustion.

15.5.2.1 Transaction Isolation Levels

Transaction isolation is one of the foundations of database processing. Isolation is the I in the acronym [ACID](#); the isolation level is the setting that fine-tunes the balance between performance and reliability, consistency, and reproducibility of results when multiple transactions are making changes and performing queries at the same time.

InnoDB offers all four transaction isolation levels described by the SQL:1992 standard: `READ UNCOMMITTED`, `READ COMMITTED`, `REPEATABLE READ`, and `SERIALIZABLE`. The default isolation level for InnoDB is `REPEATABLE READ`.

A user can change the isolation level for a single session or for all subsequent connections with the `SET TRANSACTION` statement. To set the server's default isolation level for all connections, use the `--transaction-isolation` option on the command line or in an option file. For detailed information about isolation levels and level-setting syntax, see [Section 13.3.6, “SET TRANSACTION Syntax”](#).

InnoDB supports each of the transaction isolation levels described here using different [locking](#) strategies. You can enforce a high degree of consistency with the default `REPEATABLE READ` level, for operations on crucial data where [ACID](#) compliance is important. Or you can relax the consistency rules with `READ COMMITTED` or even `READ UNCOMMITTED`, in situations such as bulk reporting where precise consistency and repeatable results are less important than minimizing the amount of overhead for locking. `SERIALIZABLE` enforces even stricter rules than `REPEATABLE READ`, and is used mainly

in specialized situations, such as with [XA](#) transactions and for troubleshooting issues with concurrency and [deadlocks](#).

The following list describes how MySQL supports the different transaction levels. The list goes from the most commonly used level to the least used.

- [REPEATABLE READ](#)

This is the default isolation level for [InnoDB](#). [Consistent reads](#) within the same transaction read the [snapshot](#) established by the first read. This means that if you issue several plain (nonlocking) [SELECT](#) statements within the same transaction, these [SELECT](#) statements are consistent also with respect to each other. See [Section 15.5.2.3, “Consistent Nonlocking Reads”](#).

For [locking reads](#) ([SELECT](#) with [FOR UPDATE](#) or [FOR SHARE](#)), [UPDATE](#), and [DELETE](#) statements, locking depends on whether the statement uses a unique index with a unique search condition, or a range-type search condition.

- For a unique index with a unique search condition, [InnoDB](#) locks only the index record found, not the [gap](#) before it.
- For other search conditions, [InnoDB](#) locks the index range scanned, using [gap locks](#) or [next-key locks](#) to block insertions by other sessions into the gaps covered by the range. For information about gap locks and next-key locks, see [Section 15.5.1, “InnoDB Locking”](#).

- [READ COMMITTED](#)

Each consistent read, even within the same transaction, sets and reads its own fresh snapshot. For information about consistent reads, see [Section 15.5.2.3, “Consistent Nonlocking Reads”](#).

For locking reads ([SELECT](#) with [FOR UPDATE](#) or [FOR SHARE](#)), [UPDATE](#) statements, and [DELETE](#) statements, [InnoDB](#) locks only index records, not the gaps before them, and thus permits the free insertion of new records next to locked records. Gap locking is only used for foreign-key constraint checking and duplicate-key checking.

Because gap locking is disabled, phantom problems may occur, as other sessions can insert new rows into the gaps. For information about phantoms, see [Section 15.5.4, “Phantom Rows”](#).

If you use [READ COMMITTED](#), you *must* use row-based binary logging.

Using [READ COMMITTED](#) has additional effects:

- For [UPDATE](#) or [DELETE](#) statements, [InnoDB](#) holds locks only for rows that it updates or deletes. Record locks for nonmatching rows are released after MySQL has evaluated the [WHERE](#) condition. This greatly reduces the probability of deadlocks, but they can still happen.
- For [UPDATE](#) statements, if a row is already locked, [InnoDB](#) performs a “semi-consistent” read, returning the latest committed version to MySQL so that MySQL can determine whether the row matches the [WHERE](#) condition of the [UPDATE](#). If the row matches (must be updated), MySQL reads the row again and this time [InnoDB](#) either locks it or waits for a lock on it.

Consider the following example, beginning with this table:

```
CREATE TABLE t (a INT NOT NULL, b INT) ENGINE = InnoDB;
INSERT INTO t VALUES (1,2),(2,3),(3,2),(4,3),(5,2);
COMMIT;
```

In this case, table has no indexes, so searches and index scans use the hidden clustered index for record locking (see [Section 15.8.2.1, “Clustered and Secondary Indexes”](#)).

Suppose that one client performs an [UPDATE](#) using these statements:

```
SET autocommit = 0;
UPDATE t SET b = 5 WHERE b = 3;
```

Suppose also that a second client performs an `UPDATE` by executing these statements following those of the first client:

```
SET autocommit = 0;
UPDATE t SET b = 4 WHERE b = 2;
```

As `InnoDB` executes each `UPDATE`, it first acquires an exclusive lock for each row, and then determines whether to modify it. If `InnoDB` does not modify the row, it releases the lock. Otherwise, `InnoDB` retains the lock until the end of the transaction. This affects transaction processing as follows.

When using the default `REPEATABLE READ` isolation level, the first `UPDATE` acquires x-locks and does not release any of them:

```
x-lock(1,2); retain x-lock
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); retain x-lock
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); retain x-lock
```

The second `UPDATE` blocks as soon as it tries to acquire any locks (because first update has retained locks on all rows), and does not proceed until the first `UPDATE` commits or rolls back:

```
x-lock(1,2); block and wait for first UPDATE to commit or roll back
```

If `READ COMMITTED` is used instead, the first `UPDATE` acquires x-locks and releases those for rows that it does not modify:

```
x-lock(1,2); unlock(1,2)
x-lock(2,3); update(2,3) to (2,5); retain x-lock
x-lock(3,2); unlock(3,2)
x-lock(4,3); update(4,3) to (4,5); retain x-lock
x-lock(5,2); unlock(5,2)
```

For the second `UPDATE`, `InnoDB` does a “semi-consistent” read, returning the latest committed version of each row to MySQL so that MySQL can determine whether the row matches the `WHERE` condition of the `UPDATE`:

```
x-lock(1,2); update(1,2) to (1,4); retain x-lock
x-lock(2,3); unlock(2,3)
x-lock(3,2); update(3,2) to (3,4); retain x-lock
x-lock(4,3); unlock(4,3)
x-lock(5,2); update(5,2) to (5,4); retain x-lock
```

- `READ UNCOMMITTED`

`SELECT` statements are performed in a nonlocking fashion, but a possible earlier version of a row might be used. Thus, using this isolation level, such reads are not consistent. This is also called a [dirty read](#). Otherwise, this isolation level works like `READ COMMITTED`.

- `SERIALIZABLE`

This level is like `REPEATABLE READ`, but `InnoDB` implicitly converts all plain `SELECT` statements to `SELECT ... FOR SHARE` if `autocommit` is disabled. If `autocommit` is enabled, the `SELECT` is its own transaction. It therefore is known to be read only and can be serialized if performed as a

consistent (nonlocking) read and need not block for other transactions. (To force a plain `SELECT` to block if other transactions have modified the selected rows, disable `autocommit`.)

15.5.2.2 autocommit, Commit, and Rollback

In `InnoDB`, all user activity occurs inside a transaction. If `autocommit` mode is enabled, each SQL statement forms a single transaction on its own. By default, MySQL starts the session for each new connection with `autocommit` enabled, so MySQL does a commit after each SQL statement if that statement did not return an error. If a statement returns an error, the commit or rollback behavior depends on the error. See [Section 15.20.4, “InnoDB Error Handling”](#).

A session that has `autocommit` enabled can perform a multiple-statement transaction by starting it with an explicit `START TRANSACTION` or `BEGIN` statement and ending it with a `COMMIT` or `ROLLBACK` statement. See [Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

If `autocommit` mode is disabled within a session with `SET autocommit = 0`, the session always has a transaction open. A `COMMIT` or `ROLLBACK` statement ends the current transaction and a new one starts.

If a session that has `autocommit` disabled ends without explicitly committing the final transaction, MySQL rolls back that transaction.

Some statements implicitly end a transaction, as if you had done a `COMMIT` before executing the statement. For details, see [Section 13.3.3, “Statements That Cause an Implicit Commit”](#).

A `COMMIT` means that the changes made in the current transaction are made permanent and become visible to other sessions. A `ROLLBACK` statement, on the other hand, cancels all modifications made by the current transaction. Both `COMMIT` and `ROLLBACK` release all `InnoDB` locks that were set during the current transaction.

Grouping DML Operations with Transactions

By default, connection to the MySQL server begins with `autocommit` mode enabled, which automatically commits every SQL statement as you execute it. This mode of operation might be unfamiliar if you have experience with other database systems, where it is standard practice to issue a sequence of `DML` statements and commit them or roll them back all together.

To use multiple-statement `transactions`, switch `autocommit` off with the SQL statement `SET autocommit = 0` and end each transaction with `COMMIT` or `ROLLBACK` as appropriate. To leave `autocommit` on, begin each transaction with `START TRANSACTION` and end it with `COMMIT` or `ROLLBACK`. The following example shows two transactions. The first is committed; the second is rolled back.

```
shell> mysql test

mysql> CREATE TABLE customer (a INT, b CHAR (20), INDEX (a));
Query OK, 0 rows affected (0.00 sec)
mysql> -- Do a transaction with autocommit turned on.
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (10, 'Heikki');
Query OK, 1 row affected (0.00 sec)
mysql> COMMIT;
Query OK, 0 rows affected (0.00 sec)
mysql> -- Do another transaction with autocommit turned off.
mysql> SET autocommit=0;
Query OK, 0 rows affected (0.00 sec)
mysql> INSERT INTO customer VALUES (15, 'John');
Query OK, 1 row affected (0.00 sec)
mysql> INSERT INTO customer VALUES (20, 'Paul');
Query OK, 1 row affected (0.00 sec)
mysql> DELETE FROM customer WHERE b = 'Heikki';
Query OK, 1 row affected (0.00 sec)
```

```
mysql> -- Now we undo those last 2 inserts and the delete.
mysql> ROLLBACK;
Query OK, 0 rows affected (0.00 sec)
mysql> SELECT * FROM customer;
+-----+-----+
| a     | b     |
+-----+-----+
| 10    | Heikki |
+-----+-----+
1 row in set (0.00 sec)
mysql>
```

Transactions in Client-Side Languages

In APIs such as PHP, Perl DBI, JDBC, ODBC, or the standard C call interface of MySQL, you can send transaction control statements such as `COMMIT` to the MySQL server as strings just like any other SQL statements such as `SELECT` or `INSERT`. Some APIs also offer separate special transaction commit and rollback functions or methods.

15.5.2.3 Consistent Nonlocking Reads

A [consistent read](#) means that InnoDB uses multi-versioning to present to a query a snapshot of the database at a point in time. The query sees the changes made by transactions that committed before that point of time, and no changes made by later or uncommitted transactions. The exception to this rule is that the query sees the changes made by earlier statements within the same transaction. This exception causes the following anomaly: If you update some rows in a table, a `SELECT` sees the latest version of the updated rows, but it might also see older versions of any rows. If other sessions simultaneously update the same table, the anomaly means that you might see the table in a state that never existed in the database.

If the transaction [isolation level](#) is `REPEATABLE READ` (the default level), all consistent reads within the same transaction read the snapshot established by the first such read in that transaction. You can get a fresher snapshot for your queries by committing the current transaction and after that issuing new queries.

With `READ COMMITTED` isolation level, each consistent read within a transaction sets and reads its own fresh snapshot.

Consistent read is the default mode in which InnoDB processes `SELECT` statements in `READ COMMITTED` and `REPEATABLE READ` isolation levels. A consistent read does not set any locks on the tables it accesses, and therefore other sessions are free to modify those tables at the same time a consistent read is being performed on the table.

Suppose that you are running in the default `REPEATABLE READ` isolation level. When you issue a consistent read (that is, an ordinary `SELECT` statement), InnoDB gives your transaction a timepoint according to which your query sees the database. If another transaction deletes a row and commits after your timepoint was assigned, you do not see the row as having been deleted. Inserts and updates are treated similarly.

Note

The snapshot of the database state applies to `SELECT` statements within a transaction, not necessarily to `DML` statements. If you insert or modify some rows and then commit that transaction, a `DELETE` or `UPDATE` statement issued from another concurrent `REPEATABLE READ` transaction could affect those just-committed rows, even though the session could not query them. If a transaction does update or delete rows committed by a different transaction, those changes do become visible to the current transaction. For example, you might encounter a situation like the following:

```
SELECT COUNT(c1) FROM t1 WHERE c1 = 'xyz';
-- Returns 0: no rows match.
```

```
DELETE FROM t1 WHERE c1 = 'xyz';
-- Deletes several rows recently committed by other transaction.

SELECT COUNT(c2) FROM t1 WHERE c2 = 'abc';
-- Returns 0: no rows match.
UPDATE t1 SET c2 = 'cba' WHERE c2 = 'abc';
-- Affects 10 rows: another txn just committed 10 rows with 'abc' values.
SELECT COUNT(c2) FROM t1 WHERE c2 = 'cba';
-- Returns 10: this txn can now see the rows it just updated.
```

You can advance your timepoint by committing your transaction and then doing another `SELECT` or `START TRANSACTION WITH CONSISTENT SNAPSHOT`.

This is called *multi-versioned concurrency control*.

In the following example, session A sees the row inserted by B only when B has committed the insert and A has committed as well, so that the timepoint is advanced past the commit of B.

	Session A	Session B
time	SET autocommit=0;	SET autocommit=0;
	SELECT * FROM t;	
	empty set	
		INSERT INTO t VALUES (1, 2);
v	SELECT * FROM t;	
	empty set	COMMIT;
	SELECT * FROM t;	
	empty set	
	COMMIT;	
	SELECT * FROM t;	

	1 2	

If you want to see the “freshest” state of the database, use either the `READ COMMITTED` isolation level or a `locking read`:

```
SELECT * FROM t FOR SHARE;
```

With `READ COMMITTED` isolation level, each consistent read within a transaction sets and reads its own fresh snapshot. With `FOR SHARE`, a locking read occurs instead: A `SELECT` blocks until the transaction containing the freshest rows ends (see [Section 15.5.2.4, “Locking Reads”](#)).

Consistent read does not work over certain DDL statements:

- Consistent read does not work over `DROP TABLE`, because MySQL cannot use a table that has been dropped and `InnoDB` destroys the table.
- Consistent read does not work over `ALTER TABLE`, because that statement makes a temporary copy of the original table and deletes the original table when the temporary copy is built. When you reissue a consistent read within a transaction, rows in the new table are not visible because those rows did not exist when the transaction's snapshot was taken. In this case, the transaction returns an error: `ER_TABLE_DEF_CHANGED`, “Table definition has changed, please retry transaction”.

The type of read varies for selects in clauses like `INSERT INTO ... SELECT`, `UPDATE ... (SELECT)`, and `CREATE TABLE ... SELECT` that do not specify `FOR UPDATE` or `FOR SHARE`:

- By default, `InnoDB` uses stronger locks and the `SELECT` part acts like `READ COMMITTED`, where each consistent read, even within the same transaction, sets and reads its own fresh snapshot.

- To use a consistent read in such cases, set the isolation level of the transaction to [READ UNCOMMITTED](#), [READ COMMITTED](#), or [REPEATABLE READ](#) (that is, anything other than [SERIALIZABLE](#)). In this case, no locks are set on rows read from the selected table.

15.5.2.4 Locking Reads

If you query data and then insert or update related data within the same transaction, the regular [SELECT](#) statement does not give enough protection. Other transactions can update or delete the same rows you just queried. InnoDB supports two types of [locking reads](#) that offer extra safety:

- [SELECT ... FOR SHARE](#)

Sets a shared mode lock on any rows that are read. Other sessions can read the rows, but cannot modify them until your transaction commits. If any of these rows were changed by another transaction that has not yet committed, your query waits until that transaction ends and then uses the latest values.

Note

[SELECT ... FOR SHARE](#) is a replacement for [SELECT ... LOCK IN SHARE MODE](#), but [LOCK IN SHARE MODE](#) remains available for backward compatibility. The statements are equivalent. However, [FOR SHARE](#) supports [OF table_name](#), [NOWAIT](#), and [SKIP LOCKED](#) options. See [Locking Read Concurrency with NOWAIT and SKIP LOCKED](#).

- [SELECT ... FOR UPDATE](#)

For index records the search encounters, locks the rows and any associated index entries, the same as if you issued an [UPDATE](#) statement for those rows. Other transactions are blocked from updating those rows, from doing [SELECT ... FOR SHARE](#), or from reading the data in certain transaction isolation levels. Consistent reads ignore any locks set on the records that exist in the read view. (Old versions of a record cannot be locked; they are reconstructed by applying [undo logs](#) on an in-memory copy of the record.)

These clauses are primarily useful when dealing with tree-structured or graph-structured data, either in a single table or split across multiple tables. You traverse edges or tree branches from one place to another, while reserving the right to come back and change any of these “pointer” values.

All locks set by [FOR SHARE](#) and [FOR UPDATE](#) queries are released when the transaction is committed or rolled back.

Note

Locking of rows for update using [SELECT FOR UPDATE](#) only applies when autocommit is disabled (either by beginning transaction with [START TRANSACTION](#) or by setting [autocommit](#) to 0. If autocommit is enabled, the rows matching the specification are not locked.

Locking Read Examples

Suppose that you want to insert a new row into a table [child](#), and make sure that the child row has a parent row in table [parent](#). Your application code can ensure referential integrity throughout this sequence of operations.

First, use a consistent read to query the table [PARENT](#) and verify that the parent row exists. Can you safely insert the child row to table [CHILD](#)? No, because some other session could delete the parent row in the moment between your [SELECT](#) and your [INSERT](#), without you being aware of it.

To avoid this potential issue, perform the [SELECT](#) using [FOR SHARE](#):

```
SELECT * FROM parent WHERE NAME = 'Jones' FOR SHARE;
```

After the `FOR SHARE` query returns the parent 'Jones', you can safely add the child record to the `CHILD` table and commit the transaction. Any transaction that tries to acquire an exclusive lock in the applicable row in the `PARENT` table waits until you are finished, that is, until the data in all tables is in a consistent state.

For another example, consider an integer counter field in a table `CHILD_CODES`, used to assign a unique identifier to each child added to table `CHILD`. Do not use either consistent read or a shared mode read to read the present value of the counter, because two users of the database could see the same value for the counter, and a duplicate-key error occurs if two transactions attempt to add rows with the same identifier to the `CHILD` table.

Here, `FOR SHARE` is not a good solution because if two users read the counter at the same time, at least one of them ends up in deadlock when it attempts to update the counter.

To implement reading and incrementing the counter, first perform a locking read of the counter using `FOR UPDATE`, and then increment the counter. For example:

```
SELECT counter_field FROM child_codes FOR UPDATE;
UPDATE child_codes SET counter_field = counter_field + 1;
```

A `SELECT ... FOR UPDATE` reads the latest available data, setting exclusive locks on each row it reads. Thus, it sets the same locks a searched SQL `UPDATE` would set on the rows.

The preceding description is merely an example of how `SELECT ... FOR UPDATE` works. In MySQL, the specific task of generating a unique identifier actually can be accomplished using only a single access to the table:

```
UPDATE child_codes SET counter_field = LAST_INSERT_ID(counter_field + 1);
SELECT LAST_INSERT_ID();
```

The `SELECT` statement merely retrieves the identifier information (specific to the current connection). It does not access any table.

Locking Read Concurrency with `NOWAIT` and `SKIP LOCKED`

If a row is locked by a transaction, a `SELECT ... FOR UPDATE` or `SELECT ... FOR SHARE` transaction that requests the same locked row must wait until the blocking transaction releases the row lock. This behavior prevents transactions from updating or deleting rows that are queried for updates by other transactions. However, waiting for a row lock to be released is not necessary if you want the query to return immediately when a requested row is locked, or if excluding locked rows from the result set is acceptable.

To avoid waiting for other transactions to release row locks, `NO WAIT` and `SKIP LOCKED` options may be used with `SELECT ... FOR UPDATE` or `SELECT ... FOR SHARE` locking read statements.

- `NOWAIT`

A locking read that uses `NOWAIT` never waits to acquire a row lock. The query executes immediately, failing with an error if a requested row is locked.

- `SKIP LOCKED`

A locking read that uses `SKIP LOCKED` never waits to acquire a row lock. The query executes immediately, removing locked rows from the result set.

Note

Queries that skip locked rows return an inconsistent view of the data. `SKIP LOCKED` is therefore not suitable for general transactional work. However, it may be used to avoid lock contention when multiple sessions access the same queue-like table.

`NO WAIT` and `SKIP LOCKED` only apply to row-level locks.

Statements that use `NO WAIT` or `SKIP LOCKED` are unsafe for statement based replication.

The following example demonstrates `NOWAIT` and `SKIP LOCKED`. Session 1 starts a transaction that takes a row lock on a single record. Session 2 attempts a locking read on the same record using the `NOWAIT` option. Because the requested row is locked by Session 1, the locking read returns immediately with an error. In Session 3, the locking read with `SKIP LOCKED` returns the requested rows except for the row that is locked by Session 1.

```
# Session 1:
mysql> CREATE TABLE t (i INT, PRIMARY KEY (i)) ENGINE = InnoDB;
mysql> INSERT INTO t (i) VALUES(1),(2),(3);
mysql> START TRANSACTION;
mysql> SELECT * FROM t WHERE i = 2 FOR UPDATE;
+----+
| i  |
+----+
| 2  |
+----+

# Session 2:
mysql> START TRANSACTION;
mysql> SELECT * FROM t WHERE i = 2 FOR UPDATE NOWAIT;
ERROR 3572 (HY000): Do not wait for lock.

# Session 3:
mysql> START TRANSACTION;
mysql> SELECT * FROM t FOR UPDATE SKIP LOCKED;
+----+
| i  |
+----+
| 1  |
| 3  |
+----+
```

15.5.3 Locks Set by Different SQL Statements in InnoDB

A [locking read](#), an `UPDATE`, or a `DELETE` generally set record locks on every index record that is scanned in the processing of the SQL statement. It does not matter whether there are `WHERE` conditions in the statement that would exclude the row. `InnoDB` does not remember the exact `WHERE` condition, but only knows which index ranges were scanned. The locks are normally [next-key locks](#) that also block inserts into the “gap” immediately before the record. However, [gap locking](#) can be disabled explicitly, which causes next-key locking not to be used. For more information, see [Section 15.5.1, “InnoDB Locking”](#). The transaction isolation level also can affect which locks are set; see [Section 15.5.2.1, “Transaction Isolation Levels”](#).

If a secondary index is used in a search and index record locks to be set are exclusive, `InnoDB` also retrieves the corresponding clustered index records and sets locks on them.

Differences between shared and exclusive locks are described in [Section 15.5.1, “InnoDB Locking”](#).

If you have no indexes suitable for your statement and MySQL must scan the entire table to process the statement, every row of the table becomes locked, which in turn blocks all inserts by other users to the table. It is important to create good indexes so that your queries do not unnecessarily scan many rows.

For `SELECT ... FOR UPDATE` or `SELECT ... FOR SHARE`, locks are acquired for scanned rows, and expected to be released for rows that do not qualify for inclusion in the result set (for example, if they do not meet the criteria given in the `WHERE` clause). However, in some cases, rows might not be unlocked immediately because the relationship between a result row and its original source is lost during query execution. For example, in a `UNION`, scanned (and locked) rows from a table might be inserted into a temporary table before evaluation whether they qualify for the result set. In this circumstance, the relationship of the rows in the temporary table to the rows in the original table is lost and the latter rows are not unlocked until the end of query execution.

InnoDB sets specific types of locks as follows.

- `SELECT ... FROM` is a consistent read, reading a snapshot of the database and setting no locks unless the transaction isolation level is set to `SERIALIZABLE`. For `SERIALIZABLE` level, the search sets shared next-key locks on the index records it encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.
- `SELECT ... FROM ... FOR SHARE` sets shared next-key locks on all index records the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.
- `SELECT ... FROM ... FOR UPDATE` sets an exclusive next-key lock on every record the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.

For index records the search encounters, `SELECT ... FROM ... FOR UPDATE` blocks other sessions from doing `SELECT ... FROM ... FOR SHARE` or from reading in certain transaction isolation levels. Consistent reads ignore any locks set on the records that exist in the read view.

- `UPDATE ... WHERE ...` sets an exclusive next-key lock on every record the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.
- When `UPDATE` modifies a clustered index record, implicit locks are taken on affected secondary index records. The `UPDATE` operation also takes shared locks on affected secondary index records when performing duplicate check scans prior to inserting new secondary index records, and when inserting new secondary index records.
- `DELETE FROM ... WHERE ...` sets an exclusive next-key lock on every record the search encounters. However, only an index record lock is required for statements that lock rows using a unique index to search for a unique row.
- `INSERT` sets an exclusive lock on the inserted row. This lock is an index-record lock, not a next-key lock (that is, there is no gap lock) and does not prevent other sessions from inserting into the gap before the inserted row.

Prior to inserting the row, a type of gap lock called an insert intention gap lock is set. This lock signals the intent to insert in such a way that multiple transactions inserting into the same index gap need not wait for each other if they are not inserting at the same position within the gap. Suppose that there are index records with values of 4 and 7. Separate transactions that attempt to insert values of 5 and 6 each lock the gap between 4 and 7 with insert intention locks prior to obtaining the exclusive lock on the inserted row, but do not block each other because the rows are nonconflicting.

If a duplicate-key error occurs, a shared lock on the duplicate index record is set. This use of a shared lock can result in deadlock should there be multiple sessions trying to insert the same row if another session already has an exclusive lock. This can occur if another session deletes the row. Suppose that an InnoDB table `t1` has the following structure:

```
CREATE TABLE t1 (i INT, PRIMARY KEY (i)) ENGINE = InnoDB;
```

Now suppose that three sessions perform the following operations in order:

Session 1:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 2:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 3:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 1:

```
ROLLBACK;
```

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 rolls back, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

A similar situation occurs if the table already contains a row with key value 1 and three sessions perform the following operations in order:

Session 1:

```
START TRANSACTION;
DELETE FROM t1 WHERE i = 1;
```

Session 2:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 3:

```
START TRANSACTION;
INSERT INTO t1 VALUES(1);
```

Session 1:

```
COMMIT;
```

The first operation by session 1 acquires an exclusive lock for the row. The operations by sessions 2 and 3 both result in a duplicate-key error and they both request a shared lock for the row. When session 1 commits, it releases its exclusive lock on the row and the queued shared lock requests for sessions 2 and 3 are granted. At this point, sessions 2 and 3 deadlock: Neither can acquire an exclusive lock for the row because of the shared lock held by the other.

- `INSERT ... ON DUPLICATE KEY UPDATE` differs from a simple `INSERT` in that an exclusive lock rather than a shared lock is placed on the row to be updated when a duplicate-key error occurs. An exclusive index-record lock is taken for a duplicate primary key value. An exclusive next-key lock is taken for a duplicate unique key value.

- `REPLACE` is done like an `INSERT` if there is no collision on a unique key. Otherwise, an exclusive next-key lock is placed on the row to be replaced.
- `INSERT INTO T SELECT ... FROM S WHERE ...` sets an exclusive index record lock (without a gap lock) on each row inserted into `T`. If the transaction isolation level is `READ COMMITTED`, `InnoDB` does the search on `S` as a consistent read (no locks). Otherwise, `InnoDB` sets shared next-key locks on rows from `S`. `InnoDB` has to set locks in the latter case: In roll-forward recovery from a backup, every SQL statement must be executed in exactly the same way it was done originally.

`CREATE TABLE ... SELECT ...` performs the `SELECT` with shared next-key locks or as a consistent read, as for `INSERT ... SELECT`.

When a `SELECT` is used in the constructs `REPLACE INTO t SELECT ... FROM s WHERE ...` or `UPDATE t ... WHERE col IN (SELECT ... FROM s ...)`, `InnoDB` sets shared next-key locks on rows from table `s`.

- While initializing a previously specified `AUTO_INCREMENT` column on a table, `InnoDB` sets an exclusive lock on the end of the index associated with the `AUTO_INCREMENT` column. In accessing the auto-increment counter, `InnoDB` uses a specific `AUTO-INC` table lock mode where the lock lasts only to the end of the current SQL statement, not to the end of the entire transaction. Other sessions cannot insert into the table while the `AUTO-INC` table lock is held; see [Section 15.5.2, “InnoDB Transaction Model”](#).

`InnoDB` fetches the value of a previously initialized `AUTO_INCREMENT` column without setting any locks.

- If a `FOREIGN KEY` constraint is defined on a table, any insert, update, or delete that requires the constraint condition to be checked sets shared record-level locks on the records that it looks at to check the constraint. `InnoDB` also sets these locks in the case where the constraint fails.
- `LOCK TABLES` sets table locks, but it is the higher MySQL layer above the `InnoDB` layer that sets these locks. `InnoDB` is aware of table locks if `innodb_table_locks = 1` (the default) and `autocommit = 0`, and the MySQL layer above `InnoDB` knows about row-level locks.

Otherwise, `InnoDB`'s automatic deadlock detection cannot detect deadlocks where such table locks are involved. Also, because in this case the higher MySQL layer does not know about row-level locks, it is possible to get a table lock on a table where another session currently has row-level locks. However, this does not endanger transaction integrity, as discussed in [Section 15.5.5.2, “Deadlock Detection and Rollback”](#). See also [Section 15.8.1.7, “Limits on InnoDB Tables”](#).

15.5.4 Phantom Rows

The so-called *phantom* problem occurs within a transaction when the same query produces different sets of rows at different times. For example, if a `SELECT` is executed twice, but returns a row the second time that was not returned the first time, the row is a “phantom” row.

Suppose that there is an index on the `id` column of the `child` table and that you want to read and lock all rows from the table having an identifier value larger than 100, with the intention of updating some column in the selected rows later:

```
SELECT * FROM child WHERE id > 100 FOR UPDATE;
```

The query scans the index starting from the first record where `id` is bigger than 100. Let the table contain rows having `id` values of 90 and 102. If the locks set on the index records in the scanned range do not lock out inserts made in the gaps (in this case, the gap between 90 and 102), another session can insert a new row into the table with an `id` of 101. If you were to execute the same `SELECT` within the same transaction, you would see a new row with an `id` of 101 (a “phantom”) in the result set returned by the query. If we regard a set of rows as a data item, the new phantom child would violate the isolation principle of transactions that a transaction should be able to run so that the data it has read does not change during the transaction.

To prevent phantoms, InnoDB uses an algorithm called *next-key locking* that combines index-row locking with gap locking. InnoDB performs row-level locking in such a way that when it searches or scans a table index, it sets shared or exclusive locks on the index records it encounters. Thus, the row-level locks are actually index-record locks. In addition, a next-key lock on an index record also affects the “gap” before that index record. That is, a next-key lock is an index-record lock plus a gap lock on the gap preceding the index record. If one session has a shared or exclusive lock on record *R* in an index, another session cannot insert a new index record in the gap immediately before *R* in the index order.

When InnoDB scans an index, it can also lock the gap after the last record in the index. Just that happens in the preceding example: To prevent any insert into the table where *id* would be bigger than 100, the locks set by InnoDB include a lock on the gap following *id* value 102.

You can use next-key locking to implement a uniqueness check in your application: If you read your data in share mode and do not see a duplicate for a row you are going to insert, then you can safely insert your row and know that the next-key lock set on the successor of your row during the read prevents anyone meanwhile inserting a duplicate for your row. Thus, the next-key locking enables you to “lock” the nonexistence of something in your table.

Gap locking can be disabled as discussed in [Section 15.5.1, “InnoDB Locking”](#). This may cause phantom problems because other sessions can insert new rows into the gaps when gap locking is disabled.

15.5.5 Deadlocks in InnoDB

A deadlock is a situation where different transactions are unable to proceed because each holds a lock that the other needs. Because both transactions are waiting for a resource to become available, neither ever release the locks it holds.

A deadlock can occur when transactions lock rows in multiple tables (through statements such as `UPDATE` or `SELECT ... FOR UPDATE`), but in the opposite order. A deadlock can also occur when such statements lock ranges of index records and gaps, with each transaction acquiring some locks but not others due to a timing issue. For a deadlock example, see [Section 15.5.5.1, “An InnoDB Deadlock Example”](#).

To reduce the possibility of deadlocks, use transactions rather than `LOCK TABLES` statements; keep transactions that insert or update data small enough that they do not stay open for long periods of time; when different transactions update multiple tables or large ranges of rows, use the same order of operations (such as `SELECT ... FOR UPDATE`) in each transaction; create indexes on the columns used in `SELECT ... FOR UPDATE` and `UPDATE ... WHERE` statements. The possibility of deadlocks is not affected by the isolation level, because the isolation level changes the behavior of read operations, while deadlocks occur because of write operations. For more information about avoiding and recovering from deadlock conditions, see [Section 15.5.5.3, “How to Minimize and Handle Deadlocks”](#).

When deadlock detection is enabled (the default) and a deadlock does occur, InnoDB detects the condition and rolls back one of the transactions (the victim). If deadlock detection is disabled using the `innodb_deadlock_detect` configuration option, InnoDB relies on the `innodb_lock_wait_timeout` setting to roll back transactions in case of a deadlock. Thus, even if your application logic is correct, you must still handle the case where a transaction must be retried. To see the last deadlock in an InnoDB user transaction, use the `SHOW ENGINE INNODB STATUS` command. If frequent deadlocks highlight a problem with transaction structure or application error handling, run with the `innodb_print_all_deadlocks` setting enabled to print information about all deadlocks to the `mysqld` error log. For more information about how deadlocks are automatically detected and handled, see [Section 15.5.5.2, “Deadlock Detection and Rollback”](#).

15.5.5.1 An InnoDB Deadlock Example

The following example illustrates how an error can occur when a lock request would cause a deadlock. The example involves two clients, A and B.

First, client A creates a table containing one row, and then begins a transaction. Within the transaction, A obtains an *S* lock on the row by selecting it in share mode:

```
mysql> CREATE TABLE t (i INT) ENGINE = InnoDB;
Query OK, 0 rows affected (1.07 sec)

mysql> INSERT INTO t (i) VALUES(1);
Query OK, 1 row affected (0.09 sec)

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM t WHERE i = 1 FOR SHARE;
+-----+
| i     |
+-----+
| 1    |
+-----+
```

Next, client B begins a transaction and attempts to delete the row from the table:

```
mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> DELETE FROM t WHERE i = 1;
```

The delete operation requires an *X* lock. The lock cannot be granted because it is incompatible with the *S* lock that client A holds, so the request goes on the queue of lock requests for the row and client B blocks.

Finally, client A also attempts to delete the row from the table:

```
mysql> DELETE FROM t WHERE i = 1;
ERROR 1213 (40001): Deadlock found when trying to get lock;
try restarting transaction
```

Deadlock occurs here because client A needs an *X* lock to delete the row. However, that lock request cannot be granted because client B already has a request for an *X* lock and is waiting for client A to release its *S* lock. Nor can the *S* lock held by A be upgraded to an *X* lock because of the prior request by B for an *X* lock. As a result, InnoDB generates an error for one of the clients and releases its locks. The client returns this error:

```
ERROR 1213 (40001): Deadlock found when trying to get lock;
try restarting transaction
```

At that point, the lock request for the other client can be granted and it deletes the row from the table.

15.5.5.2 Deadlock Detection and Rollback

When [deadlock detection](#) is enabled (the default), InnoDB automatically detects transaction [deadlocks](#) and rolls back a transaction or transactions to break the deadlock. InnoDB tries to pick small transactions to roll back, where the size of a transaction is determined by the number of rows inserted, updated, or deleted.

InnoDB is aware of table locks if `innodb_table_locks = 1` (the default) and `autocommit = 0`, and the MySQL layer above it knows about row-level locks. Otherwise, InnoDB cannot detect deadlocks where a table lock set by a MySQL `LOCK TABLES` statement or a lock set by a storage engine other than InnoDB is involved. Resolve these situations by setting the value of the `innodb_lock_wait_timeout` system variable.

When InnoDB performs a complete rollback of a transaction, all locks set by the transaction are released. However, if just a single SQL statement is rolled back as a result of an error, some of the

locks set by the statement may be preserved. This happens because [InnoDB](#) stores row locks in a format such that it cannot know afterward which lock was set by which statement.

If a [SELECT](#) calls a stored function in a transaction, and a statement within the function fails, that statement rolls back. Furthermore, if [ROLLBACK](#) is executed after that, the entire transaction rolls back.

If the [LATEST DETECTED DEADLOCK](#) section of [InnoDB Monitor](#) output includes a message stating, “TOO DEEP OR LONG SEARCH IN THE LOCK TABLE WAITS-FOR GRAPH, WE WILL ROLL BACK FOLLOWING TRANSACTION,” this indicates that the number of transactions on the wait-for list has reached a limit of 200. A wait-for list that exceeds 200 transactions is treated as a deadlock and the transaction attempting to check the wait-for list is rolled back. The same error may also occur if the locking thread must look at more than 1,000,000 locks owned by transactions on the wait-for list.

For techniques to organize database operations to avoid deadlocks, see [Section 15.5.5, “Deadlocks in InnoDB”](#).

Disabling Deadlock Detection

On high concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. At times, it may be more efficient to disable deadlock detection and rely on the [innodb_lock_wait_timeout](#) setting for transaction rollback when a deadlock occurs. Deadlock detection can be disabled using the [innodb_deadlock_detect](#) configuration option.

15.5.5.3 How to Minimize and Handle Deadlocks

This section builds on the conceptual information about deadlocks in [Section 15.5.5.2, “Deadlock Detection and Rollback”](#). It explains how to organize database operations to minimize deadlocks and the subsequent error handling required in applications.

[Deadlocks](#) are a classic problem in transactional databases, but they are not dangerous unless they are so frequent that you cannot run certain transactions at all. Normally, you must write your applications so that they are always prepared to re-issue a transaction if it gets rolled back because of a deadlock.

[InnoDB](#) uses automatic row-level locking. You can get deadlocks even in the case of transactions that just insert or delete a single row. That is because these operations are not really “atomic”; they automatically set locks on the (possibly several) index records of the row inserted or deleted.

You can cope with deadlocks and reduce the likelihood of their occurrence with the following techniques:

- At any time, issue the [SHOW ENGINE INNODB STATUS](#) command to determine the cause of the most recent deadlock. That can help you to tune your application to avoid deadlocks.
- If frequent deadlock warnings cause concern, collect more extensive debugging information by enabling the [innodb_print_all_deadlocks](#) configuration option. Information about each deadlock, not just the latest one, is recorded in the MySQL [error log](#). Disable this option when you are finished debugging.
- Always be prepared to re-issue a transaction if it fails due to deadlock. Deadlocks are not dangerous. Just try again.
- Keep transactions small and short in duration to make them less prone to collision.
- Commit transactions immediately after making a set of related changes to make them less prone to collision. In particular, do not leave an interactive [mysql](#) session open for a long time with an uncommitted transaction.
- If you use [locking reads](#) ([SELECT ... FOR UPDATE](#) or [SELECT ... FOR SHARE](#)), try using a lower isolation level such as [READ COMMITTED](#).

- When modifying multiple tables within a transaction, or different sets of rows in the same table, do those operations in a consistent order each time. Then transactions form well-defined queues and do not deadlock. For example, organize database operations into functions within your application, or call stored routines, rather than coding multiple similar sequences of `INSERT`, `UPDATE`, and `DELETE` statements in different places.
- Add well-chosen indexes to your tables. Then your queries need to scan fewer index records and consequently set fewer locks. Use `EXPLAIN SELECT` to determine which indexes the MySQL server regards as the most appropriate for your queries.
- Use less locking. If you can afford to permit a `SELECT` to return data from an old snapshot, do not add the clause `FOR UPDATE` or `FOR SHARE` to it. Using the `READ COMMITTED` isolation level is good here, because each consistent read within the same transaction reads from its own fresh snapshot.
- If nothing else helps, serialize your transactions with table-level locks. The correct way to use `LOCK TABLES` with transactional tables, such as InnoDB tables, is to begin a transaction with `SET autocommit = 0` (not `START TRANSACTION`) followed by `LOCK TABLES`, and to not call `UNLOCK TABLES` until you commit the transaction explicitly. For example, if you need to write to table `t1` and read from table `t2`, you can do this:

```
SET autocommit=0;
LOCK TABLES t1 WRITE, t2 READ, ...;
... do something with tables t1 and t2 here ...
COMMIT;
UNLOCK TABLES;
```

Table-level locks prevent concurrent updates to the table, avoiding deadlocks at the expense of less responsiveness for a busy system.

- Another way to serialize transactions is to create an auxiliary “semaphore” table that contains just a single row. Have each transaction update that row before accessing other tables. In that way, all transactions happen in a serial fashion. Note that the InnoDB instant deadlock detection algorithm also works in this case, because the serializing lock is a row-level lock. With MySQL table-level locks, the timeout method must be used to resolve deadlocks.

15.6 InnoDB Configuration

This section provides configuration information and procedures for InnoDB initialization, startup, and various components and features of the InnoDB storage engine. For information about optimizing database operations for InnoDB tables, see [Section 8.5, “Optimizing for InnoDB Tables”](#).

15.6.1 InnoDB Startup Configuration

The first decisions to make about InnoDB configuration involve the configuration of data files, log files, page size, and memory buffers. It is recommended that you define data file, log file, and page size configuration before creating the InnoDB instance. Modifying data file or log file configuration after the InnoDB instance is created may involve a non-trivial procedure, and page size can only be defined when the InnoDB instance is first initialized.

In addition to these topics, this section provides information about specifying InnoDB options in a configuration file, viewing InnoDB initialization information, and important storage considerations.

- [Specifying Options in a MySQL Configuration File](#)
- [Viewing InnoDB Initialization Information](#)
- [Important Storage Considerations](#)
- [System Tablespace Data File Configuration](#)

- [InnoDB Log File Configuration](#)
- [InnoDB Undo Tablespace Configuration](#)
- [InnoDB Temporary Tablespace Configuration](#)
- [InnoDB Page Size Configuration](#)
- [InnoDB Memory Configuration](#)

Specifying Options in a MySQL Configuration File

Because MySQL uses data file, log file, and page size configuration settings to initialize the [InnoDB](#) instance, it is recommended that you define these settings in a configuration file that MySQL reads at startup, prior to initializing [InnoDB](#) for the first time. [InnoDB](#) is initialized when the MySQL server is started, and the first initialization of [InnoDB](#) normally occurs the first time you start the MySQL server.

You can place [InnoDB](#) options in the `[mysqld]` group of any option file that your server reads when it starts. The locations of MySQL option files are described in [Section 4.2.6, “Using Option Files”](#).

To make sure that `mysqld` reads options only from a specific file (and `mysqld-auto.cnf`), use the `--defaults-file` option as the first option on the command line when starting the server:

```
mysqld --defaults-file=path_to_configuration_file
```

Viewing InnoDB Initialization Information

To view [InnoDB](#) initialization information during startup, start `mysqld` from a command prompt. When `mysqld` is started from a command prompt, initialization information is printed to the console.

For example, on Windows, if `mysqld` is located in `C:\Program Files\MySQL\MySQL Server 8.0\bin`, start the MySQL server like this:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqld" --console
```

On Unix-like systems, `mysqld` is located in the `bin` directory of your MySQL installation:

```
sell> bin/mysqld --user=mysql &
```

If you do not send server output to the console, check the error log after startup to see the initialization information [InnoDB](#) printed during the startup process.

For information about starting MySQL using other methods, see [Section 2.9.5, “Starting and Stopping MySQL Automatically”](#).

Important Storage Considerations

Review the following storage-related considerations before proceeding with your startup configuration.

- In some cases, database performance improves if the data is not all placed on the same physical disk. Putting log files on a different disk from data is very often beneficial for performance. For example, you can place system tablespace data files and log files on different disks. You can also use raw disk partitions (raw devices) for [InnoDB](#) data files, which may speed up I/O. See [Section 15.7.3, “Using Raw Disk Partitions for the System Tablespace”](#).
- [InnoDB](#) is a transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. **However, it cannot do so** if the underlying operating system or hardware does not work as advertised. Many operating systems or disk subsystems may delay or reorder write operations to improve performance. On some operating systems, the very `fsync()` system call that should wait until all unwritten data for a file has been

flushed might actually return before the data has been flushed to stable storage. Because of this, an operating system crash or a power outage may destroy recently committed data, or in the worst case, even corrupt the database because of write operations having been reordered. If data integrity is important to you, perform some “pull-the-plug” tests before using anything in production. On OS X 10.3 and higher, InnoDB uses a special `fcntl()` file flush method. Under Linux, it is advisable to **disable the write-back cache**.

On ATA/SATA disk drives, a command such `hdparm -W0 /dev/hda` may work to disable the write-back cache. **Beware that some drives or disk controllers may be unable to disable the write-back cache.**

- With regard to InnoDB recovery capabilities that protect user data, InnoDB uses a file flush technique involving a structure called the `doublewrite` buffer, which is enabled by default (`innodb_doublewrite=ON`). The doublewrite buffer adds safety to recovery following a crash or power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations. It is recommended that the `innodb_doublewrite` option remains enabled if you are concerned with data integrity or possible failures. For additional information about the doublewrite buffer, see [Section 15.11.1, “InnoDB Disk I/O”](#).
- Before using NFS with InnoDB, review potential issues outlined in [Using NFS with MySQL](#).

System Tablespace Data File Configuration

System tablespace data files are configured using the `innodb_data_file_path` and `innodb_data_home_dir` configuration options.

The `innodb_data_file_path` configuration option is used to configure the InnoDB system tablespace data files. The value of `innodb_data_file_path` should be a list of one or more data file specifications. If you name more than one data file, separate them by semicolon (;) characters:

```
innodb_data_file_path=logfile_spec1[:logfile_spec2]...
```

For example, the following setting explicitly creates a minimally sized system tablespace:

```
[mysqld]
innodb_data_file_path=ibdata1:12M:autoextend
```

This setting configures a single 12MB data file named `ibdata1` that is auto-extending. No location for the file is given, so by default, InnoDB creates it in the MySQL data directory.

Sizes are specified using `K`, `M`, or `G` suffix letters to indicate units of KB, MB, or GB.

A tablespace containing a fixed-size 50MB data file named `ibdata1` and a 50MB auto-extending file named `ibdata2` in the data directory can be configured like this:

```
[mysqld]
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

The full syntax for a data file specification includes the file name, its size, and several optional attributes:

```
file_name:file_size[:autoextend[:max:max_file_size]]
```

The `autoextend` and `max` attributes can be used only for the last data file in the `innodb_data_file_path` line.

If you specify the `autoextend` option for the last data file, InnoDB extends the data file if it runs out of free space in the tablespace. The increment is 64MB at a time by default. To modify the increment, change the `innodb_autoextend_increment` system variable.

If the disk becomes full, you might want to add another data file on another disk. For tablespace reconfiguration instructions, see [Section 15.7.1, “Resizing the InnoDB System Tablespace”](#).

InnoDB is not aware of the file system maximum file size, so be cautious on file systems where the maximum file size is a small value such as 2GB. To specify a maximum size for an auto-extending data file, use the `max` attribute following the `autoextend` attribute. Use the `max` attribute only in cases where constraining disk usage is of critical importance, because exceeding the maximum size causes a fatal error, possibly including a crash. The following configuration permits `ibdata1` to grow up to a limit of 500MB:

```
[mysqld]
innodb_data_file_path=ibdata1:12M:autoextend:max:500M
```

InnoDB creates tablespace files in the MySQL data directory by default (`datadir`). To specify a location explicitly, use the `innodb_data_home_dir` option. For example, to create two files named `ibdata1` and `ibdata2` in a directory named `myibdata`, configure InnoDB like this:

```
[mysqld]
innodb_data_home_dir = /path/to/myibdata/
innodb_data_file_path=ibdata1:50M;ibdata2:50M:autoextend
```

Note

A trailing slash is required when specifying a value for `innodb_data_home_dir`.

InnoDB does not create directories, so make sure that the `myibdata` directory exists before you start the server. Use the Unix or DOS `mkdir` command to create any necessary directories.

Make sure that the MySQL server has the proper access rights to create files in the data directory. More generally, the server must have access rights in any directory where it needs to create data files.

InnoDB forms the directory path for each data file by textually concatenating the value of `innodb_data_home_dir` to the data file name. If the `innodb_data_home_dir` option is not specified in `my.cnf` at all, the default value is the “dot” directory `./`, which means the MySQL data directory. (The MySQL server changes its current working directory to its data directory when it begins executing.)

If you specify `innodb_data_home_dir` as an empty string, you can specify absolute paths for the data files listed in the `innodb_data_file_path` value. The following example is equivalent to the preceding one:

```
[mysqld]
innodb_data_home_dir =
innodb_data_file_path=/path/to/myibdata/ibdata1:50M;/path/to/myibdata/ibdata2:50M:autoextend
```

InnoDB Log File Configuration

By default, InnoDB creates two 48MB log files in the MySQL data directory (`datadir`) named `ib_logfile0` and `ib_logfile1`.

The following options can be used to modify the default configuration:

- `innodb_log_group_home_dir` defines directory path to the InnoDB log files (the redo logs). If this option is not configured, InnoDB log files are created in the MySQL data directory (`datadir`).

You might use this option to place InnoDB log files in a different physical storage location than InnoDB data files to avoid potential I/O resource conflicts. For example:

```
[mysqld]
innodb_log_group_home_dir = /dr3/iblogs
```

Note

InnoDB does not create directories, so make sure that the log directory exists before you start the server. Use the Unix or DOS `mkdir` command to create any necessary directories.

Make sure that the MySQL server has the proper access rights to create files in the log directory. More generally, the server must have access rights in any directory where it needs to create log files.

- `innodb_log_files_in_group` defines the number of log files in the log group. The default and recommended value is 2.
- `innodb_log_file_size` defines the size in bytes of each log file in the log group. The combined size of log files (`innodb_log_file_size * innodb_log_files_in_group`) cannot exceed a maximum value that is slightly less than 512GB. A pair of 255 GB log files, for example, approaches the limit but does not exceed it. The default log file size is 48MB. Generally, the combined size of the log files should be large enough that the server can smooth out peaks and troughs in workload activity, which often means that there is enough redo log space to handle more than an hour of write activity. The larger the value, the less checkpoint flush activity is needed in the buffer pool, saving disk I/O. For additional information, see [Section 8.5.4, “Optimizing InnoDB Redo Logging”](#).

InnoDB Undo Tablespace Configuration

By default, InnoDB undo logs are part of the system tablespace. However, you can choose to store InnoDB undo logs in one or more separate undo tablespaces, typically on a different storage device.

The `innodb_undo_directory` configuration option defines the path where InnoDB creates separate tablespaces for the undo logs. This option is typically used in conjunction with the `innodb_rollback_segments` and `innodb_undo_tablespaces` options, which determine the disk layout of the undo logs outside the system tablespace.

For more information, see [Section 15.7.7, “Storing InnoDB Undo Logs in Separate Tablespaces”](#).

InnoDB Temporary Tablespace Configuration

By default, InnoDB creates a single auto-extending temporary tablespace data file named `ibtmp1` that is slightly larger than 12MB in the `innodb_data_home_dir` directory. The default temporary tablespace data file configuration can be modified at startup using the `innodb_temp_data_file_path` configuration option.

The `innodb_temp_data_file_path` option specifies the path, file name, and file size for InnoDB temporary tablespace data files. The full directory path for a file is formed by concatenating `innodb_data_home_dir` to the path specified by `innodb_temp_data_file_path`. File size is specified in KB, MB, or GB (1024MB) by appending K, M, or G to the size value. The sum of the sizes of the files must be slightly larger than 12MB.

The `innodb_data_home_dir` default value is the MySQL data directory (`datadir`).

InnoDB Page Size Configuration

The `innodb_page_size` option specifies the page size for all InnoDB tablespaces in a MySQL instance. This value is set when the instance is created and remains constant afterward. Valid values are 64k, 32k, 16k (the default), 8k, and 4k. Alternatively, you can specify page size in bytes (65536, 32768, 16384, 8192, 4096).

The default page size of 16k is appropriate for a wide range of workloads, particularly for queries involving table scans and DML operations involving bulk updates. Smaller page sizes might be more efficient for OLTP workloads involving many small writes, where contention can be an issue when a single page contains many rows. Smaller pages might also be efficient with SSD storage devices, which typically use small block sizes. Keeping the `InnoDB` page size close to the storage device block size minimizes the amount of unchanged data that is rewritten to disk.

InnoDB Memory Configuration

MySQL allocates memory to various caches and buffers to improve performance of database operations. When allocating memory for `InnoDB`, always consider memory required by the operating system, memory allocated to other applications, and memory allocated for other MySQL buffers and caches. For example, if you use `MyISAM` tables, consider the amount of memory allocated for the key buffer (`key_buffer_size`). For an overview of MySQL buffers and caches, see [Section 8.12.3.1, “How MySQL Uses Memory”](#).

Buffers specific to `InnoDB` are configured using the following parameters:

- `innodb_buffer_pool_size` defines size of the buffer pool, which is the memory area that holds cached data for `InnoDB` tables, indexes, and other auxiliary buffers. The size of the buffer pool is important for system performance, and it is typically recommended that `innodb_buffer_pool_size` is configured to 50 to 75 percent of system memory. The default buffer pool size is 128MB. For additional guidance, see [Section 8.12.3.1, “How MySQL Uses Memory”](#). For information about how to configure `InnoDB` buffer pool size, see [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#). Buffer pool size can be configured at startup or dynamically.

On systems with a large amount of memory, you can improve concurrency by dividing the buffer pool into multiple buffer pool instances. The number of buffer pool instances is controlled by the `innodb_buffer_pool_instances` option. By default, `InnoDB` creates one buffer pool instance. The number of buffer pool instances can be configured at startup. For more information, see [Section 15.6.3.3, “Configuring Multiple Buffer Pool Instances”](#).

- `innodb_log_buffer_size` defines the size in bytes of the buffer that `InnoDB` uses to write to the log files on disk. The default size is 16MB. A large log buffer enables large transactions to run without a need to write the log to disk before the transactions commit. If you have transactions that update, insert, or delete many rows, you might consider increasing the size of the log buffer to save disk I/O. `innodb_log_buffer_size` can be configured at startup. For related information, see [Section 8.5.4, “Optimizing InnoDB Redo Logging”](#).

Warning

On 32-bit GNU/Linux x86, be careful not to set memory usage too high. `glibc` may permit the process heap to grow over thread stacks, which crashes your server. It is a risk if the memory allocated to the `mysqld` process for global and per-thread buffers and caches is close to or exceeds 2GB.

A formula similar to the following that calculates global and per-thread memory allocation for MySQL can be used to estimate MySQL memory usage. You may need to modify the formula to account for buffers and caches in your MySQL version and configuration. For an overview of MySQL buffers and caches, see [Section 8.12.3.1, “How MySQL Uses Memory”](#).

```
innodb_buffer_pool_size
+ key_buffer_size
+ max_connections*(sort_buffer_size+read_buffer_size+binlog_cache_size)
+ max_connections*2MB
```

Each thread uses a stack (often 2MB, but only 256KB in MySQL binaries provided by Oracle Corporation.) and in the worst case also uses `sort_buffer_size + read_buffer_size` additional memory.

On Linux, if the kernel is enabled for large page support, InnoDB can use large pages to allocate memory for its buffer pool. See [Section 8.12.3.2, “Enabling Large Page Support”](#).

15.6.2 Configuring InnoDB for Read-Only Operation

You can now query InnoDB tables where the MySQL data directory is on read-only media, by enabling the `--innodb-read-only` configuration option at server startup.

How to Enable

To prepare an instance for read-only operation, make sure all the necessary information is **flushed** to the data files before storing it on the read-only medium. Run the server with change buffering disabled (`innodb_change_buffering=0`) and do a **slow shutdown**.

To enable read-only mode for an entire MySQL instance, specify the following configuration options at server startup:

- `--innodb-read-only=1`
- If the instance is on read-only media such as a DVD or CD, or the `/var` directory is not writeable by all: `--pid-file=path_on_writeable_media` and `--event-scheduler=disabled`

As of MySQL 8.0, enabling `innodb_read_only` prevents table creation and drop operations for all storage engines. These operations modify data dictionary tables in the `mysql` system database, but those tables use the InnoDB storage engine and cannot be modified when `innodb_read_only` is enabled. The same restriction applies to any operation that modifies data dictionary tables, such as `ANALYZE TABLE` and `ALTER TABLE tbl_name ENGINE=engine_name`.

In addition, other tables in the `mysql` system database use the InnoDB storage engine in MySQL 8.0. Making those tables read only results in restrictions on operations that modify them. For example, `CREATE USER`, `GRANT`, `REVOKE`, and `INSTALL PLUGIN` operations are not permitted in read-only mode.

Usage Scenarios

This mode of operation is appropriate in situations such as:

- Distributing a MySQL application, or a set of MySQL data, on a read-only storage medium such as a DVD or CD.
- Multiple MySQL instances querying the same data directory simultaneously, typically in a data warehousing configuration. You might use this technique to avoid **bottlenecks** that can occur with a heavily loaded MySQL instance, or you might use different configuration options for the various instances to tune each one for particular kinds of queries.
- Querying data that has been put into a read-only state for security or data integrity reasons, such as archived backup data.

Note

This feature is mainly intended for flexibility in distribution and deployment, rather than raw performance based on the read-only aspect. See [Section 8.5.3, “Optimizing InnoDB Read-Only Transactions”](#) for ways to tune the performance of read-only queries, which do not require making the entire server read-only.

How It Works

When the server is run in read-only mode through the `--innodb-read-only` option, certain InnoDB features and components are reduced or turned off entirely:

- No [change buffering](#) is done, in particular no merges from the change buffer. To make sure the change buffer is empty when you prepare the instance for read-only operation, disable change buffering (`innodb_change_buffering=0`) and do a [slow shutdown](#) first.
- There is no [crash recovery](#) phase at startup. The instance must have performed a [slow shutdown](#) before being put into the read-only state.
- Because the [redo log](#) is not used in read-only operation, you can set `innodb_log_file_size` to the smallest size possible (1 MB) before making the instance read-only.
- All background threads other than I/O read threads are turned off. As a consequence, a read-only instance cannot encounter any [deadlock](#).
- Information about deadlocks, monitor output, and so on is not written to temporary files. As a consequence, `SHOW ENGINE INNODB STATUS` does not produce any output.
- Changes to configuration option settings that would normally change the behavior of write operations, have no effect when the server is in read-only mode.
- The [MVCC](#) processing to enforce [isolation levels](#) is turned off. All queries read the latest version of a record, because update and deletes are not possible.
- The [undo log](#) is not used. Disable any settings for the `innodb_undo_tablespaces` and `innodb_undo_directory` configuration options.

15.6.3 InnoDB Buffer Pool Configuration

This section provides configuration and tuning information for the [InnoDB](#) buffer pool.

15.6.3.1 The InnoDB Buffer Pool

[InnoDB](#) maintains a storage area called the [buffer pool](#) for caching data and indexes in memory. Knowing how the [InnoDB](#) buffer pool works, and taking advantage of it to keep frequently accessed data in memory, is an important aspect of MySQL tuning. For information about how the [InnoDB](#) buffer pool works, see [InnoDB Buffer Pool LRU Algorithm](#).

You can configure the various aspects of the [InnoDB](#) buffer pool to improve performance.

- Ideally, you set the size of the buffer pool to as large a value as practical, leaving enough memory for other processes on the server to run without excessive paging. The larger the buffer pool, the more [InnoDB](#) acts like an in-memory database, reading data from disk once and then accessing the data from memory during subsequent reads. See [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#).
- With 64-bit systems with large memory sizes, you can split the buffer pool into multiple parts, to minimize contention for the memory structures among concurrent operations. For details, see [Section 15.6.3.3, “Configuring Multiple Buffer Pool Instances”](#).
- You can keep frequently accessed data in memory despite sudden spikes of activity for operations such as backups or reporting. For details, see [Section 15.6.3.4, “Making the Buffer Pool Scan Resistant”](#).
- You can control when and how [InnoDB](#) performs read-ahead requests to prefetch pages into the buffer pool asynchronously, in anticipation that the pages will be needed soon. For details, see [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#).
- You can control when background flushing of dirty pages occurs and whether or not [InnoDB](#) dynamically adjusts the rate of flushing based on workload. For details, see [Section 15.6.3.6, “Configuring InnoDB Buffer Pool Flushing”](#).
- You can fine-tune aspects of [InnoDB](#) buffer pool flushing behavior to improve performance. For details, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#).

- You can configure how [InnoDB](#) preserves the current buffer pool state to avoid a lengthy warmup period after a server restart. You can also save the current buffer pool state while the server is running. For details, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

InnoDB Buffer Pool LRU Algorithm

[InnoDB](#) manages the buffer pool as a list, using a variation of the least recently used (LRU) algorithm. When room is needed to add a new page to the pool, [InnoDB](#) evicts the least recently used page and adds the new page to the middle of the list. This “midpoint insertion strategy” treats the list as two sublists:

- At the head, a sublist of “new” (or “young”) pages that were accessed recently.
- At the tail, a sublist of “old” pages that were accessed less recently.

This algorithm keeps pages that are heavily used by queries in the new sublist. The old sublist contains less-used pages; these pages are candidates for [eviction](#).

The LRU algorithm operates as follows by default:

- 3/8 of the buffer pool is devoted to the old sublist.
- The midpoint of the list is the boundary where the tail of the new sublist meets the head of the old sublist.
- When [InnoDB](#) reads a page into the buffer pool, it initially inserts it at the midpoint (the head of the old sublist). A page can be read in because it is required for a user-specified operation such as an SQL query, or as part of a [read-ahead](#) operation performed automatically by [InnoDB](#).
- Accessing a page in the old sublist makes it “young”, moving it to the head of the buffer pool (the head of the new sublist). If the page was read in because it was required, the first access occurs immediately and the page is made young. If the page was read in due to read-ahead, the first access does not occur immediately (and might not occur at all before the page is evicted).
- As the database operates, pages in the buffer pool that are not accessed “age” by moving toward the tail of the list. Pages in both the new and old sublists age as other pages are made new. Pages in the old sublist also age as pages are inserted at the midpoint. Eventually, a page that remains unused for long enough reaches the tail of the old sublist and is evicted.

By default, pages read by queries immediately move into the new sublist, meaning they stay in the buffer pool longer. A table scan (such as performed for a [mysqldump](#) operation, or a [SELECT](#) statement with no [WHERE](#) clause) can bring a large amount of data into the buffer pool and evict an equivalent amount of older data, even if the new data is never used again. Similarly, pages that are loaded by the read-ahead background thread and then accessed only once move to the head of the new list. These situations can push frequently used pages to the old sublist, where they become subject to eviction. For information about optimizing this behavior, see [Section 15.6.3.4, “Making the Buffer Pool Scan Resistant”](#), and [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#).

[InnoDB](#) Standard Monitor output contains several fields in the [BUFFER POOL AND MEMORY](#) section that pertain to operation of the buffer pool LRU algorithm. For details, see [Section 15.6.3.9, “Monitoring the Buffer Pool Using the InnoDB Standard Monitor”](#).

InnoDB Buffer Pool Configuration Options

Several configuration options affect different aspects of the [InnoDB](#) buffer pool.

- [innodb_buffer_pool_size](#)

Specifies the size of the buffer pool. If the buffer pool is small and you have sufficient memory, making the buffer pool larger can improve performance by reducing the amount of disk I/O needed as queries access [InnoDB](#) tables. The [innodb_buffer_pool_size](#) option is dynamic, which

allows you to configure buffer pool size without restarting the server. See [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#) for more information.

- `innodb_buffer_pool_chunk_size`

Defines the chunk size for InnoDB buffer pool resizing operations. See [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#) for more information.

- `innodb_buffer_pool_instances`

Divides the buffer pool into a user-specified number of separate regions, each with its own LRU list and related data structures, to reduce contention during concurrent memory read and write operations. This option only takes effect when you set `innodb_buffer_pool_size` to a value of 1GB or more. The total size you specify is divided among all the buffer pools. For best efficiency, specify a combination of `innodb_buffer_pool_instances` and `innodb_buffer_pool_size` so that each buffer pool instance is at least 1 gigabyte. See [Section 15.6.3.3, “Configuring Multiple Buffer Pool Instances”](#) for more information.

- `innodb_old_blocks_pct`

Specifies the approximate percentage of the buffer pool that InnoDB uses for the old block sublist. The range of values is 5 to 95. The default value is 37 (that is, 3/8 of the pool). See [Section 15.6.3.4, “Making the Buffer Pool Scan Resistant”](#) for more information.

- `innodb_old_blocks_time`

Specifies how long in milliseconds (ms) a page inserted into the old `sublist` must stay there after its first access before it can be moved to the new sublist. If the value is 0, a page inserted into the old sublist moves immediately to the new sublist the first time it is accessed, no matter how soon after insertion the access occurs. If the value is greater than 0, pages remain in the old sublist until an access occurs at least that many milliseconds after the first access. For example, a value of 1000 causes pages to stay in the old sublist for 1 second after the first access before they become eligible to move to the new sublist.

Setting `innodb_old_blocks_time` greater than 0 prevents one-time table scans from flooding the new sublist with pages used only for the scan. Rows in a page read in for a scan are accessed many times in rapid succession, but the page is unused after that. If `innodb_old_blocks_time` is set to a value greater than time to process the page, the page remains in the “old” sublist and ages to the tail of the list to be evicted quickly. This way, pages used only for a one-time scan do not act to the detriment of heavily used pages in the new sublist.

`innodb_old_blocks_time` can be set at runtime, so you can change it temporarily while performing operations such as table scans and dumps:

```
SET GLOBAL innodb_old_blocks_time = 1000;
... perform queries that scan tables ...
SET GLOBAL innodb_old_blocks_time = 0;
```

This strategy does not apply if your intent is to “warm up” the buffer pool by filling it with a table's content. For example, benchmark tests often perform a table or index scan at server startup, because that data would normally be in the buffer pool after a period of normal use. In this case, leave `innodb_old_blocks_time` set to 0, at least until the warmup phase is complete.

See [Section 15.6.3.4, “Making the Buffer Pool Scan Resistant”](#) for more information.

- `innodb_read_ahead_threshold`

Controls the sensitivity of linear `read-ahead` that InnoDB uses to prefetch pages into the `buffer pool`.

See [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#) for more information.

- `innodb_random_read_ahead`

Enables random [read-ahead](#) technique for prefetching pages into the buffer pool. Random read-ahead is a technique that predicts when pages might be needed soon based on pages already in the buffer pool, regardless of the order in which those pages were read. `innodb_random_read_ahead` is disabled by default.

See [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#) for more information.

- `innodb_adaptive_flushing`

Specifies whether to dynamically adjust the rate of flushing [dirty pages](#) in the buffer pool based on workload. Adjusting the flush rate dynamically is intended to avoid bursts of I/O activity. This setting is enabled by default.

See [Section 15.6.3.6, “Configuring InnoDB Buffer Pool Flushing”](#) for more information.

- `innodb_adaptive_flushing_lwm`

Low water mark representing percentage of [redo log](#) capacity at which [adaptive flushing](#) is enabled.

See [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#) for more information.

- `innodb_flush_neighbors`

Specifies whether [flushing](#) a page from the buffer pool also flushes other [dirty pages](#) in the same [extent](#).

See [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#) for more information.

- `innodb_flushing_avg_loops`

Number of iterations for which InnoDB keeps the previously calculated snapshot of the flushing state, controlling how quickly [adaptive flushing](#) responds to changing [workloads](#).

See [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#) for more information.

- `innodb_lru_scan_depth`

A parameter that influences the algorithms and heuristics for the [flush](#) operation for the buffer pool. Primarily of interest to performance experts tuning I/O-intensive workloads. It specifies, per buffer pool instance, how far down the buffer pool LRU list the [page_cleaner](#) thread scans looking for [dirty pages](#) to flush.

See [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#) for more information.

- `innodb_max_dirty_pages_pct`

InnoDB tries to [flush](#) data from the buffer pool so that the percentage of [dirty pages](#) does not exceed this value. Specify an integer in the range from 0 to 99. The default value is 75.

See [Section 15.6.3.6, “Configuring InnoDB Buffer Pool Flushing”](#) for more information.

- `innodb_max_dirty_pages_pct_lwm`

Low water mark representing percentage of [dirty pages](#) where preflushing is enabled to control the dirty page ratio. The default of 0 disables the pre-flushing behavior entirely.

See [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#) for more information.

Specifies the name of the file that holds the list of tablespace IDs and page IDs produced by `innodb_buffer_pool_dump_at_shutdown` or `innodb_buffer_pool_dump_now`.

See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#) for more information.

- `innodb_buffer_pool_dump_at_shutdown`

Specifies whether to record the pages cached in the buffer pool when the MySQL server is shut down, to shorten the `warmup` process at the next restart.

See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#) for more information.

- `innodb_buffer_pool_load_at_startup`

Specifies that, on MySQL server startup, the buffer pool is automatically `warmed up` by loading the same pages it held at an earlier time. Typically used in combination with `innodb_buffer_pool_dump_at_shutdown`.

See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#) for more information.

- `innodb_buffer_pool_dump_now`

Immediately records the pages cached in the buffer pool.

See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#) for more information.

- `innodb_buffer_pool_load_now`

Immediately `warms up` the buffer pool by loading a set of data pages, without waiting for a server restart. Can be useful to bring cache memory back to a known state during benchmarking, or to ready the MySQL server to resume its normal workload after running queries for reports or maintenance. Typically used with `innodb_buffer_pool_dump_now`.

See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#) for more information.

- `innodb_buffer_pool_dump_pct`

Specifies the percentage of the most recently used pages for each buffer pool to read out and dump. The range is 1 to 100.

See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#) for more information.

- `innodb_buffer_pool_load_abort`

Interrupts the process of restoring `buffer pool` contents triggered by `innodb_buffer_pool_load_at_startup` or `innodb_buffer_pool_load_now`.

See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#) for more information.

15.6.3.2 Configuring InnoDB Buffer Pool Size

You can configure `InnoDB` buffer pool size offline (at startup) or online, while the server is running. Behavior described in this section applies to both methods. For additional information about configuring buffer pool size online, see [Configuring InnoDB Buffer Pool Size Online](#).

When increasing or decreasing `innodb_buffer_pool_size`, the operation is performed in chunks. Chunk size is defined by the `innodb_buffer_pool_chunk_size` configuration option, which has a default of `128M`. For more information, see [Configuring InnoDB Buffer Pool Chunk Size](#).

Buffer pool size must always be equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`. If you configure `innodb_buffer_pool_size` to a value that is not equal to or a multiple of `innodb_buffer_pool_chunk_size *`

`innodb_buffer_pool_instances`, buffer pool size is automatically adjusted to a value that is equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances` that is not less than the specified buffer pool size.

In the following example, `innodb_buffer_pool_size` is set to 8G, and `innodb_buffer_pool_instances` is set to 16. `innodb_buffer_pool_chunk_size` is 128M, which is the default value.

8G is a valid `innodb_buffer_pool_size` value because 8G is a multiple of `innodb_buffer_pool_instances=16 * innodb_buffer_pool_chunk_size=128M`, which is 2G.

```
shell> mysqld --innodb_buffer_pool_size=8G --innodb_buffer_pool_instances=16
```

```
mysql> SELECT @@innodb_buffer_pool_size/1024/1024/1024;
```

```
+-----+
| @@innodb_buffer_pool_size/1024/1024/1024 |
+-----+
|                                     8.000000000000 |
+-----+
```

In this example, `innodb_buffer_pool_size` is set to 9G, and `innodb_buffer_pool_instances` is set to 16. `innodb_buffer_pool_chunk_size` is 128M, which is the default value. In this case, 9G is not a multiple of `innodb_buffer_pool_instances=16 * innodb_buffer_pool_chunk_size=128M`, so `innodb_buffer_pool_size` is adjusted to 10G, which is the next multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances` that is not less than the specified buffer pool size.

```
shell> mysqld --innodb_buffer_pool_size=9G --innodb_buffer_pool_instances=16
```

```
mysql> SELECT @@innodb_buffer_pool_size/1024/1024/1024;
```

```
+-----+
| @@innodb_buffer_pool_size/1024/1024/1024 |
+-----+
|                                     10.000000000000 |
+-----+
```

Configuring InnoDB Buffer Pool Chunk Size

`innodb_buffer_pool_chunk_size` can be increased or decreased in 1MB (1048576 byte) units but can only be modified at startup, in a command line string or in a MySQL configuration file.

Command line:

```
shell> mysqld --innodb_buffer_pool_chunk_size=134217728
```

Configuration file:

```
[mysqld]
innodb_buffer_pool_chunk_size=134217728
```

The following conditions apply when altering `innodb_buffer_pool_chunk_size`:

- If the new `innodb_buffer_pool_chunk_size` value * `innodb_buffer_pool_instances` is larger than the current buffer pool size when the buffer pool is initialized, `innodb_buffer_pool_chunk_size` is truncated to `innodb_buffer_pool_size / innodb_buffer_pool_instances`.

For example, if the buffer pool is initialized with a size of 2GB (2147483648 bytes), 4 buffer pool instances, and a chunk size of 1GB (1073741824 bytes), chunk size is truncated to a value equal to `innodb_buffer_pool_size / innodb_buffer_pool_instances`, as shown below:

```
shell> mysqld --innodb_buffer_pool_size=2147483648 --innodb_buffer_pool_instances=4
--innodb_buffer_pool_chunk_size=1073741824;
```

```
mysql> SELECT @@innodb_buffer_pool_size;
```

```
+-----+
```

```

| @@innodb_buffer_pool_size |
+-----+
|                2147483648 |
+-----+

mysql> SELECT @@innodb_buffer_pool_instances;
+-----+
| @@innodb_buffer_pool_instances |
+-----+
|                4 |
+-----+

# Chunk size was set to 1GB (1073741824 bytes) on startup but was
# truncated to innodb_buffer_pool_size / innodb_buffer_pool_instances

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+-----+
| @@innodb_buffer_pool_chunk_size |
+-----+
|                536870912 |
+-----+

```

- Buffer pool size must always be equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`. If you alter `innodb_buffer_pool_chunk_size`, `innodb_buffer_pool_size` is automatically adjusted to a value that is equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances` that is not less than current buffer pool size. The adjustment occurs when the buffer pool is initialized. This behavior is demonstrated in the following example:

```

# The buffer pool has a default size of 128MB (134217728 bytes)

mysql> SELECT @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
|                134217728 |
+-----+

# The chunk size is also 128MB (134217728 bytes)

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+-----+
| @@innodb_buffer_pool_chunk_size |
+-----+
|                134217728 |
+-----+

# There is a single buffer pool instance

mysql> SELECT @@innodb_buffer_pool_instances;
+-----+
| @@innodb_buffer_pool_instances |
+-----+
|                1 |
+-----+

# Chunk size is decreased by 1MB (1048576 bytes) at startup
# (134217728 - 1048576 = 133169152):

shell> mysqld --innodb_buffer_pool_chunk_size=133169152

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+-----+
| @@innodb_buffer_pool_chunk_size |
+-----+
|                133169152 |
+-----+

# Buffer pool size increases from 134217728 to 266338304
# Buffer pool size is automatically adjusted to a value that is equal to
# or a multiple of innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances

```

InnoDB Buffer Pool Configuration

```
# that is not less than current buffer pool size

mysql> SELECT @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+

| @@innodb_buffer_pool_instances |
+-----+
|                                4 |
+-----+

# Chunk size is decreased by 1MB (1048576 bytes) at startup
# (536870912 - 1048576 = 535822336):

shell> mysqld --innodb_buffer_pool_chunk_size=535822336

mysql> SELECT @@innodb_buffer_pool_chunk_size;
+-----+
| @@innodb_buffer_pool_chunk_size |
+-----+
|                535822336 |
+-----+

# Buffer pool size increases from 2147483648 to 4286578688
# Buffer pool size is automatically adjusted to a value that is equal to
# or a multiple of innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances
# that is not less than current buffer pool size of 2147483648

mysql> SELECT @@innodb_buffer_pool_size;
+-----+
| @@innodb_buffer_pool_size |
+-----+
|                4286578688 |
+-----+
```

Care should be taken when changing `innodb_buffer_pool_chunk_size`, as changing this value can increase the size of the buffer pool, as shown in the examples above. Before you change `innodb_buffer_pool_chunk_size`, calculate the effect on `innodb_buffer_pool_size` to ensure that the resulting buffer pool size is acceptable.

**Note**

To avoid potential performance issues, the number of chunks (`innodb_buffer_pool_size / innodb_buffer_pool_chunk_size`) should not exceed 1000.

Configuring InnoDB Buffer Pool Size Online

The `innodb_buffer_pool_size` configuration option can be set dynamically using a `SET` statement, allowing you to resize the buffer pool without restarting the server. For example:

```
mysql> SET GLOBAL innodb_buffer_pool_size=402653184;
```

Active transactions and operations performed through InnoDB APIs should be completed before resizing the buffer pool. When initiating a resizing operation, the operation does not start until all active transactions are completed. Once the resizing operation is in progress, new transactions and operations that require access to the buffer pool must wait until the resizing operation finishes. The exception to the rule is that concurrent access to the buffer pool is permitted while the buffer pool is defragmented and pages are withdrawn when buffer pool size is decreased. A drawback of allowing concurrent access is that it could result in a temporary shortage of available pages while pages are being withdrawn.

**Note**

Nested transactions could fail if initiated after the buffer pool resizing operation begins.

Monitoring Online Buffer Pool Resizing Progress

The `InnoDB_buffer_pool_resize_status` reports buffer pool resizing progress. For example:

```
mysql> SHOW STATUS WHERE Variable_name='InnoDB_buffer_pool_resize_status';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| InnoDB_buffer_pool_resize_status | Resizing also other hash tables. |
+-----+-----+
```

Buffer pool resizing progress is also logged in the server error log file. This example shows notes that are logged when increasing the size of the buffer pool:

```
[Note] InnoDB: Resizing buffer pool from 134217728 to 4294967296. (unit=134217728)
[Note] InnoDB: disabled adaptive hash index.
[Note] InnoDB: buffer pool 0 : 31 chunks (253952 blocks) was added.
[Note] InnoDB: buffer pool 0 : hash tables were resized.
[Note] InnoDB: Resized hash tables at lock_sys, adaptive hash index, dictionary.
[Note] InnoDB: completed to resize buffer pool from 134217728 to 4294967296.
[Note] InnoDB: re-enabled adaptive hash index.
```

This example shows notes that are logged when decreasing the size of the buffer pool:

```
[Note] InnoDB: Resizing buffer pool from 4294967296 to 134217728. (unit=134217728)
[Note] InnoDB: disabled adaptive hash index.
[Note] InnoDB: buffer pool 0 : start to withdraw the last 253952 blocks.
[Note] InnoDB: buffer pool 0 : withdrew 253952 blocks from free list. tried to relocate 0 pages.
(253952/253952)
[Note] InnoDB: buffer pool 0 : withdrawn target 253952 blocks.
[Note] InnoDB: buffer pool 0 : 31 chunks (253952 blocks) was freed.
[Note] InnoDB: buffer pool 0 : hash tables were resized.
[Note] InnoDB: Resized hash tables at lock_sys, adaptive hash index, dictionary.
[Note] InnoDB: completed to resize buffer pool from 4294967296 to 134217728.
[Note] InnoDB: re-enabled adaptive hash index.
```

Online Buffer Pool Resizing Internals

The resizing operation is performed by a background thread. When increasing the size of the buffer pool, the resizing operation:

- Adds pages in `chunks` (chunk size is defined by `innodb_buffer_pool_chunk_size`)
- Coverts hash tables, lists, and pointers to use new addresses in memory
- Adds new pages to the free list

While these operations are in progress, other threads are blocked from accessing the buffer pool.

When decreasing the size of the buffer pool, the resizing operation:

- Defragments the buffer pool and withdraws (frees) pages
- Removes pages in `chunks` (chunk size is defined by `innodb_buffer_pool_chunk_size`)
- Coverts hash tables, lists, and pointers to use new addresses in memory

Of these operations, only defragmenting the buffer pool and withdrawing pages allow other threads to access to the buffer pool concurrently.

15.6.3.3 Configuring Multiple Buffer Pool Instances

For systems with buffer pools in the multi-gigabyte range, dividing the buffer pool into separate instances can improve concurrency, by reducing contention as different threads read and write to cached pages. This feature is typically intended for systems with a `buffer pool` size in the multi-gigabyte range. Multiple buffer pool instances are configured using the `innodb_buffer_pool_instances` configuration option, and you might also adjust the `innodb_buffer_pool_size` value.

When the `InnoDB` buffer pool is large, many data requests can be satisfied by retrieving from memory. You might encounter bottlenecks from multiple threads trying to access the buffer pool at once. You can enable multiple buffer pools to minimize this contention. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pools randomly, using a hashing function. Each buffer pool manages its own free lists, flush lists, LRUs, and all other data structures connected to a buffer pool. Prior to MySQL 8.0, each buffer pool was protected by its own buffer pool mutex. In MySQL 8.0 and later, the buffer pool mutex was replaced by several list and hash protecting mutexes, to reduce contention.

To enable multiple buffer pool instances, set the `innodb_buffer_pool_instances` configuration option to a value greater than 1 (the default) up to 64 (the maximum). This option takes effect only when you set `innodb_buffer_pool_size` to a size of 1GB or more. The total size you specify is divided among all the buffer pools. For best efficiency, specify a combination of `innodb_buffer_pool_instances` and `innodb_buffer_pool_size` so that each buffer pool instance is at least 1GB.

For information about modifying `InnoDB` buffer pool size, see [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#).

15.6.3.4 Making the Buffer Pool Scan Resistant

Rather than using a strict `LRU` algorithm, `InnoDB` uses a technique to minimize the amount of data that is brought into the `buffer pool` and never accessed again. The goal is to make sure that frequently accessed (“hot”) pages remain in the buffer pool, even as `read-ahead` and `full table scans` bring in new blocks that might or might not be accessed afterward.

Newly read blocks are inserted into the middle of the `LRU` list. All newly read pages are inserted at a location that by default is $3/8$ from the tail of the `LRU` list. The pages are moved to the front of the list (the most-recently used end) when they are accessed in the buffer pool for the first time. Thus, pages that are never accessed never make it to the front portion of the `LRU` list, and “age out” sooner than with a strict `LRU` approach. This arrangement divides the `LRU` list into two segments, where the pages downstream of the insertion point are considered “old” and are desirable victims for `LRU` eviction.

For an explanation of the inner workings of the [InnoDB](#) buffer pool and specifics about the LRU algorithm, see [Section 15.6.3.1, “The InnoDB Buffer Pool”](#).

You can control the insertion point in the LRU list and choose whether [InnoDB](#) applies the same optimization to blocks brought into the buffer pool by table or index scans. The configuration parameter `innodb_old_blocks_pct` controls the percentage of “old” blocks in the LRU list. The default value of `innodb_old_blocks_pct` is 37, corresponding to the original fixed ratio of 3/8. The value range is 5 (new pages in the buffer pool age out very quickly) to 95 (only 5% of the buffer pool is reserved for hot pages, making the algorithm close to the familiar LRU strategy).

The optimization that keeps the buffer pool from being churned by read-ahead can avoid similar problems due to table or index scans. In these scans, a data page is typically accessed a few times in quick succession and is never touched again. The configuration parameter `innodb_old_blocks_time` specifies the time window (in milliseconds) after the first access to a page during which it can be accessed without being moved to the front (most-recently used end) of the LRU list. The default value of `innodb_old_blocks_time` is 1000. Increasing this value makes more and more blocks likely to age out faster from the buffer pool.

Both `innodb_old_blocks_pct` and `innodb_old_blocks_time` are dynamic, global and can be specified in the MySQL option file (`my.cnf` or `my.ini`) or changed at runtime with the `SET GLOBAL` command. Changing the setting requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege.

To help you gauge the effect of setting these parameters, the `SHOW ENGINE INNODB STATUS` command reports buffer pool statistics. For details, see [Section 15.6.3.9, “Monitoring the Buffer Pool Using the InnoDB Standard Monitor”](#).

Because the effects of these parameters can vary widely based on your hardware configuration, your data, and the details of your workload, always benchmark to verify the effectiveness before changing these settings in any performance-critical or production environment.

In mixed workloads where most of the activity is OLTP type with periodic batch reporting queries which result in large scans, setting the value of `innodb_old_blocks_time` during the batch runs can help keep the working set of the normal workload in the buffer pool.

When scanning large tables that cannot fit entirely in the buffer pool, setting `innodb_old_blocks_pct` to a small value keeps the data that is only read once from consuming a significant portion of the buffer pool. For example, setting `innodb_old_blocks_pct=5` restricts this data that is only read once to 5% of the buffer pool.

When scanning small tables that do fit into memory, there is less overhead for moving pages around within the buffer pool, so you can leave `innodb_old_blocks_pct` at its default value, or even higher, such as `innodb_old_blocks_pct=50`.

The effect of the `innodb_old_blocks_time` parameter is harder to predict than the `innodb_old_blocks_pct` parameter, is relatively small, and varies more with the workload. To arrive at an optimal value, conduct your own benchmarks if the performance improvement from adjusting `innodb_old_blocks_pct` is not sufficient.

15.6.3.5 Configuring InnoDB Buffer Pool Prefetching (Read-Ahead)

A [read-ahead](#) request is an I/O request to prefetch multiple pages in the [buffer pool](#) asynchronously, in anticipation that these pages will be needed soon. The requests bring in all the pages in one [extent](#). [InnoDB](#) uses two read-ahead algorithms to improve I/O performance:

Linear read-ahead is a technique that predicts what pages might be needed soon based on pages in the buffer pool being accessed sequentially. You control when [InnoDB](#) performs a read-ahead operation by adjusting the number of sequential page accesses required to trigger an asynchronous read request, using the configuration parameter `innodb_read_ahead_threshold`. Before this

parameter was added, `InnoDB` would only calculate whether to issue an asynchronous prefetch request for the entire next extent when it read in the last page of the current extent.

The configuration parameter `innodb_read_ahead_threshold` controls how sensitive `InnoDB` is in detecting patterns of sequential page access. If the number of pages read sequentially from an extent is greater than or equal to `innodb_read_ahead_threshold`, `InnoDB` initiates an asynchronous read-ahead operation of the entire following extent. `innodb_read_ahead_threshold` can be set to any value from 0-64. The default value is 56. The higher the value, the more strict the access pattern check. For example, if you set the value to 48, `InnoDB` triggers a linear read-ahead request only when 48 pages in the current extent have been accessed sequentially. If the value is 8, `InnoDB` triggers an asynchronous read-ahead even if as few as 8 pages in the extent are accessed sequentially. You can set the value of this parameter in the MySQL [configuration file](#), or change it dynamically with the `SET GLOBAL` command, which requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege.

Random read-ahead is a technique that predicts when pages might be needed soon based on pages already in the buffer pool, regardless of the order in which those pages were read. If 13 consecutive pages from the same extent are found in the buffer pool, `InnoDB` asynchronously issues a request to prefetch the remaining pages of the extent. To enable this feature, set the configuration variable `innodb_random_read_ahead` to `ON`.

The `SHOW ENGINE INNODB STATUS` command displays statistics to help you evaluate the effectiveness of the read-ahead algorithm. Statistics include counter information for the following global status variables:

- `Innodb_buffer_pool_read_ahead`
- `Innodb_buffer_pool_read_ahead_evicted`
- `Innodb_buffer_pool_read_ahead_rnd`

This information can be useful when fine-tuning the `innodb_random_read_ahead` setting.

For more information about I/O performance, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#) and [Section 8.12.1, “Optimizing Disk I/O”](#).

15.6.3.6 Configuring InnoDB Buffer Pool Flushing

`InnoDB` performs certain tasks in the background, including [flushing of dirty pages](#) (those pages that have been changed but are not yet written to the database files) from the [buffer pool](#).

`InnoDB` starts flushing buffer pool pages when the percentage of dirty pages in the buffer pool reaches the low water mark setting defined by `innodb_max_dirty_pages_pct_lwm`. This option is intended to control the ratio of dirty pages in the buffer pool and ideally prevent the percentage of dirty pages from reaching `innodb_max_dirty_pages_pct`. If the percentage of dirty pages in the buffer pool exceeds `innodb_max_dirty_pages_pct`, `InnoDB` begins to aggressively flush buffer pool pages.

`InnoDB` uses an algorithm to estimate the required rate of flushing, based on the speed of redo log generation and the current rate of flushing. The intent is to smooth overall performance by ensuring that buffer flush activity keeps up with the need to keep the buffer pool “clean”. Automatically adjusting the rate of flushing can help to avoid sudden dips in throughput, when excessive buffer pool flushing limits the I/O capacity available for ordinary read and write activity.

`InnoDB` uses its log files in a circular fashion. Before reusing a portion of a log file, `InnoDB` flushes to disk all dirty buffer pool pages whose redo entries are contained in that portion of the log file, a process known as a [sharp checkpoint](#). If a workload is write-intensive, it generates a lot of redo information, all written to the log file. If all available space in the log files is used up, a sharp checkpoint occurs, causing a temporary reduction in throughput. This situation can happen even if `innodb_max_dirty_pages_pct` is not reached.

`InnoDB` uses a heuristic-based algorithm to avoid such a scenario, by measuring the number of dirty pages in the buffer pool and the rate at which redo is being generated. Based on these numbers,

InnoDB decides how many dirty pages to flush from the buffer pool each second. This self-adapting algorithm is able to deal with sudden changes in workload.

Internal benchmarking has shown that this algorithm not only maintains throughput over time, but can also improve overall throughput significantly.

Because adaptive flushing can significantly affect the I/O pattern of a workload, the `innodb_adaptive_flushing` configuration parameter lets you turn off this feature. The default value for `innodb_adaptive_flushing` is `ON`, enabling the adaptive flushing algorithm. You can set the value of this parameter in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically with the `SET GLOBAL` command, which requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege.

For information about fine-tuning InnoDB buffer pool flushing behavior, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#).

For more information about InnoDB I/O performance, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

15.6.3.7 Fine-tuning InnoDB Buffer Pool Flushing

The configuration options `innodb_flush_neighbors` and `innodb_lru_scan_depth` let you fine-tune certain aspects of the flushing process for the InnoDB buffer pool. These options primarily help write-intensive workloads. With heavy DML activity, flushing can fall behind if it is not aggressive enough, resulting in excessive memory use in the buffer pool; or, disk writes due to flushing can saturate your I/O capacity if that mechanism is too aggressive. The ideal settings depend on your workload, data access patterns, and storage configuration (for example, whether data is stored on HDD or SSD devices).

For systems with constant heavy workloads, or workloads that fluctuate widely, several configuration options let you fine-tune the flushing behavior for InnoDB tables:

- `innodb_adaptive_flushing_lwm`
- `innodb_max_dirty_pages_pct_lwm`
- `innodb_io_capacity_max`
- `innodb_flushing_avg_loops`

These options feed into the formula used by the `innodb_adaptive_flushing` option.

The `innodb_adaptive_flushing`, `innodb_io_capacity` and `innodb_max_dirty_pages_pct` options are limited or extended by the following options:

- `innodb_adaptive_flushing_lwm`
- `innodb_io_capacity_max`
- `innodb_max_dirty_pages_pct_lwm`

The InnoDB adaptive flushing mechanism is not appropriate in all cases. It gives the most benefit when the redo log is in danger of filling up. The `innodb_adaptive_flushing_lwm` option specifies a “low water mark” percentage of redo log capacity; when that threshold is crossed, InnoDB turns on adaptive flushing even if not specified by the `innodb_adaptive_flushing` option.

If flushing activity falls far behind, InnoDB can flush more aggressively than specified by `innodb_io_capacity`. `innodb_io_capacity_max` represents an upper limit on the I/O capacity used in such emergency situations, so that the spike in I/O does not consume all the capacity of the server.

InnoDB tries to flush data from the buffer pool so that the percentage of dirty pages does not exceed the value of `innodb_max_dirty_pages_pct`. The default value for `innodb_max_dirty_pages_pct` is 75.

**Note**

The `innodb_max_dirty_pages_pct` setting establishes a target for flushing activity. It does not affect the rate of flushing. For information about managing the rate of flushing, see [Section 15.6.3.6, “Configuring InnoDB Buffer Pool Flushing”](#).

The `innodb_max_dirty_pages_pct_lwm` option specifies a “low water mark” value that represents the percentage of dirty pages where pre-flushing is enabled to control the dirty page ratio and ideally prevent the percentage of dirty pages from reaching `innodb_max_dirty_pages_pct`. A value of `innodb_max_dirty_pages_pct_lwm=0` disables the “pre-flushing” behavior.

Most of the options referenced above are most applicable to servers that run write-heavy workloads for long periods of time and have little reduced load time to catch up with changes waiting to be written to disk.

`innodb_flushing_avg_loops` defines the number of iterations for which InnoDB keeps the previously calculated snapshot of the flushing state, which controls how quickly adaptive flushing responds to foreground load changes. Setting a high value for `innodb_flushing_avg_loops` means that InnoDB keeps the previously calculated snapshot longer, so adaptive flushing responds more slowly. A high value also reduces positive feedback between foreground and background work, but when setting a high value it is important to ensure that InnoDB redo log utilization does not reach 75% (the hardcoded limit at which async flushing starts) and that the `innodb_max_dirty_pages_pct` setting keeps the number of dirty pages to a level that is appropriate for the workload.

Systems with consistent workloads, a large `innodb_log_file_size`, and small spikes that do not reach 75% redo log space utilization should use a high `innodb_flushing_avg_loops` value to keep flushing as smooth as possible. For systems with extreme load spikes or log files that do not provide a lot of space, consider a smaller `innodb_flushing_avg_loops` value. A smaller value allows flushing to closely track the load and helps avoid reaching 75% redo log space utilization.

15.6.3.8 Saving and Restoring the Buffer Pool State

To reduce the `warmup` period after restarting the server, InnoDB saves a percentage of the most recently used pages for each buffer pool at server shutdown and restores these pages at server startup. The percentage of recently used pages that is stored is defined by the `innodb_buffer_pool_dump_at_shutdown` configuration option.

After restarting a busy server, there is typically a warmup period with steadily increasing throughput, as disk pages that were in the buffer pool are brought back into memory (as the same data is queried, updated, and so on). The ability to restore the buffer pool at startup shortens the warmup period by reloading disk pages that were in the buffer pool before the restart rather than waiting for DML operations to access corresponding rows. Also, I/O requests can be performed in large batches, making the overall I/O faster. Page loading happens in the background, and does not delay database startup.

In addition to saving the buffer pool state at shutdown and restoring it at startup, you can save and restore the buffer pool state at any time, while the server is running. For example, you can save the state of the buffer pool after reaching a stable throughput under a steady workload. You could also restore the previous buffer pool state after running reports or maintenance jobs that bring data pages into the buffer pool that are only required for those operations, or after running some other non-typical workload.

Even though a buffer pool can be many gigabytes in size, the buffer pool data that InnoDB saves to disk is tiny by comparison. Only tablespace IDs and page IDs necessary to locate the appropriate pages are saved to disk. This information is derived from the `INNODB_BUFFER_PAGE_LRU_INFORMATION_SCHEMA` table. By default, tablespace ID and page ID data is saved in a file named `ib_buffer_pool`, which is saved to the InnoDB data directory. The file name and location can be modified using the `innodb_buffer_pool_filename` configuration parameter.

Because data is cached in and aged out of the buffer pool as it is with regular database operations, there is no problem if the disk pages are recently updated, or if a DML operation involves data that has not yet been loaded. The loading mechanism skips requested pages that no longer exist.

The underlying mechanism involves a background thread that is dispatched to perform the dump and load operations.

Disk pages from compressed tables are loaded into the buffer pool in their compressed form. Pages are uncompressed as usual when page contents are accessed during DML operations. Because uncompressing pages is a CPU-intensive process, it is more efficient for concurrency to perform the operation in a connection thread rather than in the single thread that performs the buffer pool restore operation.

Operations related to saving and restoring the buffer pool state are described in the following topics:

- [Configuring the Dump Percentage for Buffer Pool Pages](#)
- [Saving the Buffer Pool State at Shutdown and Restoring it at Startup](#)
- [Saving and Restoring the Buffer Pool State Online](#)
- [Displaying Buffer Pool Dump Progress](#)
- [Displaying Buffer Pool Load Progress](#)
- [Aborting a Buffer Pool Load Operation](#)
- [Monitoring Buffer Pool Load Progress Using Performance Schema](#)

Configuring the Dump Percentage for Buffer Pool Pages

Before dumping pages from the buffer pool, you can configure the percentage of most-recently-used buffer pool pages that you want to dump by setting the `innodb_buffer_pool_dump_pct` option. If you plan to dump buffer pool pages while the server is running, you can configure the option dynamically:

```
SET GLOBAL innodb_buffer_pool_dump_pct=40;
```

If you plan to dump buffer pool pages at server shutdown, set `innodb_buffer_pool_dump_pct` in your configuration file.

```
[mysqld]
innodb_buffer_pool_dump_pct=40
```

The `innodb_buffer_pool_dump_pct` default value is 25 (dump 25% of most-recently-used pages).

Saving the Buffer Pool State at Shutdown and Restoring it at Startup

To save the state of the buffer pool at server shutdown, issue the following statement prior to shutting down the server:

```
SET GLOBAL innodb_buffer_pool_dump_at_shutdown=ON;
```

`innodb_buffer_pool_dump_at_shutdown` is enabled by default.

To restore the buffer pool state at server startup, specify the `--innodb_buffer_pool_load_at_startup` option when starting the server:

```
mysqld --innodb_buffer_pool_load_at_startup=ON;
```

`innodb_buffer_pool_load_at_startup` is enabled by default.

Saving and Restoring the Buffer Pool State Online

To save the state of the buffer pool while MySQL server is running, issue the following statement:

```
SET GLOBAL innodb_buffer_pool_dump_now=ON;
```

To restore the buffer pool state while MySQL is running, issue the following statement:

```
SET GLOBAL innodb_buffer_pool_load_now=ON;
```

Displaying Buffer Pool Dump Progress

To display progress when saving the buffer pool state to disk, issue the following statement:

```
SHOW STATUS LIKE 'Innodb_buffer_pool_dump_status';
```

If the operation has not yet started, “not started” is returned. If the operation is complete, the completion time is printed (e.g. Finished at 110505 12:18:02). If the operation is in progress, status information is provided (e.g. Dumping buffer pool 5/7, page 237/2873).

Displaying Buffer Pool Load Progress

To display progress when loading the buffer pool, issue the following statement:

```
SHOW STATUS LIKE 'Innodb_buffer_pool_load_status';
```

If the operation has not yet started, “not started” is returned. If the operation is complete, the completion time is printed (e.g. Finished at 110505 12:23:24). If the operation is in progress, status information is provided (e.g. Loaded 123/22301 pages).

Aborting a Buffer Pool Load Operation

To abort a buffer pool load operation, issue the following statement:

```
SET GLOBAL innodb_buffer_pool_load_abort=ON;
```

Monitoring Buffer Pool Load Progress Using Performance Schema

You can monitor buffer pool load progress using [Performance Schema](#).

The following example demonstrates how to enable the `stage/innodb/buffer pool load` stage event instrument and related consumer tables to monitor buffer pool load progress.

For information about buffer pool dump and load procedures used in this example, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#). For information about Performance Schema stage event instruments and related consumers, see [Section 25.11.5, “Performance Schema Stage Event Tables”](#).

1. Enable the `stage/innodb/buffer pool load` instrument:

```
mysql> UPDATE performance_schema.setup_instruments SET ENABLED = 'YES'  
WHERE NAME LIKE 'stage/innodb/buffer%';
```

2. Enable the stage event consumer tables, which include `events_stages_current`, `events_stages_history`, and `events_stages_history_long`.

```
mysql> UPDATE performance_schema.setup_consumers SET ENABLED = 'YES'  
WHERE NAME LIKE '%stages%';
```

3. Dump the current buffer pool state by enabling `innodb_buffer_pool_dump_now`.

```
mysql> SET GLOBAL innodb_buffer_pool_dump_now=ON;
```

4. Check the buffer pool dump status to ensure that the operation has completed.

```
mysql> SHOW STATUS LIKE 'Innodb_buffer_pool_dump_status'\G
***** 1. row *****
Variable_name: Innodb_buffer_pool_dump_status
Value: Buffer pool(s) dump completed at 150202 16:38:58
```

5. Load the buffer pool by enabling `innodb_buffer_pool_load_now`:

```
mysql> SET GLOBAL innodb_buffer_pool_load_now=ON;
```

6. Check the current status of the buffer pool load operation by querying the Performance Schema `events_stages_current` table. The `WORK_COMPLETED` column shows the number of buffer pool pages loaded. The `WORK_ESTIMATED` column provides an estimate of the remaining work, in pages.

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED
FROM performance_schema.events_stages_current;
+-----+-----+-----+
| EVENT_NAME | WORK_COMPLETED | WORK_ESTIMATED |
+-----+-----+-----+
| stage/innodb/buffer pool load | 5353 | 7167 |
+-----+-----+-----+
```

The `events_stages_current` table returns an empty set if the buffer pool load operation has completed. In this case, you can check the `events_stages_history` table to view data for the completed event. For example:

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED
FROM performance_schema.events_stages_history;
+-----+-----+-----+
| EVENT_NAME | WORK_COMPLETED | WORK_ESTIMATED |
+-----+-----+-----+
| stage/innodb/buffer pool load | 7167 | 7167 |
+-----+-----+-----+
```

Note

You can also monitor buffer pool load progress using Performance Schema when loading the buffer pool at startup using `innodb_buffer_pool_load_at_startup`. In this case, the `stage/innodb/buffer pool load` instrument and related consumers must be enabled at startup. For more information, see [Section 25.3, “Performance Schema Startup Configuration”](#).

15.6.3.9 Monitoring the Buffer Pool Using the InnoDB Standard Monitor

InnoDB Standard Monitor output, which can be accessed using `SHOW ENGINE INNODB STATUS`, provides metrics that pertain to operation of the InnoDB buffer pool. Buffer pool metrics are located in the `BUFFER POOL AND MEMORY` section of InnoDB Standard Monitor output and appear similar to the following:

```
-----
BUFFER POOL AND MEMORY
-----
Total large memory allocated 2198863872
Dictionary memory allocated 776332
Buffer pool size 131072
```

```
Free buffers          124908
Database pages       5720
Old database pages   2071
Modified db pages    910
Pending reads        0
Pending writes: LRU 0, flush list 0, single page 0
Pages made young    4, not young 0
0.10 youngs/s, 0.00 non-youngs/s
Pages read 197, created 5523, written 5060
0.00 reads/s, 190.89 creates/s, 244.94 writes/s
Buffer pool hit rate 1000 / 1000, young-making rate 0 / 1000 not
0 / 1000
Pages read ahead 0.00/s, evicted without access 0.00/s, Random read
ahead 0.00/s
LRU len: 5720, unzip_LRU len: 0
I/O sum[0]:cur[0], unzip sum[0]:cur[0]
```

The following table describes [InnoDB](#) buffer pool metrics reported by the [InnoDB](#) Standard Monitor.

Note

Per second averages provided in [InnoDB](#) Standard Monitor output are based on the elapsed time since [InnoDB](#) Standard Monitor output was last printed.

Table 15.2 InnoDB Buffer Pool Metrics

Name	Description
Total memory allocated	The total memory allocated for the buffer pool in bytes.
Dictionary memory allocated	The total memory allocated for the InnoDB data dictionary in bytes.
Buffer pool size	The total size in pages allocated to the buffer pool.
Free buffers	The total size in pages of the buffer pool free list.
Database pages	The total size in pages of the buffer pool LRU list.
Old database pages	The total size in pages of the buffer pool old LRU sublist.
Modified db pages	The current number of pages modified in the buffer pool.
Pending reads	The number of buffer pool pages waiting to be read in to the buffer pool.
Pending writes LRU	The number of old dirty pages within the buffer pool to be written from the bottom of the LRU list.
Pending writes flush list	The number of buffer pool pages to be flushed during checkpointing.
Pending writes single page	The number of pending independent page writes within the buffer pool.
Pages made young	The total number of pages made young in the buffer pool LRU list (moved to the head of sublist of “new” pages).
Pages made not young	The total number of pages not made young in the buffer pool LRU list (pages that have remained in the “old” sublist without being made young).
youngs/s	The per second average of accesses to old pages in the buffer pool LRU list that have resulted in making pages young. See the notes that follow this table for more information.
non-youngs/s	The per second average of accesses to old pages in the buffer pool LRU list that have resulted in not making pages young. See the notes that follow this table for more information.
Pages read	The total number of pages read from the buffer pool.
Pages created	The total number of pages created within the buffer pool.

Name	Description
Pages written	The total number of pages written from the buffer pool.
reads/s	The per second average number of buffer pool page reads per second.
creates/s	The per second average number of buffer pool pages created per second.
writes/s	The per second average number of buffer pool page writes per second.
Buffer pool hit rate	The buffer pool page hit rate for pages read from the buffer pool memory vs from disk storage.
young-making rate	The average hit rate at which page accesses have resulted in making pages young. See the notes that follow this table for more information.
not (young-making rate)	The average hit rate at which page accesses have not resulted in making pages young. See the notes that follow this table for more information.
Pages read ahead	The per second average of read ahead operations.
Pages evicted without access	The per second average of the pages evicted without being accessed from the buffer pool.
Random read ahead	The per second average of random read ahead operations.
LRU len	The total size in pages of the buffer pool LRU list.
unzip_LRU len	The total size in pages of the buffer pool unzip_LRU list.
I/O sum	The total number of buffer pool LRU list pages accessed, for the last 50 seconds.
I/O cur	The total number of buffer pool LRU list pages accessed.
I/O unzip sum	The total number of buffer pool unzip_LRU list pages accessed.
I/O unzip cur	The total number of buffer pool unzip_LRU list pages accessed.

Notes:

- The `young/s` metric only relates to old pages. It is based on the number of accesses to pages and not the number of pages. There can be multiple accesses to a given page, all of which are counted. If you see very low `young/s` values when there are no large scans occurring, you might need to reduce the delay time or increase the percentage of the buffer pool used for the old sublist. Increasing the percentage makes the old sublist larger, so pages in that sublist take longer to move to the tail and to be evicted. This increases the likelihood that the pages will be accessed again and be made young.
- The `non-young/s` metric only relates to old pages. It is based on the number of accesses to pages and not the number of pages. There can be multiple accesses to a given page, all of which are counted. If you do not see a lot of `non-young/s` when you are doing large table scans (and lots of `young/s`), increase the delay value.
- The `young-making` rate accounts for accesses to all buffer pool pages, not just accesses to pages in the old sublist. The `young-making` rate and `not` rate do not normally add up to the overall buffer pool hit rate. Page hits in the old sublist cause pages to move to the new sublist, but page hits in the new sublist cause pages to move to the head of the list only if they are a certain distance from the head.
- `not (young-making rate)` is the average hit rate at which page accesses have not resulted in making pages young due to the delay defined by `innodb_old_blocks_time` not being met, or due to page hits in the new sublist that did not result in pages being moved to the head. This rate accounts for accesses to all buffer pool pages, not just accesses to pages in the old sublist.

InnoDB buffer pool [server status variables](#) and the `INNODB_BUFFER_POOL_STATS` table provide many of the same buffer pool metrics found in InnoDB Standard Monitor output. For more information about the `INNODB_BUFFER_POOL_STATS` table, see [Example 15.10, “Querying the INNODB_BUFFER_POOL_STATS Table”](#).

15.6.4 Configuring InnoDB Change Buffering

When `INSERT`, `UPDATE`, and `DELETE` operations are performed on a table, the values of indexed columns (particularly the values of secondary keys) are often in an unsorted order, requiring substantial I/O to bring secondary indexes up to date. InnoDB has a [change buffer](#) that caches changes to secondary index entries when the relevant [page](#) is not in the [buffer pool](#), thus avoiding expensive I/O operations by not immediately reading in the page from disk. The buffered changes are merged when the page is loaded to the buffer pool, and the updated page is later flushed to disk. The InnoDB main thread merges buffered changes when the server is nearly idle, and during a [slow shutdown](#).

Because it can result in fewer disk reads and writes, the change buffer feature is most valuable for workloads that are I/O-bound, for example applications with a high volume of DML operations such as bulk inserts.

However, the change buffer occupies a part of the buffer pool, reducing the memory available to cache data pages. If the working set almost fits in the buffer pool, or if your tables have relatively few secondary indexes, it may be useful to disable change buffering. If the working set fits entirely within the buffer, change buffering does not impose extra overhead, because it only applies to pages that are not in the buffer pool.

You can control the extent to which InnoDB performs change buffering using the `innodb_change_buffering` configuration parameter. You can enable or disable buffering for inserts, delete operations (when index records are initially marked for deletion) and purge operations (when index records are physically deleted). An update operation is a combination of an insert and a delete. The default `innodb_change_buffering` value is `all`.

Permitted `innodb_change_buffering` values include:

- `all`
The default value: buffer inserts, delete-marking operations, and purges.
- `none`
Do not buffer any operations.
- `inserts`
Buffer insert operations.
- `deletes`
Buffer delete-marking operations.
- `changes`
Buffer both inserts and delete-marking operations.
- `purges`
Buffer the physical deletion operations that happen in the background.

You can set the `innodb_change_buffering` parameter in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically with the `SET GLOBAL` command, which requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege. Changing the setting affects the buffering of new operations; the merging of existing buffered entries is not affected.

Change buffering is not supported for a secondary index if the index contains a descending index column or if the primary key includes a descending index column.

For related information, see [Section 15.4.2, “Change Buffer”](#). For information about configuring change buffer size, see [Section 15.6.4.1, “Configuring the Change Buffer Maximum Size”](#).

15.6.4.1 Configuring the Change Buffer Maximum Size

The `innodb_change_buffer_max_size` configuration option allows you to configure the maximum size of the change buffer as a percentage of the total size of the buffer pool. By default, `innodb_change_buffer_max_size` is set to 25. The maximum setting is 50.

You might consider increasing `innodb_change_buffer_max_size` on a MySQL server with heavy insert, update, and delete activity, where change buffer merging does not keep pace with new change buffer entries, causing the change buffer to reach its maximum size limit.

You might consider decreasing `innodb_change_buffer_max_size` on a MySQL server with static data used for reporting, or if the change buffer consumes too much of the memory space that is shared with the buffer pool, causing pages to age out of the buffer pool sooner than desired.

Test different settings with a representative workload to determine an optimal configuration. The `innodb_change_buffer_max_size` setting is dynamic, which allows you modify the setting without restarting the server.

15.6.5 Configuring Thread Concurrency for InnoDB

InnoDB uses operating system [threads](#) to process requests from user transactions. (Transactions may issue many requests to InnoDB before they commit or roll back.) On modern operating systems and servers with multi-core processors, where context switching is efficient, most workloads run well without any limit on the number of concurrent threads.

In situations where it is helpful to minimize context switching between threads, InnoDB can use a number of techniques to limit the number of concurrently executing operating system threads (and thus the number of requests that are processed at any one time). When InnoDB receives a new request from a user session, if the number of threads concurrently executing is at a pre-defined limit, the new request sleeps for a short time before it tries again. A request that cannot be rescheduled after the sleep is put in a first-in/first-out queue and eventually is processed. Threads waiting for locks are not counted in the number of concurrently executing threads.

You can limit the number of concurrent threads by setting the configuration parameter `innodb_thread_concurrency`. Once the number of executing threads reaches this limit, additional threads sleep for a number of microseconds, set by the configuration parameter `innodb_thread_sleep_delay`, before being placed into the queue.

You can set the configuration option `innodb_adaptive_max_sleep_delay` to the highest value you would allow for `innodb_thread_sleep_delay`, and InnoDB automatically adjusts `innodb_thread_sleep_delay` up or down depending on the current thread-scheduling activity. This dynamic adjustment helps the thread scheduling mechanism to work smoothly during times when the system is lightly loaded and when it is operating near full capacity.

The default value for `innodb_thread_concurrency` and the implied default limit on the number of concurrent threads has been changed in various releases of MySQL and InnoDB. The default value of `innodb_thread_concurrency` is 0, so that by default there is no limit on the number of concurrently executing threads.

InnoDB causes threads to sleep only when the number of concurrent threads is limited. When there is no limit on the number of threads, all contend equally to be scheduled. That is, if `innodb_thread_concurrency` is 0, the value of `innodb_thread_sleep_delay` is ignored.

When there is a limit on the number of threads (when `innodb_thread_concurrency` is > 0), InnoDB reduces context switching overhead by permitting multiple requests made during

the execution of a *single SQL statement* to enter InnoDB without observing the limit set by `innodb_thread_concurrency`. Since an SQL statement (such as a join) may comprise multiple row operations within InnoDB, InnoDB assigns a specified number of “tickets” that allow a thread to be scheduled repeatedly with minimal overhead.

When a new SQL statement starts, a thread has no tickets, and it must observe `innodb_thread_concurrency`. Once the thread is entitled to enter InnoDB, it is assigned a number of tickets that it can use for subsequently entering InnoDB to perform row operations. If the tickets run out, the thread is evicted, and `innodb_thread_concurrency` is observed again which may place the thread back into the first-in/first-out queue of waiting threads. When the thread is once again entitled to enter InnoDB, tickets are assigned again. The number of tickets assigned is specified by the global option `innodb_concurrency_tickets`, which is 5000 by default. A thread that is waiting for a lock is given one ticket once the lock becomes available.

The correct values of these variables depend on your environment and workload. Try a range of different values to determine what value works for your applications. Before limiting the number of concurrently executing threads, review configuration options that may improve the performance of InnoDB on multi-core and multi-processor computers, such as `innodb_adaptive_hash_index`.

For general performance information about MySQL thread handling, see [Section 8.12.4.1, “How MySQL Uses Threads for Client Connections”](#).

15.6.6 Configuring the Number of Background InnoDB I/O Threads

InnoDB uses background [threads](#) to service various types of I/O requests. You can configure the number of background threads that service read and write I/O on data pages using the `innodb_read_io_threads` and `innodb_write_io_threads` configuration parameters. These parameters signify the number of background threads used for read and write requests, respectively. They are effective on all supported platforms. You can set values for these parameters in the MySQL option file (`my.cnf` or `my.ini`); you cannot change values dynamically. The default value for these parameters is 4 and permissible values range from 1–64.

The purpose of these configuration options to make InnoDB more scalable on high end systems. Each background thread can handle up to 256 pending I/O requests. A major source of background I/O is [read-ahead](#) requests. InnoDB tries to balance the load of incoming requests in such way that most background threads share work equally. InnoDB also attempts to allocate read requests from the same extent to the same thread, to increase the chances of coalescing the requests. If you have a high end I/O subsystem and you see more than $64 \times \text{innodb_read_io_threads}$ pending read requests in `SHOW ENGINE INNODB STATUS` output, you might improve performance by increasing the value of `innodb_read_io_threads`.

On Linux systems, InnoDB uses the asynchronous I/O subsystem by default to perform read-ahead and write requests for data file pages, which changes the way that InnoDB background threads service these types of I/O requests. For more information, see [Section 15.6.7, “Using Asynchronous I/O on Linux”](#).

For more information about InnoDB I/O performance, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

15.6.7 Using Asynchronous I/O on Linux

InnoDB uses the asynchronous I/O subsystem (native AIO) on Linux to perform read-ahead and write requests for data file pages. This behavior is controlled by the `innodb_use_native_aio` configuration option, which applies to Linux systems only and is enabled by default. On other Unix-like systems, InnoDB uses synchronous I/O only. Historically, InnoDB only used asynchronous I/O on Windows systems. Using the asynchronous I/O subsystem on Linux requires the `libaio` library.

With synchronous I/O, query threads queue I/O requests, and InnoDB background threads retrieve the queued requests one at a time, issuing a synchronous I/O call for each. When an I/O request is completed and the I/O call returns, the InnoDB background thread that is handling the request

calls an I/O completion routine and returns to process the next request. The number of requests that can be processed in parallel is n , where n is the number of InnoDB background threads. The number of InnoDB background threads is controlled by `innodb_read_io_threads` and `innodb_write_io_threads`. See Section 15.6.6, “Configuring the Number of Background InnoDB I/O Threads”.

With native AIO, query threads dispatch I/O requests directly to the operating system, thereby removing the limit imposed by the number of background threads. InnoDB background threads wait for I/O events to signal completed requests. When a request is completed, a background thread calls an I/O completion routine and resumes waiting for I/O events.

The advantage of native AIO is scalability for heavily I/O-bound systems that typically show many pending reads/writes in `SHOW ENGINE INNODB STATUS\G` output. The increase in parallel processing when using native AIO means that the type of I/O scheduler or properties of the disk array controller have a greater influence on I/O performance.

A potential disadvantage of native AIO for heavily I/O-bound systems is lack of control over the number of I/O write requests dispatched to the operating system at once. Too many I/O write requests dispatched to the operating system for parallel processing could, in some cases, result in I/O read starvation, depending on the amount of I/O activity and system capabilities.

If a problem with the asynchronous I/O subsystem in the OS prevents InnoDB from starting, you can start the server with `innodb_use_native_aio=0`. This option may also be disabled automatically during startup if InnoDB detects a potential problem such as a combination of `tmpdir` location, `tmpfs` file system, and Linux kernel that does not support asynchronous I/O on `tmpfs`.

15.6.8 Configuring the InnoDB Master Thread I/O Rate

The `master thread` in InnoDB is a thread that performs various tasks in the background. Most of these tasks are I/O related, such as flushing dirty pages from the buffer pool or writing changes from the insert buffer to the appropriate secondary indexes. The master thread attempts to perform these tasks in a way that does not adversely affect the normal working of the server. It tries to estimate the free I/O bandwidth available and tune its activities to take advantage of this free capacity. Historically, InnoDB has used a hard coded value of 100 IOPs (input/output operations per second) as the total I/O capacity of the server.

The parameter `innodb_io_capacity` indicates the overall I/O capacity available to InnoDB. This parameter should be set to approximately the number of I/O operations that the system can perform per second. The value depends on your system configuration. When `innodb_io_capacity` is set, the master threads estimates the I/O bandwidth available for background tasks based on the set value. Setting the value to `100` reverts to the old behavior.

You can set the value of `innodb_io_capacity` to any number 100 or greater. The default value is `200`, reflecting that the performance of typical modern I/O devices is higher than in the early days of MySQL. Typically, values around the previous default of 100 are appropriate for consumer-level storage devices, such as hard drives up to 7200 RPMs. Faster hard drives, RAID configurations, and SSDs benefit from higher values.

The `innodb_io_capacity` setting is a total limit for all buffer pool instances. When dirty pages are flushed, the `innodb_io_capacity` limit is divided equally among buffer pool instances. For more information, see the `innodb_io_capacity` system variable description.

You can set the value of this parameter in the MySQL option file (`my.cnf` or `my.ini`) or change it dynamically with the `SET GLOBAL` command, which requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege.

The `innodb_flush_sync` configuration option causes the `innodb_io_capacity` setting to be ignored during bursts of I/O activity that occur at checkpoints. `innodb_flush_sync` is enabled by default.

In earlier MySQL releases, the [InnoDB](#) master thread also performed any needed [purge](#) operations. Those I/O operations are now performed by other background threads, whose number is controlled by the [innodb_purge_threads](#) configuration option.

For more information about InnoDB I/O performance, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

15.6.9 Configuring Spin Lock Polling

Many InnoDB [mutexes](#) and [rw-locks](#) are reserved for a short time. On a multi-core system, it can be more efficient for a thread to continuously check if it can acquire a mutex or rw-lock for a while before sleeping. If the mutex or rw-lock becomes available during this polling period, the thread can continue immediately, in the same time slice. However, too-frequent polling by multiple threads of a shared object can cause “cache ping pong”, different processors invalidating portions of each others' cache. InnoDB minimizes this issue by waiting a random time between subsequent polls. The delay is implemented as a busy loop.

You can control the maximum delay between testing a mutex or rw-lock using the parameter [innodb_spin_wait_delay](#). The duration of the delay loop depends on the C compiler and the target processor. (In the 100MHz Pentium era, the unit of delay was one microsecond.) On a system where all processor cores share a fast cache memory, you might reduce the maximum delay or disable the busy loop altogether by setting [innodb_spin_wait_delay=0](#). On a system with multiple processor chips, the effect of cache invalidation can be more significant and you might increase the maximum delay.

The default value of [innodb_spin_wait_delay](#) is 6. The spin wait delay is a dynamic, global parameter that you can specify in the MySQL option file ([my.cnf](#) or [my.ini](#)) or change at runtime with the command `SET GLOBAL innodb_spin_wait_delay=delay`, where *delay* is the desired maximum delay. Changing the setting requires the [SYSTEM_VARIABLES_ADMIN](#) or [SUPER](#) privilege.

For performance considerations for InnoDB locking operations, see [Section 8.11, “Optimizing Locking Operations”](#).

15.6.10 Configuring InnoDB Purge Scheduling

The [purge](#) operations (a type of garbage collection) that InnoDB performs automatically may be performed by one or more separate threads rather than as part of the [master thread](#). The use of separate threads improves scalability by allowing the main database operations to run independently from maintenance work happening in the background.

To control this feature, increase the value of the configuration option [innodb_purge_threads](#). If DML action is concentrated on a single table or a few tables, keep the setting low so that the threads do not contend with each other for access to the busy tables. If DML operations are spread across many tables, increase the setting. Its maximum is 32. [innodb_purge_threads](#) is a non-dynamic configuration option, which means it cannot be configured at runtime.

There is another related configuration option, [innodb_purge_batch_size](#) with a default value of 300 and maximum value of 5000. This option is mainly intended for experimentation and tuning of purge operations, and should not be interesting to typical users.

For more information about InnoDB I/O performance, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

15.6.11 Configuring Optimizer Statistics for InnoDB

This section describes how to configure persistent and non-persistent optimizer statistics for [InnoDB](#) tables.

Persistent optimizer statistics are persisted across server restarts, allowing for greater [plan stability](#) and more consistent query performance. Persistent optimizer statistics also provide control and flexibility with these additional benefits:

- You can use the `innodb_stats_auto_recalc` configuration option to control whether statistics are updated automatically after substantial changes to a table.
- You can use the `STATS_PERSISTENT`, `STATS_AUTO_RECALC`, and `STATS_SAMPLE_PAGES` clauses with `CREATE TABLE` and `ALTER TABLE` statements to configure optimizer statistics for individual tables.
- You can query optimizer statistics data in the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables.
- You can view the `last_update` column of the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables to see when statistics were last updated.
- You can manually modify the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables to force a specific query optimization plan or to test alternative plans without modifying the database.

The persistent optimizer statistics feature is enabled by default (`innodb_stats_persistent=ON`).

Non-persistent optimizer statistics are cleared on each server restart and after some other operations, and recomputed on the next table access. As a result, different estimates could be produced when recomputing statistics, leading to different choices in execution plans and variations in query performance.

This section also provides information about estimating `ANALYZE TABLE` complexity, which may be useful when attempting to achieve a balance between accurate statistics and `ANALYZE TABLE` execution time.

15.6.11.1 Configuring Persistent Optimizer Statistics Parameters

The persistent optimizer statistics feature improves [plan stability](#) by storing statistics to disk and making them persistent across server restarts so that the [optimizer](#) is more likely to make consistent choices each time for a given query.

Optimizer statistics are persisted to disk when `innodb_stats_persistent=ON` or when individual tables are created or altered with `STATS_PERSISTENT=1`. `innodb_stats_persistent` is enabled by default.

Formerly, optimizer statistics were cleared on each server restart and after some other operations, and recomputed on the next table access. Consequently, different estimates could be produced when recalculating statistics, leading to different choices in query execution plans and thus variations in query performance.

Persistent statistics are stored in the `mysql.innodb_table_stats` and `mysql.innodb_index_stats` tables, as described in [InnoDB Persistent Statistics Tables](#).

To revert to using non-persistent optimizer statistics, you can modify tables using an `ALTER TABLE tbl_name STATS_PERSISTENT=0` statement. For related information, see [Section 15.6.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”](#)

Configuring Automatic Statistics Calculation for Persistent Optimizer Statistics

The `innodb_stats_auto_recalc` configuration option, which is enabled by default, determines whether statistics are calculated automatically whenever a table undergoes substantial changes (to more than 10% of the rows). You can also configure automatic statistics recalculation for individual tables using a `STATS_AUTO_RECALC` clause in a `CREATE TABLE` or `ALTER TABLE` statement. `innodb_stats_auto_recalc` is enabled by default.

Because of the asynchronous nature of automatic statistics recalculation (which occurs in the background), statistics may not be recalculated instantly after running a DML operation that affects more than 10% of a table, even when `innodb_stats_auto_recalc` is enabled. In

some cases, statistics recalculation may be delayed by a few seconds. If up-to-date statistics are required immediately after changing significant portions of a table, run `ANALYZE TABLE` to initiate a synchronous (foreground) recalculation of statistics.

If `innodb_stats_auto_recalc` is disabled, ensure the accuracy of optimizer statistics by issuing the `ANALYZE TABLE` statement for each applicable table after making substantial changes to indexed columns. You might run this statement in your setup scripts after representative data has been loaded into the table, and run it periodically after DML operations significantly change the contents of indexed columns, or on a schedule at times of low activity. When a new index is added to an existing table, index statistics are calculated and added to the `innodb_index_stats` table regardless of the value of `innodb_stats_auto_recalc`.

Caution

To ensure statistics are gathered when a new index is created, either enable the `innodb_stats_auto_recalc` option, or run `ANALYZE TABLE` after creating each new index when the persistent statistics mode is enabled.

Configuring Optimizer Statistics Parameters for Individual Tables

`innodb_stats_persistent`, `innodb_stats_auto_recalc`, and `innodb_stats_persistent_sample_pages` are global configuration options. To override these system-wide settings and configure optimizer statistics parameters for individual tables, you can define `STATS_PERSISTENT`, `STATS_AUTO_RECALC`, and `STATS_SAMPLE_PAGES` clauses in `CREATE TABLE` or `ALTER TABLE` statements.

- `STATS_PERSISTENT` specifies whether to enable [persistent statistics](#) for an InnoDB table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_persistent` configuration option. The value `1` enables persistent statistics for the table, while the value `0` turns off this feature. After enabling persistent statistics through a `CREATE TABLE` or `ALTER TABLE` statement, issue an `ANALYZE TABLE` statement to calculate the statistics, after loading representative data into the table.
- `STATS_AUTO_RECALC` specifies whether to automatically recalculate [persistent statistics](#) for an InnoDB table. The value `DEFAULT` causes the persistent statistics setting for the table to be determined by the `innodb_stats_auto_recalc` configuration option. The value `1` causes statistics to be recalculated when 10% of the data in the table has changed. The value `0` prevents automatic recalculation for this table; with this setting, issue an `ANALYZE TABLE` statement to recalculate the statistics after making substantial changes to the table.
- `STATS_SAMPLE_PAGES` specifies the number of index pages to sample when estimating cardinality and other statistics for an indexed column, such as those calculated by `ANALYZE TABLE`.

All three clauses are specified in the following `CREATE TABLE` example:

```
CREATE TABLE `t1` (
  `id` int(8) NOT NULL auto_increment,
  `data` varchar(255),
  `date` datetime,
  PRIMARY KEY (`id`),
  INDEX `DATE_IX` (`date`)
) ENGINE=InnoDB,
  STATS_PERSISTENT=1,
  STATS_AUTO_RECALC=1,
  STATS_SAMPLE_PAGES=25;
```

Configuring the Number of Sampled Pages for InnoDB Optimizer Statistics

The MySQL query optimizer uses estimated [statistics](#) about key distributions to choose the indexes for an execution plan, based on the relative [selectivity](#) of the index. Operations such as `ANALYZE TABLE` cause InnoDB to sample random pages from each index on a table to estimate the [cardinality](#) of the index. (This technique is known as [random dives](#).)

To give you control over the quality of the statistics estimate (and thus better information for the query optimizer), you can change the number of sampled pages using the parameter `innodb_stats_persistent_sample_pages`, which can be set at runtime.

`innodb_stats_persistent_sample_pages` has a default value of 20. As a general guideline, consider modifying this parameter when encountering the following issues:

1. *Statistics are not accurate enough and the optimizer chooses suboptimal plans*, as shown by `EXPLAIN` output. The accuracy of statistics can be checked by comparing the actual cardinality of an index (as returned by running `SELECT DISTINCT` on the index columns) with the estimates provided in the `mysql.innodb_index_stats` persistent statistics table.

If it is determined that statistics are not accurate enough, the value of `innodb_stats_persistent_sample_pages` should be increased until the statistics estimates are sufficiently accurate. Increasing `innodb_stats_persistent_sample_pages` too much, however, could cause `ANALYZE TABLE` to run slowly.

2. *ANALYZE TABLE is too slow*. In this case `innodb_stats_persistent_sample_pages` should be decreased until `ANALYZE TABLE` execution time is acceptable. Decreasing the value too much, however, could lead to the first problem of inaccurate statistics and suboptimal query execution plans.

If a balance cannot be achieved between accurate statistics and `ANALYZE TABLE` execution time, consider decreasing the number of indexed columns in the table or limiting the number of partitions to reduce `ANALYZE TABLE` complexity. The number of columns in the table's primary key is also important to consider, as primary key columns are appended to each non-unique index.

For related information, see [Section 15.6.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”](#).

Including Delete-marked Records in Persistent Statistics Calculations

By default, InnoDB reads uncommitted data when calculating statistics. In the case of an uncommitted transaction that deletes rows from a table, InnoDB excludes records that are delete-marked when calculating row estimates and index statistics, which can lead to non-optimal execution plans for other transactions that are operating on the table concurrently using a transaction isolation level other than `READ UNCOMMITTED`. To avoid this scenario, `innodb_stats_include_delete_marked` can be enabled to ensure that InnoDB includes delete-marked records when calculating persistent optimizer statistics.

When `innodb_stats_include_delete_marked` is enabled, `ANALYZE TABLE` considers delete-marked records when recalculating statistics.

`innodb_stats_include_delete_marked` is a global setting that affects all InnoDB tables, and it is only applicable to persistent optimizer statistics.

InnoDB Persistent Statistics Tables

The persistent statistics feature relies on the internally managed tables in the `mysql` database, named `innodb_table_stats` and `innodb_index_stats`. These tables are set up automatically in all install, upgrade, and build-from-source procedures.

Table 15.3 Columns of `innodb_table_stats`

Column name	Description
<code>database_name</code>	Database name
<code>table_name</code>	Table name, partition name, or subpartition name
<code>last_update</code>	A timestamp indicating the last time that InnoDB updated this row

Column name	Description
<code>n_rows</code>	The number of rows in the table
<code>clustered_index_size</code>	The size of the primary index, in pages
<code>sum_of_other_index_size</code>	The total size of other (non-primary) indexes, in pages

Table 15.4 Columns of `innodb_index_stats`

Column name	Description
<code>database_name</code>	Database name
<code>table_name</code>	Table name, partition name, or subpartition name
<code>index_name</code>	Index name
<code>last_update</code>	A timestamp indicating the last time that InnoDB updated this row
<code>stat_name</code>	The name of the statistic, whose value is reported in the <code>stat_value</code> column
<code>stat_value</code>	The value of the statistic that is named in <code>stat_name</code> column
<code>sample_size</code>	The number of pages sampled for the estimate provided in the <code>stat_value</code> column
<code>stat_description</code>	Description of the statistic that is named in the <code>stat_name</code> column

Both the `innodb_table_stats` and `innodb_index_stats` tables include a `last_update` column showing when InnoDB last updated index statistics, as shown in the following example:

```
mysql> select * from innodb_table_stats \G
***** 1. row *****
      database_name: sakila
      table_name: actor
      last_update: 2014-05-28 16:16:44
      n_rows: 200
      clustered_index_size: 1
      sum_of_other_index_size: 1
      ...
```

```
mysql> select * from innodb_index_stats \G
***** 1. row *****
      database_name: sakila
      table_name: actor
      index_name: PRIMARY
      last_update: 2014-05-28 16:16:44
      stat_name: n_diff_pfx01
      stat_value: 200
      sample_size: 1
      ...
```

The `innodb_table_stats` and `innodb_index_stats` tables are ordinary tables and can be updated manually. The ability to update statistics manually makes it possible to force a specific query optimization plan or test alternative plans without modifying the database. If you manually update statistics, issue the `FLUSH TABLE tbl_name` command to make MySQL reload the updated statistics.

InnoDB Persistent Statistics Tables Example

The `innodb_table_stats` table contains one row per table. The data collected is demonstrated in the following example.

Table `t1` contains a primary index (columns `a`, `b`) secondary index (columns `c`, `d`), and unique index (columns `e`, `f`):

```
CREATE TABLE t1 (
  a INT, b INT, c INT, d INT, e INT, f INT,
```

```
PRIMARY KEY (a, b), KEY i1 (c, d), UNIQUE KEY i2uniq (e, f)
) ENGINE=INNODB;
```

After inserting five rows of sample data, the table appears as follows:

```
mysql> SELECT * FROM t1;
+-----+-----+-----+-----+-----+-----+
| a | b | c | d | e | f |
+-----+-----+-----+-----+-----+-----+
| 1 | 1 | 10 | 11 | 100 | 101 |
| 1 | 2 | 10 | 11 | 200 | 102 |
| 1 | 3 | 10 | 11 | 100 | 103 |
| 1 | 4 | 10 | 12 | 200 | 104 |
| 1 | 5 | 10 | 12 | 100 | 105 |
+-----+-----+-----+-----+-----+-----+
```

To immediately update statistics, run `ANALYZE TABLE` (if `innodb_stats_auto_recalc` is enabled, statistics are updated automatically within a few seconds assuming that the 10% threshold for changed table rows is reached):

```
mysql> ANALYZE TABLE t1;
+-----+-----+-----+-----+
| Table | Op | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.t1 | analyze | status | OK |
+-----+-----+-----+-----+
```

Table statistics for table `t1` show the last time InnoDB updated the table statistics (2014-03-14 14:36:34), the number of rows in the table (5), the clustered index size (1 page), and the combined size of the other indexes (2 pages).

```
mysql> SELECT * FROM mysql.innodb_table_stats WHERE table_name like 't1'\G
***** 1. row *****
      database_name: test
      table_name: t1
      last_update: 2014-03-14 14:36:34
      n_rows: 5
      clustered_index_size: 1
      sum_of_other_index_sizes: 2
```

The `innodb_index_stats` table contains multiple rows for each index. Each row in the `innodb_index_stats` table provides data related to a particular index statistic which is named in the `stat_name` column and described in the `stat_description` column. For example:

```
mysql> SELECT index_name, stat_name, stat_value, stat_description
-> FROM mysql.innodb_index_stats WHERE table_name like 't1';
+-----+-----+-----+-----+
| index_name | stat_name | stat_value | stat_description |
+-----+-----+-----+-----+
| PRIMARY | n_diff_pfx01 | 1 | a |
| PRIMARY | n_diff_pfx02 | 5 | a,b |
| PRIMARY | n_leaf_pages | 1 | Number of leaf pages in the index |
| PRIMARY | size | 1 | Number of pages in the index |
| i1 | n_diff_pfx01 | 1 | c |
| i1 | n_diff_pfx02 | 2 | c,d |
| i1 | n_diff_pfx03 | 2 | c,d,a |
| i1 | n_diff_pfx04 | 5 | c,d,a,b |
| i1 | n_leaf_pages | 1 | Number of leaf pages in the index |
| i1 | size | 1 | Number of pages in the index |
| i2uniq | n_diff_pfx01 | 2 | e |
| i2uniq | n_diff_pfx02 | 5 | e,f |
| i2uniq | n_leaf_pages | 1 | Number of leaf pages in the index |
| i2uniq | size | 1 | Number of pages in the index |
+-----+-----+-----+-----+
```

The `stat_name` column shows the following types of statistics:

- `size`: Where `stat_name=size`, the `stat_value` column displays the total number of pages in the index.

- `n_leaf_pages`: Where `stat_name=n_leaf_pages`, the `stat_value` column displays the number of leaf pages in the index.
- `n_diff_pfxNN`: Where `stat_name=n_diff_pfx01`, the `stat_value` column displays the number of distinct values in the first column of the index. Where `stat_name=n_diff_pfx02`, the `stat_value` column displays the number of distinct values in the first two columns of the index, and so on. Additionally, where `stat_name=n_diff_pfxNN`, the `stat_description` column shows a comma separated list of the index columns that are counted.

To further illustrate the `n_diff_pfxNN` statistic, which provides cardinality data, consider the `t1` table example. As shown below, the `t1` table is created with a primary index (columns `a`, `b`), a secondary index (columns `c`, `d`), and a unique index (columns `e`, `f`):

```
CREATE TABLE t1 (
  a INT, b INT, c INT, d INT, e INT, f INT,
  PRIMARY KEY (a, b), KEY i1 (c, d), UNIQUE KEY i2uniq (e, f)
) ENGINE=INNODB;
```

After inserting five rows of sample data, the table appears as follows:

```
mysql> SELECT * FROM t1;
+-----+-----+-----+-----+-----+-----+
| a | b | c | d | e | f |
+-----+-----+-----+-----+-----+-----+
| 1 | 1 | 10 | 11 | 100 | 101 |
| 1 | 2 | 10 | 11 | 200 | 102 |
| 1 | 3 | 10 | 11 | 100 | 103 |
| 1 | 4 | 10 | 12 | 200 | 104 |
| 1 | 5 | 10 | 12 | 100 | 105 |
+-----+-----+-----+-----+-----+-----+
```

When you query the `index_name`, `stat_name`, `stat_value`, and `stat_description` where `stat_name LIKE 'n_diff%'`, the following result set is returned:

```
mysql> SELECT index_name, stat_name, stat_value, stat_description
-> FROM mysql.innodb_index_stats
-> WHERE table_name like 't1' AND stat_name LIKE 'n_diff%';
+-----+-----+-----+-----+
| index_name | stat_name | stat_value | stat_description |
+-----+-----+-----+-----+
| PRIMARY   | n_diff_pfx01 | 1 | a |
| PRIMARY   | n_diff_pfx02 | 5 | a,b |
| i1        | n_diff_pfx01 | 1 | c |
| i1        | n_diff_pfx02 | 2 | c,d |
| i1        | n_diff_pfx03 | 2 | c,d,a |
| i1        | n_diff_pfx04 | 5 | c,d,a,b |
| i2uniq    | n_diff_pfx01 | 2 | e |
| i2uniq    | n_diff_pfx02 | 5 | e,f |
+-----+-----+-----+-----+
```

For the `PRIMARY` index, there are two `n_diff%` rows. The number of rows is equal to the number of columns in the index.

Note

For non-unique indexes, InnoDB appends the columns of the primary key.

- Where `index_name=PRIMARY` and `stat_name=n_diff_pfx01`, the `stat_value` is 1, which indicates that there is a single distinct value in the first column of the index (column `a`). The number of distinct values in column `a` is confirmed by viewing the data in column `a` in table `t1`, in which there is a single distinct value (1). The counted column (`a`) is shown in the `stat_description` column of the result set.
- Where `index_name=PRIMARY` and `stat_name=n_diff_pfx02`, the `stat_value` is 5, which indicates that there are five distinct values in the two columns of the index (`a`, `b`). The number of distinct values in columns `a` and `b` is confirmed by viewing the data in columns `a` and `b` in table `t1`,

in which there are five distinct values: (1, 1), (1, 2), (1, 3), (1, 4) and (1, 5). The counted columns (a, b) are shown in the `stat_description` column of the result set.

For the secondary index (`i1`), there are four `n_diff%` rows. Only two columns are defined for the secondary index (`c, d`) but there are four `n_diff%` rows for the secondary index because InnoDB suffixes all non-unique indexes with the primary key. As a result, there are four `n_diff%` rows instead of two to account for the both the secondary index columns (`c, d`) and the primary key columns (`a, b`).

- Where `index_name=i1` and `stat_name=n_diff_pfx01`, the `stat_value` is 1, which indicates that there is a single distinct value in the first column of the index (column `c`). The number of distinct values in column `c` is confirmed by viewing the data in column `c` in table `t1`, in which there is a single distinct value: (10). The counted column (`c`) is shown in the `stat_description` column of the result set.
- Where `index_name=i1` and `stat_name=n_diff_pfx02`, the `stat_value` is 2, which indicates that there are two distinct values in the first two columns of the index (`c, d`). The number of distinct values in columns `c` and `d` is confirmed by viewing the data in columns `c` and `d` in table `t1`, in which there are two distinct values: (10, 11) and (10, 12). The counted columns (`c, d`) are shown in the `stat_description` column of the result set.
- Where `index_name=i1` and `stat_name=n_diff_pfx03`, the `stat_value` is 2, which indicates that there are two distinct values in the first three columns of the index (`c, d, a`). The number of distinct values in columns `c, d, and a` is confirmed by viewing the data in column `c, d, and a` in table `t1`, in which there are two distinct values: (10, 11, 1) and (10, 12, 1). The counted columns (`c, d, a`) are shown in the `stat_description` column of the result set.
- Where `index_name=i1` and `stat_name=n_diff_pfx04`, the `stat_value` is 5, which indicates that there are five distinct values in the four columns of the index (`c, d, a, b`). The number of distinct values in columns `c, d, a and b` is confirmed by viewing the data in columns `c, d, a, and b` in table `t1`, in which there are five distinct values: (10, 11, 1, 1), (10, 11, 1, 2), (10, 11, 1, 3), (10, 12, 1, 4) and (10, 12, 1, 5). The counted columns (`c, d, a, b`) are shown in the `stat_description` column of the result set.

For the unique index (`i2uniq`), there are two `n_diff%` rows.

- Where `index_name=i2uniq` and `stat_name=n_diff_pfx01`, the `stat_value` is 2, which indicates that there are two distinct values in the first column of the index (column `e`). The number of distinct values in column `e` is confirmed by viewing the data in column `e` in table `t1`, in which there are two distinct values: (100) and (200). The counted column (`e`) is shown in the `stat_description` column of the result set.
- Where `index_name=i2uniq` and `stat_name=n_diff_pfx02`, the `stat_value` is 5, which indicates that there are five distinct values in the two columns of the index (`e, f`). The number of distinct values in columns `e and f` is confirmed by viewing the data in columns `e and f` in table `t1`, in which there are five distinct values: (100, 101), (200, 102), (100, 103), (200, 104) and (100, 105). The counted columns (`e, f`) are shown in the `stat_description` column of the result set.

Retrieving Index Size Using the `innodb_index_stats` Table

The size of indexes for tables, partitions, or subpartitions can be retrieved using the `innodb_index_stats` table. In the following example, index sizes are retrieved for table `t1`. For a definition of table `t1` and corresponding index statistics, see [InnoDB Persistent Statistics Tables Example](#).

```
mysql> SELECT SUM(stat_value) pages, index_name,
-> SUM(stat_value)*@@innodb_page_size size
-> FROM mysql.innodb_index_stats WHERE table_name='t1'
-> AND stat_name = 'size' GROUP BY index_name;
```

pages	index_name	size
1	PRIMARY	16384

1	i1	16384
1	i2uniq	16384

For partitions or subpartitions, the same query with a modified `WHERE` clause can be used to retrieve index sizes. For example, the following query retrieves index sizes for partitions of table `t1`:

```
mysql> SELECT SUM(stat_value) pages, index_name,
-> SUM(stat_value)*@@innodb_page_size size
-> FROM mysql.innodb_index_stats WHERE table_name like 't1#P%'
-> AND stat_name = 'size' GROUP BY index_name;
```

15.6.11.2 Configuring Non-Persistent Optimizer Statistics Parameters

This section describes how to configure non-persistent optimizer statistics. Optimizer statistics are not persisted to disk when `innodb_stats_persistent=OFF` or when individual tables are created or altered with `STATS_PERSISTENT=0`. Instead, statistics are stored in memory, and are lost when the server is shut down. Statistics are also updated periodically by certain operations and under certain conditions.

Optimizer statistics are persisted to disk by default, enabled by the `innodb_stats_persistent` configuration option. For information about persistent optimizer statistics, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

Optimizer Statistics Updates

Non-persistent optimizer statistics are updated when:

- Running `ANALYZE TABLE`.
- Running `SHOW TABLE STATUS`, `SHOW INDEX`, or querying the `INFORMATION_SCHEMA.TABLES` or `INFORMATION_SCHEMA.STATISTICS` tables with the `innodb_stats_on_metadata` option enabled.

The default setting for `innodb_stats_on_metadata` is `OFF`. Enabling `innodb_stats_on_metadata` may reduce access speed for schemas that have a large number of tables or indexes, and reduce stability of execution plans for queries that involve InnoDB tables. `innodb_stats_on_metadata` is configured globally using a `SET` statement.

```
SET GLOBAL innodb_stats_on_metadata=ON
```

Note

`innodb_stats_on_metadata` only applies when optimizer `statistics` are configured to be non-persistent (when `innodb_stats_persistent` is disabled).

- Starting a `mysql` client with the `--auto-rehash` option enabled, which is the default. The `auto-rehash` option causes all InnoDB tables to be opened, and the open table operations cause statistics to be recalculated.

To improve the start up time of the `mysql` client and to updating statistics, you can turn off `auto-rehash` using the `--disable-auto-rehash` option. The `auto-rehash` feature enables automatic name completion of database, table, and column names for interactive users.

- A table is first opened.
- InnoDB detects that 1 / 16 of table has been modified since the last time statistics were updated.

Configuring the Number of Sampled Pages

The MySQL query optimizer uses estimated `statistics` about key distributions to choose the indexes for an execution plan, based on the relative `selectivity` of the index. When InnoDB updates optimizer

statistics, it samples random pages from each index on a table to estimate the [cardinality](#) of the index. (This technique is known as [random dives](#).)

To give you control over the quality of the statistics estimate (and thus better information for the query optimizer), you can change the number of sampled pages using the parameter `innodb_stats_transient_sample_pages`. The default number of sampled pages is 8, which could be insufficient to produce an accurate estimate, leading to poor index choices by the query optimizer. This technique is especially important for large tables and tables used in [joins](#). Unnecessary [full table scans](#) for such tables can be a substantial performance issue. See [Section 8.2.1.20, “Avoiding Full Table Scans”](#) for tips on tuning such queries. `innodb_stats_transient_sample_pages` is a global parameter that can be set at runtime.

The value of `innodb_stats_transient_sample_pages` affects the index sampling for all InnoDB tables and indexes when `innodb_stats_persistent=0`. Be aware of the following potentially significant impacts when you change the index sample size:

- Small values like 1 or 2 can result in inaccurate estimates of cardinality.
- Increasing the `innodb_stats_transient_sample_pages` value might require more disk reads. Values much larger than 8 (say, 100), can cause a significant slowdown in the time it takes to open a table or execute `SHOW TABLE STATUS`.
- The optimizer might choose very different query plans based on different estimates of index selectivity.

Whatever value of `innodb_stats_transient_sample_pages` works best for a system, set the option and leave it at that value. Choose a value that results in reasonably accurate estimates for all tables in your database without requiring excessive I/O. Because the statistics are automatically recalculated at various times other than on execution of `ANALYZE TABLE`, it does not make sense to increase the index sample size, run `ANALYZE TABLE`, then decrease sample size again.

Smaller tables generally require fewer index samples than larger tables. If your database has many large tables, consider using a higher value for `innodb_stats_transient_sample_pages` than if you have mostly smaller tables.

15.6.11.3 Estimating ANALYZE TABLE Complexity for InnoDB Tables

`ANALYZE TABLE` complexity for InnoDB tables is dependent on:

- The number of pages sampled, as defined by `innodb_stats_persistent_sample_pages`.
- The number of indexed columns in a table
- The number of partitions. If a table has no partitions, the number of partitions is considered to be 1.

Using these parameters, an approximate formula for estimating `ANALYZE TABLE` complexity would be:

The value of `innodb_stats_persistent_sample_pages` * number of indexed columns in a table * the number of partitions

Typically, the greater the resulting value, the greater the execution time for `ANALYZE TABLE`.

Note

`innodb_stats_persistent_sample_pages` defines the number of pages sampled at a global level. To set the number of pages sampled for an individual table, use the `STATS_SAMPLE_PAGES` option with `CREATE TABLE` or `ALTER TABLE`. For more information, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

If `innodb_stats_persistent=OFF`, the number of pages sampled is defined by `innodb_stats_transient_sample_pages`. See [Section 15.6.11.2,](#)

“[Configuring Non-Persistent Optimizer Statistics Parameters](#)” for additional information.

For a more in-depth approach to estimating `ANALYZE TABLE` complexity, consider the following example.

In **Big O notation**, `ANALYZE TABLE` complexity is described as:

```
O(n_sample
  * (n_cols_in_uniq_i
    + n_cols_in_non_uniq_i
    + n_cols_in_pk * (1 + n_non_uniq_i))
  * n_part)
```

where:

- `n_sample` is the number of pages sampled (defined by `innodb_stats_persistent_sample_pages`)
- `n_cols_in_uniq_i` is total number of all columns in all unique indexes (not counting the primary key columns)
- `n_cols_in_non_uniq_i` is the total number of all columns in all non-unique indexes
- `n_cols_in_pk` is the number of columns in the primary key (if a primary key is not defined, InnoDB creates a single column primary key internally)
- `n_non_uniq_i` is the number of non-unique indexes in the table
- `n_part` is the number of partitions. If no partitions are defined, the table is considered to be a single partition.

Now, consider the following table (table `t`), which has a primary key (2 columns), a unique index (2 columns), and two non-unique indexes (two columns each):

```
CREATE TABLE t (
  a INT,
  b INT,
  c INT,
  d INT,
  e INT,
  f INT,
  g INT,
  h INT,
  PRIMARY KEY (a, b),
  UNIQUE KEY iluniq (c, d),
  KEY i2nonuniq (e, f),
  KEY i3nonuniq (g, h)
);
```

For the column and index data required by the algorithm described above, query the `mysql.innodb_index_stats` persistent index statistics table for table `t`. The `n_diff_pfx%` statistics show the columns that are counted for each index. For example, columns `a` and `b` are counted for the primary key index. For the non-unique indexes, the primary key columns (`a`,`b`) are counted in addition to the user defined columns.

Note

For additional information about the InnoDB persistent statistics tables, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#)

```
SELECT index_name, stat_name, stat_description
FROM mysql.innodb_index_stats
WHERE
  database_name='test' AND
  table_name='t' AND
```

```
stat_name like 'n_diff_pfx%';
```

index_name	stat_name	stat_description
PRIMARY	n_diff_pfx01	a
PRIMARY	n_diff_pfx02	a,b
iluniq	n_diff_pfx01	c
iluniq	n_diff_pfx02	c,d
i2nonuniq	n_diff_pfx01	e
i2nonuniq	n_diff_pfx02	e,f
i2nonuniq	n_diff_pfx03	e,f,a
i2nonuniq	n_diff_pfx04	e,f,a,b
i3nonuniq	n_diff_pfx01	g
i3nonuniq	n_diff_pfx02	g,h
i3nonuniq	n_diff_pfx03	g,h,a
i3nonuniq	n_diff_pfx04	g,h,a,b

Based on the index statistics data shown above and the table definition, the following values can be determined:

- `n_cols_in_uniq_i`, the total number of all columns in all unique indexes not counting the primary key columns, is 2 (c and d)
- `n_cols_in_non_uniq_i`, the total number of all columns in all non-unique indexes, is 4 (e, f, g and h)
- `n_cols_in_pk`, the number of columns in the primary key, is 2 (a and b)
- `n_non_uniq_i`, the number of non-unique indexes in the table, is 2 (i2nonuniq and i3nonuniq)
- `n_part`, the number of partitions, is 1.

You can now calculate `innodb_stats_persistent_sample_pages * (2 + 4 + 2 * (1 + 2)) * 1` to determine the number of leaf pages that are scanned. With `innodb_stats_persistent_sample_pages` set to the default value of 20, and with a default page size of 16 KiB (`innodb_page_size=16384`), you can then estimate that `20 * 12 * 16384 bytes` are read for table `t`, or about 4 MiB.

Note

All 4 MiB may not be read from disk, as some leaf pages may already be cached in the buffer pool.

15.6.12 Configuring the Merge Threshold for Index Pages

You can configure the `MERGE_THRESHOLD` value for index pages. If the “page-full” percentage for an index page falls below the `MERGE_THRESHOLD` value when a row is deleted or when a row is shortened by an `UPDATE` operation, InnoDB attempts to merge the index page with a neighboring index page. The default `MERGE_THRESHOLD` value is 50, which is the previously hardcoded value. The minimum `MERGE_THRESHOLD` value is 1 and the maximum value is 50.

When the “page-full” percentage for an index page falls below 50%, which is the default `MERGE_THRESHOLD` setting, InnoDB attempts to merge the index page with a neighboring page. If both pages are close to 50% full, a page split can occur soon after the pages are merged. If this merge-split behavior occurs frequently, it can have an adverse affect on performance. To avoid frequent merge-splits, you can lower the `MERGE_THRESHOLD` value so that InnoDB attempts page merges at a lower “page-full” percentage. Merging pages at a lower page-full percentage leaves more room in index pages and helps reduce merge-split behavior.

The `MERGE_THRESHOLD` for index pages can be defined for a table or for individual indexes. A `MERGE_THRESHOLD` value defined for an individual index takes priority over a `MERGE_THRESHOLD` value defined for the table. If undefined, the `MERGE_THRESHOLD` value defaults to 50.

Setting MERGE_THRESHOLD for a Table

You can set the `MERGE_THRESHOLD` value for a table using the `table_option COMMENT` clause of the `CREATE TABLE` statement. For example:

```
CREATE TABLE t1 (
  id INT,
  KEY id_index (id)
) COMMENT='MERGE_THRESHOLD=45';
```

You can also set the `MERGE_THRESHOLD` value for an existing table using the `table_option COMMENT` clause with `ALTER TABLE`:

```
CREATE TABLE t1 (
  id INT,
  KEY id_index (id)
);

ALTER TABLE t1 COMMENT='MERGE_THRESHOLD=40';
```

Setting MERGE_THRESHOLD for Individual Indexes

To set the `MERGE_THRESHOLD` value for an individual index, you can use the `index_option COMMENT` clause with `CREATE TABLE`, `ALTER TABLE`, or `CREATE INDEX`, as shown in the following examples:

- Setting `MERGE_THRESHOLD` for an individual index using `CREATE TABLE`:

```
CREATE TABLE t1 (
  id INT,
  KEY id_index (id) COMMENT 'MERGE_THRESHOLD=40'
);
```

- Setting `MERGE_THRESHOLD` for an individual index using `ALTER TABLE`:

```
CREATE TABLE t1 (
  id INT,
  KEY id_index (id)
);

ALTER TABLE t1 DROP KEY id_index;
ALTER TABLE t1 ADD KEY id_index (id) COMMENT 'MERGE_THRESHOLD=40';
```

- Setting `MERGE_THRESHOLD` for an individual index using `CREATE INDEX`:

```
CREATE TABLE t1 (id INT);
CREATE INDEX id_index ON t1 (id) COMMENT 'MERGE_THRESHOLD=40';
```

Note

You cannot modify the `MERGE_THRESHOLD` value at the index level for `GEN_CLUST_INDEX`, which is the clustered index created by `InnoDB` when an `InnoDB` table is created without a primary key or unique key index. You can only modify the `MERGE_THRESHOLD` value for `GEN_CLUST_INDEX` by setting `MERGE_THRESHOLD` for the table.

Querying the MERGE_THRESHOLD Value for an Index

The current `MERGE_THRESHOLD` value for an index can be obtained by querying the `INNODB_SYS_INDEXES` table. For example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_INDEXES WHERE NAME='id_index' \G
***** 1. row *****
INDEX_ID: 91
NAME: id_index
TABLE_ID: 68
TYPE: 0
```

```
N_FIELDS: 1
PAGE_NO: 4
SPACE: 57
MERGE_THRESHOLD: 40
```

You can use `SHOW CREATE TABLE` to view the `MERGE_THRESHOLD` value for a table, if explicitly defined using the `table_option COMMENT` clause:

```
mysql> SHOW CREATE TABLE t2 \G
***** 1. row *****
      Table: t2
Create Table: CREATE TABLE `t2` (
  `id` int(11) DEFAULT NULL,
  KEY `id_index` (`id`) COMMENT 'MERGE_THRESHOLD=40'
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4
```

Note

A `MERGE_THRESHOLD` value defined at the index level takes priority over a `MERGE_THRESHOLD` value defined for the table. If undefined, `MERGE_THRESHOLD` defaults to 50% (`MERGE_THRESHOLD=50`, which is the previously hardcoded value).

Likewise, you can use `SHOW INDEX` to view the `MERGE_THRESHOLD` value for an index, if explicitly defined using the `index_option COMMENT` clause:

```
mysql> SHOW INDEX FROM t2 \G
***** 1. row *****
      Table: t2
      Non_unique: 1
      Key_name: id_index
      Seq_in_index: 1
      Column_name: id
      Collation: A
      Cardinality: 0
      Sub_part: NULL
      Packed: NULL
      Null: YES
      Index_type: BTREE
      Comment:
      Index_comment: MERGE_THRESHOLD=40
```

Measuring the Effect of MERGE_THRESHOLD Settings

The `INNODB_METRICS` table provides two counters that can be used to measure the effect of a `MERGE_THRESHOLD` setting on index page merges.

```
mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS
WHERE NAME like '%index_page_merge%';
+-----+-----+
| NAME                                | COMMENT                                |
+-----+-----+
| index_page_merge_attempts           | Number of index page merge attempts   |
| index_page_merge_successful         | Number of successful index page merges |
+-----+-----+
```

When lowering the `MERGE_THRESHOLD` value, the objectives are:

- A smaller number of page merge attempts and successful page merges
- A similar number of page merge attempts and successful page merges

A `MERGE_THRESHOLD` setting that is too small could result in large data files due to an excessive amount of empty page space.

For information about using `INNODB_METRICS` counters, see [Section 15.14.6, “InnoDB INFORMATION_SCHEMA Metrics Table”](#).

15.7 InnoDB Tablespaces

This section covers topics related to [InnoDB](#) tablespaces.

15.7.1 Resizing the InnoDB System Tablespace

This section describes how to increase or decrease the size of the [InnoDB](#) system tablespace.

Increasing the Size of the InnoDB System Tablespace

The easiest way to increase the size of the [InnoDB](#) system tablespace is to configure it from the beginning to be auto-extending. Specify the `autoextend` attribute for the last data file in the tablespace definition. Then [InnoDB](#) increases the size of that file automatically in 64MB increments when it runs out of space. The increment size can be changed by setting the value of the `innodb_autoextend_increment` system variable, which is measured in megabytes.

You can expand the system tablespace by a defined amount by adding another data file:

1. Shut down the MySQL server.
2. If the previous last data file is defined with the keyword `autoextend`, change its definition to use a fixed size, based on how large it has actually grown. Check the size of the data file, round it down to the closest multiple of 1024 × 1024 bytes (= 1MB), and specify this rounded size explicitly in `innodb_data_file_path`.
3. Add a new data file to the end of `innodb_data_file_path`, optionally making that file auto-extending. Only the last data file in the `innodb_data_file_path` can be specified as auto-extending.
4. Start the MySQL server again.

For example, this tablespace has just one auto-extending data file `ibdata1`:

```
innodb_data_home_dir =
innodb_data_file_path = /ibdata/ibdata1:10M:autoextend
```

Suppose that this data file, over time, has grown to 988MB. Here is the configuration line after modifying the original data file to use a fixed size and adding a new auto-extending data file:

```
innodb_data_home_dir =
innodb_data_file_path = /ibdata/ibdata1:988M;/disk2/ibdata2:50M:autoextend
```

When you add a new data file to the system tablespace configuration, make sure that the filename does not refer to an existing file. [InnoDB](#) creates and initializes the file when you restart the server.

Decreasing the Size of the InnoDB System Tablespace

You cannot remove a data file from the system tablespace. To decrease the system tablespace size, use this procedure:

1. Use `mysqldump` to dump all your [InnoDB](#) tables, including [InnoDB](#) tables located in the MySQL database.

```
mysql> select table_name from information_schema.tables where table_schema='mysql' and engine='InnoDB';
+-----+
| table_name |
+-----+
| columns_priv |
| db |
```

```

time_zone_transition
time_zone_transition_type
user
+-----+

```

2. Stop the server.
3. Remove all the existing tablespace files (*.ibd), including the `ibdata` and `ib_log` files. Do not forget to remove *.ibd files for tables located in the MySQL database.
4. Configure a new tablespace.
5. Restart the server.
6. Import the dump files.

Note

If your databases only use the [InnoDB](#) engine, it may be simpler to dump **all** databases, stop the server, remove all databases and [InnoDB](#) log files, restart the server, and import the dump files.

15.7.2 Changing the Number or Size of InnoDB Redo Log Files

To change the number or the size of your [InnoDB redo log](#) files, perform the following steps:

1. Stop the MySQL server and make sure that it shuts down without errors.
2. Edit `my.cnf` to change the log file configuration. To change the log file size, configure `innodb_log_file_size`. To increase the number of log files, configure `innodb_log_files_in_group`.
3. Start the MySQL server again.

If [InnoDB](#) detects that the `innodb_log_file_size` differs from the redo log file size, it writes a log checkpoint, closes and removes the old log files, creates new log files at the requested size, and opens the new log files.

15.7.3 Using Raw Disk Partitions for the System Tablespace

You can use raw disk partitions as data files in the [InnoDB system tablespace](#). This technique enables nonbuffered I/O on Windows and on some Linux and Unix systems without file system overhead. Perform tests with and without raw partitions to verify whether this change actually improves performance on your system.

When you use a raw disk partition, ensure that the user ID that runs the MySQL server has read and write privileges for that partition. For example, if you run the server as the `mysql` user, the partition must be readable and writeable by `mysql`. If you run the server with the `--memlock` option, the server must be run as `root`, so the partition must be readable and writeable by `root`.

The procedures described below involve option file modification. For additional information, see [Section 4.2.6, “Using Option Files”](#).

Allocating a Raw Disk Partition on Linux and Unix Systems

1. When you create a new data file, specify the keyword `newraw` immediately after the data file size for the `innodb_data_file_path` option. The partition must be at least as large as the size that you specify. Note that 1MB in InnoDB is 1024 × 1024 bytes, whereas 1MB in disk specifications usually means 1,000,000 bytes.

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/dev/hdd1:3Gnewraw:/dev/hdd2:2Gnewraw
```

2. Restart the server. InnoDB notices the `newraw` keyword and initializes the new partition. However, do not create or change any InnoDB tables yet. Otherwise, when you next restart the server, InnoDB reinitializes the partition and your changes are lost. (As a safety measure InnoDB prevents users from modifying data when any partition with `newraw` is specified.)
3. After InnoDB has initialized the new partition, stop the server, change `newraw` in the data file specification to `raw`:

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=/dev/hdd1:3Graw:/dev/hdd2:2Graw
```

4. Restart the server. InnoDB now permits changes to be made.

Allocating a Raw Disk Partition on Windows

On Windows systems, the same steps and accompanying guidelines described for Linux and Unix systems apply except that the `innodb_data_file_path` setting differs slightly on Windows.

1. When you create a new data file, specify the keyword `newraw` immediately after the data file size for the `innodb_data_file_path` option:

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=//./D::10Gnewraw
```

The `//./` corresponds to the Windows syntax of `\\.\` for accessing physical drives. In the example above, `D:` is the drive letter of the partition.

2. Restart the server. InnoDB notices the `newraw` keyword and initializes the new partition.
3. After InnoDB has initialized the new partition, stop the server, change `newraw` in the data file specification to `raw`:

```
[mysqld]
innodb_data_home_dir=
innodb_data_file_path=//./D::10Graw
```

4. Restart the server. InnoDB now permits changes to be made.

15.7.4 InnoDB File-Per-Table Tablespaces

Historically, all InnoDB tables and indexes were stored in the [system tablespace](#). This monolithic approach was targeted at machines dedicated entirely to database processing, with carefully planned data growth, where any disk storage allocated to MySQL would never be needed for other purposes. InnoDB's [file-per-table tablespace](#) feature provides a more flexible alternative, where each InnoDB table and its indexes are stored in a separate `.ibd` data file. Each such `.ibd` data file represents an individual [tablespace](#). This feature is controlled by the `innodb_file_per_table` configuration option, which is enabled by default.

Advantages of File-Per-Table Tablespaces

- You can reclaim disk space when truncating or dropping a table stored in a file-per-table tablespace. Truncating or dropping tables stored in the shared [system tablespace](#) creates free space internally in the system tablespace data files ([ibdata files](#)) which can only be used for new InnoDB data.

Similarly, a table-copying `ALTER TABLE` operation on table that resides in a shared tablespace can increase the amount of space used by the tablespace. Such operations may require as much additional space as the data in the table plus indexes. The additional space required for the table-copying `ALTER TABLE` operation is not released back to the operating system as it is for file-per-table tablespaces.

- The `TRUNCATE TABLE` operation is faster when run on tables stored in file-per-table tablespaces.
- You can store specific tables on separate storage devices, for I/O optimization, space management, or backup purposes by specifying the location of each table using the syntax `CREATE TABLE ... DATA DIRECTORY = absolute_path_to_directory`, as explained in [Section 15.7.5, “Creating File-Per-Table Tablespaces Outside the Data Directory”](#).
- You can run `OPTIMIZE TABLE` to compact or recreate a file-per-table tablespace. When you run an `OPTIMIZE TABLE`, InnoDB creates a new `.ibd` file with a temporary name, using only the space required to store actual data. When the optimization is complete, InnoDB removes the old `.ibd` file and replaces it with the new one. If the previous `.ibd` file grew significantly but the actual data only accounted for a portion of its size, running `OPTIMIZE TABLE` can reclaim the unused space.
- You can move individual InnoDB tables rather than entire databases.
- You can copy individual InnoDB tables from one MySQL instance to another (known as the [transportable tablespace](#) feature).
- Tables created in file-per-table tablespaces support features associated with [compressed](#) and [dynamic](#) row formats.
- You can enable more efficient storage for tables with large `BLOB` or `TEXT` columns using the [dynamic row format](#).
- File-per-table tablespaces may improve chances for a successful recovery and save time when a corruption occurs, when a server cannot be restarted, or when backup and binary logs are unavailable.
- File-per-table tablespaces are convenient for per-table status reporting when copying or backing up tables.
- You can monitor table size at a file system level, without accessing MySQL.
- Common Linux file systems do not permit concurrent writes to a single file when `innodb_flush_method` is set to `O_DIRECT`. As a result, there are possible performance improvements when using file-per-table tablespaces in conjunction with `innodb_flush_method`.
- The system tablespace stores the data dictionary and undo logs, and is limited in size by InnoDB tablespace size limits. See [Section 15.8.1.7, “Limits on InnoDB Tables”](#). With file-per-table tablespaces, each table has its own tablespace, which provides room for growth.

Potential Disadvantages of File-Per-Table Tablespaces

- With file-per-table tablespaces, each table may have unused space, which can only be utilized by rows of the same table. This could lead to wasted space if not properly managed.
- `fsync` operations must run on each open table rather than on a single file. Because there is a separate `fsync` operation for each file, write operations on multiple tables cannot be combined into a single I/O operation. This may require `InnoDB` to perform a higher total number of `fsync` operations.
- `mysqld` must keep one open file handle per table, which may impact performance if you have numerous tables in file-per-table tablespaces.
- More file descriptors are used.
- `innodb_file_per_table` is enabled by default. You may consider disabling it if backward compatibility with MySQL 5.5 or earlier is a concern. Disabling `innodb_file_per_table` prevents `ALTER TABLE` from moving an `InnoDB` table from the system tablespace to an individual `.ibd` file in cases where `ALTER TABLE` recreates the table (`ALGORITHM=COPY`).

For example, when restructuring the clustered index for an `InnoDB` table, the table is re-created using the current setting for `innodb_file_per_table`. This behavior does not apply when adding or dropping `InnoDB` secondary indexes. When a secondary index is created without rebuilding the table, the index is stored in the same file as the table data, regardless of the current `innodb_file_per_table` setting. This behavior also does not apply to tables added to the system tablespace using `CREATE TABLE ... TABLESPACE` or `ALTER TABLE ... TABLESPACE` syntax. These tables are not affected by the `innodb_file_per_table` setting.

- If many tables are growing there is potential for more fragmentation which can impede `DROP TABLE` and table scan performance. However, when fragmentation is managed, having files in their own tablespace can improve performance.
- The buffer pool is scanned when dropping a file-per-table tablespace, which can take several seconds for buffer pools that are tens of gigabytes in size. The scan is performed with a broad internal lock, which may delay other operations. Tables in the system tablespace are not affected.
- The `innodb_autoextend_increment` variable, which defines increment size (in MB) for extending the size of an auto-extending shared tablespace file when it becomes full, does not apply to file-per-table tablespace files, which are auto-extending regardless of the `innodb_autoextend_increment` setting. The initial extensions are by small amounts, after which extensions occur in increments of 4MB.

15.7.4.1 Enabling and Disabling File-Per-Table Tablespaces

The `innodb_file_per_table` option is enabled by default.

To set the `innodb_file_per_table` option at startup, start the server with the `--innodb_file_per_table` command-line option, or add this line to the `[mysqld]` section of `my.cnf`:

```
[mysqld]
innodb_file_per_table=1
```

You can also set `innodb_file_per_table` dynamically, while the server is running:

```
SET GLOBAL innodb_file_per_table=1;
```

With `innodb_file_per_table` enabled, you can store `InnoDB` tables in a `tbl_name.ibd` file. Unlike the `MyISAM` storage engine, with its separate `tbl_name.MYD` and `tbl_name.MYI` files for indexes and data, `InnoDB` stores the data and the indexes together in a single `.ibd` file.

If you disable `innodb_file_per_table` in your startup options and restart the server, or disable it with the `SET GLOBAL` command, InnoDB creates new tables inside the system tablespace unless you have explicitly placed the table in file-per-table tablespace or general tablespace using the `CREATE TABLE ... TABLESPACE` option.

You can always read and write any InnoDB tables, regardless of the file-per-table setting.

To move a table from the system tablespace to its own tablespace, change the `innodb_file_per_table` setting and rebuild the table:

```
SET GLOBAL innodb_file_per_table=1;
ALTER TABLE table_name ENGINE=InnoDB;
```

Tables added to the system tablespace using `CREATE TABLE ... TABLESPACE` or `ALTER TABLE ... TABLESPACE` syntax are not affected by the `innodb_file_per_table` setting. To move these tables from the system tablespace to a file-per-table tablespace, they must be moved explicitly using `ALTER TABLE ... TABLESPACE` syntax.

Note

InnoDB always needs the system tablespace because it puts its internal [data dictionary](#) and [undo logs](#) there. The `.ibd` files are not sufficient for InnoDB to operate.

When a table is moved out of the system tablespace into its own `.ibd` file, the data files that make up the system tablespace remain the same size. The space formerly occupied by the table can be reused for new InnoDB data, but is not reclaimed for use by the operating system. When moving large InnoDB tables out of the system tablespace, where disk space is limited, you may prefer to enable `innodb_file_per_table` and recreate the entire instance using the `mysqldump` command. As mentioned above, tables added to the system tablespace using `CREATE TABLE ... TABLESPACE` or `ALTER TABLE ... TABLESPACE` syntax are not affected by the `innodb_file_per_table` setting. These tables must be moved individually.

15.7.5 Creating File-Per-Table Tablespaces Outside the Data Directory

To create a new InnoDB [file-per-table](#) tablespace in a specific location outside the MySQL data directory, use the `DATA DIRECTORY = absolute_path_to_directory` clause of the `CREATE TABLE` statement.

Plan the location in advance, because you cannot use the `DATA DIRECTORY` clause with the `ALTER TABLE` statement. The directory you specify could be on another storage device with particular performance or capacity characteristics, such as a fast [SSD](#) or a high-capacity [HDD](#).

Within the destination directory, MySQL creates a subdirectory corresponding to the database name, and within that a `.ibd` file for the new table.

The following example demonstrates creating a file-per-table tablespace outside the MySQL data directory. It shows the `.ibd` created in the specified directory.

```
mysql> USE test;
Database changed

mysql> SHOW VARIABLES LIKE 'innodb_file_per_table';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| innodb_file_per_table | ON    |
+-----+-----+
1 row in set (0.00 sec)

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) DATA DIRECTORY = '/alternative/directory';
```

```
Query OK, 0 rows affected (0.03 sec)

# MySQL creates a .ibd file for the new table in a subdirectory that corresponding
# to the database name

db_user@ubuntu:~/alternative/directory/test$ ls
t1.ibd
```

You can also use `CREATE TABLE ... TABLESPACE` in combination with the `DATA DIRECTORY` clause to create a file-per-table tablespace outside the MySQL data directory. To do so, you must specify `innodb_file_per_table` as the tablespace name.

```
CREATE TABLE t2 (c1 INT PRIMARY KEY) TABLESPACE = innodb_file_per_table
DATA DIRECTORY = '/alternative/directory';
```

You do not have to enable `innodb_file_per_table` when using this method.

Usage Notes:

- MySQL initially holds the `.ibd` file open, preventing you from dismounting the device, but might eventually close the table if the server is busy. Be careful not to accidentally dismount an external device while MySQL is running, or to start MySQL while the device is disconnected. Attempting to access a table when the associated `.ibd` file is missing causes a serious error that requires a server restart.

A server restart issues errors and warnings if the `.ibd` file is not at the expected path. In this case, you can restore the tablespace `.ibd` file from a backup or drop the table to remove the information about it from the [data dictionary](#).

- Before tables on an NFS-mounted volume, review potential issues outlined in [Using NFS with MySQL](#).
- If you use an LVM snapshot, file copy, or other file-based mechanism to back up the `.ibd` file, always use the `FLUSH TABLES ... FOR EXPORT` statement first to make sure all changes that were buffered in memory are [flushed](#) to disk before the backup occurs.
- The `DATA DIRECTORY` clause is a supported alternative to [using symbolic links](#), which has always been problematic and was never supported for individual [InnoDB](#) tables.

15.7.6 Copying File-Per-Table Tablespaces to Another Instance

This section describes how to copy a [file-per-table](#) tablespaces from one MySQL instance to another, otherwise known as the [Transportable Tablespaces](#) feature. This feature also supports partitioned [InnoDB](#) tables and individual [InnoDB](#) table partitions and subpartitions.

For information about other [InnoDB](#) table copying methods, see [Section 15.8.1.3, “Moving or Copying InnoDB Tables”](#).

There are many reasons why you might copy an [InnoDB file-per-table](#) tablespace to a different instance:

- To run reports without putting extra load on a production server.
- To set up identical data for a table on a new [slave server](#).
- To restore a backed-up version of a table or partition after a problem or mistake.
- As a faster way of moving data around than importing the results of a `mysqldump` command. The data is available immediately, rather than having to be re-inserted and the indexes rebuilt.
- To move a [file-per-table](#) tablespace to a server with storage medium that better suits system requirements. For example, you may want to have busy tables on an [SSD](#) device, or large tables on a high-capacity [HDD](#) device.

Limitations and Usage Notes

- The tablespace copy procedure is only possible when `innodb_file_per_table` is enabled, which is the default setting. Tables residing in the shared system tablespace cannot be quiesced.
- When a table is quiesced, only read-only transactions are allowed on the affected table.
- When importing a tablespace, the page size must match the page size of the importing instance.
- `ALTER TABLE ... DISCARD TABLESPACE` is supported for partitioned InnoDB tables, and `ALTER TABLE ... DISCARD PARTITION ... TABLESPACE` is supported for InnoDB table partitions.
- `DISCARD TABLESPACE` is not supported for tablespaces with a parent-child (primary key-foreign key) relationship when `foreign_key_checks` is set to 1. Before discarding a tablespace for parent-child tables, set `foreign_key_checks=0`. Partitioned InnoDB tables do not support foreign keys.
- `ALTER TABLE ... IMPORT TABLESPACE` does not enforce foreign key constraints on imported data. If there are foreign key constraints between tables, all tables should be exported at the same (logical) point in time. Partitioned InnoDB tables do not support foreign keys.
- `ALTER TABLE ... IMPORT TABLESPACE` and `ALTER TABLE ... IMPORT PARTITION ... TABLESPACE` do not require a `.cfg` metadata file to import a tablespace. However, metadata checks are not performed when importing without a `.cfg` file, and a warning similar to the following is issued:

```
Message: InnoDB: IO Read error: (2, No such file or directory) Error opening '..\
test\t.cfg', will attempt to import without schema verification
1 row in set (0.00 sec)
```

The ability to import without a `.cfg` file may be more convenient when no schema mismatches are expected. Additionally, the ability to import without a `.cfg` file could be useful in crash recovery scenarios in which metadata cannot be collected from an `.ibd` file.

If no `.cfg` file is used, InnoDB uses the equivalent of a `SELECT MAX(ai_col) FROM table_name FOR UPDATE` statement to initialize the in-memory auto-increment counter that is used in assigning values for to an `AUTO_INCREMENT` column. Otherwise, the current maximum auto-increment counter value is read from the `.cfg` metadata file. For related information, see [InnoDB AUTO_INCREMENT Counter Initialization](#).

- Due to a `.cfg` metadata file limitation, schema mismatches are not reported for partition type or partition definition differences when importing tablespace files for partitioned tables. Column differences are reported.
- When running `ALTER TABLE ... DISCARD PARTITION ... TABLESPACE` and `ALTER TABLE ... IMPORT PARTITION ... TABLESPACE` on subpartitioned tables, both partition and subpartition table names are allowed. When a partition name is specified, subpartitions of that partition are included in the operation.
- Importing a tablespace file from another MySQL server instance works if both instances have GA (General Availability) status and their versions are within the same series. Otherwise, the file must have been created on the same server instance into which it is imported.
- In replication scenarios, `innodb_file_per_table` must be set to `ON` on both the master and slave.
- On Windows, InnoDB stores database, tablespace, and table names internally in lowercase. To avoid import problems on case-sensitive operating systems such as Linux and UNIX, create all databases, tablespaces, and tables using lowercase names. A convenient way to accomplish this is to add the following line to the `[mysqld]` section of your `my.cnf` or `my.ini` file before creating databases, tablespaces, or tables:

```
[mysqld]
lower_case_table_names=1
```

- `ALTER TABLE ... DISCARD TABLESPACE` and `ALTER TABLE ... IMPORT TABLESPACE` are not supported with tables that belong to an `InnoDB` general tablespace. For more information, see `CREATE TABLESPACE`.
- The default row format for `InnoDB` tables is configurable using the `innodb_default_row_format` configuration option. Attempting to import a table that does not explicitly define a row format (`ROW_FORMAT`), or that uses `ROW_FORMAT=DEFAULT`, could result in a schema mismatch error if the `innodb_default_row_format` setting on the source instance differs from the setting on the destination instance. For related information, see [Section 15.10.2, “Specifying the Row Format for a Table”](#).
- When exporting a tablespace that is encrypted using the `InnoDB` tablespace encryption feature, `InnoDB` generates a `.cfp` file in addition to a `.cfg` metadata file. The `.cfp` file must be copied to the destination instance together with the `.cfg` file and tablespace file before performing the `ALTER TABLE ... IMPORT TABLESPACE` operation on the destination instance. The `.cfp` file contains a transfer key and an encrypted tablespace key. On import, `InnoDB` uses the transfer key to decrypt the tablespace key. For related information, see [Section 15.7.10, “InnoDB Tablespace Encryption”](#).

15.7.6.1 Transportable Tablespace Examples

Note

If you are transporting tables that are encrypted using the `InnoDB` tablespace encryption, see [Limitations and Usage Notes](#) before you begin for additional procedural information.

Example 1: Copying an InnoDB Table to Another Instance

This procedure demonstrates how to copy a regular `InnoDB` table from a running MySQL server instance to another running instance. The same procedure with minor adjustments can be used to perform a full table restore on the same instance.

1. On the source instance, create a table if one does not exist:

```
mysql> use test;
mysql> CREATE TABLE t(c1 INT) engine=InnoDB;
```

2. On the destination instance, create a table if one does not exist:

```
mysql> use test;
mysql> CREATE TABLE t(c1 INT) engine=InnoDB;
```

3. On the destination instance, discard the existing tablespace. (Before a tablespace can be imported, `InnoDB` must discard the tablespace that is attached to the receiving table.)

```
mysql> ALTER TABLE t DISCARD TABLESPACE;
```

4. On the source instance, run `FLUSH TABLES ... FOR EXPORT` to quiesce the table and create the `.cfg` metadata file:

```
mysql> use test;
mysql> FLUSH TABLES t FOR EXPORT;
```

The metadata (`.cfg`) is created in the `InnoDB` data directory.

**Note**

The `FLUSH TABLES ... FOR EXPORT` statement ensures that changes to the named table have been flushed to disk so that a binary table copy can be made while the instance is running. When `FLUSH TABLES ... FOR EXPORT` is run, InnoDB produces a `.cfg` file in the same database directory as the table. The `.cfg` file contains metadata used for schema verification when importing the tablespace file.

- Copy the `.ibd` file and `.cfg` metadata file from the source instance to the destination instance. For example:

```
shell> scp /path/to/datadir/test/t.{ibd,cfg} destination-server:/path/to/datadir/test
```

**Note**

The `.ibd` file and `.cfg` file must be copied before releasing the shared locks, as described in the next step.

- On the source instance, use `UNLOCK TABLES` to release the locks acquired by `FLUSH TABLES ... FOR EXPORT`:

```
mysql> use test;
mysql> UNLOCK TABLES;
```

- On the destination instance, import the tablespace:

```
mysql> use test;
mysql> ALTER TABLE t IMPORT TABLESPACE;
```

**Note**

The `ALTER TABLE ... IMPORT TABLESPACE` feature does not enforce foreign key constraints on imported data. If there are foreign key constraints between tables, all tables should be exported at the same (logical) point in time. In this case you would stop updating the tables, commit all transactions, acquire shared locks on the tables, and then perform the export operation.

Example 2: Copying an InnoDB Partitioned Table to Another Instance

This procedure demonstrates how to copy a partitioned InnoDB table from a running MySQL server instance to another running instance. The same procedure with minor adjustments can be used to perform a full restore of a partitioned InnoDB table on the same instance.

- On the source instance, create a partitioned table if one does not exist. In the following example, a table with three partitions (p0, p1, p2) is created:

```
mysql> use test;
mysql> CREATE TABLE t1 (i int) ENGINE = InnoDB PARTITION BY KEY (i) PARTITIONS 3;
```

In the `/datadir/test` directory, there is a separate tablespace (`.ibd`) file for each of the three partitions.

```
mysql> \! ls /path/to/datadir/test/
t1#P#p0.ibd t1#P#p1.ibd t1#P#p2.ibd
```

- On the destination instance, create the same partitioned table:

```
mysql> use test;
mysql> CREATE TABLE t1 (i int) ENGINE = InnoDB PARTITION BY KEY (i) PARTITIONS 3;
```

In the `/datadir/test` directory, there is a separate tablespace (`.ibd`) file for each of the three partitions.

```
mysql> \! ls /path/to/datadir/test/
t1#P#p0.ibd t1#P#p1.ibd t1#P#p2.ibd
```

3. On the destination instance, discard the tablespace for the partitioned table. (Before the tablespace can be imported on the destination instance, the tablespace that is attached to the receiving table must be discarded.)

```
mysql> ALTER TABLE t1 DISCARD TABLESPACE;
```

The three `.ibd` files that make up the tablespace for the partitioned table are discarded from the `/datadir/test` directory.

4. On the source instance, run `FLUSH TABLES ... FOR EXPORT` to quiesce the partitioned table and create the `.cfg` metadata files:

```
mysql> use test;
mysql> FLUSH TABLES t1 FOR EXPORT;
```

Metadata (`.cfg`) files, one for each tablespace (`.ibd`) file, are created in the `/datadir/test` directory on the source instance:

```
mysql> \! ls /path/to/datadir/test/
t1#P#p0.ibd t1#P#p1.ibd t1#P#p2.ibd
t1#P#p0.cfg t1#P#p1.cfg t1#P#p2.cfg
```

Note

`FLUSH TABLES ... FOR EXPORT` statement ensures that changes to the named table have been flushed to disk so that binary table copy can be made while the instance is running. When `FLUSH TABLES ... FOR EXPORT` is run, InnoDB produces a `.cfg` metadata file for the table's tablespace files in the same database directory as the table. The `.cfg` files contain metadata used for schema verification when importing tablespace files. `FLUSH TABLES ... FOR EXPORT` can only be run on the table, not on individual table partitions.

5. Copy the `.ibd` and `.cfg` files from the source instance database directory to the destination instance database directory. For example:

```
shell> scp /path/to/datadir/test/t1*.{ibd,cfg} destination-server:/path/to/datadir/test
```

Note

The `.ibd` and `.cfg` files must be copied before releasing the shared locks, as described in the next step.

6. On the source instance, use `UNLOCK TABLES` to release the locks acquired by `FLUSH TABLES ... FOR EXPORT`:

```
mysql> use test;
mysql> UNLOCK TABLES;
```

- On the destination instance, import the tablespace for the partitioned table:

```
mysql> use test;
mysql> ALTER TABLE t1 IMPORT TABLESPACE;
```

Example 3: Copying InnoDB Table Partitions to Another Instance

This procedure demonstrates how to copy [InnoDB](#) table partitions from a running MySQL server instance to another running instance. The same procedure with minor adjustments can be used to perform a restore of [InnoDB](#) table partitions on the same instance. In the following example, a partitioned table with four partitions (p0, p1, p2, p3) is created on the source instance. Two of the partitions (p2 and p3) are copied to the destination instance.

- On the source instance, create a partitioned table if one does not exist. In the following example, a table with four partitions (p0, p1, p2, p3) is created:

```
mysql> use test;
mysql> CREATE TABLE t1 (i int) ENGINE = InnoDB PARTITION BY KEY (i) PARTITIONS 4;
```

In the `/datadir/test` directory, there is a separate tablespace (`.ibd`) file for each of the four partitions.

```
mysql> \! ls /path/to/datadir/test/
t1#P#p0.ibd t1#P#p1.ibd t1#P#p2.ibd t1#P#p3.ibd
```

- On the destination instance, create the same partitioned table:

```
mysql> use test;
mysql> CREATE TABLE t1 (i int) ENGINE = InnoDB PARTITION BY KEY (i) PARTITIONS 4;
```

In the `/datadir/test` directory, there is a separate tablespace (`.ibd`) file for each of the four partitions.

```
mysql> \! ls /path/to/datadir/test/
t1#P#p0.ibd t1#P#p1.ibd t1#P#p2.ibd t1#P#p3.ibd
```

- On the destination instance, discard the tablespace partitions that you plan to import from the source instance. (Before tablespace partitions can be imported on the destination instance, the corresponding partitions that are attached to the receiving table must be discarded.)

```
mysql> ALTER TABLE t1 DISCARD PARTITION p2, p3 TABLESPACE;
```

The `.ibd` files for the two discarded partitions are removed from the `/datadir/test` directory on the destination instance, leaving the following files:

```
mysql> \! ls /path/to/datadir/test/
t1#P#p0.ibd t1#P#p1.ibd
```

Note

When `ALTER TABLE ... DISCARD PARTITION ... TABLESPACE` is run on subpartitioned tables, both partition and subpartition table names are allowed. When a partition name is specified, subpartitions of that partition are included in the operation.

- On the source instance, run `FLUSH TABLES ... FOR EXPORT` to quiesce the partitioned table and create the `.cfg` metadata files.

```
mysql> use test;
mysql> FLUSH TABLES t1 FOR EXPORT;
```

The metadata files (`.cfg` files) are created in the `/datadir/test` directory on the source instance. There is a `.cfg` file for each tablespace (`.ibd`) file.

```
mysql> \! ls /path/to/datadir/test/
t1#P#p0.ibd  t1#P#p1.ibd  t1#P#p2.ibd  t1#P#p3.ibd
t1#P#p0.cfg  t1#P#p1.cfg  t1#P#p2.cfg  t1#P#p3.cfg
```

Note

`FLUSH TABLES ... FOR EXPORT` statement ensures that changes to the named table have been flushed to disk so that binary table copy can be made while the instance is running. When `FLUSH TABLES ... FOR EXPORT` is run, InnoDB produces a `.cfg` metadata file for the table's tablespace files in the same database directory as the table. The `.cfg` files contain metadata used for schema verification when importing tablespace files. `FLUSH TABLES ... FOR EXPORT` can only be run on the table, not on individual table partitions.

- Copy the `.ibd` and `.cfg` files from the source instance database directory to the destination instance database directory. In this example, only the `.ibd` and `.cfg` files for partition 2 (p2) and partition 3 (p3) are copied to the `data` directory on the destination instance. Partition 0 (p0) and partition 1 (p1) remain on the source instance.

```
shell> scp t1#P#p2.ibd t1#P#p2.cfg t1#P#p3.ibd t1#P#p3.cfg destination-server:/path/to/datadir/test
```

Note

The `.ibd` files and `.cfg` files must be copied before releasing the shared locks, as described in the next step.

- On the source instance, use `UNLOCK TABLES` to release the locks acquired by `FLUSH TABLES ... FOR EXPORT`:

```
mysql> use test;
mysql> UNLOCK TABLES;
```

- On the destination instance, import the tablespace partitions (p2 and p3):

```
mysql> use test;
mysql> ALTER TABLE t1 IMPORT PARTITION p2, p3 TABLESPACE;
```

Note

When `ALTER TABLE ... IMPORT PARTITION ... TABLESPACE` is run on subpartitioned tables, both partition and subpartition table names are allowed. When a partition name is specified, subpartitions of that partition are included in the operation.

15.7.6.2 Transportable Tablespace Internals

The following information describes internals and error log messaging for the transportable tablespaces copy procedure for a regular InnoDB table.

When `ALTER TABLE ... DISCARD TABLESPACE` is run on the destination instance:

- The table is locked in X mode.

- The tablespace is detached from the table.

When `FLUSH TABLES ... FOR EXPORT` is run on the source instance:

- The table being flushed for export is locked in shared mode.
- The purge coordinator thread is stopped.
- Dirty pages are synchronized to disk.
- Table metadata is written to the binary `.cfg` file.

Expected error log messages for this operation:

```
2013-09-24T13:10:19.903526Z 2 [Note] InnoDB: Sync to disk of '"test"."t"' started.
2013-09-24T13:10:19.903586Z 2 [Note] InnoDB: Stopping purge
2013-09-24T13:10:19.903725Z 2 [Note] InnoDB: Writing table metadata to './test/t.cfg'
2013-09-24T13:10:19.904014Z 2 [Note] InnoDB: Table '"test"."t"' flushed to disk
```

When `UNLOCK TABLES` is run on the source instance:

- The binary `.cfg` file is deleted.
- The shared lock on the table or tables being imported is released and the purge coordinator thread is restarted.

Expected error log messages for this operation:

```
2013-09-24T13:10:21.181104Z 2 [Note] InnoDB: Deleting the meta-data file './test/t.cfg'
2013-09-24T13:10:21.181180Z 2 [Note] InnoDB: Resuming purge
```

When `ALTER TABLE ... IMPORT TABLESPACE` is run on the destination instance, the import algorithm performs the following operations for each tablespace being imported:

- Each tablespace page is checked for corruption.
- The space ID and log sequence numbers (LSNs) on each page are updated
- Flags are validated and LSN updated for the header page.
- Btree pages are updated.
- The page state is set to dirty so that it is written to disk.

Expected error log messages for this operation:

```
2013-07-18 15:15:01 34960 [Note] InnoDB: Importing tablespace for table 'test/t' that was exported from
2013-07-18 15:15:01 34960 [Note] InnoDB: Phase I - Update all pages
2013-07-18 15:15:01 34960 [Note] InnoDB: Sync to disk
2013-07-18 15:15:01 34960 [Note] InnoDB: Sync to disk - done!
2013-07-18 15:15:01 34960 [Note] InnoDB: Phase III - Flush changes to disk
2013-07-18 15:15:01 34960 [Note] InnoDB: Phase IV - Flush complete
```

Note

You may also receive a warning that a tablespace is discarded (if you discarded the tablespace for the destination table) and a message stating that statistics could not be calculated due to a missing `.ibd` file:

```
2013-07-18 15:14:38 34960 [Warning] InnoDB: Table "test"."t" tablespace is set as disc
2013-07-18 15:14:38 7f34d9a37700 InnoDB: cannot calculate statistics for table "test"
http://dev.mysql.com/doc/refman/5.8/en/innodb-troubleshooting.html
```

15.7.7 Storing InnoDB Undo Logs in Separate Tablespaces

Undo logs may be stored in one or more [undo tablespaces](#) instead of the [system tablespace](#). The I/O patterns for undo logs make undo tablespaces good candidates for [SSD](#) storage, while keeping the system tablespace on hard disk storage. Undo tablespaces or individual [segments](#) inside those tablespaces cannot be dropped. However, undo logs stored in undo tablespaces can be truncated. For more information, see [Section 15.7.8, “Truncating Undo Logs That Reside in Undo Tablespaces”](#).

Important

Prior to MySQL 8.0.2, the number of undo tablespaces may only be configured when initializing a new MySQL instance, as the [innodb_undo_tablespaces](#) option can only be set at initialization time. As of 8.0.2, [innodb_undo_tablespaces](#) may be set at startup or while the server is running.

To configure separate undo tablespaces for a MySQL instance, perform the following steps. It is assumed that you are performing the procedure on a test instance prior to deploying the configuration to a production system.

1. Specify a directory location for undo tablespaces using the [innodb_undo_directory](#) configuration option. If a directory location is not specified, undo tablespaces are created in the MySQL data directory.
2. Define the number of rollback segments using the [innodb_rollback_segments](#) configuration option. Start with a relatively low value and increase it incrementally over time to examine the effect on performance. The default setting for [innodb_rollback_segments](#) is 128, which is also the maximum value.
 - Prior to MySQL 8.0.2, one rollback segment is always assigned to the system tablespace. Therefore, to allocate rollback segments to undo tablespaces, set [innodb_rollback_segments](#) to a value greater than 1. For example, if you have two undo tablespaces, set [innodb_rollback_segments](#) to 3 to assign one rollback segment to each of the two undo tablespaces. Rollback segments are distributed among undo tablespaces in a circular fashion.
 - As of MySQL 8.0.2, [innodb_rollback_segments](#) defines the number of rollback segments allocated to each undo tablespace.

When you configure separate undo tablespaces, rollback segments in the system tablespace are rendered inactive.

3. Define the number of undo tablespaces using the [innodb_undo_tablespaces](#) option.
 - Prior to MySQL 8.0.2, the [innodb_undo_tablespaces](#) value can only be set when initializing the MySQL instance and cannot be changed afterward, so if you are uncertain about the optimal value, estimate on the high side.
 - As of MySQL 8.0.2, [innodb_undo_tablespaces](#) can be configured at startup or while the server is running.
4. If you are using MySQL 8.0.1 or earlier, create a new MySQL test instance using the option values you have chosen.
5. Use a realistic workload on your test instance with data volume similar to your production servers to test the configuration.
6. Benchmark the performance of I/O intensive workloads.
7. Periodically increase the value of [innodb_rollback_segments](#) and rerun performance tests until there are no further improvements in I/O performance.

15.7.8 Truncating Undo Logs That Reside in Undo Tablespaces

To truncate [undo logs](#) that reside in [undo tablespaces](#), the MySQL instance must be configured with a minimum of two undo tablespaces. A minimum of two undo tablespaces ensures that one undo tablespace remains active while the other is taken offline to be truncated. The number of undo tablespaces is defined by the `innodb_undo_tablespaces` option. The default value is 2 as of MySQL 8.0.2, and 0 before that. Use this statement to check the value of `innodb_undo_tablespaces`:

```
mysql> SELECT @@innodb_undo_tablespaces;
+-----+
| @@innodb_undo_tablespaces |
+-----+
|                2 |
+-----+
```

For information about configuring undo tablespaces, see [Section 15.7.7, “Storing InnoDB Undo Logs in Separate Tablespaces”](#).

Enabling Truncation of Undo Tablespaces

To truncate undo logs that reside in undo tablespaces, enable `innodb_undo_log_truncate`.

```
mysql> SET GLOBAL innodb_undo_log_truncate=ON;
```

When `innodb_undo_log_truncate` is enabled, undo tablespace files that exceed the size limit defined by `innodb_max_undo_log_size` are marked for truncation. `innodb_max_undo_log_size` is a dynamic global variable with a default value of 1024 MiB (1073741824 bytes).

```
mysql> SELECT @@innodb_max_undo_log_size;
+-----+
| @@innodb_max_undo_log_size |
+-----+
|          1073741824 |
+-----+
```

You can configure `innodb_max_undo_log_size` using a `SET GLOBAL` statement:

```
mysql> SET GLOBAL innodb_max_undo_log_size=2147483648;
```

When `innodb_undo_log_truncate` is enabled:

1. Undo tablespaces that exceed the `innodb_max_undo_log_size` setting are marked for truncation. Selection of an undo tablespace for truncation is performed in a circular fashion to avoid truncating the same undo tablespace each time.
2. Rollback segments residing in the selected undo tablespace are made inactive so that they are not assigned to new transactions. Existing transactions that are currently using rollback segments are allowed to complete.
3. The [purge](#) system frees rollback segments that are no longer needed.
4. After all rollback segments in the undo tablespace are freed, the truncate operation runs and the undo tablespace is truncated to its initial size. The initial size of an undo tablespace file is 10MiB.

Note

The size of an undo tablespace after a truncate operation may be larger than 10MiB due to immediate use following the completion of the operation. The `innodb_undo_directory` option defines the location of undo tablespace files. The default value of “.” represents the directory where InnoDB creates other log files by default.

```
mysql> SELECT @@innodb_undo_directory;
+-----+
| @@innodb_undo_directory |
+-----+
| . |
+-----+
```

5. The rollback segments are reactivated so that they can be assigned to new transactions.

Expediting Truncation of Undo Tablespace Files

An undo tablespace cannot be truncated until its rollback segments are freed. Normally, the purge system frees rollback segments once every 128 times that purge is invoked. To expedite the truncation of undo tablespaces, use the `innodb_purge_rseg_truncate_frequency` option to temporarily increase the frequency with which the purge system frees rollback segments. The default `innodb_purge_rseg_truncate_frequency` setting is 128, which is also the maximum value.

```
mysql> SELECT @@innodb_purge_rseg_truncate_frequency;
+-----+
| @@innodb_purge_rseg_truncate_frequency |
+-----+
| 128 |
+-----+
```

To increase the frequency with which the purge thread frees rollback segments, decrease the value of `innodb_purge_rseg_truncate_frequency`. For example:

```
mysql> SET GLOBAL innodb_purge_rseg_truncate_frequency=32;
```

Performance Impact of Truncating Undo Tablespace Files Online

While an undo tablespace is truncated, rollback segments in that tablespace are temporarily deactivated. The remaining active rollback segments in the other undo tablespaces assume responsibility for the entire system load, which may result in a slight performance degradation. The degree of performance degradation depends on a number of factors including:

- Number of undo tablespaces
- Number of undo logs
- Undo tablespace size
- Speed of the I/O subsystem
- Existing long running transactions
- System load

15.7.9 InnoDB General Tablespaces

A general tablespace is a shared `InnoDB` tablespace that is created using `CREATE TABLESPACE` syntax. General tablespace capabilities and features are described under the following topics in this section:

- [General Tablespace Capabilities](#)
- [Creating a General Tablespace](#)
- [Adding Tables to a General Tablespace](#)
- [General Tablespace Row Format Support](#)

- [Moving Non-Partitioned Tables Between Tablespaces Using ALTER TABLE](#)
- [General Tablespace Table Partition Support](#)
- [Moving Table Partitions Between Tablespaces Using ALTER TABLE](#)
- [Dropping a General Tablespace](#)
- [General Tablespace Limitations](#)

General Tablespace Capabilities

The general tablespace feature provides the following capabilities:

- Similar to the system tablespace, general tablespaces are shared tablespaces that can store data for multiple tables.
- General tablespaces have a potential memory advantage over [file-per-table tablespaces](#). The server keeps tablespace metadata in memory for the lifetime of a tablespace. Multiple tables in fewer general tablespaces consume less memory for tablespace metadata than the same number of tables in separate file-per-table tablespaces.
- General tablespace data files may be placed in a directory relative to or independent of the MySQL data directory, which provides you with many of the data file and storage management capabilities of [file-per-table tablespaces](#). As with file-per-table tablespaces, the ability to place data files outside of the MySQL data directory allows you to manage performance of critical tables separately, setup RAID or DRBD for specific tables, or bind tables to particular disks, for example.
- General tablespaces support both Antelope and Barracuda file formats, and therefore support all table row formats and associated features. With support for both file formats, general tablespaces have no dependence on `innodb_file_format` or `innodb_file_per_table` settings, nor do these variables have any effect on general tablespaces.
- The `TABLESPACE` option can be used with `CREATE TABLE` to create tables in a general tablespaces, file-per-table tablespace, or in the system tablespace.
- The `TABLESPACE` option can be used with `ALTER TABLE` to move tables between general tablespaces, file-per-table tablespaces, and the system tablespace. Previously, it was not possible to move a table from a file-per-table tablespace to the system tablespace. With the general tablespace feature, you can now do so.

Creating a General Tablespace

General tablespaces are created using `CREATE TABLESPACE` syntax.

```
CREATE TABLESPACE tablespace_name
  ADD DATAFILE 'file_name'
  [FILE_BLOCK_SIZE = value]
  [ENGINE [=] engine_name]
```

A general tablespace may be created in the MySQL data directory or in a directory outside of the MySQL data directory. To avoid conflicts with implicitly created file-per-table tablespaces, creating a general tablespace in a subdirectory under the MySQL data directory is not supported. Also, when creating a general tablespace outside of the MySQL data directory, the directory must exist prior to creating the tablespace.

Examples:

Creating a general tablespace in the MySQL data directory:

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
```

Creating a general tablespace in a directory outside of the MySQL data directory:

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE '/my/tablespace/directory/ts1.ibd' Engine=InnoDB;
```

You can specify a path that is relative to the MySQL data directory as long as the tablespace directory is not under the MySQL data directory. In this example, the `my_tablespace` directory is at the same level as the MySQL data directory:

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE '../my_tablespace/ts1.ibd' Engine=InnoDB;
```

Note

The `ENGINE = InnoDB` clause must be defined as part of the `CREATE TABLESPACE` statement or `InnoDB` must be defined as the default storage engine (`default_storage_engine=InnoDB`).

Adding Tables to a General Tablespace

After creating an InnoDB general tablespace, you can use `CREATE TABLE tbl_name ... TABLESPACE [=] tablespace_name` or `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` to add tables to the tablespace, as shown in the following examples:

CREATE TABLE:

```
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=COMPACT;
```

ALTER TABLE:

```
mysql> ALTER TABLE t2 TABLESPACE ts1;
```

For detailed syntax information, see `CREATE TABLE` and `ALTER TABLE`.

General Tablespace Row Format Support

General tablespaces support all table row formats (`REDUNDANT`, `COMPACT`, `DYNAMIC`, `COMPRESSED`) with the caveat that compressed and uncompressed tables cannot coexist in the same general tablespace due to different physical page sizes.

For a general tablespace to contain compressed tables (`ROW_FORMAT=COMPRESSED`), `FILE_BLOCK_SIZE` must be specified, and the `FILE_BLOCK_SIZE` value must be a valid compressed page size in relation to the `innodb_page_size` value. Also, the physical page size of the compressed table (`KEY_BLOCK_SIZE`) must be equal to `FILE_BLOCK_SIZE/1024`. For example, if `innodb_page_size=16K` and `FILE_BLOCK_SIZE=8K`, the `KEY_BLOCK_SIZE` of the table must be 8.

The following table shows permitted `FILE_BLOCK_SIZE` and `KEY_BLOCK_SIZE` values for each `innodb_page_size` value. `FILE_BLOCK_SIZE` values may also be specified in bytes. To determine a valid `KEY_BLOCK_SIZE` value for a given `FILE_BLOCK_SIZE`, divide the `FILE_BLOCK_SIZE` value by 1024. Table compression is not support for 32K and 64K InnoDB page sizes. For more information about `KEY_BLOCK_SIZE`, see `CREATE TABLE`, and [Section 15.9.1.2, “Creating Compressed Tables”](#).

Table 15.5 FILE_BLOCK_SIZE and KEY_BLOCK_SIZE Values for CREATE TABLESPACE

InnoDB Page Size (<code>innodb_page_size</code>)	Permitted FILE_BLOCK_SIZE Values	Permitted KEY_BLOCK_SIZE Values
64K	64K (65536)	Compression is not supported
32K	32K (32768)	Compression is not supported
16K	16K (16384)	N/A: If <code>innodb_page_size</code> is equal to <code>FILE_BLOCK_SIZE</code> , the tablespace cannot contain a compressed table.
	8K (8192)	8
	4K (4096)	4
	2K (2048)	2

InnoDB Page Size (<code>innodb_page_size</code>)	Permitted <code>FILE_BLOCK_SIZE</code> Values	Permitted <code>KEY_BLOCK_SIZE</code> Values
	1K (1024)	1
8K	8K (8192)	N/A: If <code>innodb_page_size</code> is equal to <code>FILE_BLOCK_SIZE</code> , the tablespace cannot contain a compressed table.
	4K (4096)	4
	2K (2048)	2
	1K (1024)	1
4K	4K (4096)	N/A: If <code>innodb_page_size</code> is equal to <code>FILE_BLOCK_SIZE</code> , the tablespace cannot contain a compressed table.
	2K (2048)	2
	1K (1024)	1

This example demonstrates creating a general tablespace and adding a compressed table. The example assumes a default `innodb_page_size` of 16K. The `FILE_BLOCK_SIZE` of 8192 requires that the compressed table have a `KEY_BLOCK_SIZE` of 8.

```
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t4 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED
KEY_BLOCK_SIZE=8;
Query OK, 0 rows affected (0.00 sec)
```

If you do not specify `FILE_BLOCK_SIZE` when creating a general tablespace, `FILE_BLOCK_SIZE` defaults to `innodb_page_size`. When `FILE_BLOCK_SIZE` is equal to `innodb_page_size`, the tablespace may only contain tables with an uncompressed row format (`COMPACT`, `REDUNDANT`, and `DYNAMIC` row formats).

Moving Non-Partitioned Tables Between Tablespaces Using ALTER TABLE

You can use `ALTER TABLE` with the `TABLESPACE` option to move a non-partitioned InnoDB table to an existing general tablespace, to a new file-per-table tablespace, or to the system tablespace.

To move a non-partitioned table from a file-per-table tablespace or from the system tablespace to a general tablespace, specify the name of the general tablespace. The general tablespace must exist. See `CREATE TABLESPACE` for more information.

```
ALTER TABLE tbl_name TABLESPACE [=] tablespace_name
```

To move a non-partitioned table from a general tablespace or file-per-table tablespace to the system tablespace, specify `innodb_system` as the tablespace name.

```
ALTER TABLE tbl_name ... TABLESPACE [=] innodb_system
```

To move a non-partitioned table from the system tablespace or a general tablespace to a file-per-table tablespace, specify `innodb_file_per_table` as the tablespace name.

```
ALTER TABLE tbl_name ... TABLESPACE [=] innodb_file_per_table
```

`ALTER TABLE ... TABLESPACE` operations always cause a full table rebuild, even if the `TABLESPACE` attribute has not changed from its previous value.

`ALTER TABLE ... TABLESPACE` syntax does not support moving a table from a temporary tablespace to a persistent tablespace.

The `DATA DIRECTORY` clause is permitted with `CREATE TABLE ... TABLESPACE=innodb_file_per_table` but is otherwise not supported for use in combination with the `TABLESPACE` option.

General Tablespace Table Partition Support

The `TABLESPACE` option may be used to assign individual table partitions or subpartitions to a [general tablespace](#), a separate file-per-table tablespace, or the system tablespace. All partitions must belong to the same storage engine. Usage is demonstrated in the following examples.

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' Engine=InnoDB;

mysql> CREATE TABLE t1 (a INT, b INT) ENGINE = InnoDB
-> PARTITION BY RANGE(a) SUBPARTITION BY KEY(b) (
-> PARTITION p1 VALUES LESS THAN (100) TABLESPACE=`ts1`,
-> PARTITION p2 VALUES LESS THAN (1000) TABLESPACE=`ts2`,
-> PARTITION p3 VALUES LESS THAN (10000) TABLESPACE `innodb_file_per_table`,
-> PARTITION p4 VALUES LESS THAN (100000) TABLESPACE `innodb_system`);

mysql> CREATE TABLE t2 (a INT, b INT) ENGINE = InnoDB
-> PARTITION BY RANGE(a) SUBPARTITION BY KEY(b) (
-> PARTITION p1 VALUES LESS THAN (100) TABLESPACE=`ts1`
-> (SUBPARTITION sp1,
-> SUBPARTITION sp2),
-> PARTITION p2 VALUES LESS THAN (1000)
-> (SUBPARTITION sp3,
-> SUBPARTITION sp4 TABLESPACE=`ts2`),
-> PARTITION p3 VALUES LESS THAN (10000)
-> (SUBPARTITION sp5 TABLESPACE `innodb_system`,
-> SUBPARTITION sp6 TABLESPACE `innodb_file_per_table`));
```

The `TABLESPACE` option is also supported with `ALTER TABLE`.

```
mysql> ALTER TABLE t1 ADD PARTITION (PARTITION p5 VALUES LESS THAN (1000000) TABLESPACE = `ts1`);
```

Note

If the `TABLESPACE = tablespace_name` option is not defined, the `ALTER TABLE ... ADD PARTITION` operation adds the partition to the table's default tablespace, which can be specified at the table level during `CREATE TABLE` or `ALTER TABLE`.

An `ALTER TABLE tbl_name TABLESPACE [=] tablespace_name` operation on a *partitioned* table only modifies the table's default tablespace. It does not move the table partitions. However, after changing the default tablespace, an operation that rebuilds the table, such as an `ALTER TABLE` operation that uses `ALGORITHM=COPY`, moves the partitions to the default tablespace if another tablespace is not defined explicitly using the `TABLESPACE [=] tablespace_name` clause.

To verify that partitions were placed in the specified tablespaces, you can query `INFORMATION_SCHEMA.INNODB_SYS_TABLES`:

```
mysql> SELECT NAME, SPACE, SPACE_TYPE FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES
-> WHERE NAME LIKE '%t1%';
+-----+-----+-----+
| NAME                                | SPACE | SPACE_TYPE |
+-----+-----+-----+
| test/t1#P#p1#SP#p1sp0               | 57    | General    |

| test/t1#P#p5#SP#p5sp0               | 57    | General    |
+-----+-----+-----+

mysql> SELECT NAME, SPACE, SPACE_TYPE FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES
```

```
-> WHERE NAME LIKE '%t2%';
```

NAME	SPACE	SPACE_TYPE
test/t2#P#p1#SP#sp1	57	General
test/t2#P#p1#SP#sp2	57	General
test/t2#P#p2#SP#sp3	60	Single
test/t2#P#p2#SP#sp4	58	General
test/t2#P#p3#SP#sp5	0	System
test/t2#P#p3#SP#sp6	61	Single

Moving Table Partitions Between Tablespaces Using ALTER TABLE

To move table partitions to a different tablespace, you must move each partition using an `ALTER TABLE tbl_name REORGANIZE PARTITION` statement.

The following example demonstrates how to move table partitions to a different tablespace. `INFORMATION_SCHEMA.INNODB_SYS_TABLES` and `INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES` are queried to verify that partitions are placed in the expected tablespace.

Note

If the `TABLESPACE = tablespace_name` option is not defined in the `REORGANIZE PARTITION` statement, InnoDB moves the partition to the table's default tablespace. In the example that follows, tablespace `ts1`, which is defined at the table level, is the default tablespace for table `t1`. Partition `P3` is moved from the system tablespace to tablespace `ts1` since no `TABLESPACE` option is specified in the `ALTER TABLE t1 REORGANIZE PARTITION` statement for partition `P3`.

An operation that rebuilds the table, such as an `ALTER TABLE` operation that uses `ALGORITHM=COPY`, moves partitions to the default tablespace if partitions reside in a different tablespace that is not defined explicitly using the `TABLESPACE [=] tablespace_name` clause.

```
mysql> CREATE TABLESPACE ts1 ADD DATAFILE 'ts1.ibd';
mysql> CREATE TABLESPACE ts2 ADD DATAFILE 'ts2.ibd';

mysql> CREATE TABLE t1 ( a INT NOT NULL, PRIMARY KEY (a)
-> ENGINE=InnoDB TABLESPACE ts1
-> PARTITION BY RANGE (a) PARTITIONS 3 (
-> PARTITION P1 VALUES LESS THAN (2),
-> PARTITION P2 VALUES LESS THAN (4) TABLESPACE `innodb_file_per_table`,
-> PARTITION P3 VALUES LESS THAN (6) TABLESPACE `innodb_system`);

mysql> SELECT A.NAME as partition_name, A.SPACE_TYPE as space_type, B.NAME as space_name
-> FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES A
-> LEFT JOIN INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES B
-> ON A.SPACE = B.SPACE WHERE A.NAME LIKE '%t1%' ORDER BY A.NAME;
```

partition_name	space_type	space_name
test/t1#P#P1	General	ts1
test/t1#P#P2	Single	test/t1#P#P2
test/t1#P#P3	System	NULL

```
mysql> ALTER TABLE t1 REORGANIZE PARTITION P1
-> INTO (PARTITION P1 VALUES LESS THAN (2) TABLESPACE = `ts2`);

mysql> ALTER TABLE t1 REORGANIZE PARTITION P2
-> INTO (PARTITION P2 VALUES LESS THAN (4) TABLESPACE = `ts2`);

mysql> ALTER TABLE t1 REORGANIZE PARTITION P3
```

```
-> INTO (PARTITION P3 VALUES LESS THAN (6));

mysql> SELECT A.NAME AS partition_name, A.SPACE_TYPE AS space_type, B.NAME AS space_name
-> FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES A
-> LEFT JOIN INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES B
-> ON A.SPACE = B.SPACE WHERE A.NAME LIKE '%t1%' ORDER BY A.NAME;
```

partition_name	space_type	space_name
test/t1#P#P1	General	ts2
test/t1#P#P2	General	ts2
test/t1#P#P3	General	ts1

Dropping a General Tablespace

The `DROP TABLESPACE` statement is used to drop an InnoDB general tablespace.

All tables must be dropped from the tablespace prior to a `DROP TABLESPACE` operation. If the tablespace is not empty, `DROP TABLESPACE` returns an error.

A general InnoDB tablespace is not deleted automatically when the last table in the tablespace is dropped. The tablespace must be dropped explicitly using `DROP TABLESPACE tablespace_name`.

A general tablespace does not belong to any particular database. A `DROP DATABASE` operation can drop tables that belong to a general tablespace but it cannot drop the tablespace, even if the `DROP DATABASE` operation drops all tables that belong to the tablespace. A general tablespace must be dropped explicitly using `DROP TABLESPACE tablespace_name`.

Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace `.ibd data file` which can only be used for new InnoDB data. Space is not released back to the operating system as it is when a file-per-table tablespace is deleted during a `DROP TABLE` operation.

This example demonstrates how to drop an InnoDB general tablespace. The general tablespace `ts1` is created with a single table. The table must be dropped before dropping the tablespace.

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 Engine=InnoDB;
Query OK, 0 rows affected (0.02 sec)

mysql> DROP TABLE t1;
Query OK, 0 rows affected (0.01 sec)

mysql> DROP TABLESPACE ts1;
Query OK, 0 rows affected (0.01 sec)
```

Note

`tablespace_name` is a case-sensitive identifier in MySQL.

General Tablespace Limitations

- A generated or existing tablespace cannot be changed to a general tablespace.
- Creation of temporary general tablespaces is not supported.
- General tablespaces do not support temporary tables.
- Similar to the system tablespace, truncating or dropping tables stored in a general tablespace creates free space internally in the general tablespace `.ibd data file` which can only be used for new InnoDB data. Space is not released back to the operating system as it is for `file-per-table` tablespaces.

Additionally, a table-copying `ALTER TABLE` operation on table that resides in a shared tablespace (a general tablespace or the system tablespace) can increase the amount of space used by the tablespace. Such operations require as much additional space as the data in the table plus indexes. The additional space required for the table-copying `ALTER TABLE` operation is not released back to the operating system as it is for file-per-table tablespaces.

- `ALTER TABLE ... DISCARD TABLESPACE` and `ALTER TABLE ... IMPORT TABLESPACE` are not supported for tables that belong to a general tablespace.

For more information see [Section 13.1.16, “CREATE TABLESPACE Syntax”](#).

15.7.10 InnoDB Tablespace Encryption

InnoDB supports data encryption for InnoDB tables stored in [file-per-table](#) tablespaces. This feature provides at-rest encryption for physical tablespace data files.

InnoDB tablespace encryption uses a two tier encryption key architecture, consisting of a master encryption key and tablespace keys. When an InnoDB table is encrypted, a tablespace key is encrypted and stored in the tablespace header. When an application or authenticated user wants to access encrypted tablespace data, InnoDB uses the master encryption key to decrypt the tablespace key. The master encryption key is stored in a `keyring` file in the location specified by the `keyring_file_data` configuration option. The decrypted version of a tablespace key never changes, but the master encryption key may be changed as required. This action is referred to as *master key rotation*.

The InnoDB tablespace encryption feature relies on a keyring plugin for master encryption key management.

InnoDB tablespace encryption supports the Advanced Encryption Standard (AES) block-based encryption algorithm. It uses Electronic Codebook (ECB) block encryption mode for tablespace key encryption and Cipher Block Chaining (CBC) block encryption mode for data encryption.

Note

The InnoDB tablespace encryption feature provided with MySQL Community Edition is not intended as a regulatory compliance solution. Security standards such as PCI, FIPS, and others require use of key management systems to secure, manage, and protect keys in key vaults or hardware security modules (HSMs).

For frequently asked questions about the InnoDB tablespace encryption feature, see [Section A.15, “MySQL 8.0 FAQ: InnoDB Tablespace Encryption”](#).

InnoDB Tablespace Encryption Prerequisites

- The `keyring_file` plugin must be installed. Keyring plugin installation is performed at startup using the `--early-plugin-load` option. Early loading ensures that the plugin is available prior to initialization of the InnoDB storage engine. For keyring plugin installation and configuration instructions, see [Section 6.5.4, “The MySQL Keyring”](#).

Important

Once encrypted tables are created in a MySQL instance, the keyring plugin must continue to be loaded using the `early-plugin-load` option, prior to InnoDB initialization. Failing to do so results in errors on startup and during InnoDB recovery.

To verify that the keyring plugin is active, use the `SHOW PLUGINS` statement or query the `INFORMATION_SCHEMA.PLUGINS` table. For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
       FROM INFORMATION_SCHEMA.PLUGINS
       WHERE PLUGIN_NAME LIKE 'keyring%';
+-----+-----+
| PLUGIN_NAME | PLUGIN_STATUS |
+-----+-----+
| keyring_file | ACTIVE        |
+-----+-----+
```

- The `innodb_file_per_table` option must be enabled (the default). InnoDB tablespace encryption only supports [file-per-table](#) tablespaces. Alternatively, you can specify the `TABLESPACE='innodb_file_per_table'` option when creating an encrypted table or altering an existing table to enable encryption.
- Before using the InnoDB tablespace encryption feature, ensure that you have taken steps to prevent loss of the master encryption key. *If the master encryption key is lost, data stored in encrypted tablespace files is unrecoverable.* It is recommended that you create a backup of the `keyring` file immediately after creating the first encrypted table and before and after master key rotation. The `keyring` file location is defined by the `keyring_file_data` configuration option. For keyring plugin configuration information, see [Section 6.5.4, “The MySQL Keyring”](#).

Enabling and Disabling InnoDB Tablespace Encryption

To enable encryption for a new InnoDB table, specify the `ENCRYPTION` option in a `CREATE TABLE` statement.

```
mysql> CREATE TABLE t1 (c1 INT) ENCRYPTION='Y';
```

To enable encryption for an existing InnoDB table, specify the `ENCRYPTION` option in an `ALTER TABLE` statement.

```
mysql> ALTER TABLE t1 ENCRYPTION='Y';
```

To disable encryption for an InnoDB table, set `ENCRYPTION='N'` using `ALTER TABLE`.

```
mysql> ALTER TABLE t1 ENCRYPTION='N';
```

Note

Plan appropriately when altering an existing table with the `ENCRYPTION` option. `ALTER TABLE ... ENCRYPTION` operations rebuild the table using `ALGORITHM=COPY`. `ALGORITHM=INPLACE` is not supported.

Redo Log Data Encryption

Redo log data encryption is enabled using the `innodb_redo_log_encrypt` configuration option. Redo log encryption is disabled by default.

As with tablespace data, redo log data encryption occurs when redo log data is written to disk, and decryption occurs when redo log data is read from disk. Once redo log data is read into memory, it is in unencrypted form. Redo log data is encrypted and decrypted using the tablespace encryption key.

When `innodb_redo_log_encrypt` is enabled, unencrypted redo log pages that are present on disk remain unencrypted, and new redo log pages are written to disk in encrypted form. Likewise, when `innodb_redo_log_encrypt` is disabled, encrypted redo log pages that are present on disk remain encrypted, and new redo log pages are written to disk in unencrypted form.

Redo log encryption metadata, including the tablespace encryption key, is stored in the header of the first redo log file (`ib_logfile0`). If this file is removed, redo log encryption is disabled.

Once redo log encryption is enabled, a normal restart without the keyring plugin or without the encryption key is not possible, as InnoDB must be able to scan redo pages during startup, which is not

possible if redo log pages are encrypted. Without the keyring plugin or the encryption key, only a forced startup without the redo logs (`SRV_FORCE_NO_LOG_REDO`) is possible. See [Section 15.20.2, “Forcing InnoDB Recovery”](#).

Undo Log Data Encryption

Undo log data encryption is enabled using the `innodb_undo_log_encrypt` configuration option. Undo log encryption only applies undo logs that reside in separate [undo tablespaces](#). See [Section 15.7.7, “Storing InnoDB Undo Logs in Separate Tablespaces”](#). Encryption is not supported for undo log data that resides in the system tablespace. Undo log data encryption is disabled by default.

As with tablespace data, undo log data encryption occurs when undo log data is written to disk, and decryption occurs when undo log data is read from disk. Once undo log data is read into memory, it is in unencrypted form. Undo log data is encrypted and decrypted using the tablespace encryption key.

When `innodb_undo_log_encrypt` is enabled, unencrypted undo log pages that are present on disk remain unencrypted, and new undo log pages are written to disk in encrypted form. Likewise, when `innodb_undo_log_encrypt` is disabled, encrypted undo log pages that are present on disk remain encrypted, and new undo log pages are written to disk in unencrypted form.

Undo log encryption metadata, including the tablespace encryption key, is stored in the header of the undo log file (`undoN.ibd`, where *N* is the space ID).

InnoDB Tablespace Encryption and Master Key Rotation

The master encryption key should be rotated periodically and whenever you suspect that the key may have been compromised.

Master key rotation is an atomic, instance-level operation. Each time the master encryption key is rotated, all tablespace keys in the MySQL instance are re-encrypted and saved back to their respective tablespace headers. As an atomic operation, re-encryption must succeed for all tablespace keys once a rotation operation is initiated. If master key rotation is interrupted by a server failure, [InnoDB](#) rolls the operation forward on server restart. For more information, see [InnoDB Tablespace Encryption and Recovery](#).

Rotating the master encryption key only changes the master encryption key and re-encrypts tablespace keys. It does not decrypt or re-encrypt associated tablespace data.

Rotating the master encryption key requires the `ENCRYPTION_KEY_ADMIN` or `SUPER` privilege.

To rotate the master encryption key, run:

```
mysql> ALTER INSTANCE ROTATE INNODB MASTER KEY;
```

`ALTER INSTANCE ROTATE INNODB MASTER KEY` supports concurrent DML. However, it cannot be run concurrently with `CREATE TABLE ... ENCRYPTED` or `ALTER TABLE ... ENCRYPTED` operations, and locks are taken to prevent conflicts that could arise from concurrent execution of these statements. If one of the conflicting statements is running, it must complete before another can proceed.

InnoDB Tablespace Encryption and Recovery

If a server failure occurs during master key rotation, [InnoDB](#) continues the operation on server restart.

The keyring plugin must be loaded prior to storage engine initialization so that the information necessary to decrypt tablespace data pages can be retrieved from tablespace headers before [InnoDB](#) initialization and recovery activities access tablespace data. (See [InnoDB Tablespace Encryption Prerequisites](#).)

When [InnoDB](#) initialization and recovery begin, the master key rotation operation resumes. Due to the server failure, some tablespaces keys may already be encrypted using the new master encryption key. [InnoDB](#) reads the encryption data from each tablespace header, and if the data indicates that the

tablespace key is encrypted using the old master encryption key, InnoDB retrieves the old key from the keyring and uses it to decrypt the tablespace key. InnoDB then re-encrypts the tablespace key using the new master encryption key and saves the re-encrypted tablespace key back to the tablespace header.

Exporting Encrypted Tables

When an encrypted table is exported, InnoDB generates a *transfer key* that is used to encrypt the tablespace key. The encrypted tablespace key and transfer key are stored in a `tablespace_name.cfp` file. This file together with the encrypted tablespace file is required to perform an import operation. On import, InnoDB uses the transfer key to decrypt the tablespace key in the `tablespace_name.cfp` file. For related information, see [Section 15.7.6, “Copying File-Per-Table Tablespaces to Another Instance”](#).

InnoDB Tablespace Encryption and Replication

- The `ALTER INSTANCE ROTATE INNODB MASTER KEY` statement is only supported in replication environments where the master and slaves run a version of MySQL that supports the tablespace encryption feature.
- Successful `ALTER INSTANCE ROTATE INNODB MASTER KEY` statements are written to the binary log for replication on slaves.
- If an `ALTER INSTANCE ROTATE INNODB MASTER KEY` statement fails, it is not logged to the binary log and is not replicated on slaves.
- Replication of an `ALTER INSTANCE ROTATE INNODB MASTER KEY` operation fails if the keyring plugin is installed on the master but not on the slave.
- If the `keyring_file` plugin is installed on both the master and a slave but the slave does not have a `keyring` file, the replicated `ALTER INSTANCE ROTATE INNODB MASTER KEY` statement creates the `keyring` file on the slave, assuming the `keyring` file data is not cached in memory. `ALTER INSTANCE ROTATE INNODB MASTER KEY` uses `keyring` file data that is cached in memory, if available.

Identifying Tables that Use InnoDB Tablespace Encryption

When the `ENCRYPTION` option is specified in a `CREATE TABLE` or `ALTER TABLE` statement, it is recorded in the `CREATE_OPTIONS` field of `INFORMATION_SCHEMA.TABLES`. This field may be queried to identify encrypted tables in a MySQL instance.

```
mysql> SELECT TABLE_SCHEMA, TABLE_NAME, CREATE_OPTIONS FROM INFORMATION_SCHEMA.TABLES
-> WHERE CREATE_OPTIONS LIKE '%ENCRYPTION="Y"%';
+-----+-----+-----+
| TABLE_SCHEMA | TABLE_NAME | CREATE_OPTIONS |
+-----+-----+-----+
| test          | t1          | ENCRYPTION="Y" |
+-----+-----+-----+
```

InnoDB Tablespace Encryption Usage Notes

- If the server exits or is stopped during normal operation, it is recommended to restart the server using the same encryption settings that were configured previously.
- The first master encryption key is generated when the first new or existing table is encrypted.
- Master key rotation re-encrypts tablespaces keys but does not change the tablespace key itself. To change a tablespace key, you must disable and re-enable table encryption using `ALTER TABLE tbl_name ENCRYPTION`, which is an `ALGORITHM=COPY` operation that rebuilds the table.
- If a table is created with both the `COMPRESSION` and `ENCRYPTION` options, compression is performed before tablespace data is encrypted.

- If a `keyring` file is empty or missing, the first execution of `ALTER INSTANCE ROTATE INNODB MASTER KEY` creates a master encryption key.
- Uninstalling the `keyring_file` plugin does not remove an existing `keyring` file.
- It is recommended that you not place the `keyring` file under the same directory as tablespace data files. The location of the `keyring` file is specified by the `keyring_file_data` option.
- Modifying the `keyring_file_data` option at runtime or restarting the server with a new `keyring_file_data` setting can cause previously encrypted tables to become inaccessible, resulting in the loss of data.

InnoDB Tablespace Encryption Limitations

- Advanced Encryption Standard (AES) is the only supported encryption algorithm. InnoDB tablespace encryption uses Electronic Codebook (ECB) block encryption mode for tablespace key encryption and Cipher Block Chaining (CBC) block encryption mode for data encryption.
- Altering the `ENCRYPTION` attribute of a table is an `ALGORITHM=COPY` operation. `ALGORITHM=INPLACE` is not supported.
- InnoDB tablespace encryption only supports InnoDB tables that are stored in a `file-per-table` tablespaces. Encryption is not supported for tables stored in other InnoDB tablespace types including `general tablespaces`, the `system tablespace`, undo log tablespaces, and the temporary tablespace.
- You cannot move or copy an encrypted table from a `file-per-table` tablespace to an unsupported InnoDB tablespace type.
- By default, tablespace encryption only applies to data in the tablespace. Redo log and undo log data may be encrypted using the `innodb_redo_log_encrypt` and `innodb_undo_log_encrypt` options. See [Redo Log Data Encryption](#), and [Undo Log Data Encryption](#). Binary log data is not encrypted.

15.8 InnoDB Tables and Indexes

This section covers topics related to InnoDB tables and indexes.

15.8.1 InnoDB Tables

This section covers topics related to InnoDB tables.

15.8.1.1 Creating InnoDB Tables

To create an InnoDB table, use the `CREATE TABLE` statement.

```
CREATE TABLE t1 (a INT, b CHAR (20), PRIMARY KEY (a)) ENGINE=InnoDB;
```

You do not need to specify the `ENGINE=InnoDB` clause if InnoDB is defined as the default storage engine, which it is by default. To check the default storage engine, issue the following statement:

```
mysql> SELECT @@default_storage_engine;
+-----+
| @@default_storage_engine |
+-----+
| InnoDB                   |
+-----+
```

You might still use `ENGINE=InnoDB` clause if you plan to use `mysqldump` or replication to replay the `CREATE TABLE` statement on a server where the default storage engine is not InnoDB.

An InnoDB table and its indexes can be created in the [system tablespace](#), in a [file-per-table tablespace](#), or in a [general tablespace](#). When `innodb_file_per_table` is enabled, which is the default, an InnoDB table is implicitly created in an individual file-per-table tablespace. Conversely, when `innodb_file_per_table` is disabled, an InnoDB table is implicitly created in the InnoDB system tablespace. To create a table in a general tablespace, use `CREATE TABLE ... TABLESPACE` syntax. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

When you create a table in a file-per-table tablespace, MySQL creates an `.ibd` tablespace file in a database directory under the MySQL data directory, by default. A table created in the InnoDB system tablespace is created in an existing `ibdata` file, which resides in the MySQL data directory. A table created in a general tablespace is created in an existing general tablespace `.ibd` file. General tablespace files can be created inside or outside of the MySQL data directory. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

Internally, InnoDB adds an entry for each table to the data dictionary. The entry includes the database name. For example, if table `t1` is created in the `test` database, the data dictionary entry for the database name is `'test/t1'`. This means you can create a table of the same name (`t1`) in a different database, and the table names do not collide inside InnoDB.

InnoDB Tables and Row Formats

The default row format for InnoDB tables is defined by the `innodb_default_row_format` configuration option, which has a default value of `DYNAMIC`. `Dynamic` and `Compressed` row format allow you to take advantage of InnoDB features such as table compression and efficient off-page storage of long column values. To use these row formats, `innodb_file_per_table` must be enabled (the default).

```
SET GLOBAL innodb_file_per_table=1;
CREATE TABLE t3 (a INT, b CHAR (20), PRIMARY KEY (a)) ROW_FORMAT=DYNAMIC;
CREATE TABLE t4 (a INT, b CHAR (20), PRIMARY KEY (a)) ROW_FORMAT=COMPRESSED;
```

Alternatively, you can use `CREATE TABLE ... TABLESPACE` syntax to create an InnoDB table in a general tablespace. General tablespaces support all row formats. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

```
CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=DYNAMIC;
```

`CREATE TABLE ... TABLESPACE` syntax can also be used to create InnoDB tables with a `Dynamic` row format in the system tablespace, alongside tables with a `Compact` or `Redundant` row format.

```
CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE = innodb_system ROW_FORMAT=DYNAMIC;
```

For more information about InnoDB row formats, see [Section 15.10, “InnoDB Row Storage and Row Formats”](#). For how to determine the row format of an InnoDB table and the physical characteristics of InnoDB row formats, see [Section 15.8.1.2, “The Physical Row Structure of an InnoDB Table”](#).

InnoDB Tables and Primary Keys

Always define a [primary key](#) for an InnoDB table, specifying the column or columns that:

- Are referenced by the most important queries.
- Are never left blank.
- Never have duplicate values.
- Rarely if ever change value once inserted.

For example, in a table containing information about people, you would not create a primary key on `(firstname, lastname)` because more than one person can have the same name, some people have blank last names, and sometimes people change their names. With so many constraints, often there is not an obvious set of columns to use as a primary key, so you create a new column with a

numeric ID to serve as all or part of the primary key. You can declare an [auto-increment](#) column so that ascending values are filled in automatically as rows are inserted:

```
-- The value of ID can act like a pointer between related items in different tables.
CREATE TABLE t5 (id INT AUTO_INCREMENT, b CHAR (20), PRIMARY KEY (id));

-- The primary key can consist of more than one column. Any autoinc column must come first.
CREATE TABLE t6 (id INT AUTO_INCREMENT, a INT, b CHAR (20), PRIMARY KEY (id,a));
```

Although the table works correctly without defining a primary key, the primary key is involved with many aspects of performance and is a crucial design aspect for any large or frequently used table. It is recommended that you always specify a primary key in the `CREATE TABLE` statement. If you create the table, load data, and then run `ALTER TABLE` to add a primary key later, that operation is much slower than defining the primary key when creating the table.

Viewing InnoDB Table Properties

To view the properties of an [InnoDB](#) table, issue a `SHOW TABLE STATUS` statement:

```
mysql> SHOW TABLE STATUS FROM test LIKE 't%' \G;
***** 1. row *****
      Name: t1
      Engine: InnoDB
      Version: 10
      Row_format: Compact
      Rows: 0
      Avg_row_length: 0
      Data_length: 16384
      Max_data_length: 0
      Index_length: 0
      Data_free: 0
      Auto_increment: NULL
      Create_time: 2015-03-16 15:13:31
      Update_time: NULL
      Check_time: NULL
      Collation: utf8mb4_0900_ai_ci
      Checksum: NULL
      Create_options:
      Comment:
```

For information about `SHOW TABLE STATUS` output, see [Section 13.7.5.36, “SHOW TABLE STATUS Syntax”](#).

[InnoDB](#) table properties may also be queried using the [InnoDB](#) Information Schema system tables:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME='test/t1' \G
***** 1. row *****
      TABLE_ID: 45
      NAME: test/t1
      FLAG: 1
      N_COLS: 5
      SPACE: 35
      ROW_FORMAT: Compact
      ZIP_PAGE_SIZE: 0
      SPACE_TYPE: Single
```

For more information, see [Section 15.14.3, “InnoDB INFORMATION_SCHEMA System Tables”](#).

15.8.1.2 The Physical Row Structure of an InnoDB Table

The physical row structure of an [InnoDB](#) table depends on the row format specified when the table is created. If a row format is not specified, the default row format is used. The default row format for [InnoDB](#) tables is defined by the `innodb_default_row_format` configuration option, which has a default value of `DYNAMIC`.

The following sections describe the characteristics of [InnoDB](#) row formats.

- [Determining the Row Format of an InnoDB Table](#)
- [Redundant Row Format Characteristics](#)
- [COMPACT Row Format Characteristics](#)
- [DYNAMIC and COMPRESSED Row Format Characteristics](#)

For more information about [InnoDB](#) row formats, see [Section 15.10](#), “[InnoDB Row Storage and Row Formats](#)”.

Determining the Row Format of an InnoDB Table

To determine the row format of an [InnoDB](#) table, you can use `SHOW TABLE STATUS`. For example:

```
mysql> SHOW TABLE STATUS IN test1\G
***** 1. row *****
      Name: t1
      Engine: InnoDB
      Version: 10
      Row_format: Dynamic
      Rows: 0
      Avg_row_length: 0
      Data_length: 16384
      Max_data_length: 0
      Index_length: 16384
      Data_free: 0
      Auto_increment: 1
      Create_time: 2016-09-14 16:29:38
      Update_time: NULL
      Check_time: NULL
      Collation: utf8mb4_0900_ai_ci
      Checksum: NULL
      Create_options:
      Comment:
```

You can also determine the row format of an [InnoDB](#) table by querying `INFORMATION_SCHEMA.INNODB_SYS_TABLES`.

```
mysql> SELECT NAME, ROW_FORMAT FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME='test1/t1';
+-----+-----+
| NAME      | ROW_FORMAT |
+-----+-----+
| test1/t1  | Dynamic    |
+-----+-----+
```

Redundant Row Format Characteristics

The [REDUNDANT](#) format is available to retain compatibility with older versions of MySQL.

Rows in [InnoDB](#) tables that use [REDUNDANT](#) row format have the following characteristics:

- Each index record contains a 6-byte header. The header is used to link together consecutive records, and also in row-level locking.
- Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.
- If no primary key was defined for a table, each clustered index record also contains a 6-byte row ID field.
- Each secondary index record also contains all the primary key fields defined for the clustered index key that are not in the secondary index.
- A record contains a pointer to each field of the record. If the total length of the fields in a record is less than 128 bytes, the pointer is one byte; otherwise, two bytes. The array of these pointers is called the record directory. The area where these pointers point is called the data part of the record.

- Internally, InnoDB stores fixed-length character columns such as `CHAR(10)` in a fixed-length format. InnoDB does not truncate trailing spaces from `VARCHAR` columns.
- InnoDB encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.
- An SQL `NULL` value reserves one or two bytes in the record directory. Besides that, an SQL `NULL` value reserves zero bytes in the data part of the record if stored in a variable length column. In a fixed-length column, it reserves the fixed length of the column in the data part of the record. Reserving the fixed space for `NULL` values enables an update of the column from `NULL` to a non-`NULL` value to be done in place without causing fragmentation of the index page.

COMPACT Row Format Characteristics

The `COMPACT` row format decreases row storage space by about 20% compared to the `REDUNDANT` format at the cost of increasing CPU use for some operations. If your workload is a typical one that is limited by cache hit rates and disk speed, `COMPACT` format is likely to be faster. If the workload is a rare case that is limited by CPU speed, compact format might be slower.

Rows in InnoDB tables that use `COMPACT` row format have the following characteristics:

- Each index record contains a 5-byte header that may be preceded by a variable-length header. The header is used to link together consecutive records, and also in row-level locking.
- The variable-length part of the record header contains a bit vector for indicating `NULL` columns. If the number of columns in the index that can be `NULL` is N , the bit vector occupies `CEILING(N/8)` bytes. (For example, if there are anywhere from 9 to 15 columns that can be `NULL`, the bit vector uses two bytes.) Columns that are `NULL` do not occupy space other than the bit in this vector. The variable-length part of the header also contains the lengths of variable-length columns. Each length takes one or two bytes, depending on the maximum length of the column. If all columns in the index are `NOT NULL` and have a fixed length, the record header has no variable-length part.
- For each non-`NULL` variable-length field, the record header contains the length of the column in one or two bytes. Two bytes are only needed if part of the column is stored externally in overflow pages or the maximum length exceeds 255 bytes and the actual length exceeds 127 bytes. For an externally stored column, the 2-byte length indicates the length of the internally stored part plus the 20-byte pointer to the externally stored part. The internal part is 768 bytes, so the length is 768+20. The 20-byte pointer stores the true length of the column.
- The record header is followed by the data contents of the non-`NULL` columns.
- Records in the clustered index contain fields for all user-defined columns. In addition, there is a 6-byte transaction ID field and a 7-byte roll pointer field.
- If no primary key was defined for a table, each clustered index record also contains a 6-byte row ID field.
- Each secondary index record also contains all the primary key fields defined for the clustered index key that are not in the secondary index. If any of these primary key fields are variable length, the record header for each secondary index has a variable-length part to record their lengths, even if the secondary index is defined on fixed-length columns.
- Internally, for nonvariable-length character sets, InnoDB stores fixed-length character columns such as `CHAR(10)` in a fixed-length format.
InnoDB does not truncate trailing spaces from `VARCHAR` columns.
- Internally, for variable-length character sets such as `utf8mb3` and `utf8mb4`, InnoDB attempts to store `CHAR(N)` in N bytes by trimming trailing spaces. If the byte length of a `CHAR(N)` column value exceeds N bytes, InnoDB trims trailing spaces to a minimum of the column value byte length. The maximum length of a `CHAR(N)` column is the maximum character byte length $\times N$.

InnoDB reserves a minimum of N bytes for `CHAR(N)`. Reserving the minimum space N in many cases enables column updates to be done in place without causing fragmentation of the index page. By comparison, for `ROW_FORMAT=REDUNDANT`, `CHAR(N)` columns occupy the maximum character byte length $\times N$.

InnoDB encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

`ROW_FORMAT=DYNAMIC` and `ROW_FORMAT=COMPRESSED` handle `CHAR` storage in the same way as `ROW_FORMAT=COMPACT`.

DYNAMIC and COMPRESSED Row Format Characteristics

`DYNAMIC` and `COMPRESSED` row formats are variations of the `COMPACT` row format. For information about these row formats, see [Section 15.10.3, “DYNAMIC and COMPRESSED Row Formats”](#).

15.8.1.3 Moving or Copying InnoDB Tables

This section describes techniques for moving or copying some or all InnoDB tables to a different server or instance. For example, you might move an entire MySQL instance to a larger, faster server; you might clone an entire MySQL instance to a new replication slave server; you might copy individual tables to another instance to develop and test an application, or to a data warehouse server to produce reports.

On Windows, InnoDB always stores database and table names internally in lowercase. To move databases in a binary format from Unix to Windows or from Windows to Unix, create all databases and tables using lowercase names. A convenient way to accomplish this is to add the following line to the `[mysqld]` section of your `my.cnf` or `my.ini` file before creating any databases or tables:

```
[mysqld]
lower_case_table_names=1
```

Techniques for moving or copying InnoDB tables include:

- [Transportable Tablespaces](#)
- [MySQL Enterprise Backup](#)
- [Copying Data Files \(Cold Backup Method\)](#)
- [Export and Import \(mysqldump\)](#)

Transportable Tablespaces

The transportable tablespaces feature uses `FLUSH TABLES ... FOR EXPORT` to ready InnoDB tables for copying from one server instance to another. To use this feature, InnoDB tables must be created with `innodb_file_per_table` set to `ON` so that each InnoDB table has its own tablespace. For usage information, see [Section 15.7.6, “Copying File-Per-Table Tablespaces to Another Instance”](#).

MySQL Enterprise Backup

The MySQL Enterprise Backup product lets you back up a running MySQL database, including InnoDB and MyISAM tables, with minimal disruption to operations while producing a consistent snapshot of the database. When MySQL Enterprise Backup is copying InnoDB tables, reads and writes to both InnoDB and MyISAM tables can continue. During the copying of MyISAM and other non-InnoDB tables, reads (but not writes) to those tables are permitted. In addition, MySQL Enterprise Backup can create compressed backup files, and back up subsets of InnoDB tables. In conjunction with the MySQL binary log, you can perform point-in-time recovery. MySQL Enterprise Backup is included as part of the MySQL Enterprise subscription.

For more details about MySQL Enterprise Backup, see [Section 29.2, “MySQL Enterprise Backup Overview”](#).

Copying Data Files (Cold Backup Method)

You can move an InnoDB database simply by copying all the relevant files listed under "Cold Backups" in [Section 15.17.1, “InnoDB Backup”](#).

Like MyISAM data files, InnoDB data and log files are binary-compatible on all platforms having the same floating-point number format. If the floating-point formats differ but you have not used `FLOAT` or `DOUBLE` data types in your tables, then the procedure is the same: simply copy the relevant files.

When you move or copy file-per-table `.ibd` files, the database directory name must be the same on the source and destination systems. The table definition stored in the InnoDB shared tablespace includes the database name. The transaction IDs and log sequence numbers stored in the tablespace files also differ between databases.

To move an `.ibd` file and the associated table from one database to another, use a `RENAME TABLE` statement:

```
RENAME TABLE db1.tbl_name TO db2.tbl_name;
```

If you have a “clean” backup of an `.ibd` file, you can restore it to the MySQL installation from which it originated as follows:

1. The table must not have been dropped or truncated since you copied the `.ibd` file, because doing so changes the table ID stored inside the tablespace.
2. Issue this `ALTER TABLE` statement to delete the current `.ibd` file:

```
ALTER TABLE tbl_name DISCARD TABLESPACE;
```

3. Copy the backup `.ibd` file to the proper database directory.
4. Issue this `ALTER TABLE` statement to tell InnoDB to use the new `.ibd` file for the table:

```
ALTER TABLE tbl_name IMPORT TABLESPACE;
```

Note

The `ALTER TABLE ... IMPORT TABLESPACE` feature does not enforce foreign key constraints on imported data.

In this context, a “clean” `.ibd` file backup is one for which the following requirements are satisfied:

- There are no uncommitted modifications by transactions in the `.ibd` file.
- There are no unmerged insert buffer entries in the `.ibd` file.
- Purge has removed all delete-marked index records from the `.ibd` file.
- `mysqld` has flushed all modified pages of the `.ibd` file from the buffer pool to the file.

You can make a clean backup `.ibd` file using the following method:

1. Stop all activity from the `mysqld` server and commit all transactions.
2. Wait until `SHOW ENGINE INNODB STATUS` shows that there are no active transactions in the database, and the main thread status of InnoDB is `Waiting for server activity`. Then you can make a copy of the `.ibd` file.

Another method for making a clean copy of an `.ibd` file is to use the MySQL Enterprise Backup product:

1. Use MySQL Enterprise Backup to back up the `InnoDB` installation.
2. Start a second `mysqld` server on the backup and let it clean up the `.ibd` files in the backup.

Export and Import (mysqldump)

You can use `mysqldump` to dump your tables on one machine and then import the dump files on the other machine. Using this method, it does not matter whether the formats differ or if your tables contain floating-point data.

One way to increase the performance of this method is to switch off `autocommit` mode when importing data, assuming that the tablespace has enough space for the big rollback segment that the import transactions generate. Do the commit only after importing a whole table or a segment of a table.

15.8.1.4 Converting Tables from MyISAM to InnoDB

If you have `MyISAM` tables that you want to convert to `InnoDB` for better reliability and scalability, review the following guidelines and tips before converting.

Note

Partitioned `MyISAM` tables created in previous versions of MySQL are not compatible with MySQL 8.0. Such tables must be prepared prior to upgrade, either by removing the partitioning, or by converting them to `InnoDB`. See [Section 22.6.2, “Partitioning Limitations Relating to Storage Engines”](#), for more information.

- [Adjusting Memory Usage for MyISAM and InnoDB](#)
- [Handling Too-Long Or Too-Short Transactions](#)
- [Handling Deadlocks](#)
- [Planning the Storage Layout](#)
- [Converting an Existing Table](#)
- [Cloning the Structure of a Table](#)
- [Transferring Existing Data](#)
- [Storage Requirements](#)
- [Defining a PRIMARY KEY for Each Table](#)
- [Application Performance Considerations](#)
- [Understanding Files Associated with InnoDB Tables](#)

Adjusting Memory Usage for MyISAM and InnoDB

As you transition away from `MyISAM` tables, lower the value of the `key_buffer_size` configuration option to free memory no longer needed for caching results. Increase the value of the `innodb_buffer_pool_size` configuration option, which performs a similar role of allocating cache memory for `InnoDB` tables. The `InnoDB` buffer pool caches both table data and index data, speeding up lookups for queries and keeping query results in memory for reuse. For guidance regarding buffer pool size configuration, see [Section 8.12.3.1, “How MySQL Uses Memory”](#).

On a busy server, run benchmarks with the query cache turned off. The `InnoDB` buffer pool provides similar benefits, so the query cache might be tying up memory unnecessarily. For information about the query cache, see [Section 8.10.3, “The MySQL Query Cache”](#).

Handling Too-Long Or Too-Short Transactions

Because `MyISAM` tables do not support [transactions](#), you might not have paid much attention to the `autocommit` configuration option and the `COMMIT` and `ROLLBACK` statements. These keywords are important to allow multiple sessions to read and write `InnoDB` tables concurrently, providing substantial scalability benefits in write-heavy workloads.

While a transaction is open, the system keeps a snapshot of the data as seen at the beginning of the transaction, which can cause substantial overhead if the system inserts, updates, and deletes millions of rows while a stray transaction keeps running. Thus, take care to avoid transactions that run for too long:

- If you are using a `mysql` session for interactive experiments, always `COMMIT` (to finalize the changes) or `ROLLBACK` (to undo the changes) when finished. Close down interactive sessions rather than leave them open for long periods, to avoid keeping transactions open for long periods by accident.
- Make sure that any error handlers in your application also `ROLLBACK` incomplete changes or `COMMIT` completed changes.
- `ROLLBACK` is a relatively expensive operation, because `INSERT`, `UPDATE`, and `DELETE` operations are written to `InnoDB` tables prior to the `COMMIT`, with the expectation that most changes are committed successfully and rollbacks are rare. When experimenting with large volumes of data, avoid making changes to large numbers of rows and then rolling back those changes.
- When loading large volumes of data with a sequence of `INSERT` statements, periodically `COMMIT` the results to avoid having transactions that last for hours. In typical load operations for data warehousing, if something goes wrong, you truncate the table (using `TRUNCATE TABLE`) and start over from the beginning rather than doing a `ROLLBACK`.

The preceding tips save memory and disk space that can be wasted during too-long transactions. When transactions are shorter than they should be, the problem is excessive I/O. With each `COMMIT`, MySQL makes sure each change is safely recorded to disk, which involves some I/O.

- For most operations on `InnoDB` tables, you should use the setting `autocommit=0`. From an efficiency perspective, this avoids unnecessary I/O when you issue large numbers of consecutive `INSERT`, `UPDATE`, or `DELETE` statements. From a safety perspective, this allows you to issue a `ROLLBACK` statement to recover lost or garbled data if you make a mistake on the `mysql` command line, or in an exception handler in your application.
- The time when `autocommit=1` is suitable for `InnoDB` tables is when running a sequence of queries for generating reports or analyzing statistics. In this situation, there is no I/O penalty related to `COMMIT` or `ROLLBACK`, and `InnoDB` can [automatically optimize the read-only workload](#).
- If you make a series of related changes, finalize all the changes at once with a single `COMMIT` at the end. For example, if you insert related pieces of information into several tables, do a single `COMMIT` after making all the changes. Or if you run many consecutive `INSERT` statements, do a single `COMMIT` after all the data is loaded; if you are doing millions of `INSERT` statements, perhaps split up the huge transaction by issuing a `COMMIT` every ten thousand or hundred thousand records, so the transaction does not grow too large.
- Remember that even a `SELECT` statement opens a transaction, so after running some report or debugging queries in an interactive `mysql` session, either issue a `COMMIT` or close the `mysql` session.

Handling Deadlocks

You might see warning messages referring to “deadlocks” in the MySQL error log, or the output of `SHOW ENGINE INNODB STATUS`. Despite the scary-sounding name, a [deadlock](#) is not a serious issue for `InnoDB` tables, and often does not require any corrective action. When two transactions start modifying multiple tables, accessing the tables in a different order, they can reach a state where each

transaction is waiting for the other and neither can proceed. When [deadlock detection](#) is enabled (the default), MySQL immediately detects this condition and cancels ([rolls back](#)) the “smaller” transaction, allowing the other to proceed. If deadlock detection is disabled using the `innodb_deadlock_detect` configuration option, InnoDB relies on the `innodb_lock_wait_timeout` setting to roll back transactions in case of a deadlock.

Either way, your applications need error-handling logic to restart a transaction that is forcibly cancelled due to a deadlock. When you re-issue the same SQL statements as before, the original timing issue no longer applies. Either the other transaction has already finished and yours can proceed, or the other transaction is still in progress and your transaction waits until it finishes.

If deadlock warnings occur constantly, you might review the application code to reorder the SQL operations in a consistent way, or to shorten the transactions. You can test with the `innodb_print_all_deadlocks` option enabled to see all deadlock warnings in the MySQL error log, rather than only the last warning in the `SHOW ENGINE INNODB STATUS` output.

For more information, see [Section 15.5.5, “Deadlocks in InnoDB”](#).

Planning the Storage Layout

To get the best performance from InnoDB tables, you can adjust a number of parameters related to storage layout.

When you convert MyISAM tables that are large, frequently accessed, and hold vital data, investigate and consider the `innodb_file_per_table` and `innodb_page_size` configuration options, and the `ROW_FORMAT` and `KEY_BLOCK_SIZE` clauses of the `CREATE TABLE` statement.

During your initial experiments, the most important setting is `innodb_file_per_table`. When this setting is enabled, which is the default, new InnoDB tables are implicitly created in `file-per-table` tablespaces. In contrast with the InnoDB system tablespace, file-per-table tablespaces allow disk space to be reclaimed by the operating system when a table is truncated or dropped. File-per-table tablespaces also support `DYNAMIC` and `COMPRESSED` row formats and associated features such as table compression, efficient off-page storage for long variable-length columns, and large index prefixes. For more information, see [Section 15.7.4, “InnoDB File-Per-Table Tablespaces”](#).

You can also store InnoDB tables in a shared general tablespace, which support multiple tables and all row formats. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

Converting an Existing Table

To convert a non-InnoDB table to use InnoDB use `ALTER TABLE`:

```
ALTER TABLE table_name ENGINE=InnoDB;
```

Cloning the Structure of a Table

You might make an InnoDB table that is a clone of a MyISAM table, rather than using `ALTER TABLE` to perform conversion, to test the old and new table side-by-side before switching.

Create an empty InnoDB table with identical column and index definitions. Use `SHOW CREATE TABLE table_name\G` to see the full `CREATE TABLE` statement to use. Change the `ENGINE` clause to `ENGINE=INNODB`.

Transferring Existing Data

To transfer a large volume of data into an empty InnoDB table created as shown in the previous section, insert the rows with `INSERT INTO innodb_table SELECT * FROM myisam_table ORDER BY primary_key_columns`.

You can also create the indexes for the InnoDB table after inserting the data. Historically, creating new secondary indexes was a slow operation for InnoDB, but now you can create the indexes after the data is loaded with relatively little overhead from the index creation step.

If you have [UNIQUE](#) constraints on secondary keys, you can speed up a table import by turning off the uniqueness checks temporarily during the import operation:

```
SET unique_checks=0;
... import operation ...
SET unique_checks=1;
```

For big tables, this saves disk I/O because [InnoDB](#) can use its [change buffer](#) to write secondary index records as a batch. Be certain that the data contains no duplicate keys. [unique_checks](#) permits but does not require storage engines to ignore duplicate keys.

For better control over the insertion process, you can insert big tables in pieces:

```
INSERT INTO newtable SELECT * FROM oldtable
WHERE yourkey > something AND yourkey <= somethingelse;
```

After all records are inserted, you can rename the tables.

During the conversion of big tables, increase the size of the [InnoDB](#) buffer pool to reduce disk I/O, to a maximum of 80% of physical memory. You can also increase the size of [InnoDB](#) log files.

Storage Requirements

If you intend to make several temporary copies of your data in [InnoDB](#) tables during the conversion process, it is recommended that you create the tables in file-per-table tablespaces so that you can reclaim the disk space when you drop the tables. When the [innodb_file_per_table](#) configuration option is enabled (the default), newly created [InnoDB](#) tables are implicitly created in file-per-table tablespaces.

Whether you convert the [MyISAM](#) table directly or create a cloned [InnoDB](#) table, make sure that you have sufficient disk space to hold both the old and new tables during the process. **InnoDB tables require more disk space than MyISAM tables.** If an [ALTER TABLE](#) operation runs out of space, it starts a rollback, and that can take hours if it is disk-bound. For inserts, [InnoDB](#) uses the insert buffer to merge secondary index records to indexes in batches. That saves a lot of disk I/O. For rollback, no such mechanism is used, and the rollback can take 30 times longer than the insertion.

In the case of a runaway rollback, if you do not have valuable data in your database, it may be advisable to kill the database process rather than wait for millions of disk I/O operations to complete. For the complete procedure, see [Section 15.20.2, “Forcing InnoDB Recovery”](#).

Defining a PRIMARY KEY for Each Table

The [PRIMARY KEY](#) clause is a critical factor affecting the performance of MySQL queries and the space usage for tables and indexes. The primary key uniquely identifies a row in a table. Every row in the table must have a primary key value, and no two rows can have the same primary key value.

These are guidelines for the primary key, followed by more detailed explanations.

- Declare a [PRIMARY KEY](#) for each table. Typically, it is the most important column that you refer to in [WHERE](#) clauses when looking up a single row.
- Declare the [PRIMARY KEY](#) clause in the original [CREATE TABLE](#) statement, rather than adding it later through an [ALTER TABLE](#) statement.
- Choose the column and its data type carefully. Prefer numeric columns over character or string ones.
- Consider using an auto-increment column if there is not another stable, unique, non-null, numeric column to use.
- An auto-increment column is also a good choice if there is any doubt whether the value of the primary key column could ever change. Changing the value of a primary key column is an expensive operation, possibly involving rearranging data within the table and within each secondary index.

Consider adding a [primary key](#) to any table that does not already have one. Use the smallest practical numeric type based on the maximum projected size of the table. This can make each row slightly more compact, which can yield substantial space savings for large tables. The space savings are multiplied if the table has any [secondary indexes](#), because the primary key value is repeated in each secondary index entry. In addition to reducing data size on disk, a small primary key also lets more data fit into the [buffer pool](#), speeding up all kinds of operations and improving concurrency.

If the table already has a primary key on some longer column, such as a [VARCHAR](#), consider adding a new unsigned [AUTO_INCREMENT](#) column and switching the primary key to that, even if that column is not referenced in queries. This design change can produce substantial space savings in the secondary indexes. You can designate the former primary key columns as [UNIQUE NOT NULL](#) to enforce the same constraints as the [PRIMARY KEY](#) clause, that is, to prevent duplicate or null values across all those columns.

If you spread related information across multiple tables, typically each table uses the same column for its primary key. For example, a personnel database might have several tables, each with a primary key of employee number. A sales database might have some tables with a primary key of customer number, and other tables with a primary key of order number. Because lookups using the primary key are very fast, you can construct efficient join queries for such tables.

If you leave the [PRIMARY KEY](#) clause out entirely, MySQL creates an invisible one for you. It is a 6-byte value that might be longer than you need, thus wasting space. Because it is hidden, you cannot refer to it in queries.

Application Performance Considerations

The reliability and scalability features of [InnoDB](#) require more disk storage than equivalent [MyISAM](#) tables. You might change the column and index definitions slightly, for better space utilization, reduced I/O and memory consumption when processing result sets, and better query optimization plans making efficient use of index lookups.

If you do set up a numeric ID column for the primary key, use that value to cross-reference with related values in any other tables, particularly for [join](#) queries. For example, rather than accepting a country name as input and doing queries searching for the same name, do one lookup to determine the country ID, then do other queries (or a single join query) to look up relevant information across several tables. Rather than storing a customer or catalog item number as a string of digits, potentially using up several bytes, convert it to a numeric ID for storing and querying. A 4-byte unsigned [INT](#) column can index over 4 billion items (with the US meaning of billion: 1000 million). For the ranges of the different integer types, see [Section 11.2.1, "Integer Types \(Exact Value\) - INTEGER, INT, SMALLINT, TINYINT, MEDIUMINT, BIGINT"](#).

Understanding Files Associated with InnoDB Tables

[InnoDB](#) files require more care and planning than [MyISAM](#) files do.

- You must not delete the [ibdata files](#) that represent the [InnoDB system tablespace](#).
- Methods of moving or copying [InnoDB](#) tables to a different server are described in [Section 15.8.1.3, "Moving or Copying InnoDB Tables"](#).

15.8.1.5 AUTO_INCREMENT Handling in InnoDB

[InnoDB](#) provides a configurable locking mechanism that can significantly improve scalability and performance of SQL statements that add rows to tables with [AUTO_INCREMENT](#) columns. To use the [AUTO_INCREMENT](#) mechanism with an [InnoDB](#) table, an [AUTO_INCREMENT](#) column must be defined as part of an index such that it is possible to perform the equivalent of an indexed [SELECT MAX\(ai_col\)](#) lookup on the table to obtain the maximum column value. Typically, this is achieved by making the column the first column of some table index.

This section describes the behavior of [AUTO_INCREMENT](#) lock modes, usage implications for different [AUTO_INCREMENT](#) lock mode settings, and how [InnoDB](#) initializes the [AUTO_INCREMENT](#) counter.

- [InnoDB AUTO_INCREMENT Lock Modes](#)
- [InnoDB AUTO_INCREMENT Lock Mode Usage Implications](#)
- [InnoDB AUTO_INCREMENT Counter Initialization](#)

InnoDB AUTO_INCREMENT Lock Modes

This section describes the behavior of [AUTO_INCREMENT](#) lock modes used to generate auto-increment values, and how each lock mode affects replication. Auto-increment lock modes are configured at startup using the `innodb_autoinc_lock_mode` configuration parameter.

The following terms are used in describing `innodb_autoinc_lock_mode` settings:

- “INSERT-like” statements

All statements that generate new rows in a table, including `INSERT`, `INSERT ... SELECT`, `REPLACE`, `REPLACE ... SELECT`, and `LOAD DATA`. Includes “simple-inserts”, “bulk-inserts”, and “mixed-mode” inserts.

- “Simple inserts”

Statements for which the number of rows to be inserted can be determined in advance (when the statement is initially processed). This includes single-row and multiple-row `INSERT` and `REPLACE` statements that do not have a nested subquery, but not `INSERT ... ON DUPLICATE KEY UPDATE`.

- “Bulk inserts”

Statements for which the number of rows to be inserted (and the number of required auto-increment values) is not known in advance. This includes `INSERT ... SELECT`, `REPLACE ... SELECT`, and `LOAD DATA` statements, but not plain `INSERT`. InnoDB assigns new values for the `AUTO_INCREMENT` column one at a time as each row is processed.

- “Mixed-mode inserts”

These are “simple insert” statements that specify the auto-increment value for some (but not all) of the new rows. An example follows, where `c1` is an `AUTO_INCREMENT` column of table `t1`:

```
INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

Another type of “mixed-mode insert” is `INSERT ... ON DUPLICATE KEY UPDATE`, which in the worst case is in effect an `INSERT` followed by a `UPDATE`, where the allocated value for the `AUTO_INCREMENT` column may or may not be used during the update phase.

There are three possible settings for the `innodb_autoinc_lock_mode` configuration parameter. The settings are 0, 1, or 2, for “traditional”, “consecutive”, or “interleaved” lock mode, respectively.

- `innodb_autoinc_lock_mode = 0` (“traditional” lock mode)

The traditional lock mode provides the same behavior that existed before the `innodb_autoinc_lock_mode` configuration parameter was introduced in MySQL 5.1. The traditional lock mode option is provided for backward compatibility, performance testing, and working around issues with “mixed-mode inserts”, due to possible differences in semantics.

In this lock mode, all “INSERT-like” statements obtain a special table-level `AUTO-INC` lock for inserts into tables with `AUTO_INCREMENT` columns. This lock is normally held to the end of the statement (not to the end of the transaction) to ensure that auto-increment values are assigned in a predictable and repeatable order for a given sequence of `INSERT` statements, and to ensure that auto-increment values assigned by any given statement are consecutive.

In the case of statement-based replication, this means that when an SQL statement is replicated on a slave server, the same values are used for the auto-increment column as on the master server. The result of execution of multiple `INSERT` statements is deterministic, and the slave reproduces the same data as on the master. If auto-increment values generated by multiple `INSERT` statements were interleaved, the result of two concurrent `INSERT` statements would be nondeterministic, and could not reliably be propagated to a slave server using statement-based replication.

To make this clear, consider an example that uses this table:

```
CREATE TABLE t1 (
  c1 INT(11) NOT NULL AUTO_INCREMENT,
  c2 VARCHAR(10) DEFAULT NULL,
  PRIMARY KEY (c1)
) ENGINE=InnoDB;
```

Suppose that there are two transactions running, each inserting rows into a table with an `AUTO_INCREMENT` column. One transaction is using an `INSERT ... SELECT` statement that inserts 1000 rows, and another is using a simple `INSERT` statement that inserts one row:

```
Tx1: INSERT INTO t1 (c2) SELECT 1000 rows from another table ...
Tx2: INSERT INTO t1 (c2) VALUES ('xxx');
```

InnoDB cannot tell in advance how many rows are retrieved from the `SELECT` in the `INSERT` statement in Tx1, and it assigns the auto-increment values one at a time as the statement proceeds. With a table-level lock, held to the end of the statement, only one `INSERT` statement referring to table `t1` can execute at a time, and the generation of auto-increment numbers by different statements is not interleaved. The auto-increment value generated by the Tx1 `INSERT ... SELECT` statement are consecutive, and the (single) auto-increment value used by the `INSERT` statement in Tx2 are either smaller or larger than all those used for Tx1, depending on which statement executes first.

As long as the SQL statements execute in the same order when replayed from the binary log (when using statement-based replication, or in recovery scenarios), the results are the same as they were when Tx1 and Tx2 first ran. Thus, table-level locks held until the end of a statement make `INSERT` statements using auto-increment safe for use with statement-based replication. However, those table-level locks limit concurrency and scalability when multiple transactions are executing insert statements at the same time.

In the preceding example, if there were no table-level lock, the value of the auto-increment column used for the `INSERT` in Tx2 depends on precisely when the statement executes. If the `INSERT` of Tx2 executes while the `INSERT` of Tx1 is running (rather than before it starts or after it completes), the specific auto-increment values assigned by the two `INSERT` statements are nondeterministic, and may vary from run to run.

Under the `consecutive` lock mode, InnoDB can avoid using table-level `AUTO-INC` locks for “simple insert” statements where the number of rows is known in advance, and still preserve deterministic execution and safety for statement-based replication.

If you are not using the binary log to replay SQL statements as part of recovery or replication, the `interleaved` lock mode can be used to eliminate all use of table-level `AUTO-INC` locks for even greater concurrency and performance, at the cost of permitting gaps in auto-increment numbers assigned by a statement and potentially having the numbers assigned by concurrently executing statements interleaved.

- `innodb_autoinc_lock_mode = 1` (“consecutive” lock mode)

This is the default lock mode. In this mode, “bulk inserts” use the special `AUTO-INC` table-level lock and hold it until the end of the statement. This applies to all `INSERT ... SELECT`, `REPLACE ... SELECT`, and `LOAD DATA` statements. Only one statement holding the `AUTO-INC` lock can execute

at a time. If the source table of the bulk insert operation is different from the target table, the `AUTO-INC` lock on the target table is taken after a shared lock is taken on the first row selected from the source table. If the source and target of the bulk insert operation are the same table, the `AUTO-INC` lock is taken after shared locks are taken on all selected rows.

“Simple inserts” (for which the number of rows to be inserted is known in advance) avoid table-level `AUTO-INC` locks by obtaining the required number of auto-increment values under the control of a mutex (a light-weight lock) that is only held for the duration of the allocation process, *not* until the statement completes. No table-level `AUTO-INC` lock is used unless an `AUTO-INC` lock is held by another transaction. If another transaction holds an `AUTO-INC` lock, a “simple insert” waits for the `AUTO-INC` lock, as if it were a “bulk insert”.

This lock mode ensures that, in the presence of `INSERT` statements where the number of rows is not known in advance (and where auto-increment numbers are assigned as the statement progresses), all auto-increment values assigned by any “`INSERT`-like” statement are consecutive, and operations are safe for statement-based replication.

Simply put, this lock mode significantly improves scalability while being safe for use with statement-based replication. Further, as with “traditional” lock mode, auto-increment numbers assigned by any given statement are *consecutive*. There is *no change* in semantics compared to “traditional” mode for any statement that uses auto-increment, with one important exception.

The exception is for “mixed-mode inserts”, where the user provides explicit values for an `AUTO_INCREMENT` column for some, but not all, rows in a multiple-row “simple insert”. For such inserts, InnoDB allocates more auto-increment values than the number of rows to be inserted. However, all values automatically assigned are consecutively generated (and thus higher than) the auto-increment value generated by the most recently executed previous statement. “Excess” numbers are lost.

- `innodb_autoinc_lock_mode = 2` (“interleaved” lock mode)

In this lock mode, no “`INSERT`-like” statements use the table-level `AUTO-INC` lock, and multiple statements can execute at the same time. This is the fastest and most scalable lock mode, but it is *not safe* when using statement-based replication or recovery scenarios when SQL statements are replayed from the binary log.

In this lock mode, auto-increment values are guaranteed to be unique and monotonically increasing across all concurrently executing “`INSERT`-like” statements. However, because multiple statements can be generating numbers at the same time (that is, allocation of numbers is *interleaved* across statements), the values generated for the rows inserted by any given statement may not be consecutive.

If the only statements executing are “simple inserts” where the number of rows to be inserted is known ahead of time, there are no gaps in the numbers generated for a single statement, except for “mixed-mode inserts”. However, when “bulk inserts” are executed, there may be gaps in the auto-increment values assigned by any given statement.

InnoDB AUTO_INCREMENT Lock Mode Usage Implications

- Using auto-increment with replication

If you are using statement-based replication, set `innodb_autoinc_lock_mode` to 0 or 1 and use the same value on the master and its slaves. Auto-increment values are not ensured to be the same on the slaves as on the master if you use `innodb_autoinc_lock_mode = 2` (“interleaved”) or configurations where the master and slaves do not use the same lock mode.

If you are using row-based or mixed-format replication, all of the auto-increment lock modes are safe, since row-based replication is not sensitive to the order of execution of the SQL statements (and the mixed format uses row-based replication for any statements that are unsafe for statement-based replication).

- “Lost” auto-increment values and sequence gaps

In all lock modes (0, 1, and 2), if a transaction that generated auto-increment values rolls back, those auto-increment values are “lost”. Once a value is generated for an auto-increment column, it cannot be rolled back, whether or not the “*INSERT*-like” statement is completed, and whether or not the containing transaction is rolled back. Such lost values are not reused. Thus, there may be gaps in the values stored in an `AUTO_INCREMENT` column of a table.

- Specifying NULL or 0 for the `AUTO_INCREMENT` column

In all lock modes (0, 1, and 2), if a user specifies NULL or 0 for the `AUTO_INCREMENT` column in an *INSERT*, InnoDB treats the row as if the value was not specified and generates a new value for it.

- Assigning a negative value to the `AUTO_INCREMENT` column

In all lock modes (0, 1, and 2), the behavior of the auto-increment mechanism is not defined if you assign a negative value to the `AUTO_INCREMENT` column.

- If the `AUTO_INCREMENT` value becomes larger than the maximum integer for the specified integer type

In all lock modes (0, 1, and 2), the behavior of the auto-increment mechanism is not defined if the value becomes larger than the maximum integer that can be stored in the specified integer type.

- Gaps in auto-increment values for “bulk inserts”

With `innodb_autoinc_lock_mode` set to 0 (“traditional”) or 1 (“consecutive”), the auto-increment values generated by any given statement are consecutive, without gaps, because the table-level `AUTO-INC` lock is held until the end of the statement, and only one such statement can execute at a time.

With `innodb_autoinc_lock_mode` set to 2 (“interleaved”), there may be gaps in the auto-increment values generated by “bulk inserts,” but only if there are concurrently executing “*INSERT*-like” statements.

For lock modes 1 or 2, gaps may occur between successive statements because for bulk inserts the exact number of auto-increment values required by each statement may not be known and overestimation is possible.

- Auto-increment values assigned by “mixed-mode inserts”

Consider a “mixed-mode insert,” where a “simple insert” specifies the auto-increment value for some (but not all) resulting rows. Such a statement behaves differently in lock modes 0, 1, and 2. For example, assume `c1` is an `AUTO_INCREMENT` column of table `t1`, and that the most recent automatically generated sequence number is 100.

```
mysql> CREATE TABLE t1 (
-> c1 INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
-> c2 CHAR(1)
-> ) ENGINE = INNODB;
```

Now, consider the following “mixed-mode insert” statement:

```
mysql> INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');
```

With `innodb_autoinc_lock_mode` set to 0 (“traditional”), the four new rows are:

```
mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
+-----+-----+
| c1  | c2  |
+-----+-----+
| 1  | a   |
```

```

| 101 | b |
| 5   | c |
| 102 | d |
+-----+-----+

```

The next available auto-increment value is 103 because the auto-increment values are allocated one at a time, not all at once at the beginning of statement execution. This result is true whether or not there are concurrently executing “*INSERT*-like” statements (of any type).

With `innodb_autoinc_lock_mode` set to 1 (“consecutive”), the four new rows are also:

```

mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
+-----+-----+
| c1   | c2   |
+-----+-----+
| 1    | a    |
| 101  | b    |
| 5    | c    |
| 102  | d    |
+-----+-----+

```

However, in this case, the next available auto-increment value is 105, not 103 because four auto-increment values are allocated at the time the statement is processed, but only two are used. This result is true whether or not there are concurrently executing “*INSERT*-like” statements (of any type).

With `innodb_autoinc_lock_mode` set to mode 2 (“interleaved”), the four new rows are:

```

mysql> SELECT c1, c2 FROM t1 ORDER BY c2;
+-----+-----+
| c1   | c2   |
+-----+-----+
| 1    | a    |
| x    | b    |
| 5    | c    |
| y    | d    |
+-----+-----+

```

The values of `x` and `y` are unique and larger than any previously generated rows. However, the specific values of `x` and `y` depend on the number of auto-increment values generated by concurrently executing statements.

Finally, consider the following statement, issued when the most-recently generated sequence number was the value 4:

```

mysql> INSERT INTO t1 (c1,c2) VALUES (1,'a'), (NULL,'b'), (5,'c'), (NULL,'d');

```

With any `innodb_autoinc_lock_mode` setting, this statement generates a duplicate-key error 23000 (Can't write; duplicate key in table) because 5 is allocated for the row (NULL, 'b') and insertion of the row (5, 'c') fails.

- Modifying `AUTO_INCREMENT` column values in the middle of a sequence of `INSERT` statements

In MySQL 5.7 and earlier, modifying an `AUTO_INCREMENT` column value in the middle of a sequence of `INSERT` statements could lead to “Duplicate entry” errors. For example, if you performed an `UPDATE` operation that changed an `AUTO_INCREMENT` column value to a value larger than the current maximum auto-increment value, subsequent `INSERT` operations that did not specify an unused auto-increment value could encounter “Duplicate entry” errors. In MySQL 8.0 and later, if you modify an `AUTO_INCREMENT` column value to a value larger than the current maximum auto-increment value, the new value is persisted, and subsequent `INSERT` operations allocate auto-increment values starting from the new, larger value. This behavior is demonstrated in the following example.

```

mysql> CREATE TABLE t1 (
-> c1 INT NOT NULL AUTO_INCREMENT,
-> PRIMARY KEY (c1)
-> ) ENGINE = InnoDB;

mysql> INSERT INTO t1 VALUES(0), (0), (3);

mysql> SELECT c1 FROM t1;
+-----+
| c1 |
+-----+
| 1 |
| 2 |
| 3 |
+-----+

mysql> UPDATE t1 SET c1 = 4 WHERE c1 = 1;

mysql> SELECT c1 FROM t1;
+-----+
| c1 |
+-----+
| 2 |
| 3 |
| 4 |
+-----+

mysql> INSERT INTO t1 VALUES(0);

mysql> SELECT c1 FROM t1;
+-----+
| c1 |
+-----+
| 2 |
| 3 |
| 4 |
| 5 |
+-----+

```

InnoDB AUTO_INCREMENT Counter Initialization

This section describes how [InnoDB](#) initializes [AUTO_INCREMENT](#) counters.

If you specify an [AUTO_INCREMENT](#) column for an [InnoDB](#) table, the in-memory table object contains a special counter called the auto-increment counter that is used when assigning new values for the column.

In MySQL 5.7 and earlier, the auto-increment counter is stored only in main memory, not on disk. To initialize an auto-increment counter after a server restart, [InnoDB](#) would execute the equivalent of the following statement on the first insert into a table containing an [AUTO_INCREMENT](#) column.

```
SELECT MAX(ai_col) FROM table_name FOR UPDATE;
```

In MySQL 8.0, this behavior is changed. The current maximum auto-increment counter value is written to the redo log each time it changes and is saved to an engine-private system table on each checkpoint. These changes make the current maximum auto-increment counter value persistent across server restarts.

On a server restart following a normal shutdown, [InnoDB](#) initializes the in-memory auto-increment counter using the current maximum auto-increment value stored in the data dictionary system table.

On a server restart during crash recovery, [InnoDB](#) initializes the in-memory auto-increment counter using the current maximum auto-increment value stored in the data dictionary system table and scans the redo log for auto-increment counter values written since the last checkpoint. If a redo-logged value is greater than the in-memory counter value, the redo-logged value is applied. However, in the case

of a server crash, reuse of a previously allocated auto-increment value cannot be guaranteed. Each time the current maximum auto-increment value is changed due to an `INSERT` or `UPDATE` operation, the new value is written to the redo log, but if the crash occurs before the redo log is flushed to disk, the previously allocated value could be reused when the auto-increment counter is initialized after the server is restarted.

The only circumstance in which InnoDB uses the equivalent of a `SELECT MAX(ai_col) FROM table_name FOR UPDATE` statement in MySQL 8.0 and later to initialize an auto-increment counter is when [importing a tablespace](#) without a `.cfg` metadata file. Otherwise, the current maximum auto-increment counter value is read from the `.cfg` metadata file.

In MySQL 5.7 and earlier, a server restart cancels the effect of the `AUTO_INCREMENT = N` table option, which may be used in a `CREATE TABLE` or `ALTER TABLE` statement to set an initial counter value or alter the existing counter value, respectively. In MySQL 8.0, a server restart does not cancel the effect of the `AUTO_INCREMENT = N` table option. If you initialize the auto-increment counter to a specific value, or if you alter the auto-increment counter value to a larger value, the new value is persisted across server restarts.

Note

`ALTER TABLE ... AUTO_INCREMENT = N` can only change the auto-increment counter value to a value larger than the current maximum.

In MySQL 5.7 and earlier, a server restart immediately following a `ROLLBACK` operation could result in the reuse of auto-increment values that were previously allocated to the rolled-back transaction, effectively rolling back the current maximum auto-increment value. In MySQL 8.0, the current maximum auto-increment value is persisted, preventing the reuse of previously allocated values.

If a `SHOW TABLE STATUS` statement examines a table before the auto-increment counter is initialized, InnoDB opens the table and initializes the counter value using the current maximum auto-increment value that is stored in the data dictionary system table. The value is stored in memory for use by later inserts or updates. Initialization of the counter value uses a normal exclusive-locking read on the table which lasts to the end of the transaction. InnoDB follows the same procedure when initializing the auto-increment counter for a newly created table that has a user-specified auto-increment value that is greater than 0.

After the auto-increment counter is initialized, if you do not explicitly specify an auto-increment value when inserting a row, InnoDB implicitly increments the counter and assigns the new value to the column. If you insert a row that explicitly specifies an auto-increment column value, and the value is greater than the current maximum counter value, the counter is set to the specified value.

InnoDB uses the in-memory auto-increment counter as long as the server runs. When the server is stopped and restarted, InnoDB reinitializes the auto-increment counter, as described earlier.

The `auto_increment_offset` configuration option determines the starting point for the `AUTO_INCREMENT` column value. The default setting is 1.

The `auto_increment_increment` configuration option controls the interval between successive column values. The default setting is 1.

15.8.1.6 InnoDB and FOREIGN KEY Constraints

How the InnoDB storage engine handles foreign key constraints is described under the following topics in this section:

- [Foreign Key Definitions](#)
- [Referential Actions](#)
- [Foreign Key Restrictions for Generated Columns and Virtual Indexes](#)

- [Foreign Key Usage and Error Information](#)

For foreign key usage information and examples, see [Section 13.1.15.6, “Using FOREIGN KEY Constraints”](#).

Foreign Key Definitions

Foreign key definitions for [InnoDB](#) tables are subject to the following conditions:

- [InnoDB](#) permits a foreign key to reference any index column or group of columns. However, in the referenced table, there must be an index where the referenced columns are listed as the *first* columns in the same order.
- [InnoDB](#) does not currently support foreign keys for tables with user-defined partitioning. This means that no user-partitioned [InnoDB](#) table may contain foreign key references or columns referenced by foreign keys.
- [InnoDB](#) allows a foreign key constraint to reference a non-unique key. *This is an [InnoDB](#) extension to standard SQL.*

Referential Actions

Referential actions for foreign keys of [InnoDB](#) tables are subject to the following conditions:

- While `SET DEFAULT` is allowed by the MySQL Server, it is rejected as invalid by [InnoDB](#). `CREATE TABLE` and `ALTER TABLE` statements using this clause are not allowed for [InnoDB](#) tables.
- If there are several rows in the parent table that have the same referenced key value, [InnoDB](#) acts in foreign key checks as if the other parent rows with the same key value do not exist. For example, if you have defined a `RESTRICT` type constraint, and there is a child row with several parent rows, [InnoDB](#) does not permit the deletion of any of those parent rows.
- [InnoDB](#) performs cascading operations through a depth-first algorithm, based on records in the indexes corresponding to the foreign key constraints.
- If `ON UPDATE CASCADE` or `ON UPDATE SET NULL` recurses to update the *same table* it has previously updated during the cascade, it acts like `RESTRICT`. This means that you cannot use self-referential `ON UPDATE CASCADE` or `ON UPDATE SET NULL` operations. This is to prevent infinite loops resulting from cascaded updates. A self-referential `ON DELETE SET NULL`, on the other hand, is possible, as is a self-referential `ON DELETE CASCADE`. Cascading operations may not be nested more than 15 levels deep.
- Like MySQL in general, in an SQL statement that inserts, deletes, or updates many rows, [InnoDB](#) checks `UNIQUE` and `FOREIGN KEY` constraints row-by-row. When performing foreign key checks, [InnoDB](#) sets shared row-level locks on child or parent records it has to look at. [InnoDB](#) checks foreign key constraints immediately; the check is not deferred to transaction commit. According to the SQL standard, the default behavior should be deferred checking. That is, constraints are only checked after the *entire SQL statement* has been processed. Until [InnoDB](#) implements deferred constraint checking, some things are impossible, such as deleting a record that refers to itself using a foreign key.

Foreign Key Restrictions for Generated Columns and Virtual Indexes

- A foreign key constraint on a [stored generated column](#) cannot use `ON UPDATE CASCADE`, `ON DELETE SET NULL`, `ON UPDATE SET NULL`, `ON DELETE SET DEFAULT`, or `ON UPDATE SET DEFAULT`.
- A foreign key constraint cannot reference a [virtual generated column](#).
- Prior to MySQL 8.0, a foreign key constraint cannot reference a secondary index defined on a virtual generated column.

Foreign Key Usage and Error Information

You can obtain general information about foreign keys and their usage from querying the `INFORMATION_SCHEMA.KEY_COLUMN_USAGE` table, and more information more specific to InnoDB tables can be found in the `INNODB_SYS_FOREIGN` and `INNODB_SYS_FOREIGN_COLS` tables, also in the `INFORMATION_SCHEMA` database.

In addition to `SHOW ERRORS`, in the event of a foreign key error involving InnoDB tables (usually Error 150 in the MySQL Server), you can obtain a detailed explanation of the most recent InnoDB foreign key error by checking the output of `SHOW ENGINE INNODB STATUS`.

15.8.1.7 Limits on InnoDB Tables

Limits on InnoDB tables are described under the following topics in this section:

- [Maximums and Minimums](#)
- [Restrictions on InnoDB Tables](#)
- [Locking and Transactions](#)

Warning

Before using NFS with InnoDB, review potential issues outlined in [Using NFS with MySQL](#).

Maximums and Minimums

- A table can contain a maximum of 1017 columns. Virtual generated columns are included in this limit.
- A table can contain a maximum of 64 [secondary indexes](#).
- The index key prefix length limit is 3072 bytes for InnoDB tables that use `DYNAMIC` or `COMPRESSED` row format.

The index key prefix length limit is 767 bytes for InnoDB tables that use `REDUNDANT` or `COMPACT` row format. For example, you might hit this limit with a [column prefix](#) index of more than 191 characters on a `TEXT` or `VARCHAR` column, assuming a `utf8mb4` character set and the maximum of 4 bytes for each character.

Attempting to use an index key prefix length that exceeds the limit returns an error.

The limits that apply to index key prefixes also apply to full-column index keys.

- If you reduce the [InnoDB page size](#) to 8KB or 4KB by specifying the `innodb_page_size` option when creating the MySQL instance, the maximum length of the index key is lowered proportionally, based on the limit of 3072 bytes for a 16KB page size. That is, the maximum index key length is 1536 bytes when the page size is 8KB, and 768 bytes when the page size is 4KB.
- A maximum of 16 columns is permitted for multicolumn indexes. Exceeding the limit returns an error.

```
ERROR 1070 (42000): Too many key parts specified; max 16 parts allowed
```

- The maximum row length, except for variable-length columns (`VARBINARY`, `VARCHAR`, `BLOB` and `TEXT`), is slightly less than half of a page for 4KB, 8KB, 16KB, and 32KB page sizes. For example, the maximum row length for the default `innodb_page_size` of 16KB is about 8000 bytes. For an InnoDB page size of 64KB, the maximum row length is about 16000 bytes. `LONGBLOB` and `LONGTEXT` columns must be less than 4GB, and the total row length, including `BLOB` and `TEXT` columns, must be less than 4GB.

If a row is less than half a page long, all of it is stored locally within the page. If it exceeds half a page, variable-length columns are chosen for external off-page storage until the row fits within half a page, as described in [Section 15.11.2, “File Space Management”](#).

- Although [InnoDB](#) supports row sizes larger than 65,535 bytes internally, MySQL itself imposes a row-size limit of 65,535 for the combined size of all columns:

```
mysql> CREATE TABLE t (a VARCHAR(8000), b VARCHAR(10000),
-> c VARCHAR(10000), d VARCHAR(10000), e VARCHAR(10000),
-> f VARCHAR(10000), g VARCHAR(10000)) ENGINE=InnoDB;
ERROR 1118 (42000): Row size too large. The maximum row size for the
used table type, not counting BLOBs, is 65535. You have to change some
columns to TEXT or BLOBs
```

See [Section C.10.4, “Limits on Table Column Count and Row Size”](#).

- On some older operating systems, files must be less than 2GB. This is not a limitation of [InnoDB](#) itself, but if you require a large tablespace, configure it using several smaller data files rather than one large data file.
- The combined size of the [InnoDB](#) log files can be up to 512GB.
- The minimum tablespace size is slightly larger than 10MB. The maximum tablespace size depends on the [InnoDB](#) page size.

Table 15.6 InnoDB Maximum Tablespace Size

InnoDB Page Size	Maximum Tablespace Size
4KB	16TB
8KB	32TB
16KB	64TB
32KB	128TB
64KB	256TB

The maximum tablespace size is also the maximum size for a table.

- The default page size in [InnoDB](#) is 16KB. You can increase or decrease the page size by configuring the `innodb_page_size` option when creating the MySQL instance.

32KB and 64KB page sizes are supported, but `ROW_FORMAT=COMPRESSED` is unsupported for page sizes greater than 16KB. For both 32KB and 64KB page sizes, the maximum record size is 16KB. For `innodb_page_size=32k`, extent size is 2MB. For `innodb_page_size=64k`, extent size is 4MB.

A MySQL instance using a particular [InnoDB](#) page size cannot use data files or log files from an instance that uses a different page size.

Restrictions on InnoDB Tables

- `ANALYZE TABLE` determines index cardinality (as displayed in the `Cardinality` column of `SHOW INDEX` output) by performing [random dives](#) on each of the index trees and updating index cardinality estimates accordingly. Because these are only estimates, repeated runs of `ANALYZE TABLE` could produce different numbers. This makes `ANALYZE TABLE` fast on [InnoDB](#) tables but not 100% accurate because it does not take all rows into account.

You can make the [statistics](#) collected by `ANALYZE TABLE` more precise and more stable by turning on the `innodb_stats_persistent` configuration option, as explained in [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#). When that setting is enabled, it is important to run `ANALYZE TABLE` after major changes to indexed column data, because the statistics are not recalculated periodically (such as after a server restart).

If the persistent statistics setting is enabled, you can change the number of random dives by modifying the `innodb_stats_persistent_sample_pages` system variable. If the persistent

statistics setting is disabled, modify the `innodb_stats_transient_sample_pages` system variable instead.

MySQL uses index cardinality estimates in join optimization. If a join is not optimized in the right way, try using `ANALYZE TABLE`. In the few cases that `ANALYZE TABLE` does not produce values good enough for your particular tables, you can use `FORCE INDEX` with your queries to force the use of a particular index, or set the `max_seeks_for_key` system variable to ensure that MySQL prefers index lookups over table scans. See [Section B.5.5, “Optimizer-Related Issues”](#).

- If statements or transactions are running on a table, and `ANALYZE TABLE` is run on the same table followed by a second `ANALYZE TABLE` operation, the second `ANALYZE TABLE` operation is blocked until the statements or transactions are completed. This behavior occurs because `ANALYZE TABLE` marks the currently loaded table definition as obsolete when `ANALYZE TABLE` is finished running. New statements or transactions (including a second `ANALYZE TABLE` statement) must load the new table definition into the table cache, which cannot occur until currently running statements or transactions are completed and the old table definition is purged. Loading multiple concurrent table definitions is not supported.
- `SHOW TABLE STATUS` does not give accurate statistics on InnoDB tables except for the physical size reserved by the table. The row count is only a rough estimate used in SQL optimization.
- InnoDB does not keep an internal count of rows in a table because concurrent transactions might “see” different numbers of rows at the same time. Consequently, `SELECT COUNT(*)` statements only count rows visible to the current transaction.

InnoDB processes `SELECT COUNT(*)` statements by scanning the clustered index.

Processing `SELECT COUNT(*)` statements takes some time if index records are not entirely in the buffer pool. For a faster count, you can create a counter table and let your application update it according to the inserts and deletes it does. However, this method may not scale well in situations where thousands of concurrent transactions are initiating updates to the same counter table. If an approximate row count is sufficient, `SHOW TABLE STATUS` can be used.

InnoDB handles `SELECT COUNT(*)` and `SELECT COUNT(1)` operations in the same way. There is no performance difference.

- On Windows, InnoDB always stores database and table names internally in lowercase. To move databases in a binary format from Unix to Windows or from Windows to Unix, create all databases and tables using lowercase names.
- An `AUTO_INCREMENT` column `ai_col` must be defined as part of an index such that it is possible to perform the equivalent of an indexed `SELECT MAX(ai_col)` lookup on the table to obtain the maximum column value. Typically, this is achieved by making the column the first column of some table index.
- InnoDB sets an exclusive lock on the end of the index associated with the `AUTO_INCREMENT` column while initializing a previously specified `AUTO_INCREMENT` column on a table.

With `innodb_autoinc_lock_mode=0`, InnoDB uses a special `AUTO-INC` table lock mode where the lock is obtained and held to the end of the current SQL statement while accessing the auto-increment counter. Other clients cannot insert into the table while the `AUTO-INC` table lock is held. The same behavior occurs for “bulk inserts” with `innodb_autoinc_lock_mode=1`. Table-level `AUTO-INC` locks are not used with `innodb_autoinc_lock_mode=2`. For more information, See [Section 15.8.1.5, “AUTO_INCREMENT Handling in InnoDB”](#).

- When an `AUTO_INCREMENT` integer column runs out of values, a subsequent `INSERT` operation returns a duplicate-key error. This is general MySQL behavior, similar to how `MyISAM` works.
- `DELETE FROM tbl_name` does not regenerate the table but instead deletes all rows, one by one.
- Cascaded foreign key actions do not activate triggers.

- You cannot create a table with a column name that matches the name of an internal [InnoDB](#) column (including `DB_ROW_ID`, `DB_TRX_ID`, `DB_ROLL_PTR`, and `DB_MIX_ID`). This restriction applies to use of the names in any letter case.

```
mysql> CREATE TABLE t1 (c1 INT, db_row_id INT) ENGINE=INNODB;
ERROR 1166 (42000): Incorrect column name 'db_row_id'
```

Locking and Transactions

- `LOCK TABLES` acquires two locks on each table if `innodb_table_locks=1` (the default). In addition to a table lock on the MySQL layer, it also acquires an [InnoDB](#) table lock. Versions of MySQL before 4.1.2 did not acquire [InnoDB](#) table locks; the old behavior can be selected by setting `innodb_table_locks=0`. If no [InnoDB](#) table lock is acquired, `LOCK TABLES` completes even if some records of the tables are being locked by other transactions.

In MySQL 8.0, `innodb_table_locks=0` has no effect for tables locked explicitly with `LOCK TABLES ... WRITE`. It does have an effect for tables locked for read or write by `LOCK TABLES ... WRITE` implicitly (for example, through triggers) or by `LOCK TABLES ... READ`.

- All [InnoDB](#) locks held by a transaction are released when the transaction is committed or aborted. Thus, it does not make much sense to invoke `LOCK TABLES` on [InnoDB](#) tables in `autocommit=1` mode because the acquired [InnoDB](#) table locks would be released immediately.
- You cannot lock additional tables in the middle of a transaction because `LOCK TABLES` performs an implicit `COMMIT` and `UNLOCK TABLES`.
- The limit on data-modifying transactions is $96 * 1023$ concurrent transactions that generate undo records. 32 of 128 rollback segments are assigned to non-redo logs for transactions that modify temporary tables and related objects. This means that the maximum number of concurrent data-modifying transactions is 96K. The 96K limit assumes that transactions do not modify temporary tables. If all data-modifying transactions also modify temporary tables, the limit is 32K concurrent transactions.

15.8.2 InnoDB Indexes

This section covers topics related to [InnoDB](#) indexes.

15.8.2.1 Clustered and Secondary Indexes

Every [InnoDB](#) table has a special index called the [clustered index](#) where the data for the rows is stored. Typically, the clustered index is synonymous with the [primary key](#). To get the best performance from queries, inserts, and other database operations, you must understand how [InnoDB](#) uses the clustered index to optimize the most common lookup and DML operations for each table.

- When you define a [PRIMARY KEY](#) on your table, [InnoDB](#) uses it as the clustered index. Define a primary key for each table that you create. If there is no logical unique and non-null column or set of columns, add a new [auto-increment](#) column, whose values are filled in automatically.
- If you do not define a [PRIMARY KEY](#) for your table, MySQL locates the first [UNIQUE](#) index where all the key columns are `NOT NULL` and [InnoDB](#) uses it as the clustered index.
- If the table has no [PRIMARY KEY](#) or suitable [UNIQUE](#) index, [InnoDB](#) internally generates a hidden clustered index on a synthetic column containing row ID values. The rows are ordered by the ID that [InnoDB](#) assigns to the rows in such a table. The row ID is a 6-byte field that increases monotonically as new rows are inserted. Thus, the rows ordered by the row ID are physically in insertion order.

How the Clustered Index Speeds Up Queries

Accessing a row through the clustered index is fast because the index search leads directly to the page with all the row data. If a table is large, the clustered index architecture often saves a disk I/O operation

when compared to storage organizations that store row data using a different page from the index record. (For example, [MyISAM](#) uses one file for data rows and another for index records.)

How Secondary Indexes Relate to the Clustered Index

All indexes other than the clustered index are known as [secondary indexes](#). In [InnoDB](#), each record in a secondary index contains the primary key columns for the row, as well as the columns specified for the secondary index. [InnoDB](#) uses this primary key value to search for the row in the clustered index.

If the primary key is long, the secondary indexes use more space, so it is advantageous to have a short primary key.

For guidelines to take advantage of [InnoDB](#) clustered and secondary indexes, see [Section 8.3, “Optimization and Indexes”](#).

15.8.2.2 The Physical Structure of an InnoDB Index

With the exception of spatial indexes, [InnoDB](#) indexes are [B-tree](#) data structures. Spatial indexes use [R-trees](#), which are specialized data structures for indexing multi-dimensional data. Index records are stored in the leaf pages of their B-tree or R-tree data structure. The default size of an index page is 16KB.

When new records are inserted into an [InnoDB clustered index](#), [InnoDB](#) tries to leave 1/16 of the page free for future insertions and updates of the index records. If index records are inserted in a sequential order (ascending or descending), the resulting index pages are about 15/16 full. If records are inserted in a random order, the pages are from 1/2 to 15/16 full.

[InnoDB](#) performs a bulk load when creating or rebuilding B-tree indexes. This method of index creation is known as a sorted index build. The `innodb_fill_factor` configuration option defines the percentage of space on each B-tree page that is filled during a sorted index build, with the remaining space reserved for future index growth. Sorted index builds are not supported for spatial indexes. For more information, see [Section 15.8.2.3, “Sorted Index Builds”](#). An `innodb_fill_factor` setting of 100 leaves 1/16 of the space in clustered index pages free for future index growth.

If the fill factor of an [InnoDB](#) index page drops below the `MERGE_THRESHOLD`, which is 50% by default if not specified, [InnoDB](#) tries to contract the index tree to free the page. The `MERGE_THRESHOLD` setting applies to both B-tree and R-tree indexes. For more information, see [Section 15.6.12, “Configuring the Merge Threshold for Index Pages”](#).

You can define the [page size](#) for all [InnoDB](#) tablespaces in a MySQL instance by setting the `innodb_page_size` configuration option prior to initializing the MySQL instance. Once the page size for an instance is defined, you cannot change it without reinitializing the instance. Supported sizes are 64KB, 32KB, 16KB (default), 8KB, and 4KB, corresponding to the option values `64k`, `32k`, `16k`, `8k`, and `4k`.

A MySQL instance using a particular [InnoDB](#) page size cannot use data files or log files from an instance that uses a different page size.

15.8.2.3 Sorted Index Builds

[InnoDB](#) performs a bulk load instead of inserting one index record at a time when creating or rebuilding indexes. This method of index creation is also known as a sorted index build. Sorted index builds are not supported for spatial indexes.

There are three phases to an index build. In the first phase, the [clustered index](#) is scanned, and index entries are generated and added to the sort buffer. When the [sort buffer](#) becomes full, entries are sorted and written out to a temporary intermediate file. This process is also known as a “run”. In the second phase, with one or more runs written to the temporary intermediate file, a merge sort is performed on all entries in the file. In the third and final phase, the sorted entries are inserted into the [B-tree](#).

Prior to the introduction of sorted index builds, index entries were inserted into the B-tree one record at a time using insert APIs. This method involved opening a B-tree [cursor](#) to find the insert position and then inserting entries into a B-tree page using an [optimistic](#) insert. If an insert failed due to a page being full, a [pessimistic](#) insert would be performed, which involves opening a B-tree cursor and splitting and merging B-tree nodes as necessary to find space for the entry. The drawbacks of this “top-down” method of building an index are the cost of searching for an insert position and the constant splitting and merging of B-tree nodes.

Sorted index builds use a “bottom-up” approach to building an index. With this approach, a reference to the right-most leaf page is held at all levels of the B-tree. The right-most leaf page at the necessary B-tree depth is allocated and entries are inserted according to their sorted order. Once a leaf page is full, a node pointer is appended to the parent page and a sibling leaf page is allocated for the next insert. This process continues until all entries are inserted, which may result in inserts up to the root level. When a sibling page is allocated, the reference to the previously pinned leaf page is released, and the newly allocated leaf page becomes the right-most leaf page and new default insert location.

Reserving B-tree Page Space for Future Index Growth

To set aside space for future index growth, you can use the [innodb_fill_factor](#) configuration option to reserve a percentage of B-tree page space. For example, setting [innodb_fill_factor](#) to 80 reserves 20 percent of the space in B-tree pages during a sorted index build. This setting applies to both B-tree leaf and non-leaf pages. It does not apply to external pages used for [TEXT](#) or [BLOB](#) entries. The amount of space that is reserved may not be exactly as configured, as the [innodb_fill_factor](#) value is interpreted as a hint rather than a hard limit.

Sorted Index Builds and Full-Text Index Support

Sorted index builds are supported for [fulltext indexes](#). Previously, SQL was used to insert entries into a fulltext index.

Sorted Index Builds and Compressed Tables

For [compressed tables](#), the previous index creation method appended entries to both compressed and uncompressed pages. When the modification log (representing free space on the compressed page) became full, the compressed page would be recompressed. If compression failed due to a lack of space, the page would be split. With sorted index builds, entries are only appended to uncompressed pages. When an uncompressed page becomes full, it is compressed. Adaptive padding is used to ensure that compression succeeds in most cases, but if compression fails, the page is split and compression is attempted again. This process continues until compression is successful. For more information about compression of B-Tree pages, see [Section 15.9.1.5, “How Compression Works for InnoDB Tables”](#).

Sorted Index Builds and Redo Logging

[Redo logging](#) is disabled during a sorted index build. Instead, there is a [checkpoint](#) to ensure that the index build can withstand a crash or failure. The checkpoint forces a write of all dirty pages to disk. During a sorted index build, the [page cleaner](#) thread is signaled periodically to flush [dirty pages](#) to ensure that the checkpoint operation can be processed quickly. Normally, the page cleaner thread flushes dirty pages when the number of clean pages falls below a set threshold. For sorted index builds, dirty pages are flushed promptly to reduce checkpoint overhead and to parallelize I/O and CPU activity.

Sorted Index Builds and Optimizer Statistics

Sorted index builds may result in [optimizer](#) statistics that differ from those generated by the previous method of index creation. The difference in statistics, which is not expected to affect workload performance, is due to the different algorithm used to populate the index.

15.8.2.4 InnoDB FULLTEXT Indexes

`FULLTEXT` indexes are created on text-based columns (`CHAR`, `VARCHAR`, or `TEXT` columns) to help speed up queries and DML operations on data contained within those columns, omitting any words that are defined as stopwords.

A `FULLTEXT` index is defined as part of a `CREATE TABLE` statement or added to an existing table using `ALTER TABLE` or `CREATE INDEX`.

Full-text search is performed using `MATCH() ... AGAINST` syntax. For usage information, see [Section 12.9, “Full-Text Search Functions”](#).

InnoDB `FULLTEXT` indexes are described under the following topics in this section:

- [InnoDB Full-Text Index Design](#)
- [InnoDB Full-Text Index Tables](#)
- [InnoDB Full-Text Index Cache](#)
- [InnoDB Full-Text Index Document ID and `FTS_DOC_ID` Column](#)
- [InnoDB Full-Text Index Deletion Handling](#)
- [InnoDB Full-Text Index Transaction Handling](#)
- [Monitoring InnoDB Full-Text Indexes](#)

InnoDB Full-Text Index Design

InnoDB `FULLTEXT` indexes have an inverted index design. Inverted indexes store a list of words, and for each word, a list of documents that the word appears in. To support proximity search, position information for each word is also stored, as a byte offset.

InnoDB Full-Text Index Tables

For each InnoDB `FULLTEXT` index, a set of index tables is created, as shown in the following example:

```
mysql> CREATE TABLE opening_lines (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  opening_line TEXT(500),
  author VARCHAR(200),
  title VARCHAR(200),
  FULLTEXT idx (opening_line)
) ENGINE=InnoDB;

mysql> SELECT table_id, name, space from INFORMATION_SCHEMA.INNODB_SYS_TABLES
WHERE name LIKE 'test/%';
+-----+-----+-----+
| table_id | name | space |
+-----+-----+-----+
| 333 | test/fts_0000000000000147_0000000000001c9_index_1 | 289 |
| 334 | test/fts_0000000000000147_0000000000001c9_index_2 | 290 |
| 335 | test/fts_0000000000000147_0000000000001c9_index_3 | 291 |
| 336 | test/fts_0000000000000147_0000000000001c9_index_4 | 292 |
| 337 | test/fts_0000000000000147_0000000000001c9_index_5 | 293 |
| 338 | test/fts_0000000000000147_0000000000001c9_index_6 | 294 |
| 330 | test/fts_000000000000147_being_deleted | 286 |
| 331 | test/fts_000000000000147_being_deleted_cache | 287 |
| 332 | test/fts_000000000000147_config | 288 |
| 328 | test/fts_000000000000147_deleted | 284 |
| 329 | test/fts_000000000000147_deleted_cache | 285 |
| 327 | test/opening_lines | 283 |
+-----+-----+-----+
```

The first six tables represent the inverted index and are referred to as auxiliary index tables. When incoming documents are tokenized, the individual words (also referred to as “tokens”) are inserted into the index tables along with position information and the associated Document ID (`DOC_ID`). The words

are fully sorted and partitioned among the six index tables based on the character set sort weight of the word's first character.

The inverted index is partitioned into six auxiliary index tables to support parallel index creation. By default, two threads tokenize, sort, and insert words and associated data into the index tables. The number of threads is configurable using the `innodb_ft_sort_pll_degree` option. Consider increasing the number of threads when creating `FULLTEXT` indexes on large tables.

Auxiliary index table names are prefixed with `fts_` and postfixed with `index_*`. Each index table is associated with the indexed table by a hex value in the index table name that matches the `table_id` of the indexed table. For example, the `table_id` of the `test/opening_lines` table is `327`, for which the hex value is `0x147`. As shown in the preceding example, the “147” hex value appears in the names of index tables that are associated with the `test/opening_lines` table.

A hex value representing the `index_id` of the `FULLTEXT` index also appears in auxiliary index table names. For example, in the auxiliary table name `test/fts_0000000000000147_0000000000001c9_index_1`, the hex value `1c9` has a decimal value of `457`. The index defined on the `opening_lines` table (`idx`) can be identified by querying the `INFORMATION_SCHEMA.INNODB_SYS_INDEXES` table for this value (`457`).

```
mysql> SELECT index_id, name, table_id, space from INFORMATION_SCHEMA.INNODB_SYS_INDEXES
WHERE index_id=457;
```

index_id	name	table_id	space
457	idx	327	283

Index tables are stored in their own tablespace if the primary table is created in a [file-per-table](#) tablespace.

The other index tables shown in the preceding example are used for deletion handling and for storing the internal state of the `FULLTEXT` index.

Auxiliary index table names were changed to lowercase in MySQL 8.0.2.

- `fts*_deleted` and `fts*_deleted_cache`

Contain the document IDs (`DOC_ID`) for documents that are deleted but whose data is not yet removed from the full-text index. The `fts*_deleted_cache` is the in-memory version of the `fts*_deleted` table.

- `fts*_being_deleted` and `fts*_being_deleted_cache`

Contain the document IDs (`DOC_ID`) for documents that are deleted and whose data is currently in the process of being removed from the full-text index. The `fts*_being_deleted_cache` table is the in-memory version of the `fts*_being_deleted` table.

- `fts*_config`

Stores information about the internal state of the `FULLTEXT` index. Most importantly, it stores the `FTS_SYNCED_DOC_ID`, which identifies documents that have been parsed and flushed to disk. In case of crash recovery, `FTS_SYNCED_DOC_ID` values are used to identify documents that have not been flushed to disk so that the documents can be re-parsed and added back to the `FULLTEXT` index cache. To view the data in this table, query the `INFORMATION_SCHEMA.INNODB_FT_CONFIG` table.

InnoDB Full-Text Index Cache

When a document is inserted, it is tokenized, and the individual words and associated data are inserted into the `FULLTEXT` index. This process, even for small documents, could result in numerous small insertions into the auxiliary index tables, making concurrent access to these tables a point of

contention. To avoid this problem, InnoDB uses a `FULLTEXT` index cache to temporarily cache index table insertions for recently inserted rows. This in-memory cache structure holds insertions until the cache is full and then batch flushes them to disk (to the auxiliary index tables). You can query the `INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE` table to view tokenized data for recently inserted rows.

The caching and batch flushing behavior avoids frequent updates to auxiliary index tables, which could result in concurrent access issues during busy insert and update times. The batching technique also avoids multiple insertions for the same word, and minimizes duplicate entries. Instead of flushing each word individually, insertions for the same word are merged and flushed to disk as a single entry, improving insertion efficiency while keeping auxiliary index tables as small as possible.

The `innodb_ft_cache_size` variable is used to configure the full-text index cache size (on a per-table basis), which affects how often the full-text index cache is flushed. You can also define a global full-text index cache size limit for all tables in a given instance using the `innodb_ft_total_cache_size` option.

The full-text index cache stores the same information as auxiliary index tables. However, the full-text index cache only caches tokenized data for recently inserted rows. The data that is already flushed to disk (to the full-text auxiliary tables) is not brought back into the full-text index cache when queried. The data in auxiliary index tables is queried directly, and results from the auxiliary index tables are merged with results from the full-text index cache before being returned.

InnoDB Full-Text Index Document ID and FTS_DOC_ID Column

InnoDB uses a unique document identifier referred to as a Document ID (`DOC_ID`) to map words in the full-text index to document records where the word appears. The mapping requires an `FTS_DOC_ID` column on the indexed table. If an `FTS_DOC_ID` column is not defined, InnoDB automatically adds a hidden `FTS_DOC_ID` column when the full-text index is created. The following example demonstrates this behavior.

The following table definition does not include an `FTS_DOC_ID` column:

```
mysql> CREATE TABLE opening_lines (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  opening_line TEXT(500),
  author VARCHAR(200),
  title VARCHAR(200)
) ENGINE=InnoDB;
```

When you create a full-text index on the table using `CREATE FULLTEXT INDEX` syntax, a warning is returned which reports that InnoDB is rebuilding the table to add the `FTS_DOC_ID` column.

```
mysql> CREATE FULLTEXT INDEX idx ON opening_lines(opening_line);
Query OK, 0 rows affected, 1 warning (0.19 sec)
Records: 0 Duplicates: 0 Warnings: 1

mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message |
+-----+-----+-----+
| Warning | 124 | InnoDB rebuilding table to add column FTS_DOC_ID |
+-----+-----+-----+
```

The same warning is returned when using `ALTER TABLE` to add a full-text index to a table that does not have an `FTS_DOC_ID` column. If you create a full-text index at `CREATE TABLE` time and do not specify an `FTS_DOC_ID` column, InnoDB adds a hidden `FTS_DOC_ID` column, without warning.

Defining an `FTS_DOC_ID` column at `CREATE TABLE` time is less expensive than creating a full-text index on a table that is already loaded with data. If an `FTS_DOC_ID` column is defined on a table prior to loading data, the table and its indexes do not have to be rebuilt to add the new column. If you are not concerned with `CREATE FULLTEXT INDEX` performance, leave out the `FTS_DOC_ID` column to have

InnoDB create it for you. InnoDB creates a hidden `FTS_DOC_ID` column along with a unique index (`FTS_DOC_ID_INDEX`) on the `FTS_DOC_ID` column. If you want to create your own `FTS_DOC_ID` column, the column must be defined as `BIGINT UNSIGNED NOT NULL` and named `FTS_DOC_ID` (all upper case), as in the following example:

Note

The `FTS_DOC_ID` column does not need to be defined as an `AUTO_INCREMENT` column, but `AUTO_INCREMENT` could make loading data easier.

```
mysql> CREATE TABLE opening_lines (
  FTS_DOC_ID BIGINT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  opening_line TEXT(500),
  author VARCHAR(200),
  title VARCHAR(200)
) ENGINE=InnoDB;
```

If you choose to define the `FTS_DOC_ID` column yourself, you are responsible for managing the column to avoid empty or duplicate values. `FTS_DOC_ID` values cannot be reused, which means `FTS_DOC_ID` values must be ever increasing.

Optionally, you can create the required unique `FTS_DOC_ID_INDEX` (all upper case) on the `FTS_DOC_ID` column.

```
mysql> CREATE UNIQUE INDEX FTS_DOC_ID_INDEX on opening_lines(FTS_DOC_ID);
```

If you do not create the `FTS_DOC_ID_INDEX`, InnoDB creates it automatically.

Note

`FTS_DOC_ID_INDEX` cannot be defined as a descending index because the InnoDB SQL parser does not use descending indexes.

The permitted gap between the largest used `FTS_DOC_ID` value and new `FTS_DOC_ID` value is 65535.

InnoDB Full-Text Index Deletion Handling

Deleting a record that has a full-text index column could result in numerous small deletions in the auxiliary index tables, making concurrent access to these tables a point of contention. To avoid this problem, the Document ID (`DOC_ID`) of a deleted document is logged in a special `FTS_*_DELETED` table whenever a record is deleted from an indexed table, and the indexed record remains in the full-text index. Before returning query results, information in the `FTS_*_DELETED` table is used to filter out deleted Document IDs. The benefit of this design is that deletions are fast and inexpensive. The drawback is that the size of the index is not immediately reduced after deleting records. To remove full-text index entries for deleted records, run `OPTIMIZE TABLE` on the indexed table with `innodb_optimize_fulltext_only=ON` to rebuild the full-text index. For more information, see [Optimizing InnoDB Full-Text Indexes](#).

InnoDB Full-Text Index Transaction Handling

InnoDB `FULLTEXT` indexes have special transaction handling characteristics due its caching and batch processing behavior. Specifically, updates and insertions on a `FULLTEXT` index are processed at transaction commit time, which means that a `FULLTEXT` search can only see committed data. The following example demonstrates this behavior. The `FULLTEXT` search only returns a result after the inserted lines are committed.

```
mysql> CREATE TABLE opening_lines (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  opening_line TEXT(500),
```

```

author VARCHAR(200),
title VARCHAR(200),
FULLTEXT idx (opening_line)
) ENGINE=InnoDB;

mysql> BEGIN;

mysql> INSERT INTO opening_lines(opening_line,author,title) VALUES
('Call me Ishmael.','Herman Melville','Moby-Dick'),
('A screaming comes across the sky.','Thomas Pynchon','Gravity\'s Rainbow'),
('I am an invisible man.','Ralph Ellison','Invisible Man'),
('Where now? Who now? When now?','Samuel Beckett','The Unnamable'),
('It was love at first sight.','Joseph Heller','Catch-22'),
('All this happened, more or less.','Kurt Vonnegut','Slaughterhouse-Five'),
('Mrs. Dalloway said she would buy the flowers herself.','Virginia Woolf','Mrs. Dalloway'),
('It was a pleasure to burn.','Ray Bradbury','Fahrenheit 451');

mysql> SELECT COUNT(*) FROM opening_lines WHERE MATCH(opening_line) AGAINST('Ishmael');
+-----+
| COUNT(*) |
+-----+
|         0 |
+-----+

mysql> COMMIT;

mysql> SELECT COUNT(*) FROM opening_lines WHERE MATCH(opening_line) AGAINST('Ishmael');
+-----+
| COUNT(*) |
+-----+
|         1 |
+-----+

```

Monitoring InnoDB Full-Text Indexes

You can monitor and examine the special text-processing aspects of [InnoDB FULLTEXT](#) indexes by querying the following [INFORMATION_SCHEMA](#) tables:

- [INNODB_FT_CONFIG](#)
- [INNODB_FT_INDEX_TABLE](#)
- [INNODB_FT_INDEX_CACHE](#)
- [INNODB_FT_DEFAULT_STOPWORD](#)
- [INNODB_FT_DELETED](#)
- [INNODB_FT_BEING_DELETED](#)

You can also view basic information for [FULLTEXT](#) indexes and tables by querying [INNODB_SYS_INDEXES](#) and [INNODB_SYS_TABLES](#).

For more information, see [Section 15.14.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”](#).

15.9 InnoDB Table and Page Compression

This section provides information about the [InnoDB](#) table compression and [InnoDB](#) page compression features. The page compression feature is also referred to as [transparent page compression](#).

Using the compression features of [InnoDB](#), you can create tables where the data is stored in compressed form. Compression can help to improve both raw performance and scalability. The compression means less data is transferred between disk and memory, and takes up less space on disk and in memory. The benefits are amplified for tables with [secondary indexes](#), because index data is compressed also. Compression can be especially important for [SSD](#) storage devices, because they tend to have lower capacity than [HDD](#) devices.

15.9.1 InnoDB Table Compression

This section describes [InnoDB](#) table compression, which is supported with [InnoDB](#) tables that reside in [file_per_table](#) tablespaces or [general tablespaces](#). Table compression is enabled using the `ROW_FORMAT=COMPRESSED` attribute with `CREATE TABLE` or `ALTER TABLE`.

15.9.1.1 Overview of Table Compression

Because processors and cache memories have increased in speed more than disk storage devices, many workloads are [disk-bound](#). Data [compression](#) enables smaller database size, reduced I/O, and improved throughput, at the small cost of increased CPU utilization. Compression is especially valuable for read-intensive applications, on systems with enough RAM to keep frequently used data in memory.

An [InnoDB](#) table created with `ROW_FORMAT=COMPRESSED` can use a smaller [page size](#) on disk than the configured `innodb_page_size` value. Smaller pages require less I/O to read from and write to disk, which is especially valuable for [SSD](#) devices.

The compressed page size is specified through the `CREATE TABLE` or `ALTER TABLE` `KEY_BLOCK_SIZE` parameter. The different page size requires that the table be placed in a [file-per-table](#) tablespace or [general tablespace](#) rather than in the [system tablespace](#), as the system tablespace cannot store compressed tables. For more information, see [Section 15.7.4, “InnoDB File-Per-Table Tablespaces”](#), and [Section 15.7.9, “InnoDB General Tablespaces”](#).

The level of compression is the same regardless of the `KEY_BLOCK_SIZE` value. As you specify smaller values for `KEY_BLOCK_SIZE`, you get the I/O benefits of increasingly smaller pages. But if you specify a value that is too small, there is additional overhead to reorganize the pages when data values cannot be compressed enough to fit multiple rows in each page. There is a hard limit on how small `KEY_BLOCK_SIZE` can be for a table, based on the lengths of the key columns for each of its indexes. Specify a value that is too small, and the `CREATE TABLE` or `ALTER TABLE` statement fails.

In the buffer pool, the compressed data is held in small pages, with a page size based on the `KEY_BLOCK_SIZE` value. For extracting or updating the column values, MySQL also creates an uncompressed page in the buffer pool with the uncompressed data. Within the buffer pool, any updates to the uncompressed page are also re-written back to the equivalent compressed page. You might need to size your buffer pool to accommodate the additional data of both compressed and uncompressed pages, although the uncompressed pages are [evicted](#) from the buffer pool when space is needed, and then uncompressed again on the next access.

15.9.1.2 Creating Compressed Tables

Compressed tables can be created in [file-per-table](#) tablespaces or in [general tablespaces](#). Table compression is not available for the [InnoDB system tablespace](#). The system tablespace (space 0, the `.ibdata` files) can contain user-created tables, but it also contains internal system data, which is never compressed. Thus, compression applies only to tables (and indexes) stored in file-per-table or general tablespaces.

Creating a Compressed Table in File-Per-Table Tablespace

To create a compressed table in a file-per-table tablespace, `innodb_file_per_table` must be enabled (the default). You can set this parameter in the MySQL configuration file (`my.cnf` or `my.ini`) or dynamically, using a `SET` statement.

After the `innodb_file_per_table` option is configured, specify the `ROW_FORMAT=COMPRESSED` clause or `KEY_BLOCK_SIZE` clause, or both, in a `CREATE TABLE` or `ALTER TABLE` statement to create a compressed table in a file-per-table tablespace.

For example, you might use the following statements:

```
SET GLOBAL innodb_file_per_table=1;
CREATE TABLE t1
```

```
(c1 INT PRIMARY KEY)
ROW_FORMAT=COMPRESSED
KEY_BLOCK_SIZE=8;
```

Creating a Compressed Table in a General Tablespace

To create a compressed table in a general tablespace, `FILE_BLOCK_SIZE` must be defined for the general tablespace, which is specified when the tablespace is created. The `FILE_BLOCK_SIZE` value must be a valid compressed page size in relation to the `innodb_page_size` value, and the page size of the compressed table, defined by the `CREATE TABLE` or `ALTER TABLE KEY_BLOCK_SIZE` clause, must be equal to `FILE_BLOCK_SIZE/1024`. For example, if `innodb_page_size=16384` and `FILE_BLOCK_SIZE=8192`, the `KEY_BLOCK_SIZE` of the table must be 8. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

The following example demonstrates creating a general tablespace and adding a compressed table. The example assumes a default `innodb_page_size` of 16K. The `FILE_BLOCK_SIZE` of 8192 requires that the compressed table have a `KEY_BLOCK_SIZE` of 8.

```
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t4 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED KEY_BLOCK_SIZE=8;
Query OK, 0 rows affected (0.00 sec)
```

Notes

- If you specify `ROW_FORMAT=COMPRESSED`, you can omit `KEY_BLOCK_SIZE`; the `KEY_BLOCK_SIZE` setting defaults to half the `innodb_page_size` value.
- If you specify a valid `KEY_BLOCK_SIZE` value, you can omit `ROW_FORMAT=COMPRESSED`; compression is enabled automatically.
- To determine the best value for `KEY_BLOCK_SIZE`, typically you create several copies of the same table with different values for this clause, then measure the size of the resulting `.ibd` files and see how well each performs with a realistic [workload](#). For general tablespaces, keep in mind that dropping a table does not reduce the size of the general tablespace `.ibd` file, nor does it return disk space to the operating system. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).
- The `KEY_BLOCK_SIZE` value is treated as a hint; a different size could be used by InnoDB if necessary. For file-per-table tablespaces, the `KEY_BLOCK_SIZE` can only be less than or equal to the `innodb_page_size` value. If you specify a value greater than the `innodb_page_size` value, the specified value is ignored, a warning is issued, and `KEY_BLOCK_SIZE` is set to half of the `innodb_page_size` value. If `innodb_strict_mode=ON`, specifying an invalid `KEY_BLOCK_SIZE` value returns an error. For general tablespaces, valid `KEY_BLOCK_SIZE` values depend on the `FILE_BLOCK_SIZE` setting of the tablespace. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).
- InnoDB supports 32k and 64k page sizes but these page sizes do not support compression. For more information, refer to the `innodb_page_size` documentation.
- The default uncompressed size of InnoDB data pages is 16KB. Depending on the combination of option values, MySQL uses a page size of 1KB, 2KB, 4KB, 8KB, or 16KB for the tablespace data file (`.ibd` file). The actual compression algorithm is not affected by the `KEY_BLOCK_SIZE` value; the value determines how large each compressed chunk is, which in turn affects how many rows can be packed into each compressed page.
- When creating a compressed table in a file-per-table tablespace, setting `KEY_BLOCK_SIZE` equal to the InnoDB page size does not typically result in much compression. For example, setting `KEY_BLOCK_SIZE=16` typically would not result in much compression, since the normal InnoDB page size is 16KB. This setting may still be useful for tables with many long `BLOB`, `VARCHAR` or `TEXT` columns, because such values often do compress well, and might therefore require fewer [overflow](#)

pages as described in [Section 15.9.1.5, “How Compression Works for InnoDB Tables”](#). For general tablespaces, a `KEY_BLOCK_SIZE` value equal to the InnoDB page size is not permitted. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

- All indexes of a table (including the [clustered index](#)) are compressed using the same page size, as specified in the `CREATE TABLE` or `ALTER TABLE` statement. Table attributes such as `ROW_FORMAT` and `KEY_BLOCK_SIZE` are not part of the `CREATE INDEX` syntax for InnoDB tables, and are ignored if they are specified (although, if specified, they will appear in the output of the `SHOW CREATE TABLE` statement).
- For performance-related configuration options, see [Section 15.9.1.3, “Tuning Compression for InnoDB Tables”](#).

Restrictions on Compressed Tables

- Compressed tables cannot be stored in the InnoDB system tablespace.
- General tablespaces can contain multiple tables, but compressed and uncompressed tables cannot coexist within the same general tablespace.
- Compression applies to an entire table and all its associated indexes, not to individual rows, despite the clause name `ROW_FORMAT`.
- InnoDB does not support compressed temporary tables. When `innodb_strict_mode` is enabled (the default), `CREATE TEMPORARY TABLE` returns errors if `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` is specified. If `innodb_strict_mode` is disabled, warnings are issued and the temporary table is created using a non-compressed row format. The same restrictions apply to `ALTER TABLE` operations on temporary tables.

15.9.1.3 Tuning Compression for InnoDB Tables

Most often, the internal optimizations described in [InnoDB Data Storage and Compression](#) ensure that the system runs well with compressed data. However, because the efficiency of compression depends on the nature of your data, you can make decisions that affect the performance of compressed tables:

- Which tables to compress.
- What compressed page size to use.
- Whether to adjust the size of the buffer pool based on run-time performance characteristics, such as the amount of time the system spends compressing and uncompressing data. Whether the workload is more like a [data warehouse](#) (primarily queries) or an [OLTP](#) system (mix of queries and [DML](#)).
- If the system performs DML operations on compressed tables, and the way the data is distributed leads to expensive [compression failures](#) at runtime, you might adjust additional advanced configuration options.

Use the guidelines in this section to help make those architectural and configuration choices. When you are ready to conduct long-term testing and put compressed tables into production, see [Section 15.9.1.4, “Monitoring InnoDB Table Compression at Runtime”](#) for ways to verify the effectiveness of those choices under real-world conditions.

When to Use Compression

In general, compression works best on tables that include a reasonable number of character string columns and where the data is read far more often than it is written. Because there are no guaranteed ways to predict whether or not compression benefits a particular situation, always test with a specific [workload](#) and data set running on a representative configuration. Consider the following factors when deciding which tables to compress.

Data Characteristics and Compression

A key determinant of the efficiency of compression in reducing the size of data files is the nature of the data itself. Recall that compression works by identifying repeated strings of bytes in a block of data. Completely randomized data is the worst case. Typical data often has repeated values, and so compresses effectively. Character strings often compress well, whether defined in [CHAR](#), [VARCHAR](#), [TEXT](#) or [BLOB](#) columns. On the other hand, tables containing mostly binary data (integers or floating point numbers) or data that is previously compressed (for example JPEG or PNG images) may not generally compress well, significantly or at all.

You choose whether to turn on compression for each InnoDB table. A table and all of its indexes use the same (compressed) [page size](#). It might be that the [primary key](#) (clustered) index, which contains the data for all columns of a table, compresses more effectively than the secondary indexes. For those cases where there are long rows, the use of compression might result in long column values being stored “off-page”, as discussed in [Section 15.10.3, “DYNAMIC and COMPRESSED Row Formats”](#). Those overflow pages may compress well. Given these considerations, for many applications, some tables compress more effectively than others, and you might find that your workload performs best only with a subset of tables compressed.

To determine whether or not to compress a particular table, conduct experiments. You can get a rough estimate of how efficiently your data can be compressed by using a utility that implements LZ77 compression (such as [gzip](#) or WinZip) on a copy of the [.ibd file](#) for an uncompressed table. You can expect less compression from a MySQL compressed table than from file-based compression tools, because MySQL compresses data in chunks based on the [page size](#), 16KB by default. In addition to user data, the page format includes some internal system data that is not compressed. File-based compression utilities can examine much larger chunks of data, and so might find more repeated strings in a huge file than MySQL can find in an individual page.

Another way to test compression on a specific table is to copy some data from your uncompressed table to a similar, compressed table (having all the same indexes) in a [file-per-table](#) tablespace and look at the size of the resulting [.ibd](#) file. For example:

```
use test;
set global innodb_file_per_table=1;
set global autocommit=0;

-- Create an uncompressed table with a million or two rows.
create table big_table as select * from information_schema.columns;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
insert into big_table select * from big_table;
commit;
alter table big_table add id int unsigned not null primary key auto_increment;

show create table big_table\G

select count(id) from big_table;

-- Check how much space is needed for the uncompressed table.
\! ls -l data/test/big_table.ibd

create table key_block_size_4 like big_table;
alter table key_block_size_4 key_block_size=4 row_format=compressed;

insert into key_block_size_4 select * from big_table;
commit;

-- Check how much space is needed for a compressed table
-- with particular compression settings.
\! ls -l data/test/key_block_size_4.ibd
```

This experiment produced the following numbers, which of course could vary considerably depending on your table structure and data:

```
-rw-rw---- 1 cirrus  staff  310378496 Jan  9 13:44 data/test/big_table.ibd
-rw-rw---- 1 cirrus  staff  83886080 Jan  9 15:10 data/test/key_block_size_4.ibd
```

To see whether compression is efficient for your particular [workload](#):

- For simple tests, use a MySQL instance with no other compressed tables and run queries against the `INFORMATION_SCHEMA.INNODB_CMP` table.
- For more elaborate tests involving workloads with multiple compressed tables, run queries against the `INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX` table. Because the statistics in the `INNODB_CMP_PER_INDEX` table are expensive to collect, you must enable the configuration option `innodb_cmp_per_index_enabled` before querying that table, and you might restrict such testing to a development server or a non-critical [slave server](#).
- Run some typical SQL statements against the compressed table you are testing.
- Examine the ratio of successful compression operations to overall compression operations by querying the `INFORMATION_SCHEMA.INNODB_CMP` or `INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX` table, and comparing `COMPRESS_OPS` to `COMPRESS_OPS_OK`.
- If a high percentage of compression operations complete successfully, the table might be a good candidate for compression.
- If you get a high proportion of [compression failures](#), you can adjust `innodb_compression_level`, `innodb_compression_failure_threshold_pct`, and `innodb_compression_pad_pct_max` options as described in [Section 15.9.1.6, "Compression for OLTP Workloads"](#), and try further tests.

Database Compression versus Application Compression

Decide whether to compress data in your application or in the table; do not use both types of compression for the same data. When you compress the data in the application and store the results in a compressed table, extra space savings are extremely unlikely, and the double compression just wastes CPU cycles.

Compressing in the Database

When enabled, MySQL table compression is automatic and applies to all columns and index values. The columns can still be tested with operators such as `LIKE`, and sort operations can still use indexes even when the index values are compressed. Because indexes are often a significant fraction of the total size of a database, compression could result in significant savings in storage, I/O or processor time. The compression and decompression operations happen on the database server, which likely is a powerful system that is sized to handle the expected load.

Compressing in the Application

If you compress data such as text in your application, before it is inserted into the database, You might save overhead for data that does not compress well by compressing some columns and not others. This approach uses CPU cycles for compression and uncompression on the client machine rather than the database server, which might be appropriate for a distributed application with many clients, or where the client machine has spare CPU cycles.

Hybrid Approach

Of course, it is possible to combine these approaches. For some applications, it may be appropriate to use some compressed tables and some uncompressed tables. It may be best to externally compress some data (and store it in uncompressed tables) and allow MySQL to compress (some of) the other tables in the application. As always, up-front design and real-life testing are valuable in reaching the right decision.

Workload Characteristics and Compression

In addition to choosing which tables to compress (and the page size), the workload is another key determinant of performance. If the application is dominated by reads, rather than updates, fewer pages need to be reorganized and recompressed after the index page runs out of room for the per-page “modification log” that MySQL maintains for compressed data. If the updates predominantly change non-indexed columns or those containing [BLOBs](#) or large strings that happen to be stored “off-page”, the overhead of compression may be acceptable. If the only changes to a table are [INSERTs](#) that use a monotonically increasing primary key, and there are few secondary indexes, there is little need to reorganize and recompress index pages. Since MySQL can “delete-mark” and delete rows on compressed pages “in place” by modifying uncompressed data, [DELETE](#) operations on a table are relatively efficient.

For some environments, the time it takes to load data can be as important as run-time retrieval. Especially in data warehouse environments, many tables may be read-only or read-mostly. In those cases, it might or might not be acceptable to pay the price of compression in terms of increased load time, unless the resulting savings in fewer disk reads or in storage cost is significant.

Fundamentally, compression works best when the CPU time is available for compressing and uncompressing data. Thus, if your workload is I/O bound, rather than CPU-bound, you might find that compression can improve overall performance. When you test your application performance with different compression configurations, test on a platform similar to the planned configuration of the production system.

Configuration Characteristics and Compression

Reading and writing database [pages](#) from and to disk is the slowest aspect of system performance. Compression attempts to reduce I/O by using CPU time to compress and uncompress data, and is most effective when I/O is a relatively scarce resource compared to processor cycles.

This is often especially the case when running in a multi-user environment with fast, multi-core CPUs. When a page of a compressed table is in memory, MySQL often uses additional memory, typically 16KB, in the [buffer pool](#) for an uncompressed copy of the page. The adaptive LRU algorithm attempts to balance the use of memory between compressed and uncompressed pages to take into account whether the workload is running in an I/O-bound or CPU-bound manner. Still, a configuration with more memory dedicated to the buffer pool tends to run better when using compressed tables than a configuration where memory is highly constrained.

Choosing the Compressed Page Size

The optimal setting of the compressed page size depends on the type and distribution of data that the table and its indexes contain. The compressed page size should always be bigger than the maximum record size, or operations may fail as noted in [Compression of B-Tree Pages](#).

Setting the compressed page size too large wastes some space, but the pages do not have to be compressed as often. If the compressed page size is set too small, inserts or updates may require time-consuming recompression, and the [B-tree](#) nodes may have to be split more frequently, leading to bigger data files and less efficient indexing.

Typically, you set the compressed page size to 8K or 4K bytes. Given that the maximum row size for an InnoDB table is around 8K, [KEY_BLOCK_SIZE=8](#) is usually a safe choice.

15.9.1.4 Monitoring InnoDB Table Compression at Runtime

Overall application performance, CPU and I/O utilization and the size of disk files are good indicators of how effective compression is for your application. This section builds on the performance tuning advice from [Section 15.9.1.3, “Tuning Compression for InnoDB Tables”](#), and shows how to find problems that might not turn up during initial testing.

To dig deeper into performance considerations for compressed tables, you can monitor compression performance at runtime using the [Information Schema](#) tables described in [Example 15.1, “Using the](#)

[Compression Information Schema Tables](#)". These tables reflect the internal use of memory and the rates of compression used overall.

The `INNODB_CMP` table reports information about compression activity for each compressed page size (`KEY_BLOCK_SIZE`) in use. The information in these tables is system-wide: it summarizes the compression statistics across all compressed tables in your database. You can use this data to help decide whether or not to compress a table by examining these tables when no other compressed tables are being accessed. It involves relatively low overhead on the server, so you might query it periodically on a production server to check the overall efficiency of the compression feature.

The `INNODB_CMP_PER_INDEX` table reports information about compression activity for individual tables and indexes. This information is more targeted and more useful for evaluating compression efficiency and diagnosing performance issues one table or index at a time. (Because that each InnoDB table is represented as a clustered index, MySQL does not make a big distinction between tables and indexes in this context.) The `INNODB_CMP_PER_INDEX` table does involve substantial overhead, so it is more suitable for development servers, where you can compare the effects of different [workloads](#), data, and compression settings in isolation. To guard against imposing this monitoring overhead by accident, you must enable the `innodb_cmp_per_index_enabled` configuration option before you can query the `INNODB_CMP_PER_INDEX` table.

The key statistics to consider are the number of, and amount of time spent performing, compression and uncompression operations. Since MySQL splits [B-tree](#) nodes when they are too full to contain the compressed data following a modification, compare the number of "successful" compression operations with the number of such operations overall. Based on the information in the `INNODB_CMP` and `INNODB_CMP_PER_INDEX` tables and overall application performance and hardware resource utilization, you might make changes in your hardware configuration, adjust the size of the buffer pool, choose a different page size, or select a different set of tables to compress.

If the amount of CPU time required for compressing and uncompressing is high, changing to faster or multi-core CPUs can help improve performance with the same data, application workload and set of compressed tables. Increasing the size of the buffer pool might also help performance, so that more uncompressed pages can stay in memory, reducing the need to uncompress pages that exist in memory only in compressed form.

A large number of compression operations overall (compared to the number of `INSERT`, `UPDATE` and `DELETE` operations in your application and the size of the database) could indicate that some of your compressed tables are being updated too heavily for effective compression. If so, choose a larger page size, or be more selective about which tables you compress.

If the number of "successful" compression operations (`COMPRESS_OPS_OK`) is a high percentage of the total number of compression operations (`COMPRESS_OPS`), then the system is likely performing well. If the ratio is low, then MySQL is reorganizing, recompressing, and splitting B-tree nodes more often than is desirable. In this case, avoid compressing some tables, or increase `KEY_BLOCK_SIZE` for some of the compressed tables. You might turn off compression for tables that cause the number of "compression failures" in your application to be more than 1% or 2% of the total. (Such a failure ratio might be acceptable during a temporary operation such as a data load).

15.9.1.5 How Compression Works for InnoDB Tables

This section describes some internal implementation details about [compression](#) for InnoDB tables. The information presented here may be helpful in tuning for performance, but is not necessary to know for basic use of compression.

Compression Algorithms

Some operating systems implement compression at the file system level. Files are typically divided into fixed-size blocks that are compressed into variable-size blocks, which easily leads into fragmentation. Every time something inside a block is modified, the whole block is recompressed before it is written to disk. These properties make this compression technique unsuitable for use in an update-intensive database system.

MySQL implements compression with the help of the well-known [zlib library](#), which implements the LZ77 compression algorithm. This compression algorithm is mature, robust, and efficient in both CPU utilization and in reduction of data size. The algorithm is “lossless”, so that the original uncompressed data can always be reconstructed from the compressed form. LZ77 compression works by finding sequences of data that are repeated within the data to be compressed. The patterns of values in your data determine how well it compresses, but typical user data often compresses by 50% or more.

Unlike compression performed by an application, or compression features of some other database management systems, InnoDB compression applies both to user data and to indexes. In many cases, indexes can constitute 40-50% or more of the total database size, so this difference is significant. When compression is working well for a data set, the size of the InnoDB data files (the [file-per-table](#) tablespace or [general tablespace](#) `.ibd` files) is 25% to 50% of the uncompressed size or possibly smaller. Depending on the [workload](#), this smaller database can in turn lead to a reduction in I/O, and an increase in throughput, at a modest cost in terms of increased CPU utilization. You can adjust the balance between compression level and CPU overhead by modifying the `innodb_compression_level` configuration option.

InnoDB Data Storage and Compression

All user data in InnoDB tables is stored in pages comprising a [B-tree](#) index (the [clustered index](#)). In some other database systems, this type of index is called an “index-organized table”. Each row in the index node contains the values of the (user-specified or system-generated) [primary key](#) and all the other columns of the table.

[Secondary indexes](#) in InnoDB tables are also B-trees, containing pairs of values: the index key and a pointer to a row in the clustered index. The pointer is in fact the value of the primary key of the table, which is used to access the clustered index if columns other than the index key and primary key are required. Secondary index records must always fit on a single B-tree page.

The compression of B-tree nodes (of both clustered and secondary indexes) is handled differently from compression of [overflow pages](#) used to store long [VARCHAR](#), [BLOB](#), or [TEXT](#) columns, as explained in the following sections.

Compression of B-Tree Pages

Because they are frequently updated, B-tree pages require special treatment. It is important to minimize the number of times B-tree nodes are split, as well as to minimize the need to uncompress and recompress their content.

One technique MySQL uses is to maintain some system information in the B-tree node in uncompressed form, thus facilitating certain in-place updates. For example, this allows rows to be delete-marked and deleted without any compression operation.

In addition, MySQL attempts to avoid unnecessary uncompression and recompression of index pages when they are changed. Within each B-tree page, the system keeps an uncompressed “modification log” to record changes made to the page. Updates and inserts of small records may be written to this modification log without requiring the entire page to be completely reconstructed.

When the space for the modification log runs out, InnoDB uncompresses the page, applies the changes and recompresses the page. If recompression fails (a situation known as a [compression failure](#)), the B-tree nodes are split and the process is repeated until the update or insert succeeds.

To avoid frequent compression failures in write-intensive workloads, such as for [OLTP](#) applications, MySQL sometimes reserves some empty space (padding) in the page, so that the modification log fills up sooner and the page is recompressed while there is still enough room to avoid splitting it. The amount of padding space left in each page varies as the system keeps track of the frequency of page splits. On a busy server doing frequent writes to compressed tables, you can adjust the `innodb_compression_failure_threshold_pct`, and `innodb_compression_pad_pct_max` configuration options to fine-tune this mechanism.

Generally, MySQL requires that each B-tree page in an InnoDB table can accommodate at least two records. For compressed tables, this requirement has been relaxed. Leaf pages of B-tree nodes (whether of the primary key or secondary indexes) only need to accommodate one record, but that record must fit, in uncompressed form, in the per-page modification log. If `innodb_strict_mode` is `ON`, MySQL checks the maximum row size during `CREATE TABLE` or `CREATE INDEX`. If the row does not fit, the following error message is issued: `ERROR HY000: Too big row`.

If you create a table when `innodb_strict_mode` is `OFF`, and a subsequent `INSERT` or `UPDATE` statement attempts to create an index entry that does not fit in the size of the compressed page, the operation fails with `ERROR 42000: Row size too large`. (This error message does not name the index for which the record is too large, or mention the length of the index record or the maximum record size on that particular index page.) To solve this problem, rebuild the table with `ALTER TABLE` and select a larger compressed page size (`KEY_BLOCK_SIZE`), shorten any column prefix indexes, or disable compression entirely with `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPACT`.

`innodb_strict_mode` is not applicable to general tablespaces, which also support compressed tables. Tablespace management rules for general tablespaces are strictly enforced independently of `innodb_strict_mode`. For more information, see [Section 13.1.16, “CREATE TABLESPACE Syntax”](#).

Compressing BLOB, VARCHAR, and TEXT Columns

In an InnoDB table, `BLOB`, `VARCHAR`, and `TEXT` columns that are not part of the primary key may be stored on separately allocated [overflow pages](#). We refer to these columns as [off-page columns](#). Their values are stored on singly-linked lists of overflow pages.

For tables created in `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, the values of `BLOB`, `TEXT`, or `VARCHAR` columns may be stored fully off-page, depending on their length and the length of the entire row. For columns that are stored off-page, the clustered index record only contains 20-byte pointers to the overflow pages, one per column. Whether any columns are stored off-page depends on the page size and the total size of the row. When the row is too long to fit entirely within the page of the clustered index, MySQL chooses the longest columns for off-page storage until the row fits on the clustered index page. As noted above, if a row does not fit by itself on a compressed page, an error occurs.

Note

For tables created in `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, `TEXT` and `BLOB` columns that are less than or equal to 40 bytes are always stored in-line.

Tables that use `ROW_FORMAT=REDUNDANT` and `ROW_FORMAT=COMPACT` store the first 768 bytes of `BLOB`, `VARCHAR`, and `TEXT` columns in the clustered index record along with the primary key. The 768-byte prefix is followed by a 20-byte pointer to the overflow pages that contain the rest of the column value.

When a table is in `COMPRESSED` format, all data written to overflow pages is compressed “as is”; that is, MySQL applies the `zlib` compression algorithm to the entire data item. Other than the data, compressed overflow pages contain an uncompressed header and trailer comprising a page checksum and a link to the next overflow page, among other things. Therefore, very significant storage savings can be obtained for longer `BLOB`, `TEXT`, or `VARCHAR` columns if the data is highly compressible, as is often the case with text data. Image data, such as `JPEG`, is typically already compressed and so does not benefit much from being stored in a compressed table; the double compression can waste CPU cycles for little or no space savings.

The overflow pages are of the same size as other pages. A row containing ten columns stored off-page occupies ten overflow pages, even if the total length of the columns is only 8K bytes. In an uncompressed table, ten uncompressed overflow pages occupy 160K bytes. In a compressed table with an 8K page size, they occupy only 80K bytes. Thus, it is often more efficient to use compressed table format for tables with long column values.

For [file-per-table](#) tablespaces, using a 16K compressed page size can reduce storage and I/O costs for [BLOB](#), [VARCHAR](#), or [TEXT](#) columns, because such data often compress well, and might therefore require fewer overflow pages, even though the B-tree nodes themselves take as many pages as in the uncompressed form. General tablespaces do not support a 16K compressed page size ([KEY_BLOCK_SIZE](#)). For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

Compression and the InnoDB Buffer Pool

In a compressed [InnoDB](#) table, every compressed page (whether 1K, 2K, 4K or 8K) corresponds to an uncompressed page of 16K bytes (or a smaller size if [innodb_page_size](#) is set). To access the data in a page, MySQL reads the compressed page from disk if it is not already in the [buffer pool](#), then uncompresses the page to its original form. This section describes how [InnoDB](#) manages the buffer pool with respect to pages of compressed tables.

To minimize I/O and to reduce the need to uncompress a page, at times the buffer pool contains both the compressed and uncompressed form of a database page. To make room for other required database pages, MySQL can [evict](#) from the buffer pool an uncompressed page, while leaving the compressed page in memory. Or, if a page has not been accessed in a while, the compressed form of the page might be written to disk, to free space for other data. Thus, at any given time, the buffer pool might contain both the compressed and uncompressed forms of the page, or only the compressed form of the page, or neither.

MySQL keeps track of which pages to keep in memory and which to evict using a least-recently-used ([LRU](#)) list, so that [hot](#) (frequently accessed) data tends to stay in memory. When compressed tables are accessed, MySQL uses an adaptive LRU algorithm to achieve an appropriate balance of compressed and uncompressed pages in memory. This adaptive algorithm is sensitive to whether the system is running in an [I/O-bound](#) or [CPU-bound](#) manner. The goal is to avoid spending too much processing time uncompressing pages when the CPU is busy, and to avoid doing excess I/O when the CPU has spare cycles that can be used for uncompressing compressed pages (that may already be in memory). When the system is I/O-bound, the algorithm prefers to evict the uncompressed copy of a page rather than both copies, to make more room for other disk pages to become memory resident. When the system is CPU-bound, MySQL prefers to evict both the compressed and uncompressed page, so that more memory can be used for “hot” pages and reducing the need to uncompress data in memory only in compressed form.

Compression and the InnoDB Redo Log Files

Before a compressed page is written to a [data file](#), MySQL writes a copy of the page to the redo log (if it has been recompressed since the last time it was written to the database). This is done to ensure that redo logs are usable for [crash recovery](#), even in the unlikely case that the [zlib](#) library is upgraded and that change introduces a compatibility problem with the compressed data. Therefore, some increase in the size of [log files](#), or a need for more frequent [checkpoints](#), can be expected when using compression. The amount of increase in the log file size or checkpoint frequency depends on the number of times compressed pages are modified in a way that requires reorganization and recompression.

To create a compressed table in a file-per-table tablespace, [innodb_file_per_table](#) must be enabled. There is no dependence on the [innodb_file_per_table](#) setting when creating a compressed table in a general tablespace. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

15.9.1.6 Compression for OLTP Workloads

Traditionally, the [InnoDB compression](#) feature was recommended primarily for read-only or read-mostly [workloads](#), such as in a [data warehouse](#) configuration. The rise of [SSD](#) storage devices, which are fast but relatively small and expensive, makes compression attractive also for [OLTP](#) workloads: high-traffic, interactive web sites can reduce their storage requirements and their I/O operations per second ([IOPS](#)) by using compressed tables with applications that do frequent [INSERT](#), [UPDATE](#), and [DELETE](#) operations.

These configuration options let you adjust the way compression works for a particular MySQL instance, with an emphasis on performance and scalability for write-intensive operations:

- `innodb_compression_level` lets you turn the degree of compression up or down. A higher value lets you fit more data onto a storage device, at the expense of more CPU overhead during compression. A lower value lets you reduce CPU overhead when storage space is not critical, or you expect the data is not especially compressible.
- `innodb_compression_failure_threshold_pct` specifies a cutoff point for [compression failures](#) during updates to a compressed table. When this threshold is passed, MySQL begins to leave additional free space within each new compressed page, dynamically adjusting the amount of free space up to the percentage of page size specified by `innodb_compression_pad_pct_max`
- `innodb_compression_pad_pct_max` lets you adjust the maximum amount of space reserved within each [page](#) to record changes to compressed rows, without needing to compress the entire page again. The higher the value, the more changes can be recorded without recompressing the page. MySQL uses a variable amount of free space for the pages within each compressed table, only when a designated percentage of compression operations “fail” at runtime, requiring an expensive operation to split the compressed page.
- `innodb_log_compressed_pages` lets you disable writing of images of [re-compressed pages](#) to the [redo log](#). Re-compression may occur when changes are made to compressed data. This option is enabled by default to prevent corruption that could occur if a different version of the `zlib` compression algorithm is used during recovery. If you are certain that the `zlib` version will not change, disable `innodb_log_compressed_pages` to reduce redo log generation for workloads that modify compressed data.

Because working with compressed data sometimes involves keeping both compressed and uncompressed versions of a page in memory at the same time, when using compression with an OLTP-style workload, be prepared to increase the value of the `innodb_buffer_pool_size` configuration option.

15.9.1.7 SQL Compression Syntax Warnings and Errors

This section describes syntax warnings and errors that you may encounter when using the table compression feature with [file-per-table](#) tablespaces and [general tablespaces](#).

SQL Compression Syntax Warnings and Errors for File-Per-Table Tablespaces

When `innodb_strict_mode` is enabled (the default), specifying `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` in `CREATE TABLE` or `ALTER TABLE` statements produces the following error if `innodb_file_per_table` is disabled.

```
ERROR 1031 (HY000): Table storage engine for 't1' doesn't have this option
```

Note

The table is not created if the current configuration does not permit using compressed tables.

When `innodb_strict_mode` is disabled, specifying `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` in `CREATE TABLE` or `ALTER TABLE` statements produces the following warnings if `innodb_file_per_table` is disabled.

```
mysql> SHOW WARNINGS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Warning | 1478 | InnoDB: KEY_BLOCK_SIZE requires innodb_file_per_table. |
| Warning | 1478 | InnoDB: ignoring KEY_BLOCK_SIZE=4.           |
| Warning | 1478 | InnoDB: ROW_FORMAT=COMPRESSED requires innodb_file_per_table. |
| Warning | 1478 | InnoDB: assuming ROW_FORMAT=DYNAMIC.       |
+-----+-----+-----+
```

**Note**

These messages are only warnings, not errors, and the table is created without compression, as if the options were not specified.

The “non-strict” behavior lets you import a `mysqldump` file into a database that does not support compressed tables, even if the source database contained compressed tables. In that case, MySQL creates the table in `ROW_FORMAT=DYNAMIC` instead of preventing the operation.

To import the dump file into a new database, and have the tables re-created as they exist in the original database, ensure the server has the proper setting for the `innodb_file_per_table` configuration parameter.

The attribute `KEY_BLOCK_SIZE` is permitted only when `ROW_FORMAT` is specified as `COMPRESSED` or is omitted. Specifying a `KEY_BLOCK_SIZE` with any other `ROW_FORMAT` generates a warning that you can view with `SHOW WARNINGS`. However, the table is non-compressed; the specified `KEY_BLOCK_SIZE` is ignored).

Level	Code	Message
Warning	1478	InnoDB: ignoring KEY_BLOCK_SIZE=n unless ROW_FORMAT=COMPRESSED.

If you are running with `innodb_strict_mode` enabled, the combination of a `KEY_BLOCK_SIZE` with any `ROW_FORMAT` other than `COMPRESSED` generates an error, not a warning, and the table is not created.

Table 15.7, “`ROW_FORMAT` and `KEY_BLOCK_SIZE` Options” provides an overview the `ROW_FORMAT` and `KEY_BLOCK_SIZE` options that are used with `CREATE TABLE` or `ALTER TABLE`.

Table 15.7 `ROW_FORMAT` and `KEY_BLOCK_SIZE` Options

Option	Usage Notes	Description
<code>ROW_FORMAT=REDUNDANT</code>	Storage format used prior to MySQL 5.0.3	Less efficient than <code>ROW_FORMAT=COMPACT</code> ; for backward compatibility
<code>ROW_FORMAT=COMPACT</code>	Default storage format since MySQL 5.0.3	Stores a prefix of 768 bytes of long column values in the clustered index page, with the remaining bytes stored in an overflow page
<code>ROW_FORMAT=DYNAMIC</code>		Store values within the clustered index page if they fit; if not, stores only a 20-byte pointer to an overflow page (no prefix)
<code>ROW_FORMAT=COMPRESSED</code>		Compresses the table and indexes using zlib
<code>KEY_BLOCK_SIZE=n</code>		Specifies compressed page size of 1, 2, 4, 8 or 16 kilobytes; implies <code>ROW_FORMAT=COMPRESSED</code> . For general tablespaces, a <code>KEY_BLOCK_SIZE</code> value equal to the InnoDB page size is not permitted.

Table 15.8, “`CREATE/ALTER TABLE` Warnings and Errors when InnoDB Strict Mode is OFF” summarizes error conditions that occur with certain combinations of configuration parameters and options on the `CREATE TABLE` or `ALTER TABLE` statements, and how the options appear in the output of `SHOW TABLE STATUS`.

When `innodb_strict_mode` is `OFF`, MySQL creates or alters the table, but ignores certain settings as shown below. You can see the warning messages in the MySQL error log. When `innodb_strict_mode` is `ON`, these specified combinations of options generate errors, and the table is not created or altered. To see the full description of the error condition, issue the `SHOW ERRORS` statement: example:

```
mysql> CREATE TABLE x (id INT PRIMARY KEY, c INT)
-> ENGINE=INNODB KEY_BLOCK_SIZE=33333;

ERROR 1005 (HY000): Can't create table 'test.x' (errno: 1478)

mysql> SHOW ERRORS;
+-----+-----+-----+
| Level | Code | Message                                     |
+-----+-----+-----+
| Error | 1478 | InnoDB: invalid KEY_BLOCK_SIZE=33333.     |
| Error | 1005 | Can't create table 'test.x' (errno: 1478) |
+-----+-----+-----+
```

Table 15.8 CREATE/ALTER TABLE Warnings and Errors when InnoDB Strict Mode is OFF

Syntax	Warning or Error Condition	Resulting <code>ROW_FORMAT</code> , as shown in <code>SHOW TABLE STATUS</code>
<code>ROW_FORMAT=REDUNDANT</code>	None	REDUNDANT
<code>ROW_FORMAT=COMPACT</code>	None	COMPACT
<code>ROW_FORMAT=COMPRESSED</code> or <code>ROW_FORMAT=DYNAMIC</code> or <code>KEY_BLOCK_SIZE</code> is specified	Ignored for file-per-table tablespaces unless <code>innodb_file_per_table</code> is enabled. General tablespaces support all row formats. See Section 15.7.9, “InnoDB General Tablespaces”.	the default row format for file-per-table tablespaces; the specified row format for general tablespaces
Invalid <code>KEY_BLOCK_SIZE</code> is specified (not 1, 2, 4, 8 or 16)	<code>KEY_BLOCK_SIZE</code> is ignored	the specified row format, or the default row format
<code>ROW_FORMAT=COMPRESSED</code> and valid <code>KEY_BLOCK_SIZE</code> are specified	None; <code>KEY_BLOCK_SIZE</code> specified is used	COMPRESSED
<code>KEY_BLOCK_SIZE</code> is specified with <code>REDUNDANT</code> , <code>COMPACT</code> or <code>DYNAMIC</code> row format	<code>KEY_BLOCK_SIZE</code> is ignored	REDUNDANT, COMPACT or DYNAMIC
<code>ROW_FORMAT</code> is not one of <code>REDUNDANT</code> , <code>COMPACT</code> , <code>DYNAMIC</code> or <code>COMPRESSED</code>	Ignored if recognized by the MySQL parser. Otherwise, an error is issued.	the default row format or N/A

When `innodb_strict_mode` is ON, MySQL rejects invalid `ROW_FORMAT` or `KEY_BLOCK_SIZE` parameters and issues errors. Strict mode is ON by default. When `innodb_strict_mode` is OFF, MySQL issues warnings instead of errors for ignored invalid parameters.

It is not possible to see the chosen `KEY_BLOCK_SIZE` using `SHOW TABLE STATUS`. The statement `SHOW CREATE TABLE` displays the `KEY_BLOCK_SIZE` (even if it was ignored when creating the table). The real compressed page size of the table cannot be displayed by MySQL.

SQL Compression Syntax Warnings and Errors for General Tablespaces

- If `FILE_BLOCK_SIZE` was not defined for the general tablespace when the tablespace was created, the tablespace cannot contain compressed tables. If you attempt to add a compressed table, an error is returned, as shown in the following example:

```
mysql> CREATE TABLESPACE `ts1` ADD DATAFILE 'ts1.ibd' Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY) TABLESPACE ts1 ROW_FORMAT=COMPRESSED
```

```
KEY_BLOCK_SIZE=8;
ERROR 1478 (HY000): InnoDB: Tablespace `ts1` cannot contain a COMPRESSED table
```

- Attempting to add a table with an invalid `KEY_BLOCK_SIZE` to a general tablespace returns an error, as shown in the following example:

```
mysql> CREATE TABLESPACE `ts2` ADD DATAFILE 'ts2.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t2 (c1 INT PRIMARY KEY) TABLESPACE ts2 ROW_FORMAT=COMPRESSED
KEY_BLOCK_SIZE=4;
ERROR 1478 (HY000): InnoDB: Tablespace `ts2` uses block size 8192 and cannot
contain a table with physical page size 4096
```

For general tablespaces, the `KEY_BLOCK_SIZE` of the table must be equal to the `FILE_BLOCK_SIZE` of the tablespace divided by 1024. For example, if the `FILE_BLOCK_SIZE` of the tablespace is 8192, the `KEY_BLOCK_SIZE` of the table must be 8.

- Attempting to add a table with an uncompressed row format to a general tablespace configured to store compressed tables returns an error, as shown in the following example:

```
mysql> CREATE TABLESPACE `ts3` ADD DATAFILE 'ts3.ibd' FILE_BLOCK_SIZE = 8192 Engine=InnoDB;
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE t3 (c1 INT PRIMARY KEY) TABLESPACE ts3 ROW_FORMAT=COMPACT;
ERROR 1478 (HY000): InnoDB: Tablespace `ts3` uses block size 8192 and cannot
contain a table with physical page size 16384
```

`innodb_strict_mode` is not applicable to general tablespaces. Tablespace management rules for general tablespaces are strictly enforced independently of `innodb_strict_mode`. For more information, see [Section 13.1.16, “CREATE TABLESPACE Syntax”](#).

For more information about using compressed tables with general tablespaces, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

15.9.2 InnoDB Page Compression

InnoDB supports page-level compression for tables that reside in [file-per-table](#) tablespaces. This feature is referred to as *Transparent Page Compression*. Page compression is enabled by specifying the `COMPRESSION` attribute with `CREATE TABLE` or `ALTER TABLE`. Supported compression algorithms include [Zlib](#) and [LZ4](#).

Supported Platforms

Page compression requires sparse file and hole punching support. Page compression is supported on Windows with NTFS, and on the following subset of MySQL-supported Linux platforms where the kernel level provides hole punching support:

- RHEL 7 and derived distributions that use kernel version 3.10.0-123 or higher
- OEL 5.10 (UEK2) kernel version 2.6.39 or higher
- OEL 6.5 (UEK3) kernel version 3.8.13 or higher
- OEL 7.0 kernel version 3.8.13 or higher
- SLE11 kernel version 3.0-x
- SLE12 kernel version 3.12-x
- OES11 kernel version 3.0-x
- Ubuntu 14.0.4 LTS kernel version 3.13 or higher
- Ubuntu 12.0.4 LTS kernel version 3.2 or higher

- Debian 7 kernel version 3.2 or higher

Note

All of the available file systems for a given Linux distribution may not support hole punching.

How Page Compression Works

When a page is written, it is compressed using the specified compression algorithm. The compressed data is written to disk, where the hole punching mechanism releases empty blocks from the end of the page. If compression fails, data is written out as-is.

Hole Punch Size on Linux

On Linux systems, the file system block size is the unit size used for hole punching. Therefore, page compression only works if page data can be compressed to a size that is less than or equal to the [InnoDB](#) page size minus the file system block size. For example, if `innodb_page_size=16K` and the file system block size is 4K, page data must compress to less than or equal to 12K to make hole punching possible.

Hole Punch Size on Windows

On Windows systems, the underlying infrastructure for sparse files is based on NTFS compression. Hole punching size is the NTFS compression unit, which is 16 times the NTFS cluster size. Cluster sizes and their compression units are shown in the following table:

Table 15.9 Windows NTFS Cluster Size and Compression Units

Cluster Size	Compression Unit
512 Bytes	8 KB
1 KB	16 KB
2 KB	32 KB
4 KB	64 KB

Page compression on Windows systems only works if page data can be compressed to a size that is less than or equal to the [InnoDB](#) page size minus the compression unit size.

The default NTFS cluster size is 4K, for which the compression unit size is 64K. This means that page compression has no benefit for an out-of-the box Windows NTFS configuration, as the maximum `innodb_page_size` is also 64K.

For page compression to work on Windows, the file system must be created with a cluster size smaller than 4K, and the `innodb_page_size` must be at least twice the size of the compression unit. For example, for page compression to work on Windows, you could build the file system with a cluster size of 512 Bytes (which has a compression unit of 8KB) and initialize [InnoDB](#) with an `innodb_page_size` value of 16K or greater.

Enabling Page Compression

To enable page compression, specify the `COMPRESSION` attribute in the `CREATE TABLE` statement. For example:

```
CREATE TABLE t1 (c1 INT) COMPRESSION="zlib";
```

You can also enable page compression in an `ALTER TABLE` statement. However, `ALTER TABLE ... COMPRESSION` only updates the tablespace compression attribute. Writes to the tablespace that occur after setting the new compression algorithm use the new setting, but to apply the new compression algorithm to existing pages, you must rebuild the table using `OPTIMIZE TABLE`.

```
ALTER TABLE t1 COMPRESSION="zlib";
```

```
OPTIMIZE TABLE t1;
```

Disabling Page Compression

To disable page compression, set `COMPRESSION=None` using `ALTER TABLE`. Writes to the tablespace that occur after setting `COMPRESSION=None` no longer use page compression. To uncompress existing pages, you must rebuild the table using `OPTIMIZE TABLE` after setting `COMPRESSION=None`.

```
ALTER TABLE t1 COMPRESSION="None";
OPTIMIZE TABLE t1;
```

Page Compression Metadata

Page compression metadata is found in the `INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES` table, in the following columns:

- `FS_BLOCK_SIZE`: The file system block size, which is the unit size used for hole punching.
- `FILE_SIZE`: The apparent size of the file, which represents the maximum size of the file, uncompressed.
- `ALLOCATED_SIZE`: The actual size of the file, which is the amount of space allocated on disk.

Note

On Unix-like systems, `ls -l tablespace_name.ibd` shows the apparent file size (equivalent to `FILE_SIZE`) in bytes. To view the actual amount of space allocated on disk (equivalent to `ALLOCATED_SIZE`), use `du --block-size=1 tablespace_name.ibd`. The `--block-size=1` option prints the allocated space in bytes instead of blocks, so that it can be compared to `ls -l` output.

Use `SHOW CREATE TABLE` to view the current page compression setting (`Zlib`, `Lz4`, or `None`). A table may contain a mix of pages with different compression settings.

In the following example, page compression metadata for the `employees` table is retrieved from the `INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES` table.

```
# Create the employees table with Zlib page compression

CREATE TABLE employees (
  emp_no      INT          NOT NULL,
  birth_date  DATE         NOT NULL,
  first_name  VARCHAR(14)  NOT NULL,
  last_name   VARCHAR(16)  NOT NULL,
  gender      ENUM ('M','F') NOT NULL,
  hire_date   DATE         NOT NULL,
  PRIMARY KEY (emp_no)
) COMPRESSION="zlib";

# Insert data (not shown)

# Query page compression metadata in INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES

mysql> SELECT SPACE, NAME, FS_BLOCK_SIZE, FILE_SIZE, ALLOCATED_SIZE FROM
INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE NAME='employees/employees'\G
***** 1. row *****
SPACE: 45
NAME: employees/employees
FS_BLOCK_SIZE: 4096
FILE_SIZE: 23068672
ALLOCATED_SIZE: 19415040
```

Page compression metadata for the `employees` table shows that the apparent file size is 23068672 bytes while the actual file size (with page compression) is 19415040 bytes. The file system block size is 4096 bytes, which is the block size used for hole punching.

Page Compression Limitations and Usage Notes

- Page compression is disabled if the file system block size (or compression unit size on Windows) * 2 > `innodb_page_size`.
- Page compression is not supported for tables that reside in shared tablespaces, which include the system tablespace, the temporary tablespace, and general tablespaces.
- Page compression is not supported for undo log tablespaces.
- Page compression is not supported for redo log pages.
- R-tree pages, which are used for spatial indexes, are not compressed.
- Pages that belong to compressed tables (`ROW_FORMAT=COMPRESSED`) are left as-is.
- During recovery, updated pages are written out in an uncompressed form.
- Loading a page-compressed tablespace on a server that does not support the compression algorithm that was used causes an I/O error.
- Before downgrading to an earlier version of MySQL that does not support page compression, uncompress the tables that use the page compression feature. To uncompress a table, run `ALTER TABLE ... COMPRESSION=None` and `OPTIMIZE TABLE`.
- Page-compressed tablespaces can be copied between Linux and Windows servers if the compression algorithm that was used is available on both servers.
- Preserving page compression when moving a page-compressed tablespace file from one host to another requires a utility that preserves sparse files.
- Better page compression may be achieved on Fusion-io hardware with NVMeFS than on other platforms, as NVMeFS is designed to take advantage of punch hole functionality.
- Using the page compression feature with a large InnoDB page size and relatively small file system block size could result in write amplification. For example, a maximum InnoDB page size of 64KB with a 4KB file system block size may improve compression but may also increase demand on the buffer pool, leading to increased I/O and potential write amplification.

15.10 InnoDB Row Storage and Row Formats

This section discusses how InnoDB features such as table [compression](#), off-page storage of long variable-length column values, and large index key prefixes are controlled by the row format of an InnoDB table. It also discusses considerations for choosing the right row format, and compatibility of row formats between MySQL releases.

15.10.1 Overview of InnoDB Row Storage

The storage for rows and associated columns affects performance for queries and DML operations. As more rows fit into a single disk [page](#), queries and index lookups can work faster, less cache memory is required in the InnoDB buffer pool, and less I/O is required to write out updated values for the numeric and short string columns.

The data in each InnoDB table is divided into [pages](#). The pages that make up each table are arranged in a tree data structure called a [B-tree index](#). Table data and [secondary indexes](#) both use this type of structure. The B-tree index that represents an entire table is known as the [clustered index](#), which is organized according to the [primary key](#) columns. The nodes of the index data structure contain the values of all the columns in that row (for the clustered index) or the index columns and the primary key columns (for secondary indexes).

Variable-length columns are an exception to this rule. Columns such as [BLOB](#) and [VARCHAR](#) that are too long to fit on a B-tree page are stored on separately allocated disk pages called [overflow pages](#).

We call such columns [off-page columns](#). The values of these columns are stored in singly-linked lists of overflow pages, and each such column has its own list of one or more overflow pages. In some cases, all or a prefix of the long column value is stored in the B-tree, to avoid wasting storage and eliminating the need to read a separate page.

The following sections describe how to configure the row format of [InnoDB](#) tables to control how variable-length columns values are stored. Row format configuration also determines the availability of the [table compression](#) feature and large index key prefix support.

15.10.2 Specifying the Row Format for a Table

The default row format is defined by `innodb_default_row_format`, which has a default value of `DYNAMIC`. The default row format is used when the `ROW_FORMAT` table option is not defined explicitly or when `ROW_FORMAT=DEFAULT` is specified.

The row format of a table can be defined explicitly using the `ROW_FORMAT` table option in a `CREATE TABLE` or `ALTER TABLE` statement. For example:

```
CREATE TABLE t1 (c1 INT) ROW_FORMAT=DYNAMIC;
```

An explicitly defined `ROW_FORMAT` setting overrides the implicit default. Specifying `ROW_FORMAT=DEFAULT` is equivalent to using the implicit default.

The `innodb_default_row_format` option can be set dynamically:

```
mysql> SET GLOBAL innodb_default_row_format=DYNAMIC;
```

Valid `innodb_default_row_format` options include `DYNAMIC`, `COMPACT`, and `REDUNDANT`. The `COMPRESSED` row format, which is not supported for use in the system tablespace, cannot be defined as the default. It can only be specified explicitly in a `CREATE TABLE` or `ALTER TABLE` statement. Attempting to set `innodb_default_row_format` to `COMPRESSED` returns an error:

```
mysql> SET GLOBAL innodb_default_row_format=COMPRESSED;
ERROR 1231 (42000): Variable 'innodb_default_row_format'
can't be set to the value of 'COMPRESSED'
```

Newly created tables use the row format defined by `innodb_default_row_format` when a `ROW_FORMAT` option is not specified explicitly or when `ROW_FORMAT=DEFAULT` is used. For example, the following `CREATE TABLE` statements use the row format defined by `innodb_default_row_format`.

```
CREATE TABLE t1 (c1 INT);
```

```
CREATE TABLE t2 (c1 INT) ROW_FORMAT=DEFAULT;
```

When a `ROW_FORMAT` option is not specified explicitly or when `ROW_FORMAT=DEFAULT` is used, any operation that rebuilds a table also silently changes the row format of the table to the format defined by `innodb_default_row_format`.

Table-rebuilding operations include `ALTER TABLE` operations that use `ALGORITHM=COPY` or `ALTER TABLE` operations that use `ALGORITHM=INPLACE` where table rebuilding is required. See [Table 15.10, "Online Status for DDL Operations"](#) for an overview of the online status of DDL operations. `OPTIMIZE TABLE` is also a table-rebuilding operation.

The following example demonstrates a table-rebuilding operation that silently changes the row format of a table created without an explicitly defined row format.

```
mysql> SELECT @@innodb_default_row_format;
+-----+
| @@innodb_default_row_format |
+-----+
| dynamic                    |
+-----+
mysql> CREATE TABLE t1 (c1 INT);
```

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE 'test/t1' \G
***** 1. row *****
TABLE_ID: 54
NAME: test/t1
FLAG: 33
N_COLS: 4
SPACE: 35
ROW_FORMAT: Dynamic
ZIP_PAGE_SIZE: 0
SPACE_TYPE: Single

mysql> SET GLOBAL innodb_default_row_format=COMPACT;

mysql> ALTER TABLE t1 ADD COLUMN (c2 INT);

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE 'test/t1' \G
***** 1. row *****
TABLE_ID: 55
NAME: test/t1
FLAG: 1
N_COLS: 5
SPACE: 36
ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0
SPACE_TYPE: Single
```

Consider the following potential issues before changing the row format of existing tables from [REDUNDANT](#) or [COMPACT](#) to [DYNAMIC](#).

- The [REDUNDANT](#) and [COMPACT](#) row format supports a maximum index key prefix length of 767 bytes whereas [DYNAMIC](#) and [COMPRESSED](#) row formats support an index key prefix length of 3072 bytes. In a replication environment, if `innodb_default_row_format` is set to [DYNAMIC](#) on the master and set to [COMPACT](#) on the slave, the following DDL statement, which does not explicitly define a row format, succeeds on the master but fails on the slave:

```
CREATE TABLE t1 (c1 INT PRIMARY KEY, c2 VARCHAR(5000), KEY i1(c2(3070)));
```

For related information, see [Section 15.8.1.7, “Limits on InnoDB Tables”](#).

- Importing a table that does not explicitly define a row format results in a schema mismatch error if the `innodb_default_row_format` setting on the source server differs from the setting on the destination server. For more information, refer to the limitations outlined in [Section 15.7.6, “Copying File-Per-Table Tablespaces to Another Instance”](#).

To view the row format of a table, issue a `SHOW TABLE STATUS` statement or query `INFORMATION_SCHEMA.TABLES`.

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE 'test/t1' \G
```

The row format of an [InnoDB](#) table determines its physical row structure. See [Section 15.8.1.2, “The Physical Row Structure of an InnoDB Table”](#) for more information.

15.10.3 DYNAMIC and COMPRESSED Row Formats

When a table is created with `ROW_FORMAT=DYNAMIC` or `ROW_FORMAT=COMPRESSED`, [InnoDB](#) can store long variable-length column values (for [VARCHAR](#), [VARBINARY](#), and [BLOB](#) and [TEXT](#) types) fully off-page, with the clustered index record containing only a 20-byte pointer to the overflow page. [InnoDB](#) also encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

Whether any columns are stored off-page depends on the page size and the total size of the row. When the row is too long, [InnoDB](#) chooses the longest columns for off-page storage until the clustered index record fits on the [B-tree](#) page. [TEXT](#) and [BLOB](#) columns that are less than or equal to 40 bytes are always stored in-line.

The `DYNAMIC` row format maintains the efficiency of storing the entire row in the index node if it fits (as do the `COMPACT` and `REDUNDANT` formats), but the `DYNAMIC` row format avoids the problem of filling B-tree nodes with a large number of data bytes of long columns. The `DYNAMIC` format is based on the idea that if a portion of a long data value is stored off-page, it is usually most efficient to store all of the value off-page. With `DYNAMIC` format, shorter columns are likely to remain in the B-tree node, minimizing the number of overflow pages needed for any given row.

The `COMPRESSED` row format uses similar internal details for off-page storage as the `DYNAMIC` row format, with additional storage and performance considerations from the table and index data being compressed and using smaller page sizes. With the `COMPRESSED` row format, the `KEY_BLOCK_SIZE` option controls how much column data is stored in the clustered index, and how much is placed on overflow pages. For full details about the `COMPRESSED` row format, see [Section 15.9, “InnoDB Table and Page Compression”](#).

Both `DYNAMIC` and `COMPRESSED` row formats support index key prefixes up to 3072 bytes.

Tables that use the `COMPRESSED` row format can be created in [file-per-table](#) tablespaces or [general tablespaces](#). The system tablespace does not support the `COMPRESSED` row format. To store a `COMPRESSED` table in a file-per-table tablespace, `innodb_file_per_table` must be enabled. The `innodb_file_per_table` configuration option is not applicable to general tablespaces. General tablespaces support all row formats with the caveat that compressed and uncompressed tables cannot coexist in the same general tablespace due to different physical page sizes. For more information about general tablespaces, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

`DYNAMIC` tables can be stored in file-per-table tablespaces, general tablespaces, and the system tablespace. To store `DYNAMIC` tables in the system tablespace, you can either disable `innodb_file_per_table` and use a regular `CREATE TABLE` or `ALTER TABLE` statement, or you can use the `TABLESPACE [=] innodb_system` table option with `CREATE TABLE` or `ALTER TABLE` without having to alter your `innodb_file_per_table` setting. The `innodb_file_per_table` configuration option is not applicable to general tablespaces, nor are they applicable when using the `TABLESPACE [=] innodb_system` table option to store `DYNAMIC` tables in the system tablespace.

InnoDB does not support compressed temporary tables. When `innodb_strict_mode` is enabled (the default), `CREATE TEMPORARY TABLE` returns an error if `ROW_FORMAT=COMPRESSED` or `KEY_BLOCK_SIZE` is specified. If `innodb_strict_mode` is disabled, warnings are issued and the temporary table is created using a non-compressed row format.

`DYNAMIC` and `COMPRESSED` row formats are variations of the `COMPACT` row format and therefore handle `CHAR` storage in the same way as the `COMPACT` row format. For more information, see [Section 15.8.1.2, “The Physical Row Structure of an InnoDB Table”](#).

15.10.4 COMPACT and REDUNDANT Row Formats

InnoDB tables that use the `COMPACT` or `REDUNDANT` row format store up to the first 768 bytes of variable-length columns (`VARCHAR`, `VARBINARY`, and `BLOB` and `TEXT` types) in the index record within the `B-tree` node, with the remainder stored on the overflow pages. InnoDB also encodes fixed-length fields greater than or equal to 768 bytes in length as variable-length fields, which can be stored off-page. For example, a `CHAR(255)` column can exceed 768 bytes if the maximum byte length of the character set is greater than 3, as it is with `utf8mb4`.

For `COMPACT` or `REDUNDANT` row formats, if the value of a column is 768 bytes or less, no overflow page is needed, and some savings in I/O may result, since the value is in the B-tree node. This works well for relatively short `BLOBs`, but may cause B-tree nodes to fill with data rather than key values, reducing their efficiency. Tables with many `BLOB` columns could cause B-tree nodes to become too full of data, and contain too few rows, making the entire index less efficient than if the rows were shorter or if the column values were stored off-page.

The default row format is `DYNAMIC`, as defined by the `innodb_default_row_format` configuration option. See [Section 15.10.3, “DYNAMIC and COMPRESSED Row Formats”](#) for more information.

For information about the physical row structure of tables that use the [REDUNDANT](#) or [COMPACT](#) row format, see [Section 15.8.1.2, “The Physical Row Structure of an InnoDB Table”](#).

15.11 InnoDB Disk I/O and File Space Management

As a DBA, you must manage disk I/O to keep the I/O subsystem from becoming saturated, and manage disk space to avoid filling up storage devices. The [ACID](#) design model requires a certain amount of I/O that might seem redundant, but helps to ensure data reliability. Within these constraints, [InnoDB](#) tries to optimize the database work and the organization of disk files to minimize the amount of disk I/O. Sometimes, I/O is postponed until the database is not busy, or until everything needs to be brought to a consistent state, such as during a database restart after a [fast shutdown](#).

This section discusses the main considerations for I/O and disk space with the default kind of MySQL tables (also known as [InnoDB](#) tables):

- Controlling the amount of background I/O used to improve query performance.
- Enabling or disabling features that provide extra durability at the expense of additional I/O.
- Organizing tables into many small files, a few larger files, or a combination of both.
- Balancing the size of redo log files against the I/O activity that occurs when the log files become full.
- How to reorganize a table for optimal query performance.

15.11.1 InnoDB Disk I/O

[InnoDB](#) uses asynchronous disk I/O where possible, by creating a number of threads to handle I/O operations, while permitting other database operations to proceed while the I/O is still in progress. On Linux and Windows platforms, [InnoDB](#) uses the available OS and library functions to perform “native” asynchronous I/O. On other platforms, [InnoDB](#) still uses I/O threads, but the threads may actually wait for I/O requests to complete; this technique is known as “simulated” asynchronous I/O.

Read-Ahead

If [InnoDB](#) can determine there is a high probability that data might be needed soon, it performs read-ahead operations to bring that data into the buffer pool so that it is available in memory. Making a few large read requests for contiguous data can be more efficient than making several small, spread-out requests. There are two read-ahead heuristics in [InnoDB](#):

- In sequential read-ahead, if [InnoDB](#) notices that the access pattern to a segment in the tablespace is sequential, it posts in advance a batch of reads of database pages to the I/O system.
- In random read-ahead, if [InnoDB](#) notices that some area in a tablespace seems to be in the process of being fully read into the buffer pool, it posts the remaining reads to the I/O system.

For information about configuring read-ahead heuristics, see [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#).

Doublewrite Buffer

[InnoDB](#) uses a novel file flush technique involving a structure called the [doublewrite buffer](#), which is enabled by default in most cases (`innodb_doublewrite=ON`). It adds safety to recovery following a crash or power outage, and improves performance on most varieties of Unix by reducing the need for `fsync()` operations.

Before writing pages to a data file, [InnoDB](#) first writes them to a contiguous tablespace area called the doublewrite buffer. Only after the write and the flush to the doublewrite buffer has completed does [InnoDB](#) write the pages to their proper positions in the data file. If there is an operating system, storage subsystem, or `mysqld` process crash in the middle of a page write (causing a [torn page](#) condition), [InnoDB](#) can later find a good copy of the page from the doublewrite buffer during recovery.

If system tablespace files (“ibdata files”) are located on Fusion-io devices that support atomic writes, doublewrite buffering is automatically disabled and Fusion-io atomic writes are used for all data files. Because the doublewrite buffer setting is global, doublewrite buffering is also disabled for data files residing on non-Fusion-io hardware. This feature is only supported on Fusion-io hardware and is only enabled for Fusion-io NVMFS on Linux. To take full advantage of this feature, an `innodb_flush_method` setting of `O_DIRECT` is recommended.

15.11.2 File Space Management

The data files that you define in the configuration file using the `innodb_data_file_path` configuration option form the **InnoDB system tablespace**. The files are logically concatenated to form the system tablespace. There is no striping in use. You cannot define where within the system tablespace your tables are allocated. In a newly created system tablespace, **InnoDB** allocates space starting from the first data file.

To avoid the issues that come with storing all tables and indexes inside the system tablespace, you can enable the `innodb_file_per_table` configuration option (the default), which stores each newly created table in a separate tablespace file (with extension `.ibd`). For tables stored this way, there is less fragmentation within the disk file, and when the table is truncated, the space is returned to the operating system rather than still being reserved by **InnoDB** within the system tablespace. For more information, see [Section 15.7.4, “InnoDB File-Per-Table Tablespaces”](#).

You can also store tables in **general tablespaces**. General tablespaces are shared tablespaces created using `CREATE TABLESPACE` syntax. They can be created outside of the MySQL data directory, are capable of holding multiple tables, and support tables of all row formats. For more information, see [Section 15.7.9, “InnoDB General Tablespaces”](#).

Pages, Extents, Segments, and Tablespaces

Each tablespace consists of database **pages**. Every tablespace in a MySQL instance has the same **page size**. By default, all tablespaces have a page size of 16KB; you can reduce the page size to 8KB or 4KB by specifying the `innodb_page_size` option when you create the MySQL instance. You can also increase the page size to 32KB or 64KB. For more information, refer to the `innodb_page_size` documentation.

The pages are grouped into **extents** of size 1MB for pages up to 16KB in size (64 consecutive 16KB pages, or 128 8KB pages, or 256 4KB pages). For a page size of 32KB, extent size is 2MB. For a page size of 64KB, extent size is 4MB. The “files” inside a tablespace are called **segments** in **InnoDB**. (These segments are different from the **rollback segment**, which actually contains many tablespace segments.)

When a segment grows inside the tablespace, **InnoDB** allocates the first 32 pages to it one at a time. After that, **InnoDB** starts to allocate whole extents to the segment. **InnoDB** can add up to 4 extents at a time to a large segment to ensure good sequentiality of data.

Two segments are allocated for each index in **InnoDB**. One is for nonleaf nodes of the **B-tree**, the other is for the leaf nodes. Keeping the leaf nodes contiguous on disk enables better sequential I/O operations, because these leaf nodes contain the actual table data.

Some pages in the tablespace contain bitmaps of other pages, and therefore a few extents in an **InnoDB** tablespace cannot be allocated to segments as a whole, but only as individual pages.

When you ask for available free space in the tablespace by issuing a `SHOW TABLE STATUS` statement, **InnoDB** reports the extents that are definitely free in the tablespace. **InnoDB** always reserves some extents for cleanup and other internal purposes; these reserved extents are not included in the free space.

When you delete data from a table, **InnoDB** contracts the corresponding B-tree indexes. Whether the freed space becomes available for other users depends on whether the pattern of deletes frees individual pages or extents to the tablespace. Dropping a table or deleting all rows from it is guaranteed to release the space to other users, but remember that deleted rows are physically removed only

by the [purge](#) operation, which happens automatically some time after they are no longer needed for transaction rollbacks or consistent reads. (See [Section 15.3, “InnoDB Multi-Versioning”](#).)

How Pages Relate to Table Rows

The maximum row length is slightly less than half a database page for 4KB, 8KB, 16KB, and 32KB `innodb_page_size` settings. For example, the maximum row length is slightly less than 8KB for the default 16KB InnoDB page size. For 64KB pages, the maximum row length is slightly less than 16KB.

If a row does not exceed the maximum row length, all of it is stored locally within the page. If a row exceeds the maximum row length, [variable-length columns](#) are chosen for external off-page storage until the row fits within the maximum row length limit. External off-page storage for variable-length columns differs by row format:

- *COMPACT and REDUNDANT Row Formats*

When a variable-length column is chosen for external off-page storage, InnoDB stores the first 768 bytes locally in the row, and the rest externally into overflow pages. Each such column has its own list of overflow pages. The 768-byte prefix is accompanied by a 20-byte value that stores the true length of the column and points into the overflow list where the rest of the value is stored. See [Section 15.10.4, “COMPACT and REDUNDANT Row Formats”](#).

- *DYNAMIC and COMPRESSED Row Formats*

When a variable-length column is chosen for external off-page storage, InnoDB stores a 20-byte pointer locally in the row, and the rest externally into overflow pages. See [Section 15.10.3, “DYNAMIC and COMPRESSED Row Formats”](#).

`LONGBLOB` and `LONGTEXT` columns must be less than 4GB, and the total row length, including `BLOB` and `TEXT` columns, must be less than 4GB.

15.11.3 InnoDB Checkpoints

Making your [log files](#) very large may reduce disk I/O during [checkpointing](#). It often makes sense to set the total size of the log files as large as the buffer pool or even larger.

How Checkpoint Processing Works

InnoDB implements a [checkpoint](#) mechanism known as [fuzzy checkpointing](#). InnoDB flushes modified database pages from the buffer pool in small batches. There is no need to flush the buffer pool in one single batch, which would disrupt processing of user SQL statements during the checkpointing process.

During [crash recovery](#), InnoDB looks for a checkpoint label written to the log files. It knows that all modifications to the database before the label are present in the disk image of the database. Then InnoDB scans the log files forward from the checkpoint, applying the logged modifications to the database.

15.11.4 Defragmenting a Table

Random insertions into or deletions from a secondary index can cause the index to become fragmented. Fragmentation means that the physical ordering of the index pages on the disk is not close to the index ordering of the records on the pages, or that there are many unused pages in the 64-page blocks that were allocated to the index.

One symptom of fragmentation is that a table takes more space than it “should” take. How much that is exactly, is difficult to determine. All InnoDB data and indexes are stored in [B-trees](#), and their [fill factor](#) may vary from 50% to 100%. Another symptom of fragmentation is that a table scan such as this takes more time than it “should” take:

```
SELECT COUNT(*) FROM t WHERE non_indexed_column <> 12345;
```

The preceding query requires MySQL to perform a full table scan, the slowest type of query for a large table.

To speed up index scans, you can periodically perform a “null” `ALTER TABLE` operation, which causes MySQL to rebuild the table:

```
ALTER TABLE tbl_name ENGINE=INNODB
```

You can also use `ALTER TABLE tbl_name FORCE` to perform a “null” alter operation that rebuilds the table.

Both `ALTER TABLE tbl_name ENGINE=INNODB` and `ALTER TABLE tbl_name FORCE` use [online DDL](#). For more information, see [Section 15.12.1, “Online DDL Overview”](#).

Another way to perform a defragmentation operation is to use `mysqldump` to dump the table to a text file, drop the table, and reload it from the dump file.

If the insertions into an index are always ascending and records are deleted only from the end, the [InnoDB](#) filespace management algorithm guarantees that fragmentation in the index does not occur.

15.11.5 Reclaiming Disk Space with TRUNCATE TABLE

To reclaim operating system disk space when [truncating](#) an [InnoDB](#) table, the table must be stored in its own `.ibd` file. For a table to be stored in its own `.ibd` file, `innodb_file_per_table` must be enabled when the table is created. Additionally, there cannot be a [foreign key](#) constraint between the table being truncated and other tables, otherwise the `TRUNCATE TABLE` operation fails. A foreign key constraint between two columns in the same table, however, is permitted.

When a table is truncated, it is dropped and re-created in a new `.ibd` file, and the freed space is returned to the operating system. This is in contrast to truncating [InnoDB](#) tables that are stored within the [InnoDB system tablespace](#) (tables created when `innodb_file_per_table=OFF`) and tables stored in shared [general tablespaces](#), where only [InnoDB](#) can use the freed space after the table is truncated.

The ability to truncate tables and return disk space to the operating system also means that [physical backups](#) can be smaller. Truncating tables that are stored in the system tablespace (tables created when `innodb_file_per_table=OFF`) or in a general tablespace leaves blocks of unused space in the tablespace.

15.12 InnoDB and Online DDL

The [InnoDB online DDL](#) feature permits in-place table alterations or concurrent [DML](#), or both. Benefits of this feature include:

- Improved responsiveness and availability in busy production environments, where making a table unavailable for minutes or hours is not practical.
- The ability to adjust the balance between performance and concurrency during a [DDL](#) operations using the `LOCK` clause.
 - `LOCK=EXCLUSIVE` blocks access to the table entirely.
 - `LOCK=SHARED` allows queries but not DML.
 - `LOCK=NONE` allows full query and DML access to the table.
 - `LOCK=DEFAULT` or omitting the `LOCK` clause permits as much concurrency as possible depending on the type of DDL operation.
- Avoidance of disk space usage and I/O overhead associated with copying the table and reconstructing secondary indexes.

15.12.1 Online DDL Overview

The online DDL feature enhances many DDL operations that formerly required a table copy or blocked DML operations on the table, or both. [Table 15.10, “Online Status for DDL Operations”](#) shows how the online DDL feature applies to each DDL statement.

With the exception of some `ALTER TABLE` partitioning clauses, online DDL operations for partitioned `InnoDB` tables follow the same rules that apply to regular `InnoDB` tables. For more information, see [Section 15.12.7, “Online DDL for Partitioned Tables”](#).

Some factors affect the performance, space usage, and semantics of online DDL operations. For more information, see [Section 15.12.8, “Online DDL Limitations”](#).

- The “In-Place?” column shows which operations permit the `ALGORITHM=INPLACE` clause.
- The “Rebuilds Table?” column shows which operations rebuild the table. For operations that use the `INPLACE` algorithm, the table is rebuilt in place. For operations that do not support the `INPLACE` algorithm, the table copy method is used to rebuild the table.
- The “Permits Concurrent DML?” column shows which operations are performed fully online. You can specify `LOCK=NONE` to assert that concurrent DML is permitted during the DDL operation. MySQL automatically permits concurrent DML when possible.

Concurrent queries are permitted during all online DDL operations. You can specify `LOCK=SHARED` to assert that concurrent queries are permitted during a DDL operation. MySQL automatically permits concurrent queries when possible.

- The “Notes” column provides additional information and explains exceptions and dependencies related to the “Yes/No” values of other columns. An asterisk indicates an exception or dependency.

Table 15.10 Online Status for DDL Operations

Operation	In-Place?	Rebuilds Table?	Permits Concurrent DML?	Only Modifies Metadata?	Notes
<code>CREATE INDEX, ADD INDEX</code>	Yes*	No*	Yes	No	Restrictions apply for <code>FULLTEXT</code> indexes; see next row.
<code>ADD FULLTEXT INDEX</code>	Yes*	No*	No	No	Adding the first <code>FULLTEXT</code> index rebuilds the table if there is no user-defined <code>FTS_DOC_ID</code> column. Subsequent <code>FULLTEXT</code> indexes may be added on the same table without rebuilding the table.
<code>ADD SPATIAL INDEX</code>	Yes	No	No	No	
<code>RENAME INDEX</code>	Yes	No	Yes	Yes	Only modifies table metadata.
<code>DROP INDEX</code>	Yes	No	Yes	Yes	Only modifies table metadata.
<code>OPTIMIZE TABLE</code>	Yes*	Yes	Yes	No	In-place operation is not supported for tables with <code>FULLTEXT</code> indexes.
Set column default value	Yes	No	Yes	Yes	Only modifies table metadata.
Change <code>auto-increment</code> value	Yes	No	Yes	No*	Modifies a value stored in memory, not the data file.

Operation	In-Place?	Rebuilds Table?	Permits Concurrent DML?	Only Modifies Metadata?	Notes
Add foreign key constraint	Yes*	No	Yes	Yes	The INPLACE algorithm is supported when foreign_key_checks is disabled. Otherwise, only the COPY algorithm is supported.
Drop foreign key constraint	Yes	No	Yes	Yes	foreign_key_checks can be enabled or disabled.
Rename column	Yes*	No	Yes*	Yes	To permit concurrent DML, keep the same data type and only change the column name. ALGORITHM=INPLACE is not supported for renaming a generated column .
Add column	Yes*	Yes*	Yes*	No	Concurrent DML is not permitted when adding an auto-increment column. Data is reorganized substantially, making it an expensive operation. ALGORITHM=INPLACE is supported for adding a virtual generated column but not for adding a stored generated column . Adding a virtual generated column does not require a table rebuild.
Drop column	Yes	Yes*	Yes	No	Data is reorganized substantially, making it an expensive operation. ALGORITHM=INPLACE is supported for dropping a generated column . Dropping a virtual generated column does not require a table rebuild.
Reorder columns	Yes	Yes	Yes	No	Data is reorganized substantially, making it an expensive operation.
Change ROW_FORMAT property	Yes	Yes	Yes	No	Data is reorganized substantially, making it an expensive operation.
Change KEY_BLOCK_SIZE property	Yes	Yes	Yes	No	Data is reorganized substantially, making it an expensive operation.
Make column NULL	Yes	Yes*	Yes	No	Rebuilds the table in place. Data is reorganized substantially, making it an expensive operation.
Make column NOT NULL	Yes*	Yes*	Yes	No	Rebuilds the table in place. STRICT_ALL_TABLES or STRICT_TRANS_TABLES SQL_MODE is required for the

Operation	In-Place?	Rebuilds Table?	Permits Concurrent DML?	Only Modifies Metadata?	Notes
					operation to succeed. The operation fails if the column contains NULL values. The server prohibits changes to foreign key columns that have the potential to cause loss of referential integrity. See Section 13.1.7, "ALTER TABLE Syntax" . Data is reorganized substantially, making it an expensive operation.
Change column data type	No*	Yes	No	No	VARCHAR size may be increased using online ALTER TABLE . See Modifying Column Properties for more information.
Add primary key	Yes*	Yes*	Yes	No	Rebuilds the table in place. Data is reorganized substantially, making it an expensive operation. ALGORITHM=INPLACE is not permitted under certain conditions if columns have to be converted to NOT NULL .
Drop primary key and add another	Yes	Yes	Yes	No	Data is reorganized substantially, making it an expensive operation.
Drop primary key	No	Yes	No	No	Only ALGORITHM=COPY supports dropping a primary key without adding a new one in the same ALTER TABLE statement.
Convert character set	No	Yes*	No	No	Rebuilds the table if the new character encoding is different.
Specify character set	No	Yes*	No	No	Rebuilds the table if the new character encoding is different.
Rebuild with FORCE option	Yes*	Yes	Yes	No	Uses ALGORITHM=INPLACE . ALGORITHM=INPLACE is not supported for tables with FULLTEXT indexes.
"null" rebuild using ALTER TABLE ... ENGINE=INNODB	Yes*	Yes	Yes	No	Uses ALGORITHM=INPLACE . ALGORITHM=INPLACE is not supported for tables with FULLTEXT indexes.
Set STATS_PERSISTENT , STATS_AUTO_RECALC , STATS_SAMPLE_PAGES persistent statistics options	Yes	No	Yes	Yes	Only modifies table metadata.

Operation	In-Place?	Rebuilds Table?	Permits Concurrent DML?	Only Modifies Metadata?	Notes
<code>ALTER TABLE ... ENCRYPTION</code>	No	Yes	No	Yes	
Drop a <code>STORED</code> column	Yes	Yes*	Yes	No	Rebuilds the table in place.
Modify <code>STORED</code> column order	Yes	Yes*	Yes	No	Rebuilds the table in place.
Add a <code>STORED</code> column	Yes	Yes*	Yes	No	Rebuilds the table in place.
Drop a <code>VIRTUAL</code> column	Yes	No	Yes	Yes	
Modify <code>VIRTUAL</code> column order	Yes	No	Yes	Yes	
Add a <code>VIRTUAL</code> column	Yes	No	Yes	Yes	

The sections that follow provide basic syntax and usage notes for various online DDL operations.

Adding or Dropping Secondary Indexes

- Adding a [secondary index](#):

```
CREATE INDEX name ON table (col_list);
```

```
ALTER TABLE table ADD INDEX name (col_list);
```

- Dropping a secondary index:

```
DROP INDEX name ON table;
```

```
ALTER TABLE table DROP INDEX name;
```

Although no syntax changes are required in the `CREATE INDEX` or `DROP INDEX` commands, some factors affect the performance, space usage, and semantics of this operation (see [Section 15.12.8, “Online DDL Limitations”](#)).

Creating and dropping secondary indexes on `InnoDB` tables skips the table-copying behavior.

The table remains available for read and write operations while the index is being created or dropped. The `CREATE INDEX` or `DROP INDEX` statement only finishes after all transactions that are accessing the table are completed, so that the initial state of the index reflects the most recent contents of the table. Previously, modifying the table while an index is being created or dropped typically resulted in a [deadlock](#) that cancelled the `INSERT`, `UPDATE`, or `DELETE` statement on the table.

Online DDL support for adding secondary indexes means that you can generally speed the overall process of creating and loading a table and associated indexes by creating the table without any secondary indexes, then adding the secondary indexes after the data is loaded.

Modifying Column Properties

- Modify the default value for a column:

```
ALTER TABLE tbl ALTER COLUMN col SET DEFAULT literal;
```

```
ALTER TABLE tbl ALTER COLUMN col DROP DEFAULT;
```

The default values for columns are stored in the `InnoDB` [data dictionary](#).

- Changing the [auto-increment](#) value for a column:

```
ALTER TABLE table AUTO_INCREMENT=next_value;
```

Especially in a distributed system using replication or sharding, you sometimes reset the auto-increment counter for a table to a specific value. The next row inserted into the table uses the specified value for its auto-increment column. You might also use this technique in a data warehousing environment where you periodically empty all the tables and reload them, and you can restart the auto-increment sequence from 1.

- Renaming a column:

```
ALTER TABLE tbl CHANGE old_col_name new_col_name datatype;
```

When you keep the same data type and [NOT] NULL attribute, only changing the column name, this operation can always be performed online.

You can also rename a column that is part of a foreign key constraint. The foreign key definition is automatically updated to use the new column name. Renaming a column participating in a foreign key only works with the in-place mode of `ALTER TABLE`. If you use the `ALGORITHM=COPY` clause, or some other condition causes the command to use `ALGORITHM=COPY` behind the scenes, the `ALTER TABLE` statement fails.

- Extending `VARCHAR` size using an in-place `ALTER TABLE` statement:

```
ALTER TABLE t1 ALGORITHM=INPLACE, CHANGE COLUMN c1 c1 VARCHAR(255);
```

The number of length bytes required by a `VARCHAR` column must remain the same. For `VARCHAR` values of 0 to 255, one length byte is required to encode the value. For `VARCHAR` values of 256 bytes or more, two length bytes are required. As a result, in-place `ALTER TABLE` only supports increasing `VARCHAR` size from 0 to 255 bytes or increasing `VARCHAR` size from a value equal to or greater than 256 bytes. In-place `ALTER TABLE` does not support increasing `VARCHAR` size from less than 256 bytes to a value equal to or greater than 256 bytes. In this case, the number of required length bytes would change from 1 to 2, which is only supported by a table copy (`ALGORITHM=COPY`). For example, attempting to change `VARCHAR` column size from 255 to 256 using in-place `ALTER TABLE` would return an error:

```
ALTER TABLE t1 ALGORITHM=INPLACE, CHANGE COLUMN c1 c1 VARCHAR(256);
ERROR 0A000: ALGORITHM=INPLACE is not supported. Reason: Cannot change
column type INPLACE. Try ALGORITHM=COPY.
```

Decreasing `VARCHAR` size using in-place `ALTER TABLE` is not supported. Decreasing `VARCHAR` size requires a table copy (`ALGORITHM=COPY`).

Adding or Dropping Foreign Keys

- Adding or dropping a [foreign key constraint](#):

```
ALTER TABLE tbl1 ADD CONSTRAINT fk_name FOREIGN KEY index (col1)
REFERENCES tbl2(col2) referential_actions;
```

```
ALTER TABLE tbl DROP FOREIGN KEY fk_name;
```

Dropping a foreign key can be performed online with the `foreign_key_checks` option enabled or disabled. Creating a foreign key online requires `foreign_key_checks` to be disabled.

If you do not know the names of the foreign key constraints on a particular table, issue the following statement and find the constraint name in the `CONSTRAINT` clause for each foreign key:

```
SHOW CREATE TABLE table\G
```

Or, query the `INFORMATION_SCHEMA.TABLE_CONSTRAINTS` table and use the `CONSTRAINT_NAME` and `CONSTRAINT_TYPE` columns to identify the foreign key names.

You can also drop a foreign key and its associated index in a single statement:

```
ALTER TABLE table DROP FOREIGN KEY constraint, DROP INDEX index;
```

If [foreign keys](#) are already present in the table being altered (that is, it is a [child table](#) containing a `FOREIGN KEY ... REFERENCE` clause), additional restrictions apply to online DDL operations, even those not directly involving the foreign key columns:

- An `ALTER TABLE` on the child table could wait for another transaction to commit, if a change to the parent table caused associated changes in the child table through an `ON UPDATE` or `ON DELETE` clause using the `CASCADE` or `SET NULL` parameters.
- In the same way, if a table is the [parent table](#) in a foreign key relationship, even though it does not contain any `FOREIGN KEY` clauses, it could wait for the `ALTER TABLE` to complete if an `INSERT`, `UPDATE`, or `DELETE` statement caused an `ON UPDATE` or `ON DELETE` action in the child table.

Maintaining CREATE TABLE Statements

As your database schema evolves with new columns, data types, constraints, indexes, and so on, keep your `CREATE TABLE` statements up to date with the latest table definitions. Even with the performance improvements of online DDL, it is more efficient to create stable database structures at the beginning, rather than creating part of the schema and then issuing `ALTER TABLE` statements afterward.

The main exception to this guideline is for [secondary indexes](#) on tables with large numbers of rows. It is typically most efficient to create the table with all details specified except the secondary indexes, load the data, then create the secondary indexes. You can use the same technique with [foreign keys](#) (load the data first, then set up the foreign keys) if you know the initial data is clean and do not need consistency checks during the loading process.

Whatever sequence of `CREATE TABLE`, `CREATE INDEX`, `ALTER TABLE`, and similar statements went into putting a table together, you can capture the SQL needed to reconstruct the current form of the table by issuing the statement `SHOW CREATE TABLE table\G` (uppercase `\G` required for tidy formatting). This output shows clauses such as numeric precision, `NOT NULL`, and `CHARACTER SET` that are sometimes added behind the scenes, which you may want to leave out when cloning the table on a new system or setting up foreign key columns with identical type.

15.12.2 Online DDL Performance, Concurrency, and Space Requirements

[Online DDL](#) improves several aspects of MySQL operation, such as performance, concurrency, availability, and scalability:

- Because queries and [DML](#) operations on the table can proceed while the DDL is in progress, applications that access the table are more responsive. Reduced [locking](#) and waiting for other resources throughout the MySQL server leads to greater scalability, even for operations not involving the table being altered.
- For in-place operations, by avoiding the disk I/O and CPU cycles to rebuild the table, you minimize the overall load on the database and maintain good performance and high throughput during the DDL operation.
- For in-place operations, because less data is read into the [buffer pool](#) than if all the data was copied, you avoid purging frequently accessed data from memory, which formerly could cause a temporary performance dip after a DDL operation.

If an online operation requires temporary sort files, [InnoDB](#) creates them in the temporary file directory by default, not the directory containing the original table. If this directory is not large enough to hold such files, you may need to set the `tmpdir` system variable to a different directory. Alternatively, you can define a separate temporary directory for [InnoDB](#) online `ALTER TABLE` operations using the `innodb_tmpdir` configuration option. For more information, see [Space Requirements for Online DDL Operations](#), and [Section B.5.3.5, “Where MySQL Stores Temporary Files”](#).

Locking Options for Online DDL

While an InnoDB table is being changed by a DDL operation, the table may or may not be **locked**, depending on the internal workings of that operation and the **LOCK** clause of the **ALTER TABLE** statement. By default, MySQL uses as little locking as possible during a DDL operation; you specify the clause either to make the locking more restrictive than it normally would be (thus limiting concurrent DML, or DML and queries), or to ensure that some expected degree of locking is allowed for an operation. If the **LOCK** clause specifies a level of locking that is not available for that specific kind of DDL operation, such as **LOCK=SHARED** or **LOCK=NONE** while creating or dropping a primary key, the clause works like an assertion, causing the statement to fail with an error. The following list shows the different possibilities for the **LOCK** clause, from the most permissive to the most restrictive:

- For DDL operations with **LOCK=NONE**, both queries and concurrent DML are allowed. This clause makes the **ALTER TABLE** fail if the kind of DDL operation cannot be performed with the requested type of locking, so specify **LOCK=NONE** if keeping the table fully available is vital and it is OK to cancel the DDL if that is not possible. For example, you might use this clause in DDLs for tables involving customer signups or purchases, to avoid making those tables unavailable by mistakenly issuing an expensive **ALTER TABLE** statement.
- For DDL operations with **LOCK=SHARED**, any writes to the table (that is, DML operations) are blocked, but the data in the table can be read. This clause makes the **ALTER TABLE** fail if the kind of DDL operation cannot be performed with the requested type of locking, so specify **LOCK=SHARED** if keeping the table available for queries is vital and it is OK to cancel the DDL if that is not possible. For example, you might use this clause in DDLs for tables in a data warehouse, where it is OK to delay data load operations until the DDL is finished, but queries cannot be delayed for long periods.
- For DDL operations with **LOCK=DEFAULT**, or with the **LOCK** clause omitted, MySQL uses the lowest level of locking that is available for that kind of operation, allowing concurrent queries, DML, or both wherever possible. This is the setting to use when making pre-planned, pre-tested changes that you know do not cause any availability problems based on the workload for that table.
- For DDL operations with **LOCK=EXCLUSIVE**, both queries and DML operations are blocked. This clause makes the **ALTER TABLE** fail if the kind of DDL operation cannot be performed with the requested type of locking, so specify **LOCK=EXCLUSIVE** if the primary concern is finishing the DDL in the shortest time possible, and it is OK to make applications wait when they try to access the table. You might also use **LOCK=EXCLUSIVE** if the server is supposed to be idle, to avoid unexpected accesses to the table.

In most cases, an online DDL operation on a table waits for currently executing transactions that are accessing the table to **commit** or **roll back** because it requires exclusive access to the table for a brief period while the DDL statement is being prepared. Likewise, the online DDL operation requires exclusive access to the table for a brief time before finishing. Thus, an online DDL statement also waits for transactions that are started while the DDL is in progress to commit or roll back before completing. Consequently, in the case of long running transactions that perform inserts, updates, deletes, or **SELECT ... FOR UPDATE** operations on the table, it is possible for online DDL operation to time out waiting for exclusive access to the table.

A case in which an online DDL operation on a table does not wait for a currently executing transaction to complete can occur when the table is in a foreign key relationship and a transaction is run explicitly on the other table in the foreign key relationship. In this case, the transaction holds an exclusive metadata lock on the table it is updating, but only holds shared InnoDB table lock (required for foreign key checking) on the other table. The shared InnoDB table lock permits the online DDL operation to proceed but blocks the operation at the commit phase, when an exclusive InnoDB table lock is required. This scenario can result in deadlocks as other transactions wait for the online DDL operation to commit. (See Bug #48652, and Bug #77390)

Because there is some processing work involved with recording the changes made by concurrent DML operations, then applying those changes at the end, an online DDL operation could take longer overall than the old-style mechanism that blocks table access from other sessions. The reduction

in raw performance is balanced against better responsiveness for applications that use the table. When evaluating the ideal techniques for changing table structure, consider end-user perception of performance, based on factors such as load times for web pages.

A newly created InnoDB secondary index contains only the committed data in the table at the time the `CREATE INDEX` or `ALTER TABLE` statement finishes executing. It does not contain any uncommitted values, old versions of values, or values marked for deletion but not yet removed from the old index.

Performance of In-Place versus Table-Copying DDL Operations

The raw performance of an online DDL operation is largely determined by whether the operation is performed in-place, or requires copying and rebuilding the entire table. See [Table 15.10, “Online Status for DDL Operations”](#) to see what kinds of operations can be performed in-place, and any requirements for avoiding table-copy operations.

The performance speedup from in-place DDL applies to operations on secondary indexes, not to the primary key index. The rows of an InnoDB table are stored in a [clustered index](#) organized based on the [primary key](#), forming what some database systems call an “index-organized table”. Because the table structure is closely tied to the primary key, redefining the primary key still requires copying the data.

When an operation on the primary key uses `ALGORITHM=INPLACE`, even though the data is still copied, it is more efficient than using `ALGORITHM=COPY` because:

- No undo logging or associated redo logging is required for `ALGORITHM=INPLACE`. These operations add overhead to DDL statements that use `ALGORITHM=COPY`.
- The secondary index entries are pre-sorted, and so can be loaded in order.
- The change buffer is not used, because there are no random-access inserts into the secondary indexes.

To judge the relative performance of online DDL operations, you can run such operations on a big `InnoDB` table using current and earlier versions of MySQL. You can also run all the performance tests under the latest MySQL version, simulating the previous DDL behavior for the “before” results, by setting the `old_alter_table` system variable. Issue the statement `set old_alter_table=1` in the session, and measure DDL performance to record the “before” figures. Then `set old_alter_table=0` to re-enable the newer, faster behavior, and run the DDL operations again to record the “after” figures.

For a basic idea of whether a DDL operation does its changes in-place or performs a table copy, look at the “rows affected” value displayed after the command finishes. For example, here are lines you might see after doing different types of DDL operations:

- Changing the default value of a column (super-fast, does not affect the table data at all):

```
Query OK, 0 rows affected (0.07 sec)
```

- Adding an index (takes time, but `0 rows affected` shows that the table is not copied):

```
Query OK, 0 rows affected (21.42 sec)
```

- Changing the data type of a column (takes substantial time and does require rebuilding all the rows of the table):

```
Query OK, 1671168 rows affected (1 min 35.54 sec)
```

Note

Changing the data type of a column requires rebuilding all the rows of the table with the exception of changing `VARCHAR` size, which may be performed

using online `ALTER TABLE`. See [Modifying Column Properties](#) for more information.

For example, before running a DDL operation on a big table, you might check whether the operation is fast or slow as follows:

1. Clone the table structure.
2. Populate the cloned table with a tiny amount of data.
3. Run the DDL operation on the cloned table.
4. Check whether the “rows affected” value is zero or not. A non-zero value means the operation requires rebuilding the entire table, which might require special planning. For example, you might do the DDL operation during a period of scheduled downtime, or on each replication slave server one at a time.

For a deeper understanding of the reduction in MySQL processing, examine the `performance_schema` and `INFORMATION_SCHEMA` tables related to `InnoDB` before and after DDL operations, to see the number of physical reads, writes, memory allocations, and so on.

Space Requirements for Online DDL Operations

Online DDL operations have the following space requirements:

- Space for temporary log files

There is one such log file for each index being created or table being altered. This log file stores data inserted, updated, or deleted in the table during the DDL operation. The temporary log file is extended when needed by the value of `innodb_sort_buffer_size`, up to the maximum specified by `innodb_online_alter_log_max_size`. If a temporary log file exceeds the upper size limit, the `ALTER TABLE` operation fails and all uncommitted concurrent DML operations are rolled back. Thus, a large value for this option allows more DML to happen during an online DDL operation, but also extends the period of time at the end of the DDL operation when the table is locked to apply the data from the log.

If the operation takes so long, and concurrent DML modifies the table so much, that the size of the temporary online log exceeds the value of the `innodb_online_alter_log_max_size` configuration option, the online DDL operation fails with a `DB_ONLINE_LOG_TOO_BIG` error.

- Space for temporary sort files

Online DDL operations that rebuild the table write temporary sort files to the MySQL temporary directory (`$TMPDIR` on Unix, `%TEMP%` on Windows, or the directory specified by the `--tmpdir` configuration variable) during index creation. Each temporary sort file is large enough to hold all columns defined for the new secondary index plus the columns that are part of the primary key of the clustered index, and each one is removed as soon as it is merged into the final table or index. Such operations may require temporary space equal to the amount of data in the table plus indexes. An online DDL operation that rebuilds the table can cause an error if the operation uses all of the available disk space on the file system where the data directory (`datadir`) resides.

You can use the `innodb_tmpdir` configuration option to define a separate temporary directory for online DDL operations. The `innodb_tmpdir` option was introduced to help avoid temporary directory overflows that could occur as a result of large temporary sort files created during online `ALTER TABLE` operations that rebuild the table.

- Space for an intermediate table file

Some online DDL operations that rebuild the table create a temporary intermediate table file in the same directory as the original table as opposed to rebuilding the table in place. An intermediate table file may require space equal to the size of the original table. Operations that rebuild the table in place are noted in [Section 15.12.1, “Online DDL Overview”](#).

15.12.3 Online DDL SQL Syntax

Typically, you do not need to do anything special to enable [online DDL](#) when using the `ALTER TABLE` statement for [InnoDB](#) tables. See [Table 15.10, “Online Status for DDL Operations”](#) for the kinds of DDL operations that can be performed in-place, allowing concurrent DML, or both. Some variations require particular combinations of configuration settings or `ALTER TABLE` clauses.

You can control the various aspects of a particular online DDL operation by using the `LOCK` and `ALGORITHM` clauses of the `ALTER TABLE` statement. These clauses come at the end of the statement, separated from the table and column specifications by commas. The `LOCK` clause is useful for fine-tuning the degree of concurrent access to the table. The `ALGORITHM` clause is primarily intended for performance comparisons and as a fallback to the older table-copying behavior in case you encounter any issues with existing DDL code. For example:

- To avoid accidentally making the table unavailable for reads, writes, or both, specify a clause on the `ALTER TABLE` statement such as `LOCK=NONE` (allow both reads and writes) or `LOCK=SHARED` (allow reads). The operation halts immediately if the requested level of concurrency is not available.
- To compare performance, run one statement with `ALGORITHM=INPLACE` and another with `ALGORITHM=COPY`, as an alternative to setting the `old_alter_table` configuration option.
- To avoid tying up the server with an `ALTER TABLE` operation that copies the table, include `ALGORITHM=INPLACE`. The statement halts immediately if it cannot use the in-place mechanism. See [Table 15.10, “Online Status for DDL Operations”](#) for a list of the DDL operations that can or cannot be performed in-place.

See [Section 15.12.2, “Online DDL Performance, Concurrency, and Space Requirements”](#) for more details about the `LOCK` clause.

15.12.4 Simplifying DDL Statements with Online DDL

Before the introduction of [online DDL](#), it was common practice to combine many DDL operations into a single `ALTER TABLE` statement. Because each `ALTER TABLE` statement involved copying and rebuilding the table, it was more efficient to make several changes to the same table at once, since those changes could all be done with a single rebuild operation for the table. The downside was that SQL code involving DDL operations was harder to maintain and to reuse in different scripts. If the specific changes were different each time, you might have to construct a new complex `ALTER TABLE` for each slightly different scenario.

For DDL operations that can be done in-place, as shown in [Table 15.10, “Online Status for DDL Operations”](#), now you can separate them into individual `ALTER TABLE` statements for easier scripting and maintenance, without sacrificing efficiency. For example, you might take a complicated statement such as:

```
ALTER TABLE t1 ADD INDEX i1(c1), ADD UNIQUE INDEX i2(c2),
CHANGE c4_old_name c4_new_name INTEGER UNSIGNED;
```

and break it down into simpler parts that can be tested and performed independently, such as:

```
ALTER TABLE t1 ADD INDEX i1(c1);
ALTER TABLE t1 ADD UNIQUE INDEX i2(c2);
ALTER TABLE t1 CHANGE c4_old_name c4_new_name INTEGER UNSIGNED NOT NULL;
```

You might still use multi-part `ALTER TABLE` statements for:

- Operations that must be performed in a specific sequence, such as creating an index followed by a foreign key constraint that uses that index.
- Operations all using the same specific `LOCK` clause, that you want to either succeed or fail as a group.

- Operations that cannot be performed in-place, that is, that still copy and rebuild the table.
- Operations for which you specify `ALGORITHM=COPY` or `old_alter_table=1`, to force the table-copying behavior if needed for precise backward-compatibility in specialized scenarios.

15.12.5 Online DDL Implementation Details

Each `ALTER TABLE` operation for an InnoDB table is governed by several aspects:

- Whether there is any change to the physical representation of the table, or whether it purely a change to metadata that can be done without touching the table itself.
- Whether the volume of data in the table stays the same, increases, or decreases.
- Whether a change in table data involves the clustered index, secondary indexes, or both.
- Whether there are any [foreign key](#) relationships between the table being altered and some other table. The mechanics differ depending on whether the `foreign_key_checks` configuration option is enabled or disabled.
- Whether the table is partitioned. Partitioning clauses of `ALTER TABLE` are turned into low-level operations involving one or more tables, and those operations follow the regular rules for online DDL.
- Whether the table data must be copied, whether the table can be reorganized “in-place”, or a combination of both.
- Whether the table contains any [auto-increment](#) columns.
- What degree of [locking](#) is required, either by the nature of the underlying database operations, or a `LOCK` clause that you specify in the `ALTER TABLE` statement.

Error Conditions for Online DDL

Here are the primary reasons why an online DDL operation could fail:

- If a `LOCK` clause specifies a low degree of locking (`SHARED` or `NONE`) that is not compatible with the particular type of DDL operation.
- If a timeout occurs while waiting to get an [exclusive lock](#) on the table, which may be needed briefly during the initial and final phases of the DDL operation.
- If the `tmpdir` or `innodb_tmpdir` file system runs out of disk space, while MySQL writes temporary sort files on disk during index creation. For more information, see [Section B.5.3.5, “Where MySQL Stores Temporary Files”](#).
- If the `ALTER TABLE` takes so long, and concurrent DML modifies the table so much, that the size of the temporary online log exceeds the value of the `innodb_online_alter_log_max_size` configuration option. This condition causes a `DB_ONLINE_LOG_TOO_BIG` error.
- If concurrent DML makes changes to the table that are allowed with the original table definition, but not with the new one. The operation only fails at the very end, when MySQL tries to apply all the changes from concurrent DML statements. For example, you might insert duplicate values into a column while a unique index is being created, or you might insert `NULL` values into a column while creating a [primary key](#) index on that column. The changes made by the concurrent DML take precedence, and the `ALTER TABLE` operation is effectively [rolled back](#).

Although the configuration option `innodb_file_per_table` has a dramatic effect on the representation for an InnoDB table, all online DDL operations work equally well whether that option is enabled or disabled, and whether the table is physically located in its own `.ibd` file or inside the [system tablespace](#).

InnoDB has two types of indexes: the [clustered index](#) representing all the data in the table, and optional [secondary indexes](#) to speed up queries. Since the clustered index contains the data values in its B-tree

nodes, adding or dropping a clustered index does involve copying the data, and creating a new copy of the table. A secondary index, however, contains only the index key and the value of the primary key. This type of index can be created or dropped without copying the data in the clustered index. Because each secondary index contains copies of the primary key values (used to access the clustered index when needed), when you change the definition of the primary key, all secondary indexes are recreated as well.

Dropping a secondary index is simple. Only the internal InnoDB system tables and the MySQL data dictionary tables are updated to reflect the fact that the index no longer exists. InnoDB returns the storage used for the index to the tablespace that contained it, so that new indexes or additional table rows can use the space.

To add a secondary index to an existing table, InnoDB scans the table, and sorts the rows using memory buffers and temporary files in order by the values of the secondary index key columns. The B-tree is then built in key-value order, which is more efficient than inserting rows into an index in random order. Because the B-tree nodes are split when they fill, building the index in this way results in a higher fill-factor for the index, making it more efficient for subsequent access.

15.12.6 Online DDL and Crash Recovery

Although no data is lost if the server crashes while an `ALTER TABLE` statement is executing, the [crash recovery](#) process is different for [clustered indexes](#) and [secondary indexes](#).

If the server crashes while creating an InnoDB secondary index, upon recovery, MySQL drops any partially created indexes. You must re-run the `ALTER TABLE` or `CREATE INDEX` statement.

When a crash occurs during the creation of an InnoDB clustered index, recovery is more complicated, because the data in the table must be copied to an entirely new clustered index. Remember that all InnoDB tables are stored as clustered indexes.

MySQL creates the new clustered index by copying the existing data from the original InnoDB table to a temporary table that has the desired index structure. Once the data is completely copied to this temporary table, the original table is renamed with a different temporary table name. The temporary table comprising the new clustered index is renamed with the name of the original table, and the original table is dropped from the database.

If a system crash occurs while creating a new clustered index, no data is lost, but you must complete the recovery process using the temporary tables that exist during the process. Since it is rare to re-create a clustered index or re-define primary keys on large tables, or to encounter a system crash during this operation, this manual does not provide information on recovering from this scenario.

15.12.7 Online DDL for Partitioned Tables

Some `ALTER TABLE` partitioning clauses do not go through the same internal online DDL API as regular non-partitioned InnoDB tables. As a result, online support for `ALTER TABLE` partitioning clauses varies.

The following table shows the online status for each `ALTER TABLE` partitioning statement. Regardless of the online DDL API that is used, MySQL attempts to minimize data copying and locking where possible.

- The “In-Place?” column shows which operations permit the `ALGORITHM=INPLACE` clause.
- The “Permits Concurrent DML?” column shows which operations are performed fully online. You can specify `LOCK=NONE` to assert that concurrent DML is permitted during the DDL operation. MySQL automatically permits concurrent DML where possible.

For operations that support `ALGORITHM={COPY | INPLACE}`, you can specify `LOCK=SHARED` to assert that concurrent queries are permitted during a DDL operation. MySQL automatically permits concurrent queries where possible.

- The “Notes” column provides additional information and explains exceptions and dependencies related to the “Yes/No” values of other columns. An asterisk indicates an exception or dependency.

`ALTER TABLE` partitioning options that use `ALGORITHM=COPY` or that only permit “`ALGORITHM=DEFAULT, LOCK=DEFAULT`”, repartition the table using the `COPY` algorithm. In other words, a new partitioned table is created with the new partitioning scheme. The newly created table includes any changes applied by the `ALTER TABLE` statement, and table data is copied into the new table structure.

Table 15.11 Online Status for ALTER TABLE Partitioning Clauses

Partitioning Clause	In-Place?	Permits Concurrent DML?	Notes
<code>PARTITION BY</code>	No	No	Permits <code>ALGORITHM=COPY, LOCK={DEFAULT SHARED EXCLUSIVE}</code>
<code>ADD PARTITION</code>	Yes*	Yes*	Prior to 8.0.2, only <code>ALGORITHM=DEFAULT, LOCK=DEFAULT</code> is supported. As of 8.0.2, <code>ALGORITHM=INPLACE, LOCK={DEFAULT NONE SHARED EXCLUSIVE}</code> is supported for <code>RANGE</code> and <code>LIST</code> partitions, <code>ALGORITHM=INPLACE, LOCK={DEFAULT SHARED EXCLUSIVE}</code> for <code>HASH</code> and <code>KEY</code> partitions, and <code>ALGORITHM=COPY, LOCK={SHARED EXCLUSIVE}</code> for all partition types. Does not copy existing data for tables partitioned by <code>RANGE</code> or <code>LIST</code> . Concurrent queries are permitted with <code>ALGORITHM=COPY</code> for tables partitioned by <code>HASH</code> or <code>LIST</code> , as MySQL copies the data while holding a shared lock.
<code>DROP PARTITION</code>	Yes*	Yes*	Prior to 8.0.2, only <code>ALGORITHM=DEFAULT, LOCK=DEFAULT</code> is supported. As of 8.0.2, <code>ALGORITHM=INPLACE, LOCK={DEFAULT NONE SHARED EXCLUSIVE}</code> is supported. Does not copy data for tables partitioned by <code>RANGE</code> or <code>LIST</code> . <code>DROP PARTITION</code> with <code>ALGORITHM=INPLACE</code> deletes data stored in the partition and drops the partition. However, <code>DROP PARTITION</code> with <code>ALGORITHM=COPY</code> or <code>old_alter_table=ON</code> rebuilds the partitioned table and attempts to move data from the dropped partition to another partition with a compatible <code>PARTITION ... VALUES</code> definition. Data that cannot be moved to another partition is deleted.
<code>DISCARD PARTITION</code>	No	No	Only permits <code>ALGORITHM=DEFAULT, LOCK=DEFAULT</code>

Partitioning Clause	In-Place?	Permits Concurrent DML?	Notes
<code>IMPORT PARTITION</code>	No	No	Only permits <code>ALGORITHM=DEFAULT</code> , <code>LOCK=DEFAULT</code>
<code>TRUNCATE PARTITION</code>	Yes	Yes	Does not copy existing data. It merely deletes rows; it does not alter the definition of the table itself, or of any of its partitions.
<code>COALESCE PARTITION</code>	Yes*	No	Prior to 8.0.2, only <code>ALGORITHM=DEFAULT</code> , <code>LOCK=DEFAULT</code> is supported, and concurrent queries are permitted for tables partitioned by <code>HASH</code> or <code>LIST</code> . MySQL copies the data while holding a shared lock. As of 8.0.2, <code>ALGORITHM=INPLACE</code> , <code>LOCK={DEFAULT SHARED EXCLUSIVE}</code> is supported.
<code>REORGANIZE PARTITION</code>	Yes*	No	Prior to 8.0.2, only <code>ALGORITHM=DEFAULT</code> , <code>LOCK=DEFAULT</code> is supported, and concurrent queries are permitted for tables partitioned by <code>LINEAR HASH</code> or <code>LIST</code> . MySQL copies data from affected partitions while holding a shared metadata lock. As of 8.0.2, <code>ALGORITHM=INPLACE</code> , <code>LOCK={DEFAULT SHARED EXCLUSIVE}</code> is supported.
<code>EXCHANGE PARTITION</code>	Yes	Yes	
<code>ANALYZE PARTITION</code>	Yes	Yes	
<code>CHECK PARTITION</code>	Yes	Yes	
<code>OPTIMIZE PARTITION</code>	No	No	<code>ALGORITHM</code> and <code>LOCK</code> clauses are ignored. Rebuilds the entire table. See Section 22.3.4, "Maintenance of Partitions" .
<code>REBUILD PARTITION</code>	Yes*	No	Prior to 8.0.2, only <code>ALGORITHM=DEFAULT</code> , <code>LOCK=DEFAULT</code> is supported, and concurrent queries are permitted for tables partitioned by <code>LINEAR HASH</code> or <code>LIST</code> . MySQL copies data from affected partitions while holding a shared metadata lock. As of 8.0.2, <code>ALGORITHM=INPLACE</code> , <code>LOCK={DEFAULT SHARED EXCLUSIVE}</code> is supported.
<code>REPAIR PARTITION</code>	Yes	Yes	
<code>REMOVE PARTITIONING</code>	No	No	Permits <code>ALGORITHM=COPY</code> , <code>LOCK={DEFAULT SHARED EXCLUSIVE}</code>

Non-partitioning online `ALTER TABLE` operations on partitioned tables follow the same rules that apply to regular tables. However, `ALTER TABLE` performs online operations on each table partition, which causes increased demand on system resources due to operations being performed on multiple partitions.

For additional information about `ALTER TABLE` partitioning clauses, see [Partitioning Options](#), and [Section 13.1.7.1, “ALTER TABLE Partition Operations”](#). For information about partitioning in general, see [Chapter 22, Partitioning](#).

15.12.8 Online DDL Limitations

The following limitations apply to online DDL operations:

- The table is copied, rather than using Fast Index Creation when you create an index on a `TEMPORARY TABLE`. This has been reported as MySQL Bug #39833.
- InnoDB handles error cases when users attempt to drop indexes needed for foreign keys. See [Section B.3, “Server Error Codes and Messages”](#) for information related to error 1553.
- The `ALTER TABLE` clause `LOCK=NONE` is not allowed if there are `ON...CASCADE` or `ON...SET NULL` constraints on the table.
- Depending on the internal workings of the online DDL operation and the `LOCK` clause of the `ALTER TABLE` statement, an online DDL operation may require exclusive access to the table for a brief time during the initial and final phases of the DDL operation. Thus, an online DDL operation might wait before finishing if there is a long-running transaction performing inserts, updates, deletes, or `SELECT ... FOR UPDATE` on the table; and an online DDL operation might wait before finishing if a similar long-running transaction is started while the `ALTER TABLE` is in progress.
- When running an online DDL operation, the thread that runs the `ALTER TABLE` statement applies an “online log” of DML operations that were run concurrently on the same table from other connection threads. When the DML operations are applied, it is possible to encounter a duplicate key entry error (`ERROR 1062 (23000): Duplicate entry`), even if the duplicate entry is only temporary and would be reverted by a later entry in the “online log”. This is similar to the idea of a foreign key constraint check in InnoDB in which constraints must hold during a transaction.
- `OPTIMIZE TABLE` for an InnoDB table is mapped to an `ALTER TABLE` operation to rebuild the table and update index statistics and free unused space in the clustered index. Secondary indexes are not created as efficiently because keys are inserted in the order they appeared in the primary key. `OPTIMIZE TABLE` also supports online DDL for rebuilding regular and partitioned InnoDB tables. For additional information, see [Section 15.12.1, “Online DDL Overview”](#).

Note

Prior to MySQL 5.6.17 / 5.7.4, there was not [online DDL](#) support for this operation.

- InnoDB tables created before MySQL 5.6 do not support `ALTER TABLE ... ALGORITHM=INPLACE` for tables that include temporal columns (`DATE`, `DATETIME` or `TIMESTAMP`) and have not been rebuilt using `ALTER TABLE ... ALGORITHM=COPY`. In this case, an `ALTER TABLE ... ALGORITHM=INPLACE` operation returns the following error:

```
ERROR 1846 (0A000): ALGORITHM=INPLACE is not supported.
Reason: Cannot change column type INPLACE. Try ALGORITHM=COPY.
```

- These limitations are generally applicable to online DDL operations on large tables where table copying is involved:
 - There is no mechanism to pause an online DDL operation or to throttle I/O or CPU usage for an online DDL operation.
 - Rollback of an online DDL operation can be expensive should the operation fail.
 - Long running online DDL operations can cause replication lag. An online DDL operation must finish running on the master before it is run on the slave. Also, DML that was processed

concurrently on the master is only processed on the slave after the DDL operation on the slave is completed (Bug #73196).

For additional information related to running online DDL operations on large tables, see [Section 15.12.2, “Online DDL Performance, Concurrency, and Space Requirements”](#).

15.13 InnoDB Startup Options and System Variables

- System variables that are true or false can be enabled at server startup by naming them, or disabled by using a `--skip-` prefix. For example, to enable or disable the InnoDB adaptive hash index, you can use `--innodb_adaptive_hash_index` or `--skip-innodb_adaptive_hash_index` on the command line, or `innodb_adaptive_hash_index` or `skip-innodb_adaptive_hash_index` in an option file.
- System variables that take a numeric value can be specified as `--var_name=value` on the command line or as `var_name=value` in option files.
- Many system variables can be changed at runtime (see [Section 5.1.6.2, “Dynamic System Variables”](#)).
- For information about GLOBAL and SESSION variable scope modifiers, refer to the SET statement documentation.
- Certain options control the locations and layout of the InnoDB data files. [Section 15.6.1, “InnoDB Startup Configuration”](#) explains how to use these options.
- Some options, which you might not use initially, help tune InnoDB performance characteristics based on machine capacity and your database workload.
- For more information on specifying options and system variables, see [Section 4.2.3, “Specifying Program Options”](#).

Table 15.12 InnoDB Option/Variable Reference

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynamic
daemon_memcached	Yes enable_binlog	Yes	Yes		Global	No

InnoDB Command Options

- `--ignore-builtin-innodb`

Deprecated	5.5.22	
Removed	8.0.3	
Command-Line Format	<code>--ignore-builtin-innodb</code>	
System Variable	Name	<code>ignore_builtin_innodb</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	boolean

In MySQL 5.1, this option caused the server to behave as if the built-in `InnoDB` were not present, which enabled the `InnoDB Plugin` to be used instead. In MySQL 8.0, `InnoDB` is the default storage engine and `InnoDB Plugin` is not used. This option was removed in MySQL 8.0.3.

- `--innodb[=value]`

Deprecated	5.7.5	
Command-Line Format	<code>--innodb[=value]</code>	
Permitted Values	Type	enumeration
	Default	ON
	Valid Values	OFF
		ON
	FORCE	

Controls loading of the [InnoDB](#) storage engine, if the server was compiled with [InnoDB](#) support. This option has a tristate format, with possible values of `OFF`, `ON`, or `FORCE`. See [Section 5.6.2, “Installing and Uninstalling Plugins”](#).

To disable [InnoDB](#), use `--innodb=OFF` or `--skip-innodb`. In this case, because the default storage engine is [InnoDB](#), the server does not start unless you also use `--default-storage-engine` and `--default-tmp-storage-engine` to set the default to some other engine for both permanent and `TEMPORARY` tables.

The [InnoDB](#) storage engine can no longer be disabled, and the `--innodb=OFF` and `--skip-innodb` options are deprecated and have no effect. Their use results in a warning. These options will be removed in a future MySQL release.

- `--innodb-status-file`

Command-Line Format	<code>--innodb-status-file</code>	
Permitted Values	Type	boolean
	Default	OFF

Controls whether [InnoDB](#) creates a file named `innodb_status.pid` in the MySQL data directory. If enabled, [InnoDB](#) periodically writes the output of `SHOW ENGINE INNODB STATUS` to this file.

By default, the file is not created. To create it, start `mysqld` with the `--innodb-status-file=1` option. The file is deleted during normal shutdown.

- `--skip-innodb`

Disable the [InnoDB](#) storage engine. See the description of `--innodb`.

InnoDB System Variables

- `daemon_memcached_enable_binlog`

Command-Line Format	<code>--daemon-memcached-enable-binlog=#</code>	
System Variable	Name	<code>daemon_memcached_enable_binlog</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	boolean
	Default	false

Enable this option on the [master server](#) to use the [InnoDB memcached](#) plugin (`daemon_memcached`) with the MySQL [binary log](#). This option can only be set at server startup. You must also enable the MySQL binary log on the master server using the `--log-bin` option.

For more information, see [Section 15.19.7, “The InnoDB memcached Plugin and Replication”](#).

- [daemon_memcached_engine_lib_name](#)

Command-Line Format	<code>--daemon-memcached-engine-lib-name=library</code>	
System Variable	Name	<code>daemon_memcached_engine_lib_name</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	file name
	Default	<code>innodb_engine.so</code>

Specifies the shared library that implements the `InnoDB memcached` plugin.

For more information, see [Section 15.19.3, “Setting Up the InnoDB memcached Plugin”](#).

- [daemon_memcached_engine_lib_path](#)

Command-Line Format	<code>--daemon-memcached-engine-lib-path=directory</code>	
System Variable	Name	<code>daemon_memcached_engine_lib_path</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	directory name
	Default	<code>NULL</code>

The path of the directory containing the shared library that implements the `InnoDB memcached` plugin. The default value is `NULL`, representing the MySQL plugin directory. You should not need to modify this parameter unless specifying a `memcached` plugin for a different storage engine that is located outside of the MySQL plugin directory.

For more information, see [Section 15.19.3, “Setting Up the InnoDB memcached Plugin”](#).

- [daemon_memcached_option](#)

Command-Line Format	<code>--daemon-memcached-option=options</code>	
System Variable	Name	<code>daemon_memcached_option</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	string
	Default	

Used to pass space-separated `memcached` options to the underlying `memcached` memory object caching daemon on startup. For example, you might change the port that `memcached` listens on, reduce the maximum number of simultaneous connections, change the maximum memory size for a key/value pair, or enable debugging messages for the error log.

See [Section 15.19.3, “Setting Up the InnoDB memcached Plugin”](#) for usage details. For information about `memcached` options, refer to the `memcached` man page.

- `daemon_memcached_r_batch_size`

Command-Line Format	<code>--daemon-memcached-r-batch-size=#</code>	
System Variable	Name	<code>daemon_memcached_r_batch_size</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	1

Specifies how many `memcached` read operations (`get` operations) to perform before doing a `COMMIT` to start a new transaction. Counterpart of `daemon_memcached_w_batch_size`.

This value is set to 1 by default, so that any changes made to the table through SQL statements are immediately visible to `memcached` operations. You might increase it to reduce the overhead from frequent commits on a system where the underlying table is only being accessed through the `memcached` interface. If you set the value too large, the amount of undo or redo data could impose some storage overhead, as with any long-running transaction.

For more information, see [Section 15.19.3, “Setting Up the InnoDB memcached Plugin”](#).

- `daemon_memcached_w_batch_size`

Command-Line Format	<code>--daemon-memcached-w-batch-size=#</code>	
System Variable	Name	<code>daemon_memcached_w_batch_size</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	1

Specifies how many `memcached` write operations, such as `add`, `set`, and `incr`, to perform before doing a `COMMIT` to start a new transaction. Counterpart of `daemon_memcached_r_batch_size`.

This value is set to 1 by default, on the assumption that data being stored is important to preserve in case of an outage and should immediately be committed. When storing non-critical data, you might increase this value to reduce the overhead from frequent commits; but then the last $N-1$ uncommitted write operations could be lost if a crash occurs.

For more information, see [Section 15.19.3, “Setting Up the InnoDB memcached Plugin”](#).

- `ignore_builtin_innodb`

Deprecated	5.5.22	
Removed	8.0.3	
Command-Line Format	<code>--ignore-builtin-innodb</code>	
System Variable	Name	<code>ignore_builtin_innodb</code>
	Variable Scope	Global
	Dynamic Variable	No

Permitted Values	Type	boolean
-------------------------	-------------	---------

See the description of `--ignore-builtin-innodb` under “InnoDB Command Options” earlier in this section. This variable was removed in MySQL 8.0.3.

- `innodb_adaptive_flushing`

Command-Line Format	<code>--innodb-adaptive-flushing=#</code>	
System Variable	Name	<code>innodb_adaptive_flushing</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	ON

Specifies whether to dynamically adjust the rate of flushing [dirty pages](#) in the [InnoDB buffer pool](#) based on the workload. Adjusting the flush rate dynamically is intended to avoid bursts of I/O activity. This setting is enabled by default. See [Section 15.6.3.6, “Configuring InnoDB Buffer Pool Flushing”](#) for more information. For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_adaptive_flushing_lwm`

Command-Line Format	<code>--innodb-adaptive-flushing-lwm=#</code>	
System Variable	Name	<code>innodb_adaptive_flushing_lwm</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	10
	Min Value	0
	Max Value	70

Defines the low water mark representing percentage of [redo log](#) capacity at which [adaptive flushing](#) is enabled. For more information, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#).

- `innodb_adaptive_hash_index`

Command-Line Format	<code>--innodb-adaptive-hash-index=#</code>	
System Variable	Name	<code>innodb_adaptive_hash_index</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	ON

Whether the [InnoDB adaptive hash index](#) is enabled or disabled. It may be desirable, depending on your workload, to dynamically enable or disable [adaptive hash indexing](#) to improve query performance. Because the adaptive hash index may not be useful for all workloads, conduct benchmarks with it both enabled and disabled, using realistic workloads. See [Section 15.4.3, “Adaptive Hash Index”](#) for details.

This variable is enabled by default. You can modify this parameter using the [SET GLOBAL](#) statement, without restarting the server. Changing the setting requires the [SYSTEM_VARIABLES_ADMIN](#) or [SUPER](#) privilege. You can also use `--skip-innodb_adaptive_hash_index` at server startup to disable it.

Disabling the adaptive hash index empties the hash table immediately. Normal operations can continue while the hash table is emptied, and executing queries that were using the hash table access the index B-trees directly instead. When the adaptive hash index is re-enabled, the hash table is populated again during normal operation.

- [innodb_adaptive_hash_index_parts](#)

Command-Line Format	<code>--innodb-adaptive-hash-index-parts=#</code>	
System Variable	Name	innodb_adaptive_hash_index_parts
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	numeric
	Default	8
	Min Value	1
	Max Value	512

Partitions the adaptive hash index search system. Each index is bound to a specific partition, with each partition protected by a separate latch.

The adaptive hash index search system is partitioned into 8 parts by default. The maximum setting is 512.

For related information, see [Section 15.4.3, “Adaptive Hash Index”](#).

- [innodb_adaptive_max_sleep_delay](#)

Command-Line Format	<code>--innodb-adaptive-max-sleep-delay=#</code>	
System Variable	Name	innodb_adaptive_max_sleep_delay
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	150000
	Min Value	0
	Max Value	1000000

Permits InnoDB to automatically adjust the value of `innodb_thread_sleep_delay` up or down according to the current workload. Any non-zero value enables automated, dynamic adjustment of the `innodb_thread_sleep_delay` value, up to the maximum value specified in the `innodb_adaptive_max_sleep_delay` option. The value represents the number of microseconds. This option can be useful in busy systems, with greater than 16 InnoDB threads. (In practice, it is most valuable for MySQL systems with hundreds or thousands of simultaneous connections.)

For more information, see [Section 15.6.5, “Configuring Thread Concurrency for InnoDB”](#).

- `innodb_api_bk_commit_interval`

Command-Line Format	<code>--innodb-api-bk-commit-interval=#</code>	
System Variable	Name	<code>innodb_api_bk_commit_interval</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	5
	Min Value	1
	Max Value	1073741824

How often to auto-commit idle connections that use the InnoDB `memcached` interface, in seconds. For more information, see [Section 15.19.6.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”](#).

- `innodb_api_disable_rowlock`

Command-Line Format	<code>--innodb-api-disable-rowlock=#</code>	
System Variable	Name	<code>innodb_api_disable_rowlock</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	boolean
	Default	OFF

Use this option to disable row locks when InnoDB `memcached` performs DML operations. By default, `innodb_api_disable_rowlock` is disabled, which means that `memcached` requests row locks for `get` and `set` operations. When `innodb_api_disable_rowlock` is enabled, `memcached` requests a table lock instead of row locks.

`innodb_api_disable_rowlock` is not dynamic. It must be specified on the `mysqld` command line or entered in the MySQL configuration file. Configuration takes effect when the plugin is installed, which occurs when the MySQL server is started.

For more information, see [Section 15.19.6.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”](#).

- `innodb_api_enable_binlog`

Command-Line Format	<code>--innodb-api-enable-binlog=#</code>
----------------------------	---

System Variable	Name	<code>innodb_api_enable_binlog</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	boolean
	Default	<code>OFF</code>

Lets you use the [InnoDB memcached](#) plugin with the MySQL [binary log](#). For more information, see [Enabling the InnoDB memcached Binary Log](#).

- `innodb_api_enable_md1`

Command-Line Format	<code>--innodb-api-enable-md1=#</code>	
System Variable	Name	<code>innodb_api_enable_md1</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	boolean
	Default	<code>OFF</code>

Locks the table used by the [InnoDB memcached](#) plugin, so that it cannot be dropped or altered by [DDL](#) through the SQL interface. For more information, see [Section 15.19.6.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”](#).

- `innodb_api_trx_level`

Command-Line Format	<code>--innodb-api-trx-level=#</code>	
System Variable	Name	<code>innodb_api_trx_level</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	<code>0</code>

Controls the transaction [isolation level](#) on queries processed by the [memcached](#) interface. The constants corresponding to the familiar names are:

- `0 = READ UNCOMMITTED`
- `1 = READ COMMITTED`
- `2 = REPEATABLE READ`
- `3 = SERIALIZABLE`

For more information, see [Section 15.19.6.4, “Controlling Transactional Behavior of the InnoDB memcached Plugin”](#).

- `innodb_autoextend_increment`

Command-Line Format	<code>--innodb-autoextend-increment=#</code>
----------------------------	--

System Variable	Name	<code>innodb_autoextend_increment</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	64
	Min Value	1
	Max Value	1000

The increment size (in megabytes) for extending the size of an auto-extending [InnoDB system tablespace](#) file when it becomes full. The default value is 64. For related information, see [System Tablespace Data File Configuration](#), and [Section 15.7.1, “Resizing the InnoDB System Tablespace”](#).

The `innodb_autoextend_increment` setting does not affect [file-per-table](#) tablespace files or [general tablespace](#) files. These files are auto-extending regardless of the `innodb_autoextend_increment` setting. The initial extensions are by small amounts, after which extensions occur in increments of 4MB.

- [innodb_autoinc_lock_mode](#)

Command-Line Format	<code>--innodb-autoinc-lock-mode=#</code>	
System Variable	Name	<code>innodb_autoinc_lock_mode</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	1
	Valid Values	0
		1
	2	

The [lock mode](#) to use for generating [auto-increment](#) values. Permissible values are 0, 1, or 2, for “traditional”, “consecutive”, or “interleaved”, respectively. The default setting is 1 (“consecutive”). For the characteristics of each lock mode, see [InnoDB AUTO_INCREMENT Lock Modes](#).

- [innodb_background_drop_list_empty](#)

Command-Line Format	<code>--innodb-background-drop-list-empty=#</code>	
System Variable	Name	<code>innodb_background_drop_list_empty</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	OFF

Enabling the `innodb_background_drop_list_empty` debug option helps avoid test case failures by delaying table creation until the background drop list is empty. For example, if test case A places table `t1` on the background drop list, test case B waits until the background drop list is empty before creating table `t1`.

- `innodb_buffer_pool_chunk_size`

Command-Line Format	<code>--innodb-buffer-pool-chunk-size</code>	
System Variable	Name	<code>innodb_buffer_pool_chunk_size</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	134217728
	Min Value	1048576
	Max Value	<code>innodb_buffer_pool_size / innodb_buffer_pool_instances</code>

`innodb_buffer_pool_chunk_size` defines the chunk size for InnoDB buffer pool resizing operations. The `innodb_buffer_pool_size` parameter is dynamic, which allows you to resize the buffer pool without restarting the server.

To avoid copying all buffer pool pages during resizing operations, the operation is performed in “chunks”. By default, `innodb_buffer_pool_chunk_size` is 128MB (134217728 bytes). The number of pages contained in a chunk depends on the value of `innodb_page_size`. `innodb_buffer_pool_chunk_size` can be increased or decreased in units of 1MB (1048576 bytes).

The following conditions apply when altering the `innodb_buffer_pool_chunk_size` value:

- If `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances` is larger than the current buffer pool size when the buffer pool is initialized, `innodb_buffer_pool_chunk_size` is truncated to `innodb_buffer_pool_size / innodb_buffer_pool_instances`.
- Buffer pool size must always be equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances`. If you alter `innodb_buffer_pool_chunk_size`, `innodb_buffer_pool_size` is automatically adjusted to a value that is equal to or a multiple of `innodb_buffer_pool_chunk_size * innodb_buffer_pool_instances` that is not less than the current buffer pool size. The adjustment occurs when the buffer pool is initialized.

Important

Care should be taken when changing `innodb_buffer_pool_chunk_size`, as changing this value can automatically increase the size of the buffer pool. Before changing `innodb_buffer_pool_chunk_size`, calculate the effect it will have on `innodb_buffer_pool_size` to ensure that the resulting buffer pool size is acceptable.

To avoid potential performance issues, the number of chunks (`innodb_buffer_pool_size / innodb_buffer_pool_chunk_size`) should not exceed 1000.

See [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#) for more information.

- [innodb_buffer_pool_debug](#)

Command-Line Format	<code>--innodb-buffer-pool-debug=#</code>	
System Variable	Name	innodb_buffer_pool_debug
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	boolean
	Default	OFF

Enabling this option permits multiple buffer pool instances when the buffer pool is less than 1GB in size, ignoring the 1GB minimum buffer pool size constraint imposed on [innodb_buffer_pool_instances](#). The [innodb_buffer_pool_debug](#) option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- [innodb_buffer_pool_dump_at_shutdown](#)

Command-Line Format	<code>--innodb-buffer-pool-dump-at-shutdown=#</code>	
System Variable	Name	innodb_buffer_pool_dump_at_shutdown
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	ON

Specifies whether to record the pages cached in the [InnoDB buffer pool](#) when the MySQL server is shut down, to shorten the [warmup](#) process at the next restart. Typically used in combination with [innodb_buffer_pool_load_at_startup](#). The [innodb_buffer_pool_dump_pct](#) option defines the percentage of most recently used buffer pool pages to dump.

Both [innodb_buffer_pool_dump_at_shutdown](#) and [innodb_buffer_pool_load_at_startup](#) are enabled by default.

For more information, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- [innodb_buffer_pool_dump_now](#)

Command-Line Format	<code>--innodb-buffer-pool-dump-now=#</code>	
System Variable	Name	innodb_buffer_pool_dump_now
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	OFF

Immediately records the pages cached in the [InnoDB buffer pool](#). Typically used in combination with [innodb_buffer_pool_load_now](#).

- `innodb_buffer_pool_dump_pct`

Command-Line Format	<code>--innodb-buffer-pool-dump-pct=#</code>	
System Variable	Name	<code>innodb_buffer_pool_dump_pct</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	25
	Min Value	1
	Max Value	100

Specifies the percentage of the most recently used pages for each buffer pool to read out and dump. The range is 1 to 100. The default value is 25. For example, if there are 4 buffer pools with 100 pages each, and `innodb_buffer_pool_dump_pct` is set to 25, the 25 most recently used pages from each buffer pool are dumped.

- `innodb_buffer_pool_filename`

Command-Line Format	<code>--innodb-buffer-pool-filename=file</code>	
System Variable	Name	<code>innodb_buffer_pool_filename</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	file name
	Default	<code>ib_buffer_pool</code>

Specifies the name of the file that holds the list of tablespace IDs and page IDs produced by `innodb_buffer_pool_dump_at_shutdown` or `innodb_buffer_pool_dump_now`. Tablespace IDs and page IDs are saved in the following format: `space, page_id`. By default, the file is named `ib_buffer_pool` and is located in the InnoDB data directory. A non-default location must be specified relative to the data directory.

A file name can be specified at runtime, using a `SET` statement:

```
SET GLOBAL innodb_buffer_pool_filename='file_name';
```

You can also specify a file name at startup, in a startup string or MySQL configuration file. When specifying a file name at startup, the file must exist or InnoDB will return a startup error indicating that there is no such file or directory.

For more information, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- `innodb_buffer_pool_instances`

Command-Line Format	<code>--innodb-buffer-pool-instances=#</code>	
System Variable	Name	<code>innodb_buffer_pool_instances</code>
	Variable Scope	Global

	Dynamic Variable	No
Permitted Values (Windows, 32-bit platforms)	Type	integer
	Default	(autosized)
	Min Value	1
	Max Value	64
Permitted Values (Other)	Type	integer
	Default	8 (or 1 if <code>innodb_buffer_pool_size < 1GB</code>)
	Min Value	1
	Max Value	64

The number of regions that the [InnoDB buffer pool](#) is divided into. For systems with buffer pools in the multi-gigabyte range, dividing the buffer pool into separate instances can improve concurrency, by reducing contention as different threads read and write to cached pages. Each page that is stored in or read from the buffer pool is assigned to one of the buffer pool instances randomly, using a hashing function. Each buffer pool manages its own free lists, [flush lists](#), [LRUs](#), and all other data structures connected to a buffer pool, and is protected by its own buffer pool [mutex](#).

This option only takes effect when setting `innodb_buffer_pool_size` to 1GB or more. The total buffer pool size is divided among all the buffer pools. For best efficiency, specify a combination of `innodb_buffer_pool_instances` and `innodb_buffer_pool_size` so that each buffer pool instance is at least 1GB.

The default value on 32-bit Windows systems depends on the value of `innodb_buffer_pool_size`, as described below:

- If `innodb_buffer_pool_size` is greater than 1.3GB, the default for `innodb_buffer_pool_instances` is `innodb_buffer_pool_size/128MB`, with individual memory allocation requests for each chunk. 1.3GB was chosen as the boundary at which there is significant risk for 32-bit Windows to be unable to allocate the contiguous address space needed for a single buffer pool.
- Otherwise, the default is 1.

On all other platforms, the default value is 8 when `innodb_buffer_pool_size` is greater than or equal to 1GB. Otherwise, the default is 1.

For related information, see [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#).

- [innodb_buffer_pool_load_abort](#)

Command-Line Format	<code>--innodb-buffer-pool-load-abort=#</code>	
System Variable	Name	<code>innodb_buffer_pool_load_abort</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	OFF

Interrupts the process of restoring InnoDB buffer pool contents triggered by `innodb_buffer_pool_load_at_startup` or `innodb_buffer_pool_load_now`.

For more information, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- `innodb_buffer_pool_load_at_startup`

Command-Line Format	<code>--innodb-buffer-pool-load-at-startup=#</code>	
System Variable	Name	<code>innodb_buffer_pool_load_at_startup</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	boolean
	Default	ON

Specifies that, on MySQL server startup, the InnoDB buffer pool is automatically warmed up by loading the same pages it held at an earlier time. Typically used in combination with `innodb_buffer_pool_dump_at_shutdown`.

Both `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` are enabled by default.

For more information, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- `innodb_buffer_pool_load_now`

Command-Line Format	<code>--innodb-buffer-pool-load-now=#</code>	
System Variable	Name	<code>innodb_buffer_pool_load_now</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	OFF

Immediately warms up the InnoDB buffer pool by loading a set of data pages, without waiting for a server restart. Can be useful to bring cache memory back to a known state during benchmarking, or to ready the MySQL server to resume its normal workload after running queries for reports or maintenance.

For more information, see [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

- `innodb_buffer_pool_size`

Command-Line Format	<code>--innodb-buffer-pool-size=#</code>	
System Variable	Name	<code>innodb_buffer_pool_size</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values (32-bit platforms)	Type	integer
	Default	134217728

	Min Value	5242880
	Max Value	$2^{32}-1$
Permitted Values (64-bit platforms)	Type	integer
	Default	134217728
	Min Value	5242880
	Max Value	$2^{64}-1$

The size in bytes of the [buffer pool](#), the memory area where InnoDB caches table and index data. The default value is 128MB. The maximum value depends on the CPU architecture; the maximum is 4294967295 ($2^{32}-1$) on 32-bit systems and 18446744073709551615 ($2^{64}-1$) on 64-bit systems. On 32-bit systems, the CPU architecture and operating system may impose a lower practical maximum size than the stated maximum. When the size of the buffer pool is greater than 1GB, setting [innodb_buffer_pool_instances](#) to a value greater than 1 can improve the scalability on a busy server.

A larger buffer pool requires less disk I/O to access the same table data more than once. On a dedicated database server, you might set the buffer pool size to 80% of the machine's physical memory size. Be aware of the following potential issues when configuring buffer pool size, and be prepared to scale back the size of the buffer pool if necessary.

- Competition for physical memory can cause paging in the operating system.
- InnoDB reserves additional memory for buffers and control structures, so that the total allocated space is approximately 10% greater than the specified buffer pool size.
- Address space for the buffer pool must be contiguous, which can be an issue on Windows systems with DLLs that load at specific addresses.
- The time to initialize the buffer pool is roughly proportional to its size. On instances with large buffer pools, initialization time might be significant. To reduce the initialization period, you can save the buffer pool state at server shutdown and restore it at server startup. See [Section 15.6.3.8, “Saving and Restoring the Buffer Pool State”](#).

When you increase or decrease buffer pool size, the operation is performed in chunks. Chunk size is defined by the [innodb_buffer_pool_chunk_size](#) configuration option, which has a default of 128 MB.

Buffer pool size must always be equal to or a multiple of [innodb_buffer_pool_chunk_size](#) * [innodb_buffer_pool_instances](#). If you alter the buffer pool size to a value that is not equal to or a multiple of [innodb_buffer_pool_chunk_size](#) * [innodb_buffer_pool_instances](#), buffer pool size is automatically adjusted to a value that is equal to or a multiple of [innodb_buffer_pool_chunk_size](#) * [innodb_buffer_pool_instances](#) that is not less than the specified buffer pool size.

[innodb_buffer_pool_size](#) can be set dynamically, which allows you to resize the buffer pool without restarting the server. The [Innodb_buffer_pool_resize_status](#) status variable reports the status of online buffer pool resizing operations. See [Section 15.6.3.2, “Configuring InnoDB Buffer Pool Size”](#) for more information.

- [innodb_change_buffer_max_size](#)

Command-Line Format	<code>--innodb-change-buffer-max-size=#</code>	
System Variable	Name	innodb_change_buffer_max_size

	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	25
	Min Value	0
	Max Value	50

Maximum size for the [InnoDB change buffer](#), as a percentage of the total size of the [buffer pool](#). You might increase this value for a MySQL server with heavy insert, update, and delete activity, or decrease it for a MySQL server with unchanging data used for reporting. For more information, see [Section 15.4.2, “Change Buffer”](#), and [Section 15.6.4, “Configuring InnoDB Change Buffering”](#). For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- [innodb_change_buffering](#)

Command-Line Format	<code>--innodb-change-buffering=#</code>	
System Variable	Name	<code>innodb_change_buffering</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	enumeration
	Default	<code>all</code>
	Valid Values	<code>none</code>
		<code>inserts</code>
		<code>deletes</code>
		<code>changes</code>
<code>purges</code>		
<code>all</code>		

Whether [InnoDB](#) performs [change buffering](#), an optimization that delays write operations to secondary indexes so that the I/O operations can be performed sequentially. Permitted values are described in the following table. Values may also be specified numerically.

Table 15.13 Permitted Values for `innodb_change_buffering`

Value	Numeric Value	Description
<code>none</code>	0	Do not buffer any operations.
<code>inserts</code>	1	Buffer insert operations.
<code>deletes</code>	2	Buffer delete marking operations; strictly speaking, the writes that mark index records for later deletion during a purge operation.
<code>changes</code>	3	Buffer inserts and delete-marking operations.
<code>purges</code>	4	Buffer the physical deletion operations that happen in the background.

Value	Numeric Value	Description
<code>all</code>	5	The default. Buffer inserts, delete-marking operations, and purges.

For more information, see [Section 15.4.2, “Change Buffer”](#), and [Section 15.6.4, “Configuring InnoDB Change Buffering”](#). For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_change_buffering_debug`

Command-Line Format	<code>--innodb-change-buffering-debug=#</code>	
System Variable	Name	<code>innodb_change_buffering_debug</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	0
	Max Value	2

Sets a debug flag for InnoDB change buffering. A value of 1 forces all changes to the change buffer. A value of 2 causes a crash at merge. A default value of 0 indicates that the change buffering debug flag is not set. This option is only available when debugging support is compiled in using the `WITH_DEBUG` CMake option.

- `innodb_checkpoint_disabled`

Introduced	8.0.2	
Command-Line Format	<code>--innodb-checkpoint-disabled=#</code>	
System Variable	Name	<code>innodb_checkpoint_disabled</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	OFF

This is a debug option that is only intended for expert debugging use. It disables checkpoints so that a deliberate server exit always initiates InnoDB recovery. It should only be enabled for a short interval, typically before running DML operations that write redo log entries that would require recovery following a server exit. This option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- `innodb_checksum_algorithm`

Command-Line Format	<code>--innodb-checksum-algorithm=#</code>	
System Variable	Name	<code>innodb_checksum_algorithm</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	enumeration

	Default	<code>crc32</code>
	Valid Values	<code>innodb</code>
		<code>crc32</code>
		<code>none</code>
		<code>strict_innodb</code>
		<code>strict_crc32</code>
		<code>strict_none</code>

Specifies how to generate and verify the [checksum](#) stored in the disk blocks of [InnoDB tablespaces](#). The default value for `innodb_checksum_algorithm` is `crc32`.

Versions of [MySQL Enterprise Backup](#) up to 3.8.0 do not support backing up tablespaces that use CRC32 checksums. [MySQL Enterprise Backup](#) adds CRC32 checksum support in 3.8.1, with some limitations. Refer to the [MySQL Enterprise Backup 3.8.1 Change History](#) for more information.

The value `innodb` is backward-compatible with earlier versions of MySQL. The value `crc32` uses an algorithm that is faster to compute the checksum for every modified block, and to check the checksums for each disk read. It scans blocks 32 bits at a time, which is faster than the `innodb` checksum algorithm, which scans blocks 8 bits at a time. The value `none` writes a constant value in the checksum field rather than computing a value based on the block data. The blocks in a tablespace can use a mix of old, new, and no checksum values, being updated gradually as the data is modified; once blocks in a tablespace are modified to use the `crc32` algorithm, the associated tables cannot be read by earlier versions of MySQL.

The strict form of a checksum algorithm reports an error if it encounters a valid but non-matching checksum value in a tablespace. It is recommended that you only use strict settings in a new instance, to set up tablespaces for the first time. Strict settings are somewhat faster, because they do not need to compute all checksum values during disk reads.

The following table shows the difference between the `none`, `innodb`, and `crc32` option values, and their strict counterparts. `none`, `innodb`, and `crc32` write the specified type of checksum value into each data block, but for compatibility accept other checksum values when verifying a block during a read operation. Strict settings also accept valid checksum values but print an error message when a valid non-matching checksum value is encountered. Using the strict form can make verification faster if all [InnoDB](#) data files in an instance are created under an identical `innodb_checksum_algorithm` value.

Table 15.14 innodb_checksum_algorithm Settings

Value	Generated checksum (when writing)	Permitted checksums (when reading)
<code>none</code>	A constant number.	Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> .
<code>innodb</code>	A checksum calculated in software, using the original algorithm from InnoDB .	Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> .
<code>crc32</code>	A checksum calculated using the <code>crc32</code> algorithm, possibly done with a hardware assist.	Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> .
<code>strict_none</code>	A constant number	Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> . InnoDB prints an error message if a valid but non-matching checksum is encountered.

Value	Generated checksum (when writing)	Permitted checksums (when reading)
strict_innodb	A checksum calculated in software, using the original algorithm from InnoDB.	Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> . InnoDB prints an error message if a valid but non-matching checksum is encountered.
strict_crc32	A checksum calculated using the <code>crc32</code> algorithm, possibly done with a hardware assist.	Any of the checksums generated by <code>none</code> , <code>innodb</code> , or <code>crc32</code> . InnoDB prints an error message if a valid but non-matching checksum is encountered.

- `innodb_cmp_per_index_enabled`

Command-Line Format	<code>--innodb-cmp-per-index-enabled=#</code>	
System Variable	Name	<code>innodb_cmp_per_index_enabled</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	<code>OFF</code>
	Valid Values	<code>OFF</code>
		<code>ON</code>

Enables per-index compression-related statistics in the `INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX` table. Because these statistics can be expensive to gather, only enable this option on development, test, or slave instances during performance tuning related to [InnoDB compressed](#) tables.

For more information, see [Section 24.31.7, “The INFORMATION_SCHEMA INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET Tables”](#), and [Section 15.9.1.4, “Monitoring InnoDB Table Compression at Runtime”](#).

- `innodb_commit_concurrency`

Command-Line Format	<code>--innodb-commit-concurrency=#</code>	
System Variable	Name	<code>innodb_commit_concurrency</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	<code>0</code>
	Min Value	<code>0</code>
	Max Value	<code>1000</code>

The number of [threads](#) that can [commit](#) at the same time. A value of 0 (the default) permits any number of [transactions](#) to commit simultaneously.

The value of `innodb_commit_concurrency` cannot be changed at runtime from zero to nonzero or vice versa. The value can be changed from one nonzero value to another.

- `innodb_compress_debug`

Command-Line Format	<code>--innodb-compress-debug=#</code>	
System Variable	Name	<code>innodb_compress_debug</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	enumeration
	Default	<code>none</code>
	Valid Values	<code>none</code>
		<code>zlib</code>
<code>lz4</code>		
	<code>lz4hc</code>	

Compresses all tables using a specified compression algorithm without having to define a `COMPRESSION` attribute for each table. This option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

For related information, see [Section 15.9.2, “InnoDB Page Compression”](#).

- `innodb_compression_failure_threshold_pct`

Command-Line Format	<code>--innodb-compression-failure-threshold-pct=#</code>	
System Variable	Name	<code>innodb_compression_failure_threshold_pct</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	<code>5</code>
	Min Value	<code>0</code>
	Max Value	<code>100</code>

Sets the cutoff point at which MySQL begins adding padding within `compressed` pages to avoid expensive `compression failures`. A value of zero disables the mechanism that monitors compression efficiency and dynamically adjusts the padding amount.

For more information, see [Section 15.9.1.6, “Compression for OLTP Workloads”](#).

- `innodb_compression_level`

Command-Line Format	<code>--innodb-compression-level=#</code>	
System Variable	Name	<code>innodb_compression_level</code>
	Variable Scope	Global

	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	6
	Min Value	0
	Max Value	9

Specifies the level of zlib compression to use for [InnoDB compressed](#) tables and indexes.

For more information, see [Section 15.9.1.6, “Compression for OLTP Workloads”](#).

- [innodb_compression_pad_pct_max](#)

Command-Line Format	<code>--innodb-compression-pad-pct-max=#</code>	
System Variable	Name	innodb_compression_pad_pct_max
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	50
	Min Value	0
	Max Value	75

Specifies the maximum percentage that can be reserved as free space within each compressed [page](#), allowing room to reorganize the data and modification log within the page when a [compressed](#) table or index is updated and the data might be recompressed. Only applies when [innodb_compression_failure_threshold_pct](#) is set to a non-zero value, and the rate of [compression failures](#) passes the cutoff point.

For more information, see [Section 15.9.1.6, “Compression for OLTP Workloads”](#).

- [innodb_concurrency_tickets](#)

Command-Line Format	<code>--innodb-concurrency-tickets=#</code>	
System Variable	Name	innodb_concurrency_tickets
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	5000
	Min Value	1
	Max Value	4294967295

Determines the number of [threads](#) that can enter [InnoDB](#) concurrently. A thread is placed in a queue when it tries to enter [InnoDB](#) if the number of threads has already reached the concurrency limit. When a thread is permitted to enter [InnoDB](#), it is given a number of “tickets” equal to the value of [innodb_concurrency_tickets](#), and the thread can enter and leave [InnoDB](#) freely until it has used up its tickets. After that point, the thread again becomes subject to the concurrency check (and possible queuing) the next time it tries to enter [InnoDB](#). The default value is 5000.

With a small [innodb_concurrency_tickets](#) value, small transactions that only need to process a few rows compete fairly with larger transactions that process many rows. The disadvantage of a small [innodb_concurrency_tickets](#) value is that large transactions must loop through the queue many times before they can complete, which extends the amount of time required to complete their task.

With a large [innodb_concurrency_tickets](#) value, large transactions spend less time waiting for a position at the end of the queue (controlled by [innodb_thread_concurrency](#)) and more time retrieving rows. Large transactions also require fewer trips through the queue to complete their task. The disadvantage of a large [innodb_concurrency_tickets](#) value is that too many large transactions running at the same time can starve smaller transactions by making them wait a longer time before executing.

With a non-zero [innodb_thread_concurrency](#) value, you may need to adjust the [innodb_concurrency_tickets](#) value up or down to find the optimal balance between larger and smaller transactions. The `SHOW ENGINE INNODB STATUS` report shows the number of tickets remaining for an executing transaction in its current pass through the queue. This data may also be obtained from the `TRX_CONCURRENCY_TICKETS` column of the `INFORMATION_SCHEMA.INNODB_TRX` table.

For more information, see [Section 15.6.5, “Configuring Thread Concurrency for InnoDB”](#).

- [innodb_data_file_path](#)

Command-Line Format	<code>--innodb-data-file-path=name</code>	
System Variable	Name	<code>innodb_data_file_path</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	string
	Default	<code>ibdata1:12M:autoextend</code>

Defines the path and file size for individual [InnoDB system tablespace data files](#). The full directory path for system tablespace data files is formed by concatenating path defined by [innodb_data_home_dir](#) and [innodb_data_file_path](#). File sizes are specified KB, MB or GB (1024MB) by appending `K`, `M` or `G` to the size value. If specifying the data file size in kilobytes (KB), do so in multiples of 1024. Otherwise, KB values are rounded to nearest megabyte (MB) boundary. The sum of the sizes of the files must be at least slightly larger than 10MB. If you do not specify [innodb_data_file_path](#), the default behavior is to create a single auto-extending data file, slightly larger than 12MB, named `ibdata1`. The size limit of individual files is determined by your operating system. You can set the file size to more than 4GB on operating systems that support large files. You can also [use raw disk partitions as data files](#). For more information about configuring system tablespace data files, see [Section 15.6.1, “InnoDB Startup Configuration”](#).

The following minimum file sizes are enforced for the *first* system tablespace data file (`ibdata1`) to ensure that there is enough space for doublewrite buffer pages:

- For an [innodb_page_size](#) value of 16KB or less, the minimum data file size is 3MB.

- For an `innodb_page_size` value of 32KB, the minimum data file size is 6MB.
- For an `innodb_page_size` value of 64KB, the minimum data file size is 12MB.
- `innodb_data_home_dir`

Command-Line Format	<code>--innodb-data-home-dir=dir_name</code>	
System Variable	Name	<code>innodb_data_home_dir</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	directory name

The common part of the directory path for InnoDB [system tablespace](#) data files. This setting does not affect the location of [file-per-table](#) tablespaces when `innodb_file_per_table` is enabled. The default value is the MySQL `data` directory. If you specify the value as an empty string, you can specify an absolute file paths for `innodb_data_file_path`.

A trailing slash is required when specifying a value for `innodb_data_home_dir`. For example:

```
[mysqld]
innodb_data_home_dir = /path/to/myibdata/
```

For related information, see [Section 15.6.1, “InnoDB Startup Configuration”](#).

- `innodb_deadlock_detect`

Command-Line Format	<code>--innodb-deadlock-detect</code>	
System Variable	Name	<code>innodb_deadlock_detect</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	ON

This option is used to disable deadlock detection. On high concurrency systems, deadlock detection can cause a slowdown when numerous threads wait for the same lock. At times, it may be more efficient to disable deadlock detection and rely on the `innodb_lock_wait_timeout` setting for transaction rollback when a deadlock occurs.

For related information, see [Section 15.5.5.2, “Deadlock Detection and Rollback”](#).

- `innodb_default_row_format`

Command-Line Format	<code>--innodb-default-row-format=#</code>	
System Variable	Name	<code>innodb_default_row_format</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	enumeration

	Default	DYNAMIC
	Valid Values	DYNAMIC
		COMPACT
		REDUNDANT

The `innodb_default_row_format` option defines the default row format for InnoDB tables and user-created temporary tables. The default setting is `DYNAMIC`. Other permitted values are `COMPACT` and `REDUNDANT`. The `COMPRESSED` row format, which is not supported for use in the `system tablespace`, cannot be defined as the default.

Newly created tables use the row format defined by `innodb_default_row_format` when a `ROW_FORMAT` option is not specified explicitly or when `ROW_FORMAT=DEFAULT` is used.

When a `ROW_FORMAT` option is not specified explicitly or when `ROW_FORMAT=DEFAULT` is used, any operation that rebuilds a table also silently changes the row format of the table to the format defined by `innodb_default_row_format`. For more information, see [Section 15.10.2, “Specifying the Row Format for a Table”](#).

Internal InnoDB temporary tables created by the server to process queries use the `DYNAMIC` row format, regardless of the `innodb_default_row_format` setting.

- `innodb_disable_sort_file_cache`

Command-Line Format	<code>--innodb-disable-sort-file-cache=#</code>	
System Variable	Name	<code>innodb_disable_sort_file_cache</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	OFF

Disables the operating system file system cache for merge-sort temporary files. The effect is to open such files with the equivalent of `O_DIRECT`.

- `innodb_doublewrite`

Command-Line Format	<code>--innodb-doublewrite</code>	
System Variable	Name	<code>innodb_doublewrite</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	boolean
	Default	ON

When enabled (the default), InnoDB stores all data twice, first to the `doublewrite buffer`, then to the actual `data files`. This variable can be turned off with `--skip-innodb_doublewrite` for benchmarks or cases when top performance is needed rather than concern for data integrity or possible failures.

If system tablespace data files (`ibdata*` files) are located on Fusion-io devices that support atomic writes, doublewrite buffering is automatically disabled and Fusion-io atomic writes are used for all data files. Because the doublewrite buffer setting is global, doublewrite buffering is also disabled

for data files residing on non-Fusion-io hardware. This feature is only supported on Fusion-io hardware and only enabled for Fusion-io NVMFS on Linux. To take full advantage of this feature, an `innodb_flush_method` setting of `O_DIRECT` is recommended.

For related information, see [Section 15.4.6, “Doublewrite Buffer”](#).

- `innodb_fast_shutdown`

Command-Line Format	<code>--innodb-fast-shutdown[=#]</code>	
System Variable	Name	<code>innodb_fast_shutdown</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	1
	Valid Values	0
		1
	2	

The `InnoDB shutdown` mode. If the value is 0, `InnoDB` does a `slow shutdown`, a full `purge` and a change buffer merge before shutting down. If the value is 1 (the default), `InnoDB` skips these operations at shutdown, a process known as a `fast shutdown`. If the value is 2, `InnoDB` flushes its logs and shuts down cold, as if MySQL had crashed; no committed transactions are lost, but the `crash recovery` operation makes the next startup take longer.

The slow shutdown can take minutes, or even hours in extreme cases where substantial amounts of data are still buffered. Use the slow shutdown technique before upgrading or downgrading between MySQL major releases, so that all data files are fully prepared in case the upgrade process updates the file format.

Use `innodb_fast_shutdown=2` in emergency or troubleshooting situations, to get the absolute fastest shutdown if data is at risk of corruption.

- `innodb_fil_make_page_dirty_debug`

Command-Line Format	<code>--innodb-fil-make-page-dirty-debug=#</code>	
System Variable	Name	<code>innodb_fil_make_page_dirty_debug</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	0
	Max Value	$2^{*}32-1$

By default, setting `innodb_fil_make_page_dirty_debug` to the ID of a tablespace immediately dirties the first page of the tablespace. If `innodb_saved_page_number_debug` is set to a non-default value, setting `innodb_fil_make_page_dirty_debug` dirties the specified page. The `innodb_fil_make_page_dirty_debug` option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- `innodb_file_per_table`

Command-Line Format	<code>--innodb-file-per-table</code>	
System Variable	Name	<code>innodb_file_per_table</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	ON

When `innodb_file_per_table` is enabled (the default), InnoDB stores the data and indexes for each newly created table in a separate `.ibd` file instead of the system tablespace. The storage for these tables is reclaimed when the tables are dropped or truncated. This setting enables InnoDB features such as table [compression](#). See [Section 15.7.4, “InnoDB File-Per-Table Tablespaces”](#) for more information.

Enabling `innodb_file_per_table` also means that an `ALTER TABLE` operation moves an InnoDB table from the system tablespace to an individual `.ibd` file in cases where `ALTER TABLE` rebuilds the table (`ALGORITHM=COPY`). An exception to this rule is for tables placed in the system tablespace using the `TABLESPACE=innodb_system` option with `CREATE TABLE` or `ALTER TABLE`. These tables are unaffected by the `innodb_file_per_table` setting and can only be moved to file-per-table tablespaces using `ALTER TABLE ... TABLESPACE=innodb_file_per_table`.

When `innodb_file_per_table` is disabled, InnoDB stores the data for tables and indexes in the `ibdata` files that make up the [system tablespace](#). This setting reduces the performance overhead of file system operations for operations such as `DROP TABLE` or `TRUNCATE TABLE`. It is most appropriate for a server environment where entire storage devices are devoted to MySQL data. Because the system tablespace never shrinks, and is shared across all databases in an [instance](#), avoid loading huge amounts of temporary data on a space-constrained system when `innodb_file_per_table` is disabled. Set up a separate instance in such cases, so that you can drop the entire instance to reclaim the space.

`innodb_file_per_table` is enabled by default. Consider disabling it if backward compatibility with MySQL 5.5 or earlier is a concern. This will prevent `ALTER TABLE` from moving InnoDB tables from the system tablespace to individual `.ibd` files.

`innodb_file_per_table` is dynamic and can be set `ON` or `OFF` using `SET GLOBAL`. You can also set this option in the MySQL [configuration file](#) (`my.cnf` or `my.ini`) but this requires shutting down and restarting the server.

Dynamically changing the value requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege and immediately affects the operation of all connections.

The `innodb_file_per-table` setting does not affect the creation of InnoDB temporary tables. All InnoDB temporary tables are created in the shared temporary tablespace.

- `innodb_fill_factor`

Command-Line Format	<code>--innodb-fill-factor=#</code>	
System Variable	Name	<code>innodb_fill_factor</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer

	Default	100
	Min Value	10
	Max Value	100

InnoDB performs a bulk load when creating or rebuilding indexes. This method of index creation is known as a “sorted index build”.

`innodb_fill_factor` defines the percentage of space on each B-tree page that is filled during a sorted index build, with the remaining space reserved for future index growth. For example, setting `innodb_fill_factor` to 80 reserves 20 percent of the space on each B-tree page for future index growth. Actual percentages may vary. The `innodb_fill_factor` setting is interpreted as a hint rather than a hard limit.

An `innodb_fill_factor` setting of 100 leaves 1/16 of the space in clustered index pages free for future index growth.

`innodb_fill_factor` applies to both B-tree leaf and non-leaf pages. It does not apply to external pages used for `TEXT` or `BLOB` entries.

For more information, see [Section 15.8.2.3, “Sorted Index Builds”](#).

- `innodb_flush_log_at_timeout`

System Variable	Name	<code>innodb_flush_log_at_timeout</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	1
	Min Value	1
	Max Value	2700

Write and flush the logs every *N* seconds. `innodb_flush_log_at_timeout` allows the timeout period between flushes to be increased in order to reduce flushing and avoid impacting performance of binary log group commit. The default setting for `innodb_flush_log_at_timeout` is once per second.

- `innodb_flush_log_at_trx_commit`

Command-Line Format	<code>--innodb-flush-log-at-trx-commit[=#]</code>	
System Variable	Name	<code>innodb_flush_log_at_trx_commit</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	enumeration
	Default	1

	Valid Values	0
		1
		2

Controls the balance between strict ACID compliance for `commit` operations and higher performance that is possible when commit-related I/O operations are rearranged and done in batches. You can achieve better performance by changing the default value but then you can lose up to a second of transactions in a crash.

- The default value of 1 is required for full ACID compliance. With this value, the contents of the `InnoDB log buffer` are written out to the `log file` at each transaction commit and the log file is `flushed` to disk.
- With a value of 0, the contents of the `InnoDB log buffer` are written to the log file approximately once per second and the log file is flushed to disk. No writes from the log buffer to the log file are performed at transaction commit. Once-per-second flushing is not 100% guaranteed to happen every second, due to process scheduling issues. Because the flush to disk operation only occurs approximately once per second, you can lose up to a second of transactions with any `mysqld` process crash.
- With a value of 2, the contents of the `InnoDB log buffer` are written to the log file after each transaction commit and the log file is flushed to disk approximately once per second. Once-per-second flushing is not guaranteed to happen every second due to process scheduling issues. Because the flush to disk operation only occurs approximately once per second, you can lose up to a second of transactions in an operating system crash or a power outage.
- `InnoDB log flushing frequency` is controlled by `innodb_flush_log_at_timeout`, which allows you to set log flushing frequency to `N` seconds (where `N` is 1 ... 2700, with a default value of 1). However, any `mysqld` process crash can erase up to `N` seconds of transactions.
- DDL changes and other internal `InnoDB` activities flush the `InnoDB log` independent of the `innodb_flush_log_at_trx_commit` setting.
- `InnoDB crash recovery` works regardless of the `innodb_flush_log_at_trx_commit` setting. Transactions are either applied entirely or erased entirely.

For durability and consistency in a replication setup that uses `InnoDB` with transactions:

- If binary logging is enabled, set `sync_binlog=1`.
- Always set `innodb_flush_log_at_trx_commit=1`.

Caution

Many operating systems and some disk hardware fool the flush-to-disk operation. They may tell `mysqld` that the flush has taken place, even though it has not. In this case, the durability of transactions is not guaranteed even with the setting 1, and in the worst case, a power outage can corrupt `InnoDB` data. Using a battery-backed disk cache in the SCSI disk controller or in the disk itself speeds up file flushes, and makes the operation safer. You can also try to disable the caching of disk writes in hardware caches.

- `innodb_flush_method`

Command-Line Format	<code>--innodb-flush-method=name</code>	
System Variable	Name	<code>innodb_flush_method</code>
	Variable Scope	Global

	Dynamic Variable	No
Permitted Values (Unix)	Type	string
	Default	<code>fsync</code>
	Valid Values	<code>fsync</code>
		<code>O_DSYNC</code>
		<code>littlesync</code>
		<code>nosync</code>
		<code>O_DIRECT</code>
<code>O_DIRECT_NO_FSYNC</code>		
Permitted Values (Windows)	Type	string
	Default	<code>unbuffered</code>
	Valid Values	<code>unbuffered</code>
<code>normal</code>		

Defines the method used to flush data to InnoDB data files and log files, which can affect I/O throughput.

On Unix-like systems, the default value is `fsync`. On Windows, the default value is `unbuffered`.

Note

In MySQL 8.0, `innodb_flush_method` options may be specified numerically.

The `innodb_flush_method` options for Unix-like systems include:

- `fsync` or 0: InnoDB uses the `fsync()` system call to flush both the data and log files. `fsync` is the default setting.
- `O_DSYNC` or 1: InnoDB uses `O_SYNC` to open and flush the log files, and `fsync()` to flush the data files. InnoDB does not use `O_DSYNC` directly because there have been problems with it on many varieties of Unix.
- `littlesync` or 2: This option is used for internal performance testing and is currently unsupported. Use at your own risk.
- `nosync` or 3: This option is used for internal performance testing and is currently unsupported. Use at your own risk.
- `O_DIRECT` or 4: InnoDB uses `O_DIRECT` (or `directio()` on Solaris) to open the data files, and uses `fsync()` to flush both the data and log files. This option is available on some GNU/Linux versions, FreeBSD, and Solaris.
- `O_DIRECT_NO_FSYNC` or 5: InnoDB uses `O_DIRECT` during flushing I/O, but skips the `fsync()` system call afterward. This setting is suitable for some types of file systems but not others. For example, it is not suitable for XFS. If you are not sure whether the file system you use requires an `fsync()`, for example to preserve all file metadata, use `O_DIRECT` instead.

The `innodb_flush_method` options for Windows systems include:

- `unbuffered` or 0: InnoDB uses simulated asynchronous I/O and non-buffered I/O.
- `normal` or 1: InnoDB uses simulated asynchronous I/O and buffered I/O.

How each setting affects performance depends on hardware configuration and workload. Benchmark your particular configuration to decide which setting to use, or whether to keep the default setting. Examine the `InnoDB_data_fsyncs` status variable to see the overall number of `fsync()` calls for each setting. The mix of read and write operations in your workload can affect how a setting performs. For example, on a system with a hardware RAID controller and battery-backed write cache, `O_DIRECT` can help to avoid double buffering between the InnoDB buffer pool and the operating system file system cache. On some systems where InnoDB data and log files are located on a SAN, the default value or `O_DSYNC` might be faster for a read-heavy workload with mostly `SELECT` statements. Always test this parameter with hardware and workload that reflect your production environment. For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_flush_neighbors`

Command-Line Format	<code>--innodb-flush-neighbors</code>	
System Variable	Name	<code>innodb_flush_neighbors</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	enumeration
	Default	1
	Valid Values	0
		1
	2	

Specifies whether [flushing](#) a page from the InnoDB buffer pool also flushes other [dirty pages](#) in the same [extent](#).

- The default value of 1 flushes contiguous dirty pages in the same extent from the buffer pool.
- A setting of 0 turns `innodb_flush_neighbors` off and no other dirty pages are flushed from the buffer pool.
- A setting of 2 flushes dirty pages in the same extent from the buffer pool.

When the table data is stored on a traditional [HDD](#) storage device, flushing such [neighbor pages](#) in one operation reduces I/O overhead (primarily for disk seek operations) compared to flushing individual pages at different times. For table data stored on [SSD](#), seek time is not a significant factor and you can turn this setting off to spread out write operations. For related information, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#).

- `innodb_flush_sync`

Command-Line Format	<code>--innodb-flush-sync=#</code>	
System Variable	Name	<code>innodb_flush_sync</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	ON

The `innodb_flush_sync` parameter, which is enabled by default, causes the `innodb_io_capacity` setting to be ignored for bursts of I/O activity that occur at [checkpoints](#). To adhere to the limit on InnoDB background I/O activity defined by the `innodb_io_capacity` setting, disable `innodb_flush_sync`.

For related information, see [Section 15.6.8, “Configuring the InnoDB Master Thread I/O Rate”](#).

- `innodb_flushing_avg_loops`

Command-Line Format	<code>--innodb-flushing-avg-loops=#</code>	
System Variable	Name	<code>innodb_flushing_avg_loops</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	30
	Min Value	1
	Max Value	1000

Number of iterations for which InnoDB keeps the previously calculated snapshot of the flushing state, controlling how quickly [adaptive flushing](#) responds to changing [workloads](#). Increasing the value makes the rate of [flush](#) operations change smoothly and gradually as the workload changes. Decreasing the value makes adaptive flushing adjust quickly to workload changes, which can cause spikes in flushing activity if the workload increases and decreases suddenly.

For related information, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#).

- `innodb_force_load_corrupted`

Command-Line Format	<code>--innodb-force-load-corrupted</code>	
System Variable	Name	<code>innodb_force_load_corrupted</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	boolean
	Default	OFF

Permits InnoDB to load tables at startup that are marked as corrupted. Use only during troubleshooting, to recover data that is otherwise inaccessible. When troubleshooting is complete, disable this setting and restart the server.

- `innodb_force_recovery`

Command-Line Format	<code>--innodb-force-recovery=#</code>	
System Variable	Name	<code>innodb_force_recovery</code>
	Variable Scope	Global

	Dynamic Variable	No
Permitted Values	Type	integer
	Default	0
	Min Value	0
	Max Value	6

The [crash recovery](#) mode, typically only changed in serious troubleshooting situations. Possible values are from 0 to 6. For the meanings of these values and important information about [innodb_force_recovery](#), see [Section 15.20.2, “Forcing InnoDB Recovery”](#).

Warning

Only set this variable to a value greater than 0 in an emergency situation so that you can start InnoDB and dump your tables. As a safety measure, InnoDB prevents `INSERT`, `UPDATE`, or `DELETE` operations when [innodb_force_recovery](#) is greater than 0. An [innodb_force_recovery](#) setting of 4 or greater places InnoDB into read-only mode.

These restrictions may cause replication administration commands to fail with an error, as replication options such as `--relay-log-info-repository=TABLE` and `--master-info-repository=TABLE` store information in InnoDB tables.

- [innodb_ft_aux_table](#)

Command-Line Format	<code>--innodb-ft-aux-table=#</code>	
System Variable	Name	innodb_ft_aux_table
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	string

Specifies the qualified name of an InnoDB table containing a `FULLTEXT` index. This variable is intended for diagnostic purposes.

After you set this variable to a name in the format `db_name/table_name`, the `INFORMATION_SCHEMA` tables `INNODB_FT_INDEX_TABLE`, `INNODB_FT_INDEX_CACHE`, `INNODB_FT_CONFIG`, `INNODB_FT_DELETED`, and `INNODB_FT_BEING_DELETED` show information about the search index for the specified table.

For more information, see [Section 15.14.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”](#).

- [innodb_ft_cache_size](#)

Command-Line Format	<code>--innodb-ft-cache-size=#</code>	
System Variable	Name	innodb_ft_cache_size
	Variable Scope	Global
	Dynamic Variable	Yes

	Dynamic Variable	No
Permitted Values	Type	integer
	Default	8000000
	Min Value	1600000
	Max Value	80000000

The memory allocated, in bytes, for the `InnoDB FULLTEXT` search index cache, which holds a parsed document in memory while creating an `InnoDB FULLTEXT` index. Index inserts and updates are only committed to disk when the `innodb_ft_cache_size` size limit is reached. `innodb_ft_cache_size` defines the cache size on a per table basis. To set a global limit for all tables, see `innodb_ft_total_cache_size`.

For more information, see [InnoDB Full-Text Index Cache](#).

- `innodb_ft_enable_diag_print`

Command-Line Format	<code>--innodb-ft-enable-diag-print=#</code>	
System Variable	Name	<code>innodb_ft_enable_diag_print</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	<code>OFF</code>

Whether to enable additional full-text search (FTS) diagnostic output. This option is primarily intended for advanced FTS debugging and will not be of interest to most users. Output is printed to the error log and includes information such as:

- FTS index sync progress (when the FTS cache limit is reached). For example:

```
FTS SYNC for table test, deleted count: 100 size: 10000 bytes
SYNC words: 100
```

- FTS optimize progress. For example:

```
FTS start optimize test
FTS_OPTIMIZE: optimize "mysql"
FTS_OPTIMIZE: processed "mysql"
```

- FTS index build progress. For example:

```
Number of doc processed: 1000
```

- For FTS queries, the query parsing tree, word weight, query processing time, and memory usage are printed. For example:

```
FTS Search Processing time: 1 secs: 100 millisc: row(s) 10000
Full Search Memory: 245666 (bytes), Row: 10000
```

- `innodb_ft_enable_stopword`

Command-Line Format	<code>--innodb-ft-enable-stopword=#</code>	
System Variable	Name	<code>innodb_ft_enable_stopword</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	ON

Specifies that a set of [stopwords](#) is associated with an InnoDB `FULLTEXT` index at the time the index is created. If the `innodb_ft_user_stopword_table` option is set, the stopwords are taken from that table. Else, if the `innodb_ft_server_stopword_table` option is set, the stopwords are taken from that table. Otherwise, a built-in set of default stopwords is used.

For more information, see [Section 12.9.4, “Full-Text Stopwords”](#).

- `innodb_ft_max_token_size`

Command-Line Format	<code>--innodb-ft-max-token-size=#</code>	
System Variable	Name	<code>innodb_ft_max_token_size</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	84
	Min Value	10
	Max Value	84
Permitted Values	Type	integer
	Default	84
	Min Value	10
	Max Value	84

Maximum character length of words that are stored in an InnoDB `FULLTEXT` index. Setting a limit on this value reduces the size of the index, thus speeding up queries, by omitting long keywords or arbitrary collections of letters that are not real words and are not likely to be search terms.

For more information, see [Section 12.9.6, “Fine-Tuning MySQL Full-Text Search”](#).

- `innodb_ft_min_token_size`

Command-Line Format	<code>--innodb-ft-min-token-size=#</code>	
System Variable	Name	<code>innodb_ft_min_token_size</code>
	Variable Scope	Global

	Dynamic Variable	No
Permitted Values	Type	integer
	Default	3
	Min Value	0
	Max Value	16

Minimum length of words that are stored in an `InnoDB FULLTEXT` index. Increasing this value reduces the size of the index, thus speeding up queries, by omitting common words that are unlikely to be significant in a search context, such as the English words “a” and “to”. For content using a CJK (Chinese, Japanese, Korean) character set, specify a value of 1.

For more information, see [Section 12.9.6, “Fine-Tuning MySQL Full-Text Search”](#).

- `innodb_ft_num_word_optimize`

Command-Line Format	<code>--innodb-ft-num-word-optimize=#</code>	
System Variable	Name	<code>innodb_ft_num_word_optimize</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	2000

Number of words to process during each `OPTIMIZE TABLE` operation on an `InnoDB FULLTEXT` index. Because a bulk insert or update operation to a table containing a full-text search index could require substantial index maintenance to incorporate all changes, you might do a series of `OPTIMIZE TABLE` statements, each picking up where the last left off.

For more information, see [Section 12.9.6, “Fine-Tuning MySQL Full-Text Search”](#).

- `innodb_ft_result_cache_limit`

Command-Line Format	<code>--innodb-ft-result-cache-limit=#</code>	
System Variable	Name	<code>innodb_ft_result_cache_limit</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	2000000000
	Min Value	1000000
	Max Value	$2^{32}-1$

The `InnoDB` full-text search query result cache limit (defined in bytes) per full-text search query or per thread. Intermediate and final `InnoDB` full-text search query results are handled in memory. Use `innodb_ft_result_cache_limit` to place a size limit on the full-text search query result cache.

to avoid excessive memory consumption in case of very large InnoDB full-text search query results (millions or hundreds of millions of rows, for example). Memory is allocated as required when a full-text search query is processed. If the result cache size limit is reached, an error is returned indicating that the query exceeds the maximum allowed memory.

The maximum value of `innodb_ft_result_cache_limit` for all platform types and bit sizes is $2^{32}-1$.

- `innodb_ft_server_stopword_table`

Command-Line Format	<code>--innodb-ft-server-stopword-table=db_name/table_name</code>	
System Variable	Name	<code>innodb_ft_server_stopword_table</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	string
	Default	<code>NULL</code>

This option is used to specify your own InnoDB FULLTEXT index stopword list for all InnoDB tables. To configure your own stopword list for a specific InnoDB table, use `innodb_ft_user_stopword_table`.

Set `innodb_ft_server_stopword_table` to the name of the table containing a list of stopwords, in the format `db_name/table_name`.

The stopword table must exist before you configure `innodb_ft_server_stopword_table`. `innodb_ft_enable_stopword` must be enabled and `innodb_ft_server_stopword_table` option must be configured before you create the FULLTEXT index.

The stopword table must be an InnoDB table, containing a single VARCHAR column named `value`.

For more information, see [Section 12.9.4, “Full-Text Stopwords”](#).

- `innodb_ft_sort_pll_degree`

Command-Line Format	<code>--innodb-ft-sort-pll-degree=#</code>	
System Variable	Name	<code>innodb_ft_sort_pll_degree</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	2
	Min Value	1
	Max Value	32

Number of threads used in parallel to index and tokenize text in an InnoDB FULLTEXT index when building a [search index](#).

- `innodb_ft_total_cache_size`

Command-Line Format	<code>--innodb-ft-total-cache-size=#</code>	
System Variable	Name	<code>innodb_ft_total_cache_size</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	640000000
	Min Value	32000000
	Max Value	1600000000

The total memory allocated, in bytes, for the InnoDB full-text search index cache for all tables. Creating numerous tables, each with a `FULLTEXT` search index, could consume a significant portion of available memory. `innodb_ft_total_cache_size` defines a global memory limit for all full-text search indexes to help avoid excessive memory consumption. If the global limit is reached by an index operation, a forced sync is triggered.

For more information, see [InnoDB Full-Text Index Cache](#).

- `innodb_ft_user_stopword_table`

Command-Line Format	<code>--innodb-ft-user-stopword-table=db_name/table_name</code>	
System Variable	Name	<code>innodb_ft_user_stopword_table</code>
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values	Type	string
	Default	<code>NULL</code>

This option is used to specify your own InnoDB `FULLTEXT` index stopwords list on a specific table. To configure your own stopwords list for all InnoDB tables, use `innodb_ft_server_stopword_table`.

Set `innodb_ft_user_stopword_table` to the name of the table containing a list of stopwords, in the format `db_name/table_name`.

The stopwords table must exist before you configure `innodb_ft_user_stopword_table`. `innodb_ft_enable_stopword` must be enabled and `innodb_ft_user_stopword_table` must be configured before you create the `FULLTEXT` index.

The stopwords table must be an InnoDB table, containing a single `VARCHAR` column named `value`.

For more information, see [Section 12.9.4, “Full-Text Stopwords”](#).

- `innodb_io_capacity`

Pre-General Availability Draft	Command-Line Format	<code>--innodb-io-capacity=#</code>		Pre-General Availability Draft
	System Variable	Name	<code>innodb_io_capacity</code>	

	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values (32-bit platforms)	Type	integer
	Default	200
	Min Value	100
	Max Value	$2^{32}-1$
Permitted Values (64-bit platforms)	Type	integer
	Default	200
	Min Value	100
	Max Value	$2^{64}-1$

The `innodb_io_capacity` parameter sets an upper limit on I/O activity performed by InnoDB background tasks, such as flushing pages from the buffer pool and merging data from the change buffer.

The `innodb_io_capacity` limit is a total limit for all buffer pool instances. When dirty pages are flushed, the limit is divided equally among buffer pool instances.

`innodb_io_capacity` should be set to approximately the number of I/O operations that the system can perform per second. Ideally, keep the setting as low as practical, but not so low that background activities fall behind. If the value is too high, data is removed from the buffer pool and insert buffer too quickly for caching to provide a significant benefit.

The default value is 200. For busy systems capable of higher I/O rates, you can set a higher value to help the server handle the background maintenance work associated with a high rate of row changes.

In general, you can increase the value as a function of the number of drives used for InnoDB I/O. For example, you can increase the value on systems that use multiple disks or solid-state disks (SSD).

The default setting of 200 is generally sufficient for a lower-end SSD. For a higher-end, bus-attached SSD, consider a higher setting such as 1000, for example. For systems with individual 5400 RPM or 7200 RPM drives, you might lower the value to 100, which represents an estimated proportion of the I/O operations per second (IOPS) available to older-generation disk drives that can perform about 100 IOPS.

Although you can specify a very high value such as one million, in practice such large values have little if any benefit. Generally, a value of 20000 or higher is not recommended unless you have proven that lower values are insufficient for your workload.

Consider write workload when tuning `innodb_io_capacity`. Systems with large write workloads are likely to benefit from a higher setting. A lower setting may be sufficient for systems with a small write workload.

You can set `innodb_io_capacity` to any number 100 or greater to a maximum defined by `innodb_io_capacity_max`. `innodb_io_capacity` can be set in the MySQL option file (`my.cnf` or `my.ini`) or changed dynamically using a `SET GLOBAL` statement, which requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege.

The `innodb_flush_sync` configuration option causes the `innodb_io_capacity` setting to be ignored during bursts of I/O activity that occur at checkpoints. `innodb_flush_sync` is enabled by default.

See [Section 15.6.8, “Configuring the InnoDB Master Thread I/O Rate”](#) for more information. For general information about InnoDB I/O performance, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_io_capacity_max`

Command-Line Format	<code>--innodb-io-capacity-max=#</code>	
System Variable	Name	<code>innodb_io_capacity_max</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values (32-bit platforms)	Type	integer
	Default	see description
	Min Value	100
	Max Value	$2^{32}-1$
Permitted Values (Unix, 64-bit platforms)	Type	integer
	Default	see description
	Min Value	100
	Max Value	$2^{64}-1$
Permitted Values (Windows, 64-bit platforms)	Type	integer
	Default	see description
	Min Value	100
	Max Value	$2^{32}-1$

If flushing activity falls behind, InnoDB can flush more aggressively than the limit imposed by `innodb_io_capacity`. `innodb_io_capacity_max` defines an upper limit for I/O capacity in such situations.

The `innodb_io_capacity_max` setting is a total limit for all buffer pool instances.

If you specify an `innodb_io_capacity` setting at startup but do not specify a value for `innodb_io_capacity_max`, `innodb_io_capacity_max` defaults to twice the value of `innodb_io_capacity`, with a minimum value of 2000.

When configuring `innodb_io_capacity_max`, twice the `innodb_io_capacity` is often a good starting point. The default value of 2000 is intended for workloads that use a solid-state disk (SSD) or more than one regular disk drive. A setting of 2000 is likely too high for workloads that do not use SSD or multiple disk drives, and could allow too much flushing. For a single regular disk drive, a setting between 200 and 400 is recommended. For a high-end, bus-attached SSD, consider a higher setting such as 2500. As with the `innodb_io_capacity` setting, keep the setting as low as practical, but not so low that InnoDB cannot sufficiently extend beyond the `innodb_io_capacity` limit, if necessary.

Consider write workload when tuning `innodb_io_capacity_max`. Systems with large write workloads may benefit from a higher setting. A lower setting may be sufficient for systems with a small write workload.

`innodb_io_capacity_max` cannot be set to a value lower than the `innodb_io_capacity` value.

Setting `innodb_io_capacity_max` to `DEFAULT` using a `SET` statement (`SET GLOBAL innodb_io_capacity_max=DEFAULT`) sets `innodb_io_capacity_max` to the maximum value.

For related information, see [Section 15.6.3.7, "Fine-tuning InnoDB Buffer Pool Flushing"](#).

- `innodb_limit_optimistic_insert_debug`

Command-Line Format	<code>--innodb-limit-optimistic-insert-debug=#</code>	
System Variable	Name	<code>innodb_limit_optimistic_insert_debug</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	0
	Min Value	0
	Max Value	$2^{32}-1$

Limits the number of records per [B-tree](#) page. A default value of 0 means that no limit is imposed. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_lock_wait_timeout`

Command-Line Format	<code>--innodb-lock-wait-timeout=#</code>	
System Variable	Name	<code>innodb_lock_wait_timeout</code>
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	50
	Min Value	1
	Max Value	1073741824

The length of time in seconds an [InnoDB transaction](#) waits for a [row lock](#) before giving up. The default value is 50 seconds. A transaction that tries to access a row that is locked by another [InnoDB](#) transaction waits at most this many seconds for write access to the row before issuing the following error:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

When a lock wait timeout occurs, the current statement is [rolled back](#) (not the entire transaction). To have the entire transaction roll back, start the server with the `--innodb_rollback_on_timeout` option. See also [Section 15.20.4, “InnoDB Error Handling”](#).

You might decrease this value for highly interactive applications or [OLTP](#) systems, to display user feedback quickly or put the update into a queue for processing later. You might increase this value for long-running back-end operations, such as a transform step in a data warehouse that waits for other large insert or update operations to finish.

`innodb_lock_wait_timeout` applies to [InnoDB](#) row locks only. A MySQL [table lock](#) does not happen inside [InnoDB](#) and this timeout does not apply to waits for table locks.

The lock wait timeout value does not apply to [deadlocks](#) when `innodb_deadlock_detect` is enabled (the default) because [InnoDB](#) detects deadlocks immediately and rolls back one of the deadlocked transactions. When `innodb_deadlock_detect` is disabled, [InnoDB](#) relies on `innodb_lock_wait_timeout` for transaction rollback when a deadlock occurs. See [Section 15.5.5.2, “Deadlock Detection and Rollback”](#).

`innodb_lock_wait_timeout` can be set at runtime with the `SET GLOBAL` or `SET SESSION` statement. Changing the `GLOBAL` setting requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege and affects the operation of all clients that subsequently connect. Any client can change the `SESSION` setting for `innodb_lock_wait_timeout`, which affects only that client.

- `innodb_log_buffer_size`

Command-Line Format	<code>--innodb-log-buffer-size=#</code>	
System Variable	Name	<code>innodb_log_buffer_size</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	16777216
	Min Value	1048576
	Max Value	4294967295

The size in bytes of the buffer that [InnoDB](#) uses to write to the [log files](#) on disk. The default is 16MB. A large [log buffer](#) enables large [transactions](#) to run without the need to write the log to disk before the transactions [commit](#). Thus, if you have transactions that update, insert, or delete many rows, making the log buffer larger saves disk I/O. For related information, see [InnoDB Memory Configuration](#), and [Section 8.5.4, “Optimizing InnoDB Redo Logging”](#). For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_log_checksums`

Command-Line Format	<code>--innodb-log-checksums=#</code>	
System Variable	Name	<code>innodb_log_checksums</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean

	Default	ON
--	----------------	----

Enables or disables checksums for redo log pages.

`innodb_log_checksums=ON` enables the CRC-32C checksum algorithm for redo log pages. When `innodb_log_checksums` is disabled, the contents of the redo log page checksum field are ignored.

Checksums on the redo log header page and redo log checkpoint pages are never disabled.

- `innodb_log_compressed_pages`

Command-Line Format	<code>--innodb-log-compressed-pages=#</code>	
System Variable	Name	<code>innodb_log_compressed_pages</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	ON

Specifies whether images of [re-compressed pages](#) are written to the [redo log](#). Re-compression may occur when changes are made to compressed data.

`innodb_log_compressed_pages` is enabled by default to prevent corruption that could occur if a different version of the `zlib` compression algorithm is used during recovery. If you are certain that the `zlib` version will not change, you can disable `innodb_log_compressed_pages` to reduce redo log generation for workloads that modify compressed data.

To measure the effect of enabling or disabling `innodb_log_compressed_pages`, compare redo log generation for both settings under the same workload. Options for measuring redo log generation include observing the [Log sequence number \(LSN\)](#) in the `LOG` section of `SHOW ENGINE INNODB STATUS` output, or monitoring `InnoDB_os_log_written` status for the number of bytes written to the redo log files.

For related information, see [Section 15.9.1.6, “Compression for OLTP Workloads”](#).

- `innodb_log_file_size`

Command-Line Format	<code>--innodb-log-file-size=#</code>	
System Variable	Name	<code>innodb_log_file_size</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	50331648
	Min Value	4194304
	Max Value	512GB / <code>innodb_log_files_in_group</code>

The size in bytes of each [log file](#) in a [log group](#). The combined size of log files

(`innodb_log_file_size * innodb_log_files_in_group`) cannot exceed a maximum value

that is slightly less than 512GB. A pair of 255 GB log files, for example, approaches the limit but does not exceed it. The default value is 48MB.

Generally, the combined size of the log files should be large enough that the server can smooth out peaks and troughs in workload activity, which often means that there is enough redo log space to handle more than an hour of write activity. The larger the value, the less checkpoint flush activity is required in the buffer pool, saving disk I/O. Larger log files also make [crash recovery](#) slower, although improvements to recovery performance in MySQL 5.5 and higher make the log file size less of a consideration.

The minimum `innodb_log_file_size` is 4MB.

For related information, see [InnoDB Log File Configuration](#). For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_log_files_in_group`

Command-Line Format	<code>--innodb-log-files-in-group=#</code>	
System Variable	Name	<code>innodb_log_files_in_group</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	2
	Min Value	2
	Max Value	100

The number of [log files](#) in the [log group](#). InnoDB writes to the files in a circular fashion. The default (and recommended) value is 2. The location of the files is specified by `innodb_log_group_home_dir`. The combined size of log files (`innodb_log_file_size * innodb_log_files_in_group`) can be up to 512GB.

For related information, see [InnoDB Log File Configuration](#).

- `innodb_log_group_home_dir`

Command-Line Format	<code>--innodb-log-group-home-dir=dir_name</code>	
System Variable	Name	<code>innodb_log_group_home_dir</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	directory name

The directory path to the InnoDB [redo log](#) files, whose number is specified by `innodb_log_files_in_group`. If you do not specify any InnoDB log variables, the default is to create two files named `ib_logfile0` and `ib_logfile1` in the MySQL data directory. Log file size is given by the `innodb_log_file_size` system variable.

For related information, see [InnoDB Log File Configuration](#).

Command-Line Format	<code>--innodb-log-write-ahead-size=#</code>	
System Variable	Name	<code>innodb_log_write_ahead_size</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	8192
	Min Value	512 (log file block size)
	Max Value	Equal to <code>innodb_page_size</code>

The write-ahead block size for the redo log, in bytes. To avoid “read-on-write”, set `innodb_log_write_ahead_size` to match the operating system or file system cache block size. Read-on-write occurs when redo log blocks are not entirely cached to the operating system or file system due to a mismatch between write-ahead block size for redo logs and operating system or file system cache block size.

Valid values for `innodb_log_write_ahead_size` are multiples of the InnoDB log file block size (2^n). The minimum value is the InnoDB log file block size (512). Write-ahead does not occur when the minimum value is specified. The maximum value is equal to `innodb_page_size`. If you specify a value for `innodb_log_write_ahead_size` that is larger than the `innodb_page_size` value, the `innodb_log_write_ahead_size` value is truncated to the `innodb_page_size` value.

Setting the `innodb_log_write_ahead_size` value too low in relation to the operating system or file system cache block size results in “read-on-write”. Setting the value too high may have a slight impact on `fsync` performance for log file writes due to several blocks being written at once.

- `innodb_lru_scan_depth`

Command-Line Format	<code>--innodb-lru-scan-depth=#</code>	
System Variable	Name	<code>innodb_lru_scan_depth</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values (32-bit platforms)	Type	integer
	Default	1024
	Min Value	100
	Max Value	$2^{32}-1$
Permitted Values (64-bit platforms)	Type	integer
	Default	1024
	Min Value	100
	Max Value	$2^{64}-1$

A parameter that influences the algorithms and heuristics for the [flush](#) operation for the [InnoDB buffer pool](#). Primarily of interest to performance experts tuning I/O-intensive workloads. It specifies, per buffer pool instance, how far down the buffer pool LRU list the page cleaner thread scans looking for [dirty pages](#) to flush. This is a background operation performed once per second.

A setting smaller than the default is generally suitable for most workloads. A value that is much higher than necessary may impact performance. Only consider increasing the value if you have spare I/O capacity under a typical workload. Conversely, if a write-intensive workload saturates your I/O capacity, decrease the value, especially in the case of a large buffer pool.

When tuning [innodb_lru_scan_depth](#), start with a low value and configure the setting upward with the goal of rarely seeing zero free pages. Also, consider adjusting [innodb_lru_scan_depth](#) when changing the number of buffer pool instances, since [innodb_lru_scan_depth](#) * [innodb_buffer_pool_instances](#) defines the amount of work performed by the page cleaner thread each second.

For related information, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#). For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- [innodb_max_dirty_pages_pct](#)

Command-Line Format	<code>--innodb-max-dirty-pages-pct=#</code>	
System Variable	Name	innodb_max_dirty_pages_pct
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	numeric
	Default	75
	Min Value	0
	Max Value	99.99

InnoDB tries to [flush](#) data from the [buffer pool](#) so that the percentage of [dirty pages](#) does not exceed this value. The default value is 75.

The [innodb_max_dirty_pages_pct](#) setting establishes a target for flushing activity. It does not affect the rate of flushing. For information about managing the rate of flushing, see [Section 15.6.3.6, “Configuring InnoDB Buffer Pool Flushing”](#).

For related information, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#). For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- [innodb_max_dirty_pages_pct_lwm](#)

Command-Line Format	<code>--innodb-max-dirty-pages-pct-lwm=#</code>	
System Variable	Name	innodb_max_dirty_pages_pct_lwm
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	numeric
	Default	0

	Min Value	0
	Max Value	99.99

Defines a low water mark representing the percentage of [dirty pages](#) at which preflushing is enabled to control the dirty page ratio. The default of 0 disables the pre-flushing behavior entirely. For more information, see [Section 15.6.3.7, “Fine-tuning InnoDB Buffer Pool Flushing”](#).

- `innodb_max_purge_lag`

Command-Line Format	<code>--innodb-max-purge-lag=#</code>	
System Variable	Name	<code>innodb_max_purge_lag</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	0
	Min Value	0
	Max Value	4294967295

Controls how to delay `INSERT`, `UPDATE`, and `DELETE` operations when `purge` operations are lagging (see [Section 15.3, “InnoDB Multi-Versioning”](#)). The default value is 0 (no delays).

The InnoDB transaction system maintains a list of transactions that have index records delete-marked by `UPDATE` or `DELETE` operations. The length of the list represents the `purge_lag` value. When `purge_lag` exceeds `innodb_max_purge_lag`, `INSERT`, `UPDATE`, and `DELETE` operations are delayed.

To prevent excessive delays in extreme situations where `purge_lag` becomes huge, you can limit the delay by setting the `innodb_max_purge_lag_delay` configuration option. The delay is computed at the beginning of a purge batch.

A typical setting for a problematic workload might be 1 million, assuming that transactions are small, only 100 bytes in size, and it is permissible to have 100MB of unpurged InnoDB table rows.

The lag value is displayed as the history list length in the `TRANSACTIONS` section of [InnoDB Monitor output](#) . For example, if the output includes the following lines, the lag value is 20:

```
-----
TRANSACTIONS
-----
Trx id counter 0 290328385
Purge done for trx's n:o < 0 290315608 undo n:o < 0 17
History list length 20
```

For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_max_purge_lag_delay`

Command-Line Format	<code>--innodb-max-purge-lag-delay=#</code>	
System Variable	Name	<code>innodb_max_purge_lag_delay</code>

	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	0
	Min Value	0

Specifies the maximum delay in milliseconds for the delay imposed by the `innodb_max_purge_lag` configuration option. A non-zero value represents an upper limit on the delay period computed from the formula based on the value of `innodb_max_purge_lag`. The default of zero means that there is no upper limit imposed on the delay interval.

For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_max_undo_log_size`

Command-Line Format	<code>--innodb-max-undo-log-size=#</code>	
System Variable	Name	<code>innodb_max_undo_log_size</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	1073741824
	Min Value	10485760
	Max Value	$2^{*}64-1$

Defines a threshold size for undo tablespaces. If an undo tablespace exceeds the threshold, it can be marked for truncation when `innodb_undo_log_truncate` is enabled. The default value is 1024 MiB (1073741824 bytes).

For more information, see [Section 15.7.8, “Truncating Undo Logs That Reside in Undo Tablespaces”](#).

- `innodb_merge_threshold_set_all_debug`

Command-Line Format	<code>--innodb-merge-threshold-set-all-debug=#</code>	
System Variable	Name	<code>innodb_merge_threshold_set_all_debug</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	50
	Min Value	1

	Max Value	50
--	------------------	----

Overrides the current `MERGE_THRESHOLD` setting with the specified value for all indexes that are currently in the dictionary cache. This option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option. For related information, see [Section 15.6.12, “Configuring the Merge Threshold for Index Pages”](#).

- `innodb_monitor_disable`

Command-Line Format	<code>--innodb-monitor-disable=[counter module pattern all]</code>	
System Variable	Name	<code>innodb_monitor_disable</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	string

Disables [InnoDB metrics counters](#). Counter data may be queried using the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see [Section 15.14.6, “InnoDB INFORMATION_SCHEMA Metrics Table”](#).

`innodb_monitor_disable='latch'` disables statistics collection for `SHOW ENGINE INNODB MUTEX`. For more information, see [Section 13.7.5.15, “SHOW ENGINE Syntax”](#).

- `innodb_monitor_enable`

Command-Line Format	<code>--innodb-monitor-enable=[counter module pattern all]</code>	
System Variable	Name	<code>innodb_monitor_enable</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	string

Enables [InnoDB metrics counters](#). Counter data may be queried using the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see [Section 15.14.6, “InnoDB INFORMATION_SCHEMA Metrics Table”](#).

`innodb_monitor_enable='latch'` enables statistics collection for `SHOW ENGINE INNODB MUTEX`. For more information, see [Section 13.7.5.15, “SHOW ENGINE Syntax”](#).

- `innodb_monitor_reset`

Command-Line Format	<code>--innodb-monitor-reset=[counter module pattern all]</code>	
System Variable	Name	<code>innodb_monitor_reset</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	string

Resets the count value for [InnoDB metrics counters](#) to zero. Counter data may be queried using the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see [Section 15.14.6, “InnoDB INFORMATION_SCHEMA Metrics Table”](#).

`innodb_monitor_reset='latch'` resets statistics reported by `SHOW ENGINE INNODB MUTEX`. For more information, see [Section 13.7.5.15, “SHOW ENGINE Syntax”](#).

- `innodb_monitor_reset_all`

Command-Line Format	<code>--innodb-monitor-reset-all=[counter module pattern all]</code>	
System Variable	Name	<code>innodb_monitor_reset_all</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	string

Resets all values (minimum, maximum, and so on) for [InnoDB metrics counters](#). Counter data may be queried using the `INFORMATION_SCHEMA.INNODB_METRICS` table. For usage information, see [Section 15.14.6, “InnoDB INFORMATION_SCHEMA Metrics Table”](#).

- `innodb_numa_interleave`

Command-Line Format	<code>--innodb-numa-interleave=#</code>	
System Variable	Name	<code>innodb_numa_interleave</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	boolean
	Default	<code>OFF</code>

Enables the NUMA interleave memory policy for allocation of the [InnoDB](#) buffer pool. When `innodb_numa_interleave` is enabled, the NUMA memory policy is set to `MPOL_INTERLEAVE` for the `mysqld` process. After the [InnoDB](#) buffer pool is allocated, the NUMA memory policy is set back to `MPOL_DEFAULT`. For the `innodb_numa_interleave` option to be available, MySQL must be compiled on a NUMA-enabled Linux system.

`CMake` sets the default `WITH_NUMA` value based on whether the current platform has [NUMA](#) support. For more information, see [Section 2.8.4, “MySQL Source-Configuration Options”](#).

- `innodb_old_blocks_pct`

Command-Line Format	<code>--innodb-old-blocks-pct=#</code>	
System Variable	Name	<code>innodb_old_blocks_pct</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	<code>37</code>

	Min Value	5
	Max Value	95

Specifies the approximate percentage of the [InnoDB buffer pool](#) used for the old block [sublist](#). The range of values is 5 to 95. The default value is 37 (that is, 3/8 of the pool). Often used in combination with [innodb_old_blocks_time](#).

For more information, see [Section 15.6.3.4, “Making the Buffer Pool Scan Resistant”](#). For information about buffer pool management, the LRU algorithm, and [eviction](#) policies, see [Section 15.6.3.1, “The InnoDB Buffer Pool”](#).

- [innodb_old_blocks_time](#)

Command-Line Format	<code>--innodb-old-blocks-time=#</code>	
System Variable	Name	<code>innodb_old_blocks_time</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	1000
	Min Value	0
	Max Value	$2^{*}32-1$

Non-zero values protect against the [buffer pool](#) being filled by data that is referenced only for a brief period, such as during a [full table scan](#). Increasing this value offers more protection against full table scans interfering with data cached in the buffer pool.

Specifies how long in milliseconds a block inserted into the old [sublist](#) must stay there after its first access before it can be moved to the new sublist. If the value is 0, a block inserted into the old sublist moves immediately to the new sublist the first time it is accessed, no matter how soon after insertion the access occurs. If the value is greater than 0, blocks remain in the old sublist until an access occurs at least that many milliseconds after the first access. For example, a value of 1000 causes blocks to stay in the old sublist for 1 second after the first access before they become eligible to move to the new sublist.

The default value is 1000.

This configuration option is often used in combination with [innodb_old_blocks_pct](#). For more information, see [Section 15.6.3.4, “Making the Buffer Pool Scan Resistant”](#). For information about buffer pool management, the LRU algorithm, and [eviction](#) policies, see [Section 15.6.3.1, “The InnoDB Buffer Pool”](#).

- [innodb_online_alter_log_max_size](#)

Command-Line Format	<code>--innodb-online-alter-log-max-size=#</code>	
System Variable	Name	<code>innodb_online_alter_log_max_size</code>
	Variable Scope	Global

	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	134217728
	Min Value	65536
	Max Value	2**64-1

Specifies an upper limit on the size of the temporary log files used during [online DDL](#) operations for [InnoDB](#) tables. There is one such log file for each index being created or table being altered. This log file stores data inserted, updated, or deleted in the table during the DDL operation. The temporary log file is extended when needed by the value of `innodb_sort_buffer_size`, up to the maximum specified by `innodb_online_alter_log_max_size`. If a temporary log file exceeds the upper size limit, the `ALTER TABLE` operation fails and all uncommitted concurrent DML operations are rolled back. Thus, a large value for this option allows more DML to happen during an online DDL operation, but also extends the period of time at the end of the DDL operation when the table is locked to apply the data from the log.

- `innodb_open_files`

Command-Line Format	<code>--innodb-open-files=#</code>	
System Variable	Name	<code>innodb_open_files</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	-1 (autosized)
	Min Value	10
	Max Value	4294967295

This configuration option is only relevant if you use multiple [InnoDB tablespaces](#). It specifies the maximum number of `.ibd` files that MySQL can keep open at one time. The minimum value is 10. The default value is 300 if `innodb_file_per_table` is not enabled, and the higher of 300 and `table_open_cache` otherwise.

The file descriptors used for `.ibd` files are for [InnoDB](#) tables only. They are independent of those specified by the `--open-files-limit` server option, and do not affect the operation of the table cache. For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_optimize_fulltext_only`

Command-Line Format	<code>--innodb-optimize-fulltext-only=#</code>	
System Variable	Name	<code>innodb_optimize_fulltext_only</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean

	Default	OFF
--	----------------	-----

Changes the way `OPTIMIZE TABLE` operates on InnoDB tables. Intended to be enabled temporarily, during maintenance operations for InnoDB tables with `FULLTEXT` indexes.

By default, `OPTIMIZE TABLE` reorganizes data in the [clustered index](#) of the table. When this option is enabled, `OPTIMIZE TABLE` skips the reorganization of table data, and instead processes newly added, deleted, and updated token data for InnoDB `FULLTEXT` indexes. For more information, see [Optimizing InnoDB Full-Text Indexes](#).

- [innodb_page_cleaners](#)

Command-Line Format	<code>--innodb-page-cleaners=#</code>	
System Variable	Name	<code>innodb_page_cleaners</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	4
	Min Value	1
	Max Value	64

The number of page cleaner threads that flush dirty pages from buffer pool instances. Page cleaner threads perform flush list and LRU flushing. When there are multiple page cleaner threads, buffer pool flushing tasks for each buffer pool instance are dispatched to idle page cleaner threads. The `innodb_page_cleaners` default value is 4. If the number of page cleaner threads exceeds the number of buffer pool instances, `innodb_page_cleaners` is automatically set to the same value as `innodb_buffer_pool_instances`.

If your workload is write-IO bound when flushing dirty pages from buffer pool instances to data files, and if your system hardware has available capacity, increasing the number of page cleaner threads may help improve write-IO throughput.

Multi-threaded page cleaner support extends to shutdown and recovery phases.

The `setpriority()` system call is used on Linux platforms where it is supported, and where the `mysqld` execution user is authorized, to give `page_cleaner` threads priority over other MySQL and InnoDB threads to help page flushing keep pace with the current workload. `mysqld` execution user authorization can be configured in `/etc/security/limits.conf`. For example, if `mysqld` is run under the `mysql` user, you can authorize the `mysql` user by adding lines similar to the following to `/etc/security/limits.conf`:

```
mysql      hard    nice    -20
mysql      soft    nice    -20
```

Refer to your Linux operating system documentation for more information.

- [innodb_page_size](#)

Command-Line Format	<code>--innodb-page-size=#k</code>	
System Variable	Name	<code>innodb_page_size</code>
	Variable Scope	Global

	Dynamic Variable	No	
Permitted Values	Type	enumeration	
	Default	16384	
	Valid Values		4k
			8k
			16k
			32k
			64k
			4096
			8192
			16384
			32768
		65536	

Specifies the [page size](#) for all [InnoDB tablespaces](#) in a MySQL [instance](#). You can specify page size using the values 64k, 32k, 16k (the default), 8k, or 4k. Alternatively, you can specify page size in bytes (65536, 32768, 16384, 8192, 4096).

[innodb_page_size](#) can only be configured prior to initializing the MySQL instance and cannot be changed afterward. If no value is specified, the instance is initialized using the default page size. See [Section 15.6.1, “InnoDB Startup Configuration”](#).

For both 32k and 64k page sizes, the maximum row length is approximately 16000 bytes. [ROW_FORMAT=COMPRESSED](#) is not supported when [innodb_page_size](#) is set to 32KB or 64KB. For [innodb_page_size=32k](#), extent size is 2MB. For [innodb_page_size=64k](#), extent size is 4MB. [innodb_log_buffer_size](#) should be set to at least 16M (the default) when using 32k or 64k page sizes.

The default 16KB page size or larger is appropriate for a wide range of [workloads](#), particularly for queries involving table scans and DML operations involving bulk updates. Smaller page sizes might be more efficient for [OLTP](#) workloads involving many small writes, where contention can be an issue when single pages contain many rows. Smaller pages might also be efficient with [SSD](#) storage devices, which typically use small block sizes. Keeping the [InnoDB](#) page size close to the storage device block size minimizes the amount of unchanged data that is rewritten to disk.

The minimum file size for the first system tablespace data file ([ibdata1](#)) differs depending on the [innodb_page_size](#) value. See the [innodb_data_file_path](#) option description for more information.

For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- [innodb_print_all_deadlocks](#)

Command-Line Format	<code>--innodb-print-all-deadlocks=#</code>	
System Variable	Name	innodb_print_all_deadlocks
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	OFF

When this option is enabled, information about all [deadlocks](#) in [InnoDB](#) user transactions is recorded in the [mysqld error log](#). Otherwise, you see information about only the last deadlock, using the [SHOW ENGINE INNODB STATUS](#) command. An occasional [InnoDB](#) deadlock is not necessarily an issue, because [InnoDB](#) detects the condition immediately and rolls back one of the transactions automatically. You might use this option to troubleshoot why deadlocks are occurring if an application does not have appropriate error-handling logic to detect the rollback and retry its operation. A large number of deadlocks might indicate the need to restructure transactions that issue [DML](#) or [SELECT ... FOR UPDATE](#) statements for multiple tables, so that each transaction accesses the tables in the same order, thus avoiding the deadlock condition.

For related information, see [Section 15.5.5, “Deadlocks in InnoDB”](#).

- [innodb_purge_batch_size](#)

Command-Line Format	<code>--innodb-purge-batch-size=#</code>	
System Variable	Name	innodb_purge_batch_size
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	300
	Min Value	1
	Max Value	5000

Defines the number of undo log pages that purge parses and processes in one batch from the [history list](#). In a multi-threaded purge configuration, the coordinator purge thread divides [innodb_purge_batch_size](#) by [innodb_purge_threads](#) and assigns that number of pages to each purge thread. The [innodb_purge_batch_size](#) option also defines the number of undo log pages that purge frees after every 128 iterations through the undo logs.

The [innodb_purge_batch_size](#) option is intended for advanced performance tuning in combination with the [innodb_purge_threads](#) setting. Most MySQL users need not change [innodb_purge_batch_size](#) from its default value.

For related information, see [Section 15.6.10, “Configuring InnoDB Purge Scheduling”](#).

- [innodb_purge_threads](#)

Command-Line Format	<code>--innodb-purge-threads=#</code>	
System Variable	Name	innodb_purge_threads
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	4
	Min Value	1

	Max Value	32
--	------------------	----

The number of background threads devoted to the [InnoDB purge](#) operation. A minimum value of 1 signifies that the purge operation is always performed by a background thread, never as part of the [master thread](#). Running the purge operation in one or more background threads helps reduce internal contention within [InnoDB](#), improving scalability. Increasing the value to greater than 1 creates that many separate purge threads, which can improve efficiency on systems where [DML](#) operations are performed on multiple tables. The maximum is 32.

For related information, see [Section 15.6.10, “Configuring InnoDB Purge Scheduling”](#).

- [innodb_purge_rseg_truncate_frequency](#)

Command-Line Format	<code>--innodb-purge-rseg-truncate-frequency=#</code>	
System Variable	Name	innodb_purge_rseg_truncate_frequency
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	128
	Min Value	1
	Max Value	128

Defines the frequency with which the purge system frees rollback segments. An undo tablespace cannot be truncated until its rollback segments are freed. Normally, the purge system frees rollback segments once every 128 times that purge is invoked. Reducing the [innodb_purge_rseg_truncate_frequency](#) value increases the frequency with which the purge thread frees rollback segments. The default value is 128.

[innodb_purge_rseg_truncate_frequency](#) is intended for use with [innodb_undo_log_truncate](#). For more information, see [Section 15.7.8, “Truncating Undo Logs That Reside in Undo Tablespaces”](#).

- [innodb_random_read_ahead](#)

Command-Line Format	<code>--innodb-random-read-ahead=#</code>	
System Variable	Name	innodb_random_read_ahead
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	OFF

Enables the random [read-ahead](#) technique for optimizing [InnoDB I/O](#).

For details about performance considerations for different types of read-ahead requests, see [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#). For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_read_ahead_threshold`

Command-Line Format	<code>--innodb-read-ahead-threshold=#</code>	
System Variable	Name	<code>innodb_read_ahead_threshold</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	56
	Min Value	0
	Max Value	64

Controls the sensitivity of linear [read-ahead](#) that InnoDB uses to prefetch pages into the [buffer pool](#). If InnoDB reads at least `innodb_read_ahead_threshold` pages sequentially from an [extent](#) (64 pages), it initiates an asynchronous read for the entire following extent. The permissible range of values is 0 to 64. A value of 0 disables read-ahead. For the default of 56, InnoDB must read at least 56 pages sequentially from an extent to initiate an asynchronous read for the following extent.

Knowing how many pages are read through the read-ahead mechanism, and how many of these pages are evicted from the buffer pool without ever being accessed, can be useful when fine-tuning the `innodb_read_ahead_threshold` setting. `SHOW ENGINE INNODB STATUS` output displays counter information from the `InnoDB_buffer_pool_read_ahead` and `InnoDB_buffer_pool_read_ahead_evicted` global status variables, which report the number of pages brought into the [buffer pool](#) by read-ahead requests, and the number of such pages [evicted](#) from the buffer pool without ever being accessed, respectively. The status variables report global values since the last server restart.

`SHOW ENGINE INNODB STATUS` also shows the rate at which the read-ahead pages are read in and the rate at which such pages are evicted without being accessed. The per-second averages are based on the statistics collected since the last invocation of `SHOW ENGINE INNODB STATUS` and are displayed in the [BUFFER POOL AND MEMORY](#) section of the `SHOW ENGINE INNODB STATUS` output.

For more information, see [Section 15.6.3.5, “Configuring InnoDB Buffer Pool Prefetching \(Read-Ahead\)”](#). For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

- `innodb_read_io_threads`

Command-Line Format	<code>--innodb-read-io-threads=#</code>	
System Variable	Name	<code>innodb_read_io_threads</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	4
	Min Value	1
	Max Value	64

The number of I/O threads for read operations in `InnoDB`. Its counterpart for write threads is `innodb_write_io_threads`. For more information, see [Section 15.6.6, “Configuring the Number of Background InnoDB I/O Threads”](#). For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

Note

On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for `innodb_read_io_threads`, `innodb_write_io_threads`, and the Linux `aio-max-nr` setting can exceed system limits. Ideally, increase the `aio-max-nr` setting; as a workaround, you might reduce the settings for one or both of the MySQL configuration options.

- `innodb_read_only`

Command-Line Format	<code>--innodb-read-only=#</code>	
System Variable	Name	<code>innodb_read_only</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	boolean
	Default	<code>OFF</code>

Starts `InnoDB` in read-only mode. For distributing database applications or data sets on read-only media. Can also be used in data warehouses to share the same data directory between multiple instances. For more information, see [Section 15.6.2, “Configuring InnoDB for Read-Only Operation”](#).

Previously, enabling the `innodb_read_only` system variable prevented creating and dropping tables only for the `InnoDB` storage engine. As of MySQL 8.0, enabling `innodb_read_only` prevents these operations for all storage engines. Table creation and drop operations for any storage engine modify data dictionary tables in the `mysql` system database, but those tables use the `InnoDB` storage engine and cannot be modified when `innodb_read_only` is enabled. The same principle applies to other table operations that require modifying data dictionary tables. Examples:

- If the `innodb_read_only` system variable is enabled, `ANALYZE TABLE` may fail because it cannot update statistics tables in the data dictionary, which use `InnoDB`. For `ANALYZE TABLE` operations that update the key distribution, failure may occur even if the operation updates the table itself (for example, if it is a `MyISAM` table). To obtain the updated distribution statistics, set `information_schema_stats=LATEST`.
- `ALTER TABLE tbl_name ENGINE=engine_name` fails because it updates the storage engine designation, which is stored in the data dictionary.

In addition, other tables in the `mysql` system database use the `InnoDB` storage engine in MySQL 8.0. Making those tables read only results in restrictions on operations that modify them. Examples:

- Account-management statements such as `CREATE USER` and `GRANT` fail because the grant tables use `InnoDB`.
- The `INSTALL PLUGIN` and `UNINSTALL PLUGIN` plugin-management statements fail because the `plugin` table uses `InnoDB`.
- The `CREATE FUNCTION` and `DROP FUNCTION` UDF-management statements fail because the `func` table uses `InnoDB`.

- `innodb_redo_log_encrypt`

Introduced	8.0.1	
Command-Line Format	<code>--innodb-redo-log-encrypt=#</code>	
System Variable	Name	<code>innodb_redo_log_encrypt</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	<code>OFF</code>

Controls encryption of redo log data for tables encrypted using the [InnoDB tablespace encryption feature](#). Encryption of redo log data is disabled by default. For more information, see [Redo Log Data Encryption](#).

- `innodb_replication_delay`

Command-Line Format	<code>--innodb-replication-delay=#</code>	
System Variable	Name	<code>innodb_replication_delay</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	0
	Min Value	0
	Max Value	4294967295

The replication thread delay (in ms) on a slave server if `innodb_thread_concurrency` is reached.

- `innodb_rollback_on_timeout`

Command-Line Format	<code>--innodb-rollback-on-timeout</code>	
System Variable	Name	<code>innodb_rollback_on_timeout</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	boolean
	Default	<code>OFF</code>

InnoDB [rolls back](#) only the last statement on a transaction timeout by default. If `--innodb_rollback_on_timeout` is specified, a transaction timeout causes InnoDB to abort and roll back the entire transaction.

**Note**

If the start-transaction statement was `START TRANSACTION` or `BEGIN` statement, rollback does not cancel that statement. Further SQL statements become part of the transaction until the occurrence of `COMMIT`, `ROLLBACK`, or some SQL statement that causes an implicit commit.

For more information, see [Section 15.20.4, “InnoDB Error Handling”](#).

- `innodb_rollback_segments`

Command-Line Format	<code>--innodb-rollback-segments=#</code>	
System Variable	Name	<code>innodb_rollback_segments</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	128
	Min Value	1
	Max Value	128

As of MySQL 8.0.2, `innodb_rollback_segments` defines the number of [rollback segments](#) allocated to the system tablespace, the temporary tablespace, and each undo tablespace. Prior to MySQL 8.0.2, `innodb_rollback_segments` defines the total number of rollback segments used by InnoDB. Each rollback segment can support a maximum of 1023 data-modifying transactions.

Start with a low value for this parameter and gradually increase it to avoid allocating rollback segments that are not required. If `innodb_rollback_segments` is not set, it defaults to the maximum value of 128.

For more information about rollback segments, see [Section 15.3, “InnoDB Multi-Versioning”](#). For information about configuring separate undo tablespaces, see [Section 15.7.7, “Storing InnoDB Undo Logs in Separate Tablespaces”](#).

- `innodb_scan_directories`

Introduced	8.0.2	
Command-Line Format	<code>--innodb-scan-directories=#</code>	
System Variable	Name	<code>innodb_scan_directories</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	string
	Default	NULL

If, during recovery, InnoDB encounters redo logs written since the last checkpoint, the redo logs must be applied to affected tablespaces. The process that identifies affected tablespaces is referred to as tablespace discovery. Tablespace discovery depends on tablespace map files that map tablespace IDs in the redo logs to tablespace files. If tablespace map files are lost or corrupted, the

`innodb_scan_directories` startup option can be used to specify tablespace file directories. This option causes InnoDB to read the first page of each tablespace file in the specified directories and recreate tablespace map files so that the recovery process can apply redo logs to affected tablespaces.

`innodb_scan_directories` may be specified as an option in a startup command or in a MySQL configuration file. Quotes are used around the argument value because otherwise a semicolon (;) is interpreted as a special character by some command interpreters. (Unix shells treat it as a command terminator, for example.)

Startup command:

```
mysqld --innodb-scan-directories="directory_path_1;directory_path_2"
```

MySQL configuration file:

```
[mysqld]
innodb_scan_directories="directory_path_1;directory_path_2"
```

For more information, see [Lost or Corrupted Tablespace Map Files](#).

- `innodb_saved_page_number_debug`

Command-Line Format	<code>--innodb-saved-page-number-debug=#</code>	
System Variable	Name	<code>innodb_saved_page_number_debug</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	0
	Max Value	$2^{*}23-1$

Saves a page number. Setting the `innodb_fil_make_page_dirty_debug` option dirties the page defined by `innodb_saved_page_number_debug`. The `innodb_saved_page_number_debug` option is only available if debugging support is compiled in using the `WITH_DEBUG` CMake option.

- `innodb_sort_buffer_size`

Command-Line Format	<code>--innodb-sort-buffer-size=#</code>	
System Variable	Name	<code>innodb_sort_buffer_size</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	1048576
	Min Value	65536
	Max Value	67108864

disk. This process is referred to as a “run”. During the merge phase, pairs of buffers of the specified size are read in and merged. The larger the setting, the fewer runs and merges there are.

This sort area is only used for merge sorts during index creation, not during later index maintenance operations. Buffers are deallocated when index creation completes.

The value of this option also controls the amount by which the temporary log file is extended to record concurrent DML during [online DDL](#) operations.

Before this setting was made configurable, the size was hardcoded to 1048576 bytes (1MB), which remains the default.

During an [ALTER TABLE](#) or [CREATE TABLE](#) statement that creates an index, 3 buffers are allocated, each with a size defined by this option. Additionally, auxiliary pointers are allocated to rows in the sort buffer so that the sort can run on pointers (as opposed to moving rows during the sort operation).

For a typical sort operation, a formula such as this one can be used to estimate memory consumption:

```
(6 /*FTS_NUM_AUX_INDEX*/ * (3*@@global.innodb_sort_buffer_size)
+ 2 * number_of_partitions * number_of_secondary_indexes_created
* (2*@@global.innodb_sort_buffer_size/dict_index_get_min_size(index)*/)
* 8 /*64-bit sizeof *buf->tuples*/)
```

`@@global.innodb_sort_buffer_size/dict_index_get_min_size(index)` indicates the maximum tuples held. `2 * (2*@@global.innodb_sort_buffer_size/dict_index_get_min_size(index)*/)` * 8 /*64-bit sizeof *buf->tuples*/ indicates auxiliary pointers allocated.

Note

For 32-bit, multiply by 4 instead of 8.

For parallel sorts on a full-text index, multiply by the `innodb_ft_sort_pll_degree` setting:

```
(6 /*FTS_NUM_AUX_INDEX*/ * @@global.innodb_ft_sort_pll_degree)
```

- `innodb_spin_wait_delay`

Command-Line Format	<code>--innodb-spin-wait-delay=#</code>	
System Variable	Name	<code>innodb_spin_wait_delay</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values (32-bit platforms)	Type	integer
	Default	6
	Min Value	0
	Max Value	$2^{32}-1$
Permitted Values (64-bit platforms)	Type	integer
	Default	6

	Min Value	0
	Max Value	$2^{64}-1$

The maximum delay between polls for a [spin](#) lock. The low-level implementation of this mechanism varies depending on the combination of hardware and operating system, so the delay does not correspond to a fixed time interval. For more information, see [Section 15.6.9, “Configuring Spin Lock Polling”](#).

- [innodb_stats_auto_recalc](#)

Command-Line Format	<code>--innodb-stats-auto-recalc=#</code>	
System Variable	Name	<code>innodb_stats_auto_recalc</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	ON

Causes [InnoDB](#) to automatically recalculate [persistent statistics](#) after the data in a table is changed substantially. The threshold value is 10% of the rows in the table. This setting applies to tables created when the `innodb_stats_persistent` option is enabled. Automatic statistics recalculation may also be configured by specifying `STATS_PERSISTENT=1` in a `CREATE TABLE` or `ALTER TABLE` statement. The amount of data sampled to produce the statistics is controlled by the `innodb_stats_persistent_sample_pages` configuration option.

For more information, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- [innodb_stats_include_delete_marked](#)

Introduced	8.0.1	
Command-Line Format	<code>--innodb-stats-include-delete-marked=#</code>	
System Variable	Name	<code>innodb_stats_include_delete_marked</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	OFF

By default, [InnoDB](#) reads uncommitted data when calculating statistics. In the case of an uncommitted transaction that deletes rows from a table, [InnoDB](#) excludes records that are delete-marked when calculating row estimates and index statistics, which can lead to non-optimal execution plans for other transactions that are operating on the table concurrently using a transaction isolation level other than `READ UNCOMMITTED`. To avoid this scenario, `innodb_stats_include_delete_marked` can be enabled to ensure that [InnoDB](#) includes delete-marked records when calculating persistent optimizer statistics.

When `innodb_stats_include_delete_marked` is enabled, `ANALYZE TABLE` considers delete-marked records when recalculating statistics.

`innodb_stats_include_delete_marked` is a global setting that affects all InnoDB tables. It is only applicable to persistent optimizer statistics.

For related information, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `innodb_stats_method`

Command-Line Format	<code>--innodb-stats-method=name</code>	
System Variable	Name	<code>innodb_stats_method</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	enumeration
	Default	<code>nulls_equal</code>
	Valid Values	<code>nulls_equal</code>
		<code>nulls_unequal</code>
	<code>nulls_ignored</code>	

How the server treats `NULL` values when collecting [statistics](#) about the distribution of index values for InnoDB tables. Permitted values are `nulls_equal`, `nulls_unequal`, and `nulls_ignored`. For `nulls_equal`, all `NULL` index values are considered equal and form a single value group with a size equal to the number of `NULL` values. For `nulls_unequal`, `NULL` values are considered unequal, and each `NULL` forms a distinct value group of size 1. For `nulls_ignored`, `NULL` values are ignored.

The method used to generate table statistics influences how the optimizer chooses indexes for query execution, as described in [Section 8.3.7, “InnoDB and MyISAM Index Statistics Collection”](#).

- `innodb_stats_on_metadata`

Command-Line Format	<code>--innodb-stats-on-metadata</code>	
System Variable	Name	<code>innodb_stats_on_metadata</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	<code>OFF</code>

This option only applies when optimizer [statistics](#) are configured to be non-persistent. Optimizer statistics are not persisted to disk when `innodb_stats_persistent` is disabled or when individual tables are created or altered with `STATS_PERSISTENT=0`. For more information, see [Section 15.6.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”](#).

When `innodb_stats_on_metadata` is enabled, InnoDB updates non-persistent [statistics](#) when metadata statements such as `SHOW TABLE STATUS` or when accessing the `INFORMATION_SCHEMA.TABLES` or `INFORMATION_SCHEMA.STATISTICS` tables. (These updates are similar to what happens for `ANALYZE TABLE`.) When disabled, InnoDB does not update statistics during these operations. Leaving the setting disabled can improve access speed for schemas that have a large number of tables or indexes. It can also improve the stability of [execution plans](#) for queries that involve InnoDB tables.

To change the setting, issue the statement `SET GLOBAL innodb_stats_on_metadata=mode`, where *mode* is either `ON` or `OFF` (or `1` or `0`). Changing the setting requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege and immediately affects the operation of all connections.

- `innodb_stats_persistent`

Command-Line Format	<code>--innodb-stats-persistent=setting</code>	
System Variable	Name	<code>innodb_stats_persistent</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	<code>ON</code>
	Valid Values	<code>OFF</code>
		<code>ON</code>
<code>0</code>		
	<code>1</code>	

Specifies whether InnoDB index statistics are persisted to disk. Otherwise, statistics may be recalculated frequently which can lead to variations in [query execution plans](#). This setting is stored with each table when the table is created. You can set `innodb_stats_persistent` at the global level before creating a table, or use the `STATS_PERSISTENT` clause of the `CREATE TABLE` and `ALTER TABLE` statements to override the system-wide setting and configure persistent statistics for individual tables.

For more information, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

- `innodb_stats_persistent_sample_pages`

Command-Line Format	<code>--innodb-stats-persistent-sample-pages=#</code>	
System Variable	Name	<code>innodb_stats_persistent_sample_pages</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	<code>20</code>

The number of index [pages](#) to sample when estimating [cardinality](#) and other [statistics](#) for an indexed column, such as those calculated by `ANALYZE TABLE`. Increasing the value improves the accuracy of index statistics, which can improve the [query execution plan](#), at the expense of increased I/O during the execution of `ANALYZE TABLE` for an InnoDB table. For more information, see [Section 15.6.11.1, “Configuring Persistent Optimizer Statistics Parameters”](#).

Note

Setting a high value for `innodb_stats_persistent_sample_pages` could result in lengthy `ANALYZE TABLE` execution time. To estimate the number of database pages accessed by `ANALYZE TABLE`, see

Section 15.6.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”.

`innodb_stats_persistent_sample_pages` only applies when `innodb_stats_persistent` is enabled for a table; when `innodb_stats_persistent` is disabled, `innodb_stats_transient_sample_pages` applies instead.

- `innodb_stats_transient_sample_pages`

Command-Line Format	<code>--innodb-stats-transient-sample-pages=#</code>	
System Variable	Name	<code>innodb_stats_transient_sample_pages</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	8

The number of index [pages](#) to sample when estimating [cardinality](#) and other [statistics](#) for an indexed column, such as those calculated by `ANALYZE TABLE`. The default value is 8. Increasing the value improves the accuracy of index statistics, which can improve the [query execution plan](#), at the expense of increased I/O when opening an InnoDB table or recalculating statistics. For more information, see [Section 15.6.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”](#).

Note

Setting a high value for `innodb_stats_transient_sample_pages` could result in lengthy `ANALYZE TABLE` execution time. To estimate the number of database pages accessed by `ANALYZE TABLE`, see [Section 15.6.11.3, “Estimating ANALYZE TABLE Complexity for InnoDB Tables”](#).

`innodb_stats_transient_sample_pages` only applies when `innodb_stats_persistent` is disabled for a table; when `innodb_stats_persistent` is enabled, `innodb_stats_persistent_sample_pages` applies instead. Takes the place of `innodb_stats_sample_pages`. For more information, see [Section 15.6.11.2, “Configuring Non-Persistent Optimizer Statistics Parameters”](#).

- `innodb_status_output`

Command-Line Format	<code>--innodb-status-output</code>	
System Variable	Name	<code>innodb_status_output</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	OFF

Enables or disables periodic output for the standard InnoDB Monitor. Also used in combination with `innodb_status_output_locks` to enable or disable periodic output for the InnoDB Lock Monitor. For more information, see [Section 15.16.2, “Enabling InnoDB Monitors”](#).

- `innodb_status_output_locks`

System Variable	Name	<code>innodb_status_output_locks</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	<code>OFF</code>

Enables or disables the [InnoDB Lock Monitor](#). When enabled, the [InnoDB Lock Monitor](#) prints additional information about locks in `SHOW ENGINE INNODB STATUS` output and in periodic output printed to the MySQL error log. Periodic output for the [InnoDB Lock Monitor](#) is printed as part of the standard [InnoDB Monitor](#) output. The standard [InnoDB Monitor](#) must therefore be enabled for the [InnoDB Lock Monitor](#) to print data to the MySQL error log periodically. For more information, see [Section 15.16.2, “Enabling InnoDB Monitors”](#).

- `innodb_strict_mode`

Command-Line Format	<code>--innodb-strict-mode=#</code>	
System Variable	Name	<code>innodb_strict_mode</code>
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	<code>ON</code>

When `innodb_strict_mode` is enabled, [InnoDB](#) returns errors rather than warnings for certain conditions.

[Strict mode](#) helps guard against ignored typos and syntax errors in SQL, or other unintended consequences of various combinations of operational modes and SQL statements. When `innodb_strict_mode` is enabled, [InnoDB](#) raises error conditions in certain cases, rather than issuing a warning and processing the specified statement (perhaps with unintended behavior). This is analogous to `sql_mode` in MySQL, which controls what SQL syntax MySQL accepts, and determines whether it silently ignores errors, or validates input syntax and data values.

The `innodb_strict_mode` setting affects the handling of syntax errors for `CREATE TABLE`, `ALTER TABLE`, `CREATE INDEX`, and `OPTIMIZE TABLE` statements. `innodb_strict_mode` also enables a record size check, so that an `INSERT` or `UPDATE` never fails due to the record being too large for the selected page size.

Oracle recommends enabling `innodb_strict_mode` when using `ROW_FORMAT` and `KEY_BLOCK_SIZE` clauses in `CREATE TABLE`, `ALTER TABLE`, and `CREATE INDEX` statements. When `innodb_strict_mode` is disabled, [InnoDB](#) ignores conflicting clauses and creates the table or index with only a warning in the message log. The resulting table might have different characteristics than intended, such as lack of compression support when attempting to create a compressed table. When `innodb_strict_mode` is enabled, such problems generate an immediate error and the table or index is not created.

You can enable or disable `innodb_strict_mode` on the command line when starting `mysqld`, or in a MySQL [configuration file](#). You can also enable or disable `innodb_strict_mode` at runtime with the statement `SET [GLOBAL|SESSION] innodb_strict_mode=mode`, where `mode` is either `ON` or `OFF`. Changing the `GLOBAL` setting requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege and affects the operation of all clients that subsequently connect. Any client can change the

[SESSION](#) setting for `innodb_strict_mode`, and the setting affects only that client.

`innodb_strict_mode` is not applicable to [general tablespaces](#). Tablespace management rules for general tablespaces are strictly enforced independently of `innodb_strict_mode`. For more information, see [Section 13.1.16, “CREATE TABLESPACE Syntax”](#).

- `innodb_sync_array_size`

Command-Line Format	<code>--innodb-sync-array-size=#</code>	
System Variable	Name	<code>innodb_sync_array_size</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	1
	Min Value	1
	Max Value	1024

Splits an internal data structure used to coordinate threads, for higher concurrency in workloads with large numbers of waiting threads. This setting must be configured when the MySQL instance is starting up, and cannot be changed afterward. Increasing the value is recommended for workloads that frequently produce a large number of waiting threads, typically greater than 768.

- `innodb_sync_spin_loops`

Command-Line Format	<code>--innodb-sync-spin-loops=#</code>	
System Variable	Name	<code>innodb_sync_spin_loops</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	30
	Min Value	0
	Max Value	4294967295

The number of times a thread waits for an InnoDB mutex to be freed before the thread is suspended.

- `innodb_sync_debug`

Command-Line Format	<code>--innodb-sync-debug=#</code>	
System Variable	Name	<code>innodb_sync_debug</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	boolean

	Default	OFF
--	----------------	-----

Enables sync debug checking for the InnoDB storage engine. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_table_locks`

Command-Line Format	<code>--innodb-table-locks</code>	
System Variable	Name	<code>innodb_table_locks</code>
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	TRUE

If `autocommit = 0`, InnoDB honors `LOCK TABLES`; MySQL does not return from `LOCK TABLES ... WRITE` until all other threads have released all their locks to the table. The default value of `innodb_table_locks` is 1, which means that `LOCK TABLES` causes InnoDB to lock a table internally if `autocommit = 0`.

In MySQL 8.0, `innodb_table_locks = 0` has no effect for tables locked explicitly with `LOCK TABLES ... WRITE`. It does have an effect for tables locked for read or write by `LOCK TABLES ... WRITE` implicitly (for example, through triggers) or by `LOCK TABLES ... READ`.

For related information, see [Section 15.5, “InnoDB Locking and Transaction Model”](#).

- `innodb_temp_data_file_path`

Command-Line Format	<code>--innodb-temp-data-file-path=file</code>	
System Variable	Name	<code>innodb_temp_data_file_path</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	string
	Default	<code>ibtmp1:12M:autoextend</code>

Specifies the path, file name, and file size for InnoDB temporary tablespace data files. The full directory path for a file is formed by concatenating `innodb_data_home_dir` to the path specified by `innodb_temp_data_file_path`. File size is specified in KB, MB, or GB (1024MB) by appending `K`, `M`, or `G` to the size value. The sum of the sizes of the files must be slightly larger than 12MB. If you do not specify a value for `innodb_temp_data_file_path`, the default behavior is to create a single auto-extending temporary tablespace data file, slightly larger than 12MB, named `ibtmp1`. The size limit of individual files is determined by your operating system. You can set the file size to more than 4GB on operating systems that support big files. Use of raw disk partitions for temporary tablespace data files is not supported.

A temporary tablespace data file name cannot be the same as an InnoDB data file name. Any inability or error creating a temporary tablespace data file is treated as fatal and server startup is refused. The temporary tablespace has a dynamically generated space ID, which can change on each server restart.

Metadata about active [InnoDB](#) temporary tables is located in `INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO`.

For related information, see [Section 15.4.11](#), “Temporary Tablespace”.

- `innodb_tmpdir`

Command-Line Format	<code>--innodb-tmpdir=path</code>	
System Variable	Name	<code>innodb_tmpdir</code>
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values	Type	directory name
	Default	<code>NULL</code>

Used to define an alternate directory for temporary sort files created during online `ALTER TABLE` operations that rebuild the table.

Online `ALTER TABLE` operations that rebuild the table also create an *intermediate* table file in the same directory as the original table. The `innodb_tmpdir` option is not applicable to intermediate table files.

A valid value is any directory path other than the MySQL data directory path. If the value is `NULL` (the default), temporary files are created MySQL temporary directory (`$TMPDIR` on Unix, `%TEMP %` on Windows, or the directory specified by the `--tmpdir` configuration option). If a directory is specified, existence of the directory and permissions are only checked when `innodb_tmpdir` is configured using a `SET` statement. If a symlink is provided in a directory string, the symlink is resolved and stored as an absolute path. The path should not exceed 512 bytes. An online `ALTER TABLE` operation reports an error if `innodb_tmpdir` is set to an invalid directory. `innodb_tmpdir` overrides the MySQL `tmpdir` setting but only for online `ALTER TABLE` operations.

The `FILE` privilege is required to configure `innodb_tmpdir`.

The `innodb_tmpdir` option was introduced to help avoid overflowing a temporary file directory located on a `tmpfs` file system. Such overflows could occur as a result of large temporary sort files created during online `ALTER TABLE` operations that rebuild the table.

In replication environments, only consider replicating the `innodb_tmpdir` setting if all servers have the same operating system environment. Otherwise, replicating the `innodb_tmpdir` setting could result in a replication failure when running online `ALTER TABLE` operations that rebuild the table. If server operating environments differ, it is recommended that you configure `innodb_tmpdir` on each server individually.

For more information, see [Where InnoDB Stores Temporary Files](#). For information about online `ALTER TABLE` operations, see [Section 15.12](#), “InnoDB and Online DDL”.

- `innodb_thread_concurrency`

Command-Line Format	<code>--innodb-thread-concurrency=#</code>	
System Variable	Name	<code>innodb_thread_concurrency</code>
	Variable Scope	Global
	Dynamic Variable	Yes

Permitted Values	Type	integer
	Default	0
	Min Value	0
	Max Value	1000

InnoDB tries to keep the number of operating system threads concurrently inside InnoDB less than or equal to the limit given by this variable (InnoDB uses operating system threads to process user transactions). Once the number of threads reaches this limit, additional threads are placed into a wait state within a “First In, First Out” (FIFO) queue for execution. Threads waiting for locks are not counted in the number of concurrently executing threads.

The range of this variable is 0 to 1000. A value of 0 (the default) is interpreted as infinite concurrency (no concurrency checking). Disabling thread concurrency checking enables InnoDB to create as many threads as it needs. A value of 0 also disables the `queries inside InnoDB` and `queries in queue counters` in the `ROW OPERATIONS` section of `SHOW ENGINE INNODB STATUS` output.

Consider setting this variable if your MySQL instance shares CPU resources with other applications, or if your workload or number of concurrent users is growing. The correct setting depends on workload, computing environment, and the version of MySQL that you are running. You will need to test a range of values to determine the setting that provides the best performance. `innodb_thread_concurrency` is a dynamic variable, which allows you to experiment with different settings on a live test system. If a particular setting performs poorly, you can quickly set `innodb_thread_concurrency` back to 0.

Use the following guidelines to help find and maintain an appropriate setting:

- If the number of concurrent user threads for a workload is less than 64, set `innodb_thread_concurrency=0`.
- If your workload is consistently heavy or occasionally spikes, start by setting `innodb_thread_concurrency=128` and then lowering the value to 96, 80, 64, and so on, until you find the number of threads that provides the best performance. For example, suppose your system typically has 40 to 50 users, but periodically the number increases to 60, 70, or even 200. You find that performance is stable at 80 concurrent users but starts to show a regression above this number. In this case, you would set `innodb_thread_concurrency=80` to avoid impacting performance.
- If you do not want InnoDB to use more than a certain number of vCPUs for user threads (20 vCPUs, for example), set `innodb_thread_concurrency` to this number (or possibly lower, depending on performance results). If your goal is to isolate MySQL from other applications, you may consider binding the `mysqld` process exclusively to the vCPUs. Be aware, however, that exclusive binding could result in non-optimal hardware usage if the `mysqld` process is not consistently busy. In this case, you might bind the `mysqld` process to the vCPUs but also allow other applications to use some or all of the vCPUs.

Note

From an operating system perspective, using a resource management solution to manage how CPU time is shared among applications may be preferable to binding the `mysqld` process. For example, you could assign 90% of vCPU time to a given application while other critical processes *are not* running, and scale that value back to 40% when other critical processes *are* running.

- `innodb_thread_concurrency` values that are too high can cause performance regression due to increased contention on system internals and resources.
- In some cases, the optimal `innodb_thread_concurrency` setting can be smaller than the number of vCPUs.
- Monitor and analyze your system regularly. Changes to workload, number of users, or computing environment may require that you adjust the `innodb_thread_concurrency` setting.

For related information, see [Section 15.6.5, “Configuring Thread Concurrency for InnoDB”](#).

- `innodb_trx_purge_view_update_only_debug`

Command-Line Format	<code>--innodb-trx-purge-view-update-only-debug=#</code>	
System Variable	Name	<code>innodb_trx_purge_view_update_only_debug</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	<code>OFF</code>

Pauses purging of delete-marked records while allowing the purge view to be updated. This option artificially creates a situation in which the purge view is updated but purges have not yet been performed. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_trx_rseg_n_slots_debug`

Command-Line Format	<code>--innodb-trx-rseg-n-slots-debug=#</code>	
System Variable	Name	<code>innodb_trx_rseg_n_slots_debug</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	<code>0</code>
	Max Value	<code>1024</code>

Sets a debug flag that limits `TRX_RSEG_N_SLOTS` to a given value for the `trx_rsegf_undo_find_free` function that looks for free slots for undo log segments. This option is only available if debugging support is compiled in using the `WITH_DEBUG CMake` option.

- `innodb_thread_sleep_delay`

Command-Line Format	<code>--innodb-thread-sleep-delay=#</code>	
System Variable	Name	<code>innodb_thread_sleep_delay</code>
	Variable Scope	Global
	Dynamic Variable	Yes

Permitted Values	Type	integer
	Default	10000
	Min Value	0
	Max Value	1000000

How long InnoDB threads sleep before joining the InnoDB queue, in microseconds. The default value is 10000. A value of 0 disables sleep. You can set the configuration option `innodb_adaptive_max_sleep_delay` to the highest value you would allow for `innodb_thread_sleep_delay`, and InnoDB automatically adjusts `innodb_thread_sleep_delay` up or down depending on current thread-scheduling activity. This dynamic adjustment helps the thread scheduling mechanism to work smoothly during times when the system is lightly loaded or when it is operating near full capacity.

For more information, see [Section 15.6.5, “Configuring Thread Concurrency for InnoDB”](#).

- `innodb_undo_directory`

Command-Line Format	<code>--innodb-undo-directory=dir_name</code>	
System Variable	Name	<code>innodb_undo_directory</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	directory name

The path where InnoDB creates undo tablespaces. Typically used to place undo logs on a different storage device. Used in conjunction with `innodb_rollback_segments` and `innodb_undo_tablespaces`, which determine the disk layout of the undo logs outside the `system tablespace`.

There is no default value (it is NULL). If a path is not specified, undo tablespaces are created in the MySQL data directory, as defined by `datadir`.

For more information, see [Section 15.7.7, “Storing InnoDB Undo Logs in Separate Tablespaces”](#).

- `innodb_undo_log_encrypt`

Introduced	8.0.1	
Command-Line Format	<code>--innodb-undo-log-encrypt=#</code>	
System Variable	Name	<code>innodb_undo_log_encrypt</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	OFF

Controls encryption of undo log data for tables encrypted using the InnoDB [tablespace encryption feature](#). Only applies to undo logs that reside in separate `undo tablespaces`. See [Section 15.7.7, “Storing InnoDB Undo Logs in Separate Tablespaces”](#). Encryption is not supported for undo log data that resides in the system tablespace. For more information, see [Undo Log Data Encryption](#).

- `innodb_undo_log_truncate`

Command-Line Format	<code>--innodb-undo-log-truncate=#</code>	
System Variable	Name	<code>innodb_undo_log_truncate</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values (<= 8.0.1)	Type	boolean
	Default	<code>OFF</code>
Permitted Values (>= 8.0.2)	Type	boolean
	Default	<code>ON</code>

When enabled, undo tablespaces that exceed the threshold value defined by `innodb_max_undo_log_size` are marked for truncation. Only undo logs that reside in undo tablespaces can be truncated. Truncating undo logs that reside in the system tablespace is not supported. For truncation to occur, there must be at least two undo tablespaces.

The `innodb_purge_rseg_truncate_frequency` configuration option can be used to expedite truncation of undo tablespaces.

For more information, see [Section 15.7.8, “Truncating Undo Logs That Reside in Undo Tablespaces”](#).

- `innodb_undo_logs`

Deprecated	5.7.19	
Removed	8.0.2	
Command-Line Format	<code>--innodb-undo-logs=#</code>	
System Variable	Name	<code>innodb_undo_logs</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	<code>128</code>
	Min Value	<code>0</code>
	Max Value	<code>128</code>

Note

`innodb_undo_logs` is removed in MySQL 8.0.2.

Defines the number of [rollback segments](#) used by InnoDB. The `innodb_undo_logs` option is an alias for `innodb_rollback_segments`. For more information, see the description of `innodb_rollback_segments`.

- `innodb_undo_tablespaces`

System Variable (<= 8.0.1)	Name	<code>innodb_undo_tablespaces</code>
	Variable Scope	Global
	Dynamic Variable	No
System Variable (>= 8.0.2)	Name	<code>innodb_undo_tablespaces</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values (<= 8.0.1)	Type	integer
	Default	0
	Min Value	0
	Max Value	95
Permitted Values (>= 8.0.2)	Type	integer
	Default	2
	Min Value	0
	Max Value	127

The number of `undo tablespaces` used by `InnoDB`. The default value is 2 as of MySQL 8.0.2, and 0 before that.

Undo logs can become large during long-running transactions. Using multiple undo tablespaces reduces the size of any one undo tablespace.

A minimum of two undo tablespaces is required to enable truncation of undo logs. See [Section 15.7.8, “Truncating Undo Logs That Reside in Undo Tablespaces”](#).

Undo tablespace files are created in the location defined by `innodb_undo_directory`. File names are in the form of `undo_MNN`, where `MNN` is the undo space number. The default size of an undo tablespace file is 10MiB.

As of MySQL 8.0.2, you can configure `innodb_undo_tablespaces` at startup or while the server is running. Increasing the `innodb_undo_tablespaces` setting creates the specified number of undo tablespaces and adds them to the list of active undo tablespaces. Decreasing the `innodb_undo_tablespaces` setting removes undo tablespaces from the list of active undo tablespaces. However, these undo tablespaces remain active until they are no longer used by existing transactions. Undo tablespaces are made inactive rather than deleted so that the number of active undo tablespaces can be increased again easily.

Prior to MySQL 8.0.2, you can only configure `innodb_undo_tablespaces` when initializing the MySQL instance. The setting cannot be changed afterward. If no value is specified, the instance is initialized using the default setting of 0. Attempting to restart `InnoDB` with a greater number of undo tablespaces than specified when the MySQL instance was initialized results in a startup failure and an error stating that `InnoDB` did not find the expected number of undo tablespaces.

If `innodb_undo_tablespaces` is set to 0, the system tablespace is used for rollback segments. A setting greater than 0 creates that number of undo tablespaces. A value greater than 0 also means that rollback segments in the system tablespace are no longer assigned to transactions.

Note

Setting `innodb_undo_tablespaces` to 0 is deprecated and will not be supported in a future release.

For more information, see [Section 15.7.7, “Storing InnoDB Undo Logs in Separate Tablespaces”](#).

- `innodb_use_native_aio`

Command-Line Format	<code>--innodb-use-native-aio=#</code>	
System Variable	Name	<code>innodb_use_native_aio</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	boolean
	Default	<code>ON</code>

Specifies whether to use the Linux asynchronous I/O subsystem. This variable applies to Linux systems only, and cannot be changed while the server is running. Normally, you do not need to configure this option, because it is enabled by default.

The [asynchronous I/O](#) capability that InnoDB has on Windows systems is available on Linux systems. (Other Unix-like systems continue to use synchronous I/O calls.) This feature improves the scalability of heavily I/O-bound systems, which typically show many pending reads/writes in `SHOW ENGINE INNODB STATUS\G` output.

Running with a large number of InnoDB I/O threads, and especially running multiple such instances on the same server machine, can exceed capacity limits on Linux systems. In this case, you may receive the following error:

```
EAGAIN: The specified maxevents exceeds the user's limit of available events.
```

You can typically address this error by writing a higher limit to `/proc/sys/fs/aio-max-nr`.

However, if a problem with the asynchronous I/O subsystem in the OS prevents InnoDB from starting, you can start the server with `innodb_use_native_aio=0`. This option may also be disabled automatically during startup if InnoDB detects a potential problem such as a combination of `tmpdir` location, `tmpfs` file system, and Linux kernel that does not support AIO on `tmpfs`.

For more information, see [Section 15.6.7, “Using Asynchronous I/O on Linux”](#).

- `innodb_version`

The InnoDB version number. In MySQL 8.0, separate version numbering for InnoDB does not apply and this value is the same the `version` number of the server.

- `innodb_write_io_threads`

Command-Line Format	<code>--innodb-write-io-threads=#</code>	
System Variable	Name	<code>innodb_write_io_threads</code>
	Variable Scope	Global
	Dynamic Variable	No

Permitted Values	Type	integer
	Default	4
	Min Value	1
	Max Value	64

The number of I/O threads for write operations in `InnoDB`. The default value is 4. Its counterpart for read threads is `innodb_read_io_threads`. For more information, see [Section 15.6.6, “Configuring the Number of Background InnoDB I/O Threads”](#). For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

Note

On Linux systems, running multiple MySQL servers (typically more than 12) with default settings for `innodb_read_io_threads`, `innodb_write_io_threads`, and the Linux `aio-max-nr` setting can exceed system limits. Ideally, increase the `aio-max-nr` setting; as a workaround, you might reduce the settings for one or both of the MySQL configuration options.

Also take into consideration the value of `sync_binlog`, which controls synchronization of the binary log to disk.

For general I/O tuning advice, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

15.14 InnoDB INFORMATION_SCHEMA Tables

This section provides information and usage examples for `InnoDB INFORMATION_SCHEMA` tables.

`InnoDB INFORMATION_SCHEMA` tables provide metadata, status information, and statistics about various aspects of the `InnoDB` storage engine. You can view a list of `InnoDB INFORMATION_SCHEMA` tables by issuing a `SHOW TABLES` statement on the `INFORMATION_SCHEMA` database:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB%';
```

For table definitions, see [Section 24.31, “InnoDB INFORMATION_SCHEMA Tables”](#). For general information regarding the `MySQL INFORMATION_SCHEMA` database, see [Chapter 24, INFORMATION_SCHEMA Tables](#).

15.14.1 InnoDB INFORMATION_SCHEMA Tables about Compression

There are two pairs of `InnoDB INFORMATION_SCHEMA` tables about compression that can provide insight into how well compression is working overall:

- `INNODB_CMP` and `INNODB_CMP_RESET` contain information about the number of compression operations and the amount of time spent performing compression.
- `INNODB_CMPMEM` and `INNODB_CMP_RESET` contain information about the way memory is allocated for compression.

15.14.1.1 INNODB_CMP and INNODB_CMP_RESET

The `INNODB_CMP` and `INNODB_CMP_RESET` tables contain status information about operations related to compressed tables, which are described in [Section 15.9, “InnoDB Table and Page Compression”](#). The `PAGE_SIZE` column reports the compressed [page size](#).

These two tables have identical contents, but reading from `INNODB_CMP_RESET` resets the statistics on compression and uncompression operations. For example, if you archive the output of

`INNODB_CMP_RESET` every 60 minutes, you see the statistics for each hourly period. If you monitor the output of `INNODB_CMP` (making sure never to read `INNODB_CMP_RESET`), you see the cumulated statistics since InnoDB was started.

For the table definition, see [Section 24.31.5, “The INFORMATION_SCHEMA INNODB_CMP and INNODB_CMP_RESET Tables”](#).

15.14.1.2 INNODB_CMPMEM and INNODB_CMPMEM_RESET

The `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` tables contain status information about compressed pages that reside in the buffer pool. Please consult [Section 15.9, “InnoDB Table and Page Compression”](#) for further information on compressed tables and the use of the buffer pool. The `INNODB_CMP` and `INNODB_CMP_RESET` tables should provide more useful statistics on compression.

Internal Details

InnoDB uses a [buddy allocator](#) system to manage memory allocated to [pages of various sizes](#), from 1KB to 16KB. Each row of the two tables described here corresponds to a single page size.

The `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` tables have identical contents, but reading from `INNODB_CMPMEM_RESET` resets the statistics on relocation operations. For example, if every 60 minutes you archived the output of `INNODB_CMPMEM_RESET`, it would show the hourly statistics. If you never read `INNODB_CMPMEM_RESET` and monitored the output of `INNODB_CMPMEM` instead, it would show the cumulated statistics since InnoDB was started.

For the table definition, see [Section 24.31.6, “The INFORMATION_SCHEMA INNODB_CMPMEM and INNODB_CMPMEM_RESET Tables”](#).

15.14.1.3 Using the Compression Information Schema Tables

Example 15.1 Using the Compression Information Schema Tables

The following is sample output from a database that contains compressed tables (see [Section 15.9, “InnoDB Table and Page Compression”](#), `INNODB_CMP`, `INNODB_CMP_PER_INDEX`, and `INNODB_CMPMEM`).

The following table shows the contents of `INFORMATION_SCHEMA.INNODB_CMP` under a light [workload](#). The only compressed page size that the buffer pool contains is 8K. Compressing or uncompressing pages has consumed less than a second since the time the statistics were reset, because the columns `COMPRESS_TIME` and `UNCOMPRESS_TIME` are zero.

page size	compress ops	compress ops ok	compress time	uncompress ops	uncompress time
1024	0	0	0	0	0
2048	0	0	0	0	0
4096	0	0	0	0	0
8192	1048	921	0	61	0
16384	0	0	0	0	0

According to `INNODB_CMPMEM`, there are 6169 compressed 8KB pages in the [buffer pool](#). The only other allocated block size is 64 bytes. The smallest `PAGE_SIZE` in `INNODB_CMPMEM` is used for block descriptors of those compressed pages for which no uncompressed page exists in the buffer pool. We see that there are 5910 such pages. Indirectly, we see that 259 (6169-5910) compressed pages also exist in the buffer pool in uncompressed form.

The following table shows the contents of `INFORMATION_SCHEMA.INNODB_CMPMEM` under a light [workload](#). Some memory is unusable due to fragmentation of the memory allocator for compressed pages: `SUM(PAGE_SIZE*PAGES_FREE)=6784`. This is because small memory

allocation requests are fulfilled by splitting bigger blocks, starting from the 16K blocks that are allocated from the main buffer pool, using the buddy allocation system. The fragmentation is this low because some allocated blocks have been relocated (copied) to form bigger adjacent free blocks. This copying of `SUM(PAGE_SIZE*RELOCATION_OPS)` bytes has consumed less than a second (`SUM(RELOCATION_TIME)=0`).

page size	pages used	pages free	relocation ops	relocation time
64	5910	0	2436	0
128	0	1	0	0
256	0	0	0	0
512	0	1	0	0
1024	0	0	0	0
2048	0	1	0	0
4096	0	1	0	0
8192	6169	0	5	0
16384	0	0	0	0

15.14.2 InnoDB INFORMATION_SCHEMA Transaction and Locking Information

Note

This section describes locking information as exposed by the Performance Schema `data_locks` and `data_lock_waits` tables, which supersede the `INFORMATION_SCHEMA INNODB_LOCKS` and `INNODB_LOCK_WAITS` tables in MySQL 8.0. For similar discussion written in terms of the older `INFORMATION_SCHEMA` tables, see [InnoDB INFORMATION_SCHEMA Transaction and Locking Information](#) in [MySQL 5.7 Reference Manual](#).

One `INFORMATION_SCHEMA` table and two Performance Schema tables enable you to monitor InnoDB transactions and diagnose potential locking problems:

- `INNODB_TRX`: This `INFORMATION_SCHEMA` table contains information about every transaction currently executing inside InnoDB, including the transaction state (for example, whether it is running or waiting for a lock), when the transaction started, and the particular SQL statement the transaction is executing.
- `data_locks`: This Performance Schema table contains a row for each held lock and each lock request that is blocked waiting for a held lock to be released:
 - There is one row for each held lock, whatever the state of the transaction that holds the lock (`INNODB_TRX.TRX_STATE` is `RUNNING`, `LOCK WAIT`, `ROLLING BACK` or `COMMITTING`).
 - Each transaction in InnoDB that is waiting for another transaction to release a lock (`INNODB_TRX.TRX_STATE` is `LOCK WAIT`) is blocked by exactly one blocking lock request. That blocking lock request is for a row or table lock held by another transaction in an incompatible mode. A lock request always has a mode that is incompatible with the mode of the held lock that blocks the request (read vs. write, shared vs. exclusive).

The blocked transaction cannot proceed until the other transaction commits or rolls back, thereby releasing the requested lock. For every blocked transaction, `data_locks` contains one row that describes each lock the transaction has requested, and for which it is waiting.

- `data_lock_waits`: This Performance Schema table indicates which transactions are waiting for a given lock, or for which lock a given transaction is waiting. This table contains one or more rows for

each blocked transaction, indicating the lock it has requested and any locks that are blocking that request. The `REQUESTING_ENGINE_LOCK_ID` value refers to the lock requested by a transaction, and the `BLOCKING_ENGINE_LOCK_ID` value refers to the lock (held by another transaction) that prevents the first transaction from proceeding. For any given blocked transaction, all rows in `data_lock_waits` have the same value for `REQUESTING_ENGINE_LOCK_ID` and different values for `BLOCKING_ENGINE_LOCK_ID`.

For more information about the preceding tables, see [Section 24.31.28, “The INFORMATION_SCHEMA INNODB_TRX Table”](#), [Section 25.11.12.1, “The data_locks Table”](#), and [Section 25.11.12.2, “The data_lock_waits Table”](#).

15.14.2.1 Using InnoDB Transaction and Locking Information

Note

This section describes locking information as exposed by the Performance Schema `data_locks` and `data_lock_waits` tables, which supersede the `INFORMATION_SCHEMA INNODB_LOCKS` and `INNODB_LOCK_WAITS` tables in MySQL 8.0. For similar discussion written in terms of the older `INFORMATION_SCHEMA` tables, see [Using InnoDB Transaction and Locking Information](#) in [MySQL 5.7 Reference Manual](#).

Identifying Blocking Transactions

It is sometimes helpful to identify which transaction blocks another. The tables that contain information about InnoDB transactions and data locks enable you to determine which transaction is waiting for another, and which resource is being requested. (For descriptions of these tables, see [Section 15.14.2, “InnoDB INFORMATION_SCHEMA Transaction and Locking Information”](#).)

Suppose that three sessions are running concurrently. Each session corresponds to a MySQL thread, and executes one transaction after another. Consider the state of the system when these sessions have issued the following statements, but none has yet committed its transaction:

- Session A:

```
BEGIN;
SELECT a FROM t FOR UPDATE;
SELECT SLEEP(100);
```

- Session B:

```
SELECT b FROM t FOR UPDATE;
```

- Session C:

```
SELECT c FROM t FOR UPDATE;
```

In this scenario, use the following query to see which transactions are waiting and which transactions are blocking them:

```
SELECT
  r.trx_id waiting_trx_id,
  r.trx_mysql_thread_id waiting_thread,
  r.trx_query waiting_query,
  b.trx_id blocking_trx_id,
  b.trx_mysql_thread_id blocking_thread,
  b.trx_query blocking_query
FROM
  performance_schema.data_lock_waits w
INNER JOIN information_schema.innodb_trx b
```

```
ON b.trx_id = w.blocking_engine_transaction_id
INNER JOIN information_schema.innodb_trx r
ON r.trx_id = w.requesting_engine_transaction_id;
```

Or, more simply, use the `sys` schema `innodb_lock_waits` view:

```
SELECT
  waiting_trx_id,
  waiting_pid,
  waiting_query,
  blocking_trx_id,
  blocking_pid,
  blocking_query
FROM sys.innodb_lock_waits;
```

waiting trx id	waiting thread	waiting query	blocking trx id	blocking thread	blocking query
A4	6	SELECT b FROM t FOR UPDATE	A3	5	SELECT SLEEP(100)
A5	7	SELECT c FROM t FOR UPDATE	A3	5	SELECT SLEEP(100)
A5	7	SELECT c FROM t FOR UPDATE	A4	6	SELECT b FROM t FOR UPDATE

In the preceding table, you can identify sessions by the “waiting query” or “blocking query” columns. As you can see:

- Session B (trx id `A4`, thread `6`) and Session C (trx id `A5`, thread `7`) are both waiting for Session A (trx id `A3`, thread `5`).
- Session C is waiting for Session B as well as Session A.

You can see the underlying data in the `INFORMATION_SCHEMA.INNODB_TRX` table and Performance Schema `data_locks` and `data_lock_waits` tables.

The following table shows some sample contents of the `INNODB_TRX` table.

trx id	trx state	trx started	trx requested lock id	trx wait started	trx weight	trx mysql thread id	trx query
A3	RUNNING	2008-01-15 16:44:54	NULL	NULL	2	5	SELECT SLEEP(100)
A4	LOCK WAIT	2008-01-15 16:45:09	A4:1:3:2	2008-01-15 16:45:09	2	6	SELECT b FROM t FOR UPDATE
A5	LOCK WAIT	2008-01-15 16:45:14	A5:1:3:2	2008-01-15 16:45:14	2	7	SELECT c FROM t FOR UPDATE

The following table shows some sample contents of the `data_locks` table.

lock id	lock trx id	lock mode	lock type	lock schema	lock table	lock index	lock data
A3:1:3:2	A3	X	RECORD	test	t	PRIMARY	0x0200
A4:1:3:2	A4	X	RECORD	test	t	PRIMARY	0x0200
A5:1:3:2	A5	X	RECORD	test	t	PRIMARY	0x0200

The following table shows some sample contents of the `data_lock_waits` table.

requesting trx id	requested lock id	blocking trx id	blocking lock id
A4	A4:1:3:2	A3	A3:1:3:2
A5	A5:1:3:2	A3	A3:1:3:2
A5	A5:1:3:2	A4	A4:1:3:2

Correlating InnoDB Transactions with MySQL Sessions

Sometimes it is useful to correlate internal `InnoDB` locking information with the session-level information maintained by MySQL. For example, you might like to know, for a given `InnoDB` transaction ID, the corresponding MySQL session ID and name of the session that may be holding a lock, and thus blocking other transactions.

The following output from the `INFORMATION_SCHEMA.INNODB_TRX` table and Performance Schema `data_locks` and `data_lock_waits` tables is taken from a somewhat loaded system. As can be seen, there are several transactions running.

The following `data_locks` and `data_lock_waits` tables show that:

- Transaction `77F` (executing an `INSERT`) is waiting for transactions `77E`, `77D`, and `77B` to commit.
- Transaction `77E` (executing an `INSERT`) is waiting for transactions `77D` and `77B` to commit.
- Transaction `77D` (executing an `INSERT`) is waiting for transaction `77B` to commit.
- Transaction `77B` (executing an `INSERT`) is waiting for transaction `77A` to commit.
- Transaction `77A` is running, currently executing `SELECT`.
- Transaction `E56` (executing an `INSERT`) is waiting for transaction `E55` to commit.
- Transaction `E55` (executing an `INSERT`) is waiting for transaction `19C` to commit.
- Transaction `19C` is running, currently executing an `INSERT`.

Note

There may be inconsistencies between queries shown in the `INFORMATION_SCHEMA.PROCESSLIST` and `INNODB_TRX` tables. For an explanation, see [Section 15.14.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”](#).

The following table shows the contents of the `PROCESSLIST` table for a system running a heavy workload.

ID	USER	HOST	DB	COMMAND	TIME	STATE	INFO
384	root	localhost	test	Query	10	update	INSERT INTO t2 VALUES ...
257	root	localhost	test	Query	3	update	INSERT INTO t2 VALUES ...
130	root	localhost	test	Query	0	update	INSERT INTO t2 VALUES ...
61	root	localhost	test	Query	1	update	INSERT INTO t2 VALUES ...
8	root	localhost	test	Query	1	update	INSERT INTO t2 VALUES ...

ID	USER	HOST	DB	COMMAND	TIME	STATE	INFO
4	root	localhost	test	Query	0	preparing	SELECT * FROM PROCESSLIST
2	root	localhost	test	Sleep	566		NULL

The following table shows the contents of the `INNODB_TRX` table for a system running a heavy workload.

trx id	trx state	trx started	trx requested lock id	trx wait started	trx weight	trx mysql thread id	trx query
77F	LOCK WAIT	2008-01-15 13:10:16	77F	2008-01-15 13:10:16	1	876	INSERT INTO t09 (D, B, C) VALUES ...
77E	LOCK WAIT	2008-01-15 13:10:16	77E	2008-01-15 13:10:16	1	875	INSERT INTO t09 (D, B, C) VALUES ...
77D	LOCK WAIT	2008-01-15 13:10:16	77D	2008-01-15 13:10:16	1	874	INSERT INTO t09 (D, B, C) VALUES ...
77B	LOCK WAIT	2008-01-15 13:10:16	77B:733:12:1	2008-01-15 13:10:16	4	873	INSERT INTO t09 (D, B, C) VALUES ...
77A	RUNNING	2008-01-15 13:10:16	NULL	NULL	4	872	SELECT b, c FROM t09 WHERE ...
E56	LOCK WAIT	2008-01-15 13:10:06	E56:743:6:2	2008-01-15 13:10:06	5	384	INSERT INTO t2 VALUES ...
E55	LOCK WAIT	2008-01-15 13:10:06	E55:743:38:2	2008-01-15 13:10:13	965	257	INSERT INTO t2 VALUES ...
19C	RUNNING	2008-01-15 13:09:10	NULL	NULL	2900	130	INSERT INTO t2 VALUES ...
E15	RUNNING	2008-01-15 13:08:59	NULL	NULL	5395	61	INSERT INTO t2 VALUES ...
51D	RUNNING	2008-01-15 13:08:47	NULL	NULL	9807	8	INSERT INTO t2 VALUES ...

The following table shows the contents of the `data_lock_waits` table for a system running a heavy workload.

requesting trx id	requested lock id	blocking trx id	blocking lock id
77F	77F:806	77E	77E:806
77F	77F:806	77D	77D:806

15.14.2.2 InnoDB Lock and Lock-Wait Information

Note

This section describes locking information as exposed by the Performance Schema `data_locks` and `data_lock_waits` tables, which supersede the `INFORMATION_SCHEMA INNODB_LOCKS` and `INNODB_LOCK_WAITS` tables in MySQL 8.0. For similar discussion written in terms of the older `INFORMATION_SCHEMA` tables, see [InnoDB Lock and Lock-Wait Information](#) in [MySQL 5.7 Reference Manual](#).

When a transaction updates a row in a table, or locks it with `SELECT FOR UPDATE`, InnoDB establishes a list or queue of locks on that row. Similarly, InnoDB maintains a list of locks on a table for table-level locks. If a second transaction wants to update a row or lock a table already locked by a prior transaction in an incompatible mode, InnoDB adds a lock request for the row to the corresponding queue. For a lock to be acquired by a transaction, all incompatible lock requests previously entered into the lock queue for that row or table must be removed (which occurs when the transactions holding or requesting those locks either commit or roll back).

A transaction may have any number of lock requests for different rows or tables. At any given time, a transaction may request a lock that is held by another transaction, in which case it is blocked by that other transaction. The requesting transaction must wait for the transaction that holds the blocking lock to commit or roll back. If a transaction is not waiting for a lock, it is in a `RUNNING` state. If a transaction is waiting for a lock, it is in a `LOCK WAIT` state. (The `INFORMATION_SCHEMA INNODB_TRX` table indicates transaction state values.)

The Performance Schema `data_locks` table holds one or more rows for each `LOCK WAIT` transaction, indicating any lock requests that prevent its progress. This table also contains one row describing each lock in a queue of locks pending for a given row or table. The Performance Schema `data_lock_waits` table shows which locks already held by a transaction are blocking locks requested by other transactions.

15.14.2.3 Persistence and Consistency of InnoDB Transaction and Locking Information

Note

This section describes locking information as exposed by the Performance Schema `data_locks` and `data_lock_waits` tables, which supersede the `INFORMATION_SCHEMA INNODB_LOCKS` and `INNODB_LOCK_WAITS` tables in MySQL 8.0. For similar discussion written in terms of the older `INFORMATION_SCHEMA` tables, see [Persistence and Consistency of InnoDB Transaction and Locking Information](#) in [MySQL 5.7 Reference Manual](#).

The data exposed by the transaction and locking tables (`INFORMATION_SCHEMA INNODB_TRX` table, Performance Schema `data_locks` and `data_lock_waits` tables) represents a glimpse into fast-changing data. This is not like user tables, where the data changes only when application-initiated updates occur. The underlying data is internal system-managed data, and can change very quickly:

- Data might not be consistent between the `INNODB_TRX`, `data_locks`, and `data_lock_waits` tables.

The `data_locks` and `data_lock_waits` tables expose live data from the InnoDB storage engine, to provide lock information about the transactions in the `INNODB_TRX` table. Data retrieved from the lock tables exists when the `SELECT` is executed, but might be gone or changed by the time the query result is consumed by the client.

Joining `data_locks` with `data_lock_waits` can show rows in `data_lock_waits` that identify a parent row in `data_locks` that no longer exists or does not exist yet.

- Data in the transaction and locking tables might not be consistent with data in the `INFORMATION_SCHEMA PROCESSLIST` table or Performance Schema `threads` table.

For example, you should be careful when comparing data in the InnoDB transaction and locking tables with data in the `PROCESSLIST` table. Even if you issue a single `SELECT` (joining `INNODB_TRX` and `PROCESSLIST`, for example), the content of those tables is generally not consistent. It is possible for `INNODB_TRX` to reference rows that are not present in `PROCESSLIST` or for the currently executing SQL query of a transaction shown in `INNODB_TRX.TRX_QUERY` to differ from the one in `PROCESSLIST.INFO`.

15.14.3 InnoDB INFORMATION_SCHEMA System Tables

You can extract metadata about schema objects managed by InnoDB using InnoDB `INFORMATION_SCHEMA` system tables. This information comes from the data dictionary. Traditionally, you would get this type of information using the techniques from [Section 15.16, “InnoDB Monitors”](#), setting up InnoDB monitors and parsing the output from the `SHOW ENGINE INNODB STATUS` statement. The InnoDB `INFORMATION_SCHEMA` table interface allows you to query this data using SQL.

With the exception of `INNODB_SYS_TABLESTATS`, for which there is no corresponding internal system table, InnoDB `INFORMATION_SCHEMA` system tables are populated with data read directly from internal InnoDB system tables rather than from metadata that is cached in memory.

InnoDB `INFORMATION_SCHEMA` system tables include the tables listed below. `INNODB_SYS_DATAFILES` and `INNODB_SYS_TABLESPACES` were added in with the introduction of support for the `DATA DIRECTORY='directory'` clause of the `CREATE TABLE` statement, which allows InnoDB file-per-table tablespaces (`.ibd` files) to be created in a location outside the MySQL data directory.

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_SYS%';
+-----+
| Tables_in_information_schema (INNODB_SYS%) |
+-----+
```

```

| INNODB_SYS_DATAFILES
| INNODB_SYS_TABLESTATS
| INNODB_SYS_FOREIGN
| INNODB_SYS_COLUMNS
| INNODB_SYS_INDEXES
| INNODB_SYS_FIELDS
| INNODB_SYS_TABLESPACES
| INNODB_SYS_FOREIGN_COLS
| INNODB_SYS_TABLES
+-----+

```

The table names are indicative of the type of data provided:

- `INNODB_SYS_TABLES` provides metadata about `InnoDB` tables.
- `INNODB_SYS_COLUMNS` provides metadata about `InnoDB` table columns.
- `INNODB_SYS_INDEXES` provides metadata about `InnoDB` indexes.
- `INNODB_SYS_FIELDS` provides metadata about the key columns (fields) of `InnoDB` indexes.
- `INNODB_SYS_TABLESTATS` provides a view of low-level status information about `InnoDB` tables that is derived from in-memory data structures.
- `INNODB_SYS_DATAFILES` provides data file path information for `InnoDB` file-per-table and general tablespaces.
- `INNODB_SYS_TABLESPACES` provides metadata about `InnoDB` file-per-table and general tablespaces.
- `INNODB_SYS_FOREIGN` provides metadata about foreign keys defined on `InnoDB` tables.
- `INNODB_SYS_FOREIGN_COLS` provides metadata about the columns of foreign keys that are defined on `InnoDB` tables.

`InnoDB INFORMATION_SCHEMA` system tables can be joined together through fields such as `TABLE_ID`, `INDEX_ID`, and `SPACE`, allowing you to easily retrieve all available data for an object you want to study or monitor.

Refer to the `InnoDB INFORMATION_SCHEMA` documentation for information about the columns of each table.

Example 15.2 InnoDB INFORMATION_SCHEMA System Tables

This example uses a simple table (`t1`) with a single index (`i1`) to demonstrate the type of metadata found in the `InnoDB INFORMATION_SCHEMA` system tables.

1. Create a test database and table `t1`:

```

mysql> CREATE DATABASE test;

mysql> USE test;

mysql> CREATE TABLE t1 (
  col1 INT,
  col2 CHAR(10),
  col3 VARCHAR(10))
ENGINE = InnoDB;

mysql> CREATE INDEX i1 ON t1(col1);

```

2. After creating the table `t1`, query `INNODB_SYS_TABLES` to locate the metadata for `test/t1`:

```

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME='test/t1' \G

```

```
***** 1. row *****
TABLE_ID: 71
NAME: test/t1
FLAG: 1
N_COLS: 6
SPACE: 57
ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0
...
```

Table `t1` has a `TABLE_ID` of 71. The `FLAG` field provides bit level information about table format and storage characteristics. There are six columns, three of which are hidden columns created by InnoDB (`DB_ROW_ID`, `DB_TRX_ID`, and `DB_ROLL_PTR`). The ID of the table's `SPACE` is 57 (a value of 0 would indicate that the table resides in the system tablespace). The `ROW_FORMAT` is Compact. `ZIP_PAGE_SIZE` only applies to tables with a `Compressed` row format.

- Using the `TABLE_ID` information from `INNODB_SYS_TABLES`, query the `INNODB_SYS_COLUMNS` table for information about the table's columns.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_COLUMNS where TABLE_ID = 71 \G
***** 1. row *****
TABLE_ID: 71
NAME: col1
POS: 0
MTYPE: 6
PRTYPE: 1027
LEN: 4
***** 2. row *****
TABLE_ID: 71
NAME: col2
POS: 1
MTYPE: 2
PRTYPE: 524542
LEN: 10
***** 3. row *****
TABLE_ID: 71
NAME: col3
POS: 2
MTYPE: 1
PRTYPE: 524303
LEN: 10
```

In addition to the `TABLE_ID` and column `NAME`, `INNODB_SYS_COLUMNS` provides the ordinal position (`POS`) of each column (starting from 0 and incrementing sequentially), the column `MTYPE` or “main type” (6 = INT, 2 = CHAR, 1 = VARCHAR), the `PRTYPE` or “precise type” (a binary value with bits that represent the MySQL data type, character set code, and nullability), and the column length (`LEN`).

- Using the `TABLE_ID` information from `INNODB_SYS_TABLES` once again, query `INNODB_SYS_INDEXES` for information about the indexes associated with table `t1`.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_INDEXES WHERE TABLE_ID = 71 \G
***** 1. row *****
INDEX_ID: 111
NAME: GEN_CLUST_INDEX
TABLE_ID: 71
TYPE: 1
N_FIELDS: 0
PAGE_NO: 3
SPACE: 57
MERGE_THRESHOLD: 50
***** 2. row *****
INDEX_ID: 112
NAME: i1
TABLE_ID: 71
TYPE: 0
N_FIELDS: 1
PAGE_NO: 4
SPACE: 57
```

```
MERGE_THRESHOLD: 50
```

`INNODB_SYS_INDEXES` returns data for two indexes. The first index is `GEN_CLUST_INDEX`, which is a clustered index created by InnoDB if the table does not have a user-defined clustered index. The second index (`i1`) is the user-defined secondary index.

The `INDEX_ID` is an identifier for the index that is unique across all databases in an instance. The `TABLE_ID` identifies the table that the index is associated with. The index `TYPE` value indicates the type of index (1 = Clustered Index, 0 = Secondary index). The `N_FIELDS` value is the number of fields that comprise the index. `PAGE_NO` is the root page number of the index B-tree, and `SPACE` is the ID of the tablespace where the index resides. A non-zero value indicates that the index does not reside in the system tablespace. `MERGE_THRESHOLD` defines a percentage threshold value for the amount of data in an index page. If the amount of data in an index page falls below the this value (the default is 50%) when a row is deleted or when a row is shortened by an update operation, InnoDB attempts to merge the index page with a neighboring index page.

- Using the `INDEX_ID` information from `INNODB_SYS_INDEXES`, query `INNODB_SYS_FIELDS` for information about the fields of index `i1`.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FIELDS where INDEX_ID = 112 \G
***** 1. row *****
INDEX_ID: 112
NAME: coll
POS: 0
```

`INNODB_SYS_FIELDS` provides the `NAME` of the indexed field and its ordinal position within the index. If the index (`i1`) had been defined on multiple fields, `INNODB_SYS_FIELDS` would provide metadata for each of the indexed fields.

- Using the `SPACE` information from `INNODB_SYS_TABLES`, query `INNODB_SYS_TABLESPACES` table for information about the table's tablespace.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE SPACE = 57 \G
***** 1. row *****
SPACE: 57
NAME: test/t1
FLAG: 0
ROW_FORMAT: Compact or Redundant
PAGE_SIZE: 16384
ZIP_PAGE_SIZE: 0
```

In addition to the `SPACE` ID of the tablespace and the `NAME` of the associated table, `INNODB_SYS_TABLESPACES` provides tablespace `FLAG` data, which is bit level information about tablespace format and storage characteristics. Also provided are tablespace `ROW_FORMAT`, `PAGE_SIZE`, and `ZIP_PAGE_SIZE` data (`ZIP_PAGE_SIZE` is applicable to tablespaces with a `Compressed` row format).

- Using the `SPACE` information from `INNODB_SYS_TABLES` once again, query `INNODB_SYS_DATAFILES` for the location of the tablespace data file.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_DATAFILES WHERE SPACE = 57 \G
***** 1. row *****
SPACE: 57
PATH: ./test/t1.ibd
```

The datafile is located in the `test` directory under MySQL's `data` directory. If a `file-per-table` tablespace were created in a location outside the MySQL data directory using the `DATA DIRECTORY` clause of the `CREATE TABLE` statement, the tablespace `PATH` would be a fully qualified directory path.

- As a final step, insert a row into table `t1` (`TABLE_ID = 71`) and view the data in the `INNODB_SYS_TABLESTATS` table. The data in this table is used by the MySQL optimizer to calculate which index to use when querying an InnoDB table. This information is derived from in-memory data structures. There is no corresponding internal InnoDB system table.

```
mysql> INSERT INTO t1 VALUES(5, 'abc', 'def');
Query OK, 1 row affected (0.06 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS where TABLE_ID = 71 \G
***** 1. row *****
      TABLE_ID: 71
          NAME: test/t1
STATS_INITIALIZED: Initialized
      NUM_ROWS: 1
  CLUST_INDEX_SIZE: 1
  OTHER_INDEX_SIZE: 0
  MODIFIED_COUNTER: 1
      AUTOINC: 0
      REF_COUNT: 1
```

The `STATS_INITIALIZED` field indicates whether or not statistics have been collected for the table. `NUM_ROWS` is the current estimated number of rows in the table. The `CLUST_INDEX_SIZE` and `OTHER_INDEX_SIZE` fields report the number of pages on disk that store clustered and secondary indexes for the table, respectively. The `MODIFIED_COUNTER` value shows the number of rows modified by DML operations and cascade operations from foreign keys. The `AUTOINC` value is the next number to be issued for any autoincrement-based operation. There are no autoincrement columns defined on table `t1`, so the value is 0. The `REF_COUNT` value is a counter. When the counter reaches 0, it signifies that the table metadata can be evicted from the table cache.

Example 15.3 Foreign Key INFORMATION_SCHEMA System Tables

The `INNODB_SYS_FOREIGN` and `INNODB_SYS_FOREIGN_COLS` tables provide data about foreign key relationships. This example uses a parent table and child table with a foreign key relationship to demonstrate the data found in the `INNODB_SYS_FOREIGN` and `INNODB_SYS_FOREIGN_COLS` tables.

1. Create the test database with parent and child tables:

```
mysql> CREATE DATABASE test;

mysql> USE test;

mysql> CREATE TABLE parent (id INT NOT NULL,
-> PRIMARY KEY (id)) ENGINE=INNODB;

mysql> CREATE TABLE child (id INT, parent_id INT,
-> INDEX par_ind (parent_id),
-> CONSTRAINT fk1
-> FOREIGN KEY (parent_id) REFERENCES parent(id)
-> ON DELETE CASCADE) ENGINE=INNODB;
```

2. After the parent and child tables are created, query `INNODB_SYS_FOREIGN` and locate the foreign key data for the `test/child` and `test/parent` foreign key relationship:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN \G
***** 1. row *****
      ID: test/fk1
  FOR_NAME: test/child
  REF_NAME: test/parent
     N_COLS: 1
      TYPE: 1
```

Metadata includes the foreign key `ID` (`fk1`), which is named for the `CONSTRAINT` that was defined on the child table. The `FOR_NAME` is the name of the child table where the foreign key is defined. `REF_NAME` is the name of the parent table (the “referenced” table). `N_COLS` is the number of columns in the foreign key index. `TYPE` is a numerical value representing bit flags that provide additional information about the foreign key column. In this case, the `TYPE` value is 1, which indicates that the `ON DELETE CASCADE` option was specified for the foreign key. See the `INNODB_SYS_FOREIGN` table definition for more information about `TYPE` values.

3. Using the foreign key `ID`, query `INNODB_SYS_FOREIGN_COLS` to view data about the columns of the foreign key.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNO_DB_SYS_FOREIGN_COLS WHERE ID = 'test/fk1' \G
***** 1. row *****
      ID: test/fk1
FOR_COL_NAME: parent_id
REF_COL_NAME: id
      POS: 0
```

`FOR_COL_NAME` is the name of the foreign key column in the child table, and `REF_COL_NAME` is the name of the referenced column in the parent table. The `POS` value is the ordinal position of the key field within the foreign key index, starting at zero.

Example 15.4 Joining InnoDB INFORMATION_SCHEMA System Tables

This example demonstrates joining three InnoDB INFORMATION_SCHEMA system tables (`INNO_DB_SYS_TABLES`, `INNO_DB_SYS_TABLESPACES`, and `INNO_DB_SYS_TABLESTATS`) to gather file format, row format, page size, and index size information about tables in the employees sample database.

The following table name aliases are used to shorten the query string:

- `INFORMATION_SCHEMA.INNO_DB_SYS_TABLES`: a
- `INFORMATION_SCHEMA.INNO_DB_SYS_TABLESPACES`: b
- `INFORMATION_SCHEMA.INNO_DB_SYS_TABLESTATS`: c

An `IF()` control flow function is used to account for compressed tables. If a table is compressed, the index size is calculated using `ZIP_PAGE_SIZE` rather than `PAGE_SIZE`. `CLUST_INDEX_SIZE` and `OTHER_INDEX_SIZE`, which are reported in bytes, are divided by `1024*1024` to provide index sizes in megabytes (MBs). MB values are rounded to zero decimal spaces using the `ROUND()` function.

```
mysql> SELECT a.NAME, a.ROW_FORMAT,
@page_size :=
  IF(a.ROW_FORMAT='Compressed',
    b.ZIP_PAGE_SIZE, b.PAGE_SIZE)
  AS page_size,
ROUND((@page_size * c.CLUST_INDEX_SIZE)
/(1024*1024)) AS pk_mb,
ROUND((@page_size * c.OTHER_INDEX_SIZE)
/(1024*1024)) AS secidx_mb
FROM INFORMATION_SCHEMA.INNO_DB_SYS_TABLES a
INNER JOIN INFORMATION_SCHEMA.INNO_DB_SYS_TABLESPACES b on a.NAME = b.NAME
INNER JOIN INFORMATION_SCHEMA.INNO_DB_SYS_TABLESTATS c on b.NAME = c.NAME
WHERE a.NAME LIKE 'employees/%'
ORDER BY a.NAME DESC;
```

NAME	ROW_FORMAT	page_size	pk_mb	secidx_mb
employees/titles	Dynamic	16384	20	11
employees/salaries	Dynamic	16384	93	34
employees/employees	Dynamic	16384	15	0
employees/dept_manager	Dynamic	16384	0	0
employees/dept_emp	Dynamic	16384	12	10
employees/departments	Dynamic	16384	0	0

15.14.4 InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables

The following tables store metadata for FULLTEXT indexes:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNO_DB_FT%';
+-----+
| Tables_in_INFORMATION_SCHEMA (INNO_DB_FT%) |
+-----+
| INNO_DB_FT_CONFIG |
| INNO_DB_FT_BEING_DELETED |
```

INNODB_FT_DELETED	
INNODB_FT_DEFAULT_STOPWORD	
INNODB_FT_INDEX_TABLE	
INNODB_FT_INDEX_CACHE	

Table Overview

- **INNODB_FT_CONFIG**: Displays metadata about the **FULLTEXT** index and associated processing for an **InnoDB** table.
- **INNODB_FT_BEING_DELETED**: Provides a snapshot of the **INNODB_FT_DELETED** table that is only used during an **OPTIMIZE TABLE** maintenance operation. When **OPTIMIZE TABLE** is run, the **INNODB_FT_BEING_DELETED** table is emptied, and **DOC_IDs** are removed from the **INNODB_FT_DELETED** table. Because the contents of **INNODB_FT_BEING_DELETED** typically have a short lifetime, this table has limited utility for monitoring or debugging. For information about running **OPTIMIZE TABLE** on tables with **FULLTEXT** indexes, see [Section 12.9.6, “Fine-Tuning MySQL Full-Text Search”](#).
- **INNODB_FT_DELETED**: Records rows that are deleted from the **FULLTEXT** index for an **InnoDB** table. To avoid expensive index reorganization during DML operations for an **InnoDB FULLTEXT** index, the information about newly deleted words is stored separately, filtered out of search results when you perform a text search, and removed from the main search index only when you run **OPTIMIZE TABLE**.
- **INNODB_FT_DEFAULT_STOPWORD**: Holds a list of **stopwords** that are used by default when creating a **FULLTEXT** index.

For information about the **INNODB_FT_DEFAULT_STOPWORD** table, see [Section 12.9.4, “Full-Text Stopwords”](#).

- **INNODB_FT_INDEX_TABLE**: Contains data about the inverted index used to process text searches against the **FULLTEXT** index.
- **INNODB_FT_INDEX_CACHE**: Contains token information about newly inserted rows in a **FULLTEXT** index. To avoid expensive index reorganization during DML operations, the information about newly indexed words is stored separately, and combined with the main search index only when **OPTIMIZE TABLE** is run, when the server is shut down, or when the cache size exceeds a limit defined by **innodb_ft_cache_size** or **innodb_ft_total_cache_size**.

Note

With the exception of the **INNODB_FT_DEFAULT_STOPWORD** table, you must set the **innodb_ft_aux_table** configuration variable to the name of the table (*database_name/table_name*) that contains the **FULLTEXT** index. Otherwise, the **InnoDB FULLTEXT** index **INFORMATION_SCHEMA** tables appear empty.

Example 15.5 InnoDB FULLTEXT Index INFORMATION_SCHEMA Tables

This example uses a table with a **FULLTEXT** index to demonstrate the data contained in the **FULLTEXT** index **INFORMATION_SCHEMA** tables.

1. Create a table with a **FULLTEXT** index and insert some data:

```
mysql> CREATE TABLE articles (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  title VARCHAR(200),
  body TEXT,
  FULLTEXT (title,body)
) ENGINE=InnoDB;

INSERT INTO articles (title,body) VALUES
('MySQL Tutorial','DBMS stands for DataBase ...');
```

```
('How To Use MySQL Well','After you went through a ...'),
('Optimizing MySQL','In this tutorial we will show ...'),
('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
('MySQL vs. YourSQL','In the following database comparison ...'),
('MySQL Security','When configured properly, MySQL ...');
```

2. Set the `innodb_ft_aux_table` variable to the name of the table with the `FULLTEXT` index. If this variable is not set, the `InnoDB FULLTEXT INFORMATION_SCHEMA` tables appear empty, with the exception of the `INNODB_FT_DEFAULT_STOPWORD` table.

```
SET GLOBAL innodb_ft_aux_table = 'test/articles';
```

3. Query the `INNODB_FT_INDEX_CACHE` table, which shows information about newly inserted rows in a `FULLTEXT` index. To avoid expensive index reorganization during DML operations, data for newly inserted rows remains in the `FULLTEXT` index cache until `OPTIMIZE TABLE` is run (or until the server is shutdown or cache limits are exceeded).

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE LIMIT 5;
```

WORD	FIRST_DOC_ID	LAST_DOC_ID	DOC_COUNT	DOC_ID	POSITION
1001	5	5	1	5	0
after	3	3	1	3	22
comparison	6	6	1	6	44
configured	7	7	1	7	20
database	2	6	2	2	31

4. Enable `innodb_optimize_fulltext_only` and run `OPTIMIZE TABLE` on the table that contains the `FULLTEXT` index. This operation flushes the contents of the `FULLTEXT` index cache to the main `FULLTEXT` index. `innodb_optimize_fulltext_only` changes the way the `OPTIMIZE TABLE` statement operates on `InnoDB` tables, and is intended to be enabled temporarily, during maintenance operations on `InnoDB` tables with `FULLTEXT` indexes.

```
mysql> SET GLOBAL innodb_optimize_fulltext_only=ON;
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> OPTIMIZE TABLE articles;
```

Table	Op	Msg_type	Msg_text
test.articles	optimize	status	OK

5. Query the `INNODB_FT_INDEX_TABLE` table to view information about data in the main `FULLTEXT` index, including information about the data that was just flushed from the `FULLTEXT` index cache.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_TABLE LIMIT 5;
```

WORD	FIRST_DOC_ID	LAST_DOC_ID	DOC_COUNT	DOC_ID	POSITION
1001	5	5	1	5	0
after	3	3	1	3	22
comparison	6	6	1	6	44
configured	7	7	1	7	20
database	2	6	2	2	31

The `INNODB_FT_INDEX_CACHE` table is now empty since the `OPTIMIZE TABLE` operation flushed the `FULLTEXT` index cache.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_INDEX_CACHE LIMIT 5;
Empty set (0.00 sec)
```

6. Delete some records from the `test/articles` table.

```
mysql> DELETE FROM test.articles WHERE id < 4;
Query OK, 3 rows affected (0.11 sec)
```

7. Query the `INNODB_FT_DELETED` table. This table records rows that are deleted from the `FULLTEXT` index. To avoid expensive index reorganization during DML operations, information about newly deleted records is stored separately, filtered out of search results when you do a text search, and removed from the main search index when you run `OPTIMIZE TABLE`.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
+-----+
| DOC_ID |
+-----+
|      2 |
|      3 |
|      4 |
+-----+
```

8. Run `OPTIMIZE TABLE` to remove the deleted records.

```
mysql> OPTIMIZE TABLE articles;
+-----+-----+-----+-----+
| Table          | Op       | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.articles | optimize | status   | OK       |
+-----+-----+-----+-----+
```

The `INNODB_FT_DELETED` table should now appear empty.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
Empty set (0.00 sec)
```

9. Query the `INNODB_FT_CONFIG` table. This table contains metadata about the `FULLTEXT` index and related processing:
- `optimize_checkpoint_limit` is the number of seconds after which an `OPTIMIZE TABLE` run stops.
 - `synced_doc_id` is the next `DOC_ID` to be issued.
 - `stopword_table_name` is the `database/table` name for a user-defined stopword table. This field appears empty if there is no user-defined stopword table.
 - `use_stopword` indicates whether or not a stopword table is used, which is defined when the `FULLTEXT` index is created.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_CONFIG;
+-----+-----+
| KEY                               | VALUE |
+-----+-----+
| optimize_checkpoint_limit         | 180   |
| synced_doc_id                     | 8     |
| stopword_table_name               |       |
| use_stopword                      | 1     |
+-----+-----+
```

15.14.5 InnoDB INFORMATION_SCHEMA Buffer Pool Tables

The `InnoDB INFORMATION_SCHEMA` buffer pool tables provide buffer pool status information and metadata about the pages within the `InnoDB` buffer pool.

The `InnoDB INFORMATION_SCHEMA` buffer pool tables include those listed below:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_BUFFER%';
+-----+-----+
| Tables_in_INFORMATION_SCHEMA (INNODB_BUFFER%) |
+-----+-----+
| INNODB_BUFFER_PAGE_LRU                       |
| INNODB_BUFFER_PAGE                           |
| INNODB_BUFFER_POOL_STATS                     |
+-----+-----+
```

Table Overview

- [INNODB_BUFFER_PAGE](#): Holds information about each page in the [InnoDB](#) buffer pool.
- [INNODB_BUFFER_PAGE_LRU](#): Holds information about the pages in the [InnoDB](#) buffer pool, in particular how they are ordered in the LRU list that determines which pages to evict from the buffer pool when it becomes full. The [INNODB_BUFFER_PAGE_LRU](#) table has the same columns as the [INNODB_BUFFER_PAGE](#) table, except that the [INNODB_BUFFER_PAGE_LRU](#) table has an [LRU_POSITION](#) column instead of a [BLOCK_ID](#) column.
- [INNODB_BUFFER_POOL_STATS](#): Provides buffer pool status information. Much of the same information is provided by [SHOW ENGINE INNODB STATUS](#) output, or may be obtained using [InnoDB](#) buffer pool server status variables.

Warning

Querying the [INNODB_BUFFER_PAGE](#) table or [INNODB_BUFFER_PAGE_LRU](#) table can introduce significant performance overhead. Do not query these tables on a production system unless you are aware of the performance impact that your query may have, and have determined it to be acceptable. To avoid impacting performance, reproduce the issue you want to investigate on a test instance and run your queries on the test instance.

Example 15.6 Querying System Data in the [INNODB_BUFFER_PAGE](#) Table

This query provides an approximate count of pages that contain system data by excluding pages where the [TABLE_NAME](#) value is either [NULL](#) or includes a slash / or period . in the table name, which indicates a user-defined table.

```
SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0);
+-----+
| COUNT(*) |
+-----+
|      1516 |
+-----+
```

This query returns the approximate number of pages that contain system data, the total number of buffer pool pages, and an approximate percentage of pages that contain system data.

```
SELECT
(SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0)
) AS system_pages,
(
SELECT COUNT(*)
FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
) AS total_pages,
(
SELECT ROUND((system_pages/total_pages) * 100)
) AS system_page_percentage;
+-----+-----+-----+
| system_pages | total_pages | system_page_percentage |
+-----+-----+-----+
|           295 |          8192 |                    4 |
+-----+-----+-----+
```

The type of system data in the buffer pool can be determined by querying the [PAGE_TYPE](#) value. For example, the following query returns eight distinct [PAGE_TYPE](#) values among the pages that contain system data:

```
mysql> SELECT DISTINCT PAGE_TYPE FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NULL OR (INSTR(TABLE_NAME, '/') = 0 AND INSTR(TABLE_NAME, '.') = 0);
+-----+
| PAGE_TYPE |
+-----+
```

```

| SYSTEM
| IBUF_BITMAP
| UNKNOWN
| FILE_SPACE_HEADER
| INODE
| UNDO_LOG
| ALLOCATED
+-----+

```

Example 15.7 Querying User Data in the INNODB_BUFFER_PAGE Table

This query provides an approximate count of pages containing user data by counting pages where the `TABLE_NAME` value is `NOT NULL` and `NOT LIKE '%INNODB_SYS_TABLES%'`.

```

mysql> SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NOT NULL AND TABLE_NAME NOT LIKE '%INNODB_SYS_TABLES%';
+-----+
| COUNT(*) |
+-----+
|      7897 |
+-----+

```

This query returns the approximate number of pages that contain user data, the total number of buffer pool pages, and an approximate percentage of pages that contain user data.

```

mysql> SELECT
(SELECT COUNT(*) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NOT NULL AND (INSTR(TABLE_NAME, '/') > 0 OR INSTR(TABLE_NAME, '.') > 0)
) AS user_pages,
(
SELECT COUNT(*)
FROM information_schema.INNODB_BUFFER_PAGE
) AS total_pages,
(
SELECT ROUND((user_pages/total_pages) * 100)
) AS user_page_percentage;
+-----+-----+-----+
| user_pages | total_pages | user_page_percentage |
+-----+-----+-----+
|      7897 |          8192 |                96 |
+-----+-----+-----+

```

This query identifies user-defined tables with pages in the buffer pool:

```

mysql> SELECT DISTINCT TABLE_NAME FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME IS NOT NULL AND (INSTR(TABLE_NAME, '/') > 0 OR INSTR(TABLE_NAME, '.') > 0)
AND TABLE_NAME NOT LIKE '`mysql`.`innodb_%`;
+-----+
| TABLE_NAME
+-----+
| `employees`.`salaries`
| `employees`.`employees`
+-----+

```

Example 15.8 Querying Index Data in the INNODB_BUFFER_PAGE Table

For information about index pages, query the `INDEX_NAME` column using the name of the index. For example, the following query returns the number of pages and total data size of pages for the `emp_no` index that is defined on the `employees.salaries` table:

```

mysql> SELECT INDEX_NAME, COUNT(*) AS Pages,
ROUND(SUM(IF(COMPRESSED_SIZE = 0, @@global.innodb_page_size, COMPRESSED_SIZE))/1024/1024)
AS 'Total Data (MB)'
FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE INDEX_NAME='emp_no' AND TABLE_NAME = '`employees`.`salaries`;
+-----+-----+-----+
| INDEX_NAME | Pages | Total Data (MB) |
+-----+-----+-----+
| emp_no     | 1609 |                25 |
+-----+-----+-----+

```

This query returns the number of pages and total data size of pages for all indexes defined on the `employees.salaries` table:

```
mysql> SELECT INDEX_NAME, COUNT(*) AS Pages,
ROUND(SUM(IF(COMPRESSED_SIZE = 0, @@global.innodb_page_size, COMPRESSED_SIZE))/1024/1024)
AS 'Total Data (MB)'
FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE
WHERE TABLE_NAME = '`employees`.`salaries`'
GROUP BY INDEX_NAME;
```

INDEX_NAME	Pages	Total Data (MB)
emp_no	1608	25
PRIMARY	6086	95

Example 15.9 Querying LRU_POSITION Data in the INNODB_BUFFER_PAGE_LRU Table

The `INNODB_BUFFER_PAGE_LRU` table holds information about the pages in the InnoDB buffer pool, in particular how they are ordered that determines which pages to evict from the buffer pool when it becomes full. The definition for this page is the same as for `INNODB_BUFFER_PAGE`, except this table has an `LRU_POSITION` column instead of a `BLOCK_ID` column.

This query counts the number of positions at a specific location in the LRU list occupied by pages of the `employees.employees` table.

```
mysql> SELECT COUNT(LRU_POSITION) FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU
WHERE TABLE_NAME='`employees`.`employees`' AND LRU_POSITION < 3072;
```

COUNT(LRU_POSITION)
548

Example 15.10 Querying the INNODB_BUFFER_POOL_STATS Table

The `INNODB_BUFFER_POOL_STATS` table provides information similar to `SHOW ENGINE INNODB STATUS` and InnoDB buffer pool status variables.

```
mysql> SELECT * FROM information_schema.INNODB_BUFFER_POOL_STATS \G
***** 1. row *****
      POOL_ID: 0
      POOL_SIZE: 8192
      FREE_BUFFERS: 1
      DATABASE_PAGES: 8173
      OLD_DATABASE_PAGES: 3014
      MODIFIED_DATABASE_PAGES: 0
      PENDING_DECOMPRESS: 0
      PENDING_READS: 0
      PENDING_FLUSH_LRU: 0
      PENDING_FLUSH_LIST: 0
      PAGES_MADE_YOUNG: 15907
      PAGES_NOT_MADE_YOUNG: 3803101
      PAGES_MADE_YOUNG_RATE: 0
      PAGES_MADE_NOT_YOUNG_RATE: 0
      NUMBER_PAGES_READ: 3270
      NUMBER_PAGES_CREATED: 13176
      NUMBER_PAGES_WRITTEN: 15109
      PAGES_READ_RATE: 0
      PAGES_CREATE_RATE: 0
      PAGES_WRITTEN_RATE: 0
      NUMBER_PAGES_GET: 33069332
      HIT_RATE: 0
      YOUNG_MAKE_PER_THOUSAND_GETS: 0
      NOT_YOUNG_MAKE_PER_THOUSAND_GETS: 0
      NUMBER_PAGES_READ_AHEAD: 2713
      NUMBER_READ_AHEAD_EVICTED: 0
      READ_AHEAD_RATE: 0
      READ_AHEAD_EVICTED_RATE: 0
      LRU_IO_TOTAL: 0
      LRU_IO_CURRENT: 0
```

```
UNCOMPRESS_TOTAL: 0
UNCOMPRESS_CURRENT: 0
```

For comparison, `SHOW ENGINE INNODB STATUS` output and InnoDB buffer pool status variable output is shown below, based on the same data set.

For more information about `SHOW ENGINE INNODB STATUS` output, see [Section 15.16.3, “InnoDB Standard Monitor and Lock Monitor Output”](#).

```
mysql> SHOW ENGINE INNODB STATUS \G
...
-----
BUFFER POOL AND MEMORY
-----
Total large memory allocated 137428992
Dictionary memory allocated 579084
Buffer pool size      8192
Free buffers          1
Database pages       8173
Old database pages   3014
Modified db pages    0
Pending reads        0
Pending writes: LRU 0, flush list 0, single page 0
Pages made young 15907, not young 3803101
0.00 young/s, 0.00 non-young/s
Pages read 3270, created 13176, written 15109
0.00 reads/s, 0.00 creates/s, 0.00 writes/s
No buffer pool page gets since the last printout
Pages read ahead 0.00/s, evicted without access 0.00/s, Random read ahead 0.00/s
LRU len: 8173, unzip_LRU len: 0
I/O sum[0]:cur[0], unzip sum[0]:cur[0]
...

```

For status variable descriptions, see [Section 5.1.7, “Server Status Variables”](#).

```
mysql> SHOW STATUS LIKE 'Innodb_buffer%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Innodb_buffer_pool_dump_status | not started |
| Innodb_buffer_pool_load_status | not started |
| Innodb_buffer_pool_resize_status | not started |
| Innodb_buffer_pool_pages_data | 8173 |
| Innodb_buffer_pool_bytes_data | 133906432 |
| Innodb_buffer_pool_pages_dirty | 0 |
| Innodb_buffer_pool_bytes_dirty | 0 |
| Innodb_buffer_pool_pages_flushed | 15109 |
| Innodb_buffer_pool_pages_free | 1 |
| Innodb_buffer_pool_pages_misc | 18 |
| Innodb_buffer_pool_pages_total | 8192 |
| Innodb_buffer_pool_read_ahead_rnd | 0 |
| Innodb_buffer_pool_read_ahead | 2713 |
| Innodb_buffer_pool_read_ahead_evicted | 0 |
| Innodb_buffer_pool_read_requests | 33069332 |
| Innodb_buffer_pool_reads | 558 |
| Innodb_buffer_pool_wait_free | 0 |
| Innodb_buffer_pool_write_requests | 11985961 |
+-----+-----+

```

15.14.6 InnoDB INFORMATION_SCHEMA Metrics Table

The `INNODB_METRICS` table stores data for InnoDB performance and resource-related counters:

The columns of the `INNODB_METRICS` table are shown in the following example. For a description of each column, see [Section 24.31.16, “The INFORMATION_SCHEMA INNODB_METRICS Table”](#).

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts" \G
***** 1. row *****
      NAME: dml_inserts
  SUBSYSTEM: dml
      COUNT: 46273
```

```

MAX_COUNT: 46273
MIN_COUNT: NULL
AVG_COUNT: 492.2659574468085
COUNT_RESET: 46273
MAX_COUNT_RESET: 46273
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
TIME_ENABLED: 2014-11-28 16:07:53
TIME_DISABLED: NULL
TIME_ELAPSED: 94
TIME_RESET: NULL
STATUS: enabled
TYPE: status_counter
COMMENT: Number of rows inserted

```

Enabling, Disabling, and Resetting Counters

You can enable, disable, and reset counters using the following configuration options:

- `innodb_monitor_enable`: Enables one or more counters.

```
SET GLOBAL innodb_monitor_enable = [counter-name|module_name|pattern|all];
```

- `innodb_monitor_disable`: Disables one or more counters.

```
SET GLOBAL innodb_monitor_disable = [counter-name|module_name|pattern|all];
```

- `innodb_monitor_reset`: Resets the count value for one or more counters to zero.

```
SET GLOBAL innodb_monitor_reset = [counter-name|module_name|pattern|all];
```

- `innodb_monitor_reset_all`: Resets all values for one or more counters. A counter must be disabled before using `innodb_monitor_reset_all`.

```
SET GLOBAL innodb_monitor_reset_all = [counter-name|module_name|pattern|all];
```

You can also enable counters and counter modules at startup using the MySQL server configuration file. For example, to enable the `log` module, `metadata_table_handles_opened` and `metadata_table_handles_closed` counters, enter the following line in the `[mysqld]` section of your `my.cnf` configuration file.

```
[mysqld]
innodb_monitor_enable = module_recovery,metadata_table_handles_opened,metadata_table_handles_closed
```

When enabling multiple counters or modules in your configuration file, you must specify the `innodb_monitor_enable` configuration option followed by counter and module names separated by a comma, as shown in the example above. Only the `innodb_monitor_enable` option can be used in your configuration file. The disable and reset configuration options are only supported on the command line.

Note

Because each counter imposes some degree of runtime overhead on the server, typically you enable more counters on test and development servers during experimentation and benchmarking, and only enable counters on production servers to diagnose known issues or monitor aspects that are likely to be bottlenecks for a particular server and workload.

Counters

The counters represented in the `INNODB_METRICS` table are subject to change, so for the most up-to-date list, query a running MySQL server. The list below shows counters that are available as of MySQL 8.0.

Counters that are enabled by default correspond to those used by `SHOW ENGINE INNODB STATUS`. Counters used by `SHOW ENGINE INNODB STATUS` are always “on” at a system level but you can

disable these counters for the [INNODB_METRICS](#) table, as required. Also, counter status is not persistent. Unless specified otherwise, counters revert to their default enabled or disabled status when the server is restarted.

If you run programs that would be affected by additions or changes to the [INNODB_METRICS](#) table, it is recommended that you review releases notes and query the [INNODB_METRICS](#) table for the new release prior to upgrading.

```
mysql> SELECT name, subsystem, status FROM INFORMATION_SCHEMA.INNODB_METRICS ORDER BY NAME;
```

Counter Modules

The module names correspond to, but are not identical to, the values from the `SUBSYSTEM` column of the `INNODB_METRICS` table. Rather enabling, disabling, or resetting counters individually, you can use module names to quickly enable, disable, or reset all counters for a particular subsystem. For example, use `module_dml` to enable all counters associated with the `dml` subsystem.

```
mysql> SET GLOBAL innodb_monitor_enable = module_dml;

mysql> SELECT name, subsystem, status FROM INFORMATION_SCHEMA.INNODB_METRICS
WHERE subsystem = 'dml';
+-----+-----+-----+
| name      | subsystem | status |
+-----+-----+-----+
| dml_reads | dml       | enabled |
| dml_inserts | dml      | enabled |
| dml_deletes | dml      | enabled |
| dml_updates | dml      | enabled |
+-----+-----+-----+
```

Here are the values you can use for `module_name` with the `innodb_monitor_enable` and related configuration options, along with the corresponding `SUBSYSTEM` names:

- `module_adaptive_hash` (subsystem = `adaptive_hash_index`)
- `module_buffer` (subsystem = `buffer`)
- `module_buffer_page` (subsystem = `buffer_page_io`)
- `module_compress` (subsystem = `compression`)
- `module_ddl` (subsystem = `ddl`)
- `module_dml` (subsystem = `dml`)

- `module_file` (subsystem = `file_system`)
- `module_ibuf_system` (subsystem = `change_buffer`)
- `module_icp` (subsystem = `icp`)
- `module_index` (subsystem = `index`)
- `module_innodb` (subsystem = `innodb`)
- `module_lock` (subsystem = `lock`)
- `module_log` (subsystem = `recovery`)
- `module_metadata` (subsystem = `metadata`)
- `module_os` (subsystem = `os`)
- `module_purge` (subsystem = `purge`)
- `module_trx` (subsystem = `transaction`)

Example 15.11 Working with INNODB_METRICS Table Counters

This example demonstrates enabling, disabling, and resetting a counter, and querying counter data in the `INNODB_METRICS` table.

1. Create a simple `InnoDB` table:

```
mysql> USE test;
Database changed

mysql> CREATE TABLE t1 (c1 INT) ENGINE=INNODB;
Query OK, 0 rows affected (0.02 sec)
```

2. Enable the `dml_inserts` counter.

```
mysql> SET GLOBAL innodb_monitor_enable = dml_inserts;
Query OK, 0 rows affected (0.01 sec)
```

A description of the `dml_inserts` counter can be found in the `COMMENT` column of the `INNODB_METRICS` table:

```
mysql> SELECT NAME, COMMENT FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts";
+-----+-----+
| NAME          | COMMENT                               |
+-----+-----+
| dml_inserts  | Number of rows inserted             |
+-----+-----+
```

3. Query the `INNODB_METRICS` table for the `dml_inserts` counter data. Because no DML operations have been performed, the counter values are zero or NULL. The `TIME_ENABLED` and `TIME_ELAPSED` values indicate when the counter was last enabled and how many seconds have elapsed since this time.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts" \G
***** 1. row *****
      NAME: dml_inserts
     SUBSYSTEM: dml
        COUNT: 0
     MAX_COUNT: 0
     MIN_COUNT: NULL
     AVG_COUNT: 0
     COUNT_RESET: 0
  MAX_COUNT_RESET: 0
  MIN_COUNT_RESET: NULL
  AVG_COUNT_RESET: NULL
    TIME_ENABLED: 2014-12-04 14:18:28
    TIME_DISABLED: NULL
```

```

TIME_ELAPSED: 28
  TIME_RESET: NULL
    STATUS: enabled
      TYPE: status_counter
    COMMENT: Number of rows inserted

```

4. Insert three rows of data into the table.

```

mysql> INSERT INTO t1 values(1);
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t1 values(2);
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t1 values(3);
Query OK, 1 row affected (0.00 sec)

```

5. Query the `INNODB_METRICS` table again for the `dml_inserts` counter data. A number of counter values have now incremented including `COUNT`, `MAX_COUNT`, `AVG_COUNT`, and `COUNT_RESET`. Refer to the `INNODB_METRICS` table definition for descriptions of these values.

```

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
      NAME: dml_inserts
    SUBSYSTEM: dml
      COUNT: 3
    MAX_COUNT: 3
    MIN_COUNT: NULL
    AVG_COUNT: 0.046153846153846156
    COUNT_RESET: 3
  MAX_COUNT_RESET: 3
  MIN_COUNT_RESET: NULL
  AVG_COUNT_RESET: NULL
    TIME_ENABLED: 2014-12-04 14:18:28
    TIME_DISABLED: NULL
    TIME_ELAPSED: 65
    TIME_RESET: NULL
      STATUS: enabled
      TYPE: status_counter
    COMMENT: Number of rows inserted

```

6. Reset the `dml_inserts` counter, and query the `INNODB_METRICS` table again for the `dml_inserts` counter data. The `_%RESET` values that were reported previously, such as `COUNT_RESET` and `MAX_RESET`, are set back to zero. Values such as `COUNT`, `MAX_COUNT`, and `AVG_COUNT`, which cumulatively collect data from the time the counter is enabled, are unaffected by the reset.

```

mysql> SET GLOBAL innodb_monitor_reset = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
      NAME: dml_inserts
    SUBSYSTEM: dml
      COUNT: 3
    MAX_COUNT: 3
    MIN_COUNT: NULL
    AVG_COUNT: 0.03529411764705882
    COUNT_RESET: 0
  MAX_COUNT_RESET: 0
  MIN_COUNT_RESET: NULL
  AVG_COUNT_RESET: 0
    TIME_ENABLED: 2014-12-04 14:18:28
    TIME_DISABLED: NULL
    TIME_ELAPSED: 85
    TIME_RESET: 2014-12-04 14:19:44
      STATUS: enabled
      TYPE: status_counter
    COMMENT: Number of rows inserted

```

7. To reset all counter values, you must first disable the counter. Disabling the counter sets the `STATUS` value to `disabled`.

```
mysql> SET GLOBAL innodb_monitor_disable = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
      NAME: dml_inserts
      SUBSYSTEM: dml
      COUNT: 3
      MAX_COUNT: 3
      MIN_COUNT: NULL
      AVG_COUNT: 0.030612244897959183
      COUNT_RESET: 0
MAX_COUNT_RESET: 0
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: 0
      TIME_ENABLED: 2014-12-04 14:18:28
      TIME_DISABLED: 2014-12-04 14:20:06
      TIME_ELAPSED: 98
      TIME_RESET: NULL
      STATUS: disabled
      TYPE: status_counter
      COMMENT: Number of rows inserted
```

Note

Wildcard match is supported for counter and module names. For example, instead of specifying the full `dml_inserts` counter name, you can specify `dml_i%`. You can also enable, disable, or reset multiple counters or modules at once using a wildcard match. For example, specify `dml_%` to enable, disable, or reset all counters that begin with `dml_`.

8. After the counter is disabled, you can reset all counter values using the `innodb_monitor_reset_all` option. All values are set to zero or NULL.

```
mysql> SET GLOBAL innodb_monitor_reset_all = dml_inserts;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
      NAME: dml_inserts
      SUBSYSTEM: dml
      COUNT: 0
      MAX_COUNT: NULL
      MIN_COUNT: NULL
      AVG_COUNT: NULL
      COUNT_RESET: 0
MAX_COUNT_RESET: NULL
MIN_COUNT_RESET: NULL
AVG_COUNT_RESET: NULL
      TIME_ENABLED: NULL
      TIME_DISABLED: NULL
      TIME_ELAPSED: NULL
      TIME_RESET: NULL
      STATUS: disabled
      TYPE: status_counter
      COMMENT: Number of rows inserted
```

15.14.7 InnoDB INFORMATION_SCHEMA Temporary Table Information Table

The `INNODB_TEMP_TABLE_INFO` table provides users with a snapshot of active InnoDB temporary tables. The table contains metadata about all user and system-created temporary tables that are active within a given InnoDB instance with the exception of optimized temporary tables that are used internally by InnoDB.

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA LIKE 'INNODB_TEMP%';
+-----+
| Tables_in_INFORMATION_SCHEMA (INNODB_TEMP%) |
+-----+
| INNODB_TEMP_TABLE_INFO                       |
+-----+
```

For the table definition, see [Section 24.31.27](#), “The INFORMATION_SCHEMA INNODB_TEMP_TABLE_INFO Table”.

Example 15.12 INNODB_TEMP_TABLE_INFO

This example demonstrates characteristics of the `INNODB_TEMP_TABLE_INFO` table.

1. Create a simple InnoDB temporary table with a single column:

```
mysql> CREATE TEMPORARY TABLE t1 (c1 INT PRIMARY KEY) ENGINE=INNODB;
Query OK, 0 rows affected (0.00 sec)
```

2. Query the `INNODB_TEMP_TABLE_INFO` table to view the temporary table's metadata.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
***** 1. row *****
      TABLE_ID: 194
          NAME: #sql7a79_1_0
         N_COLS: 4
          SPACE: 182
```

The `TABLE_ID` is a unique identifier for the temporary table. The `NAME` column displays the system-generated name for the temporary table, which is prefixed with “#sql”. The number of columns (`N_COLS`) is 4 rather than 1 because InnoDB always creates three hidden table columns (`DB_ROW_ID`, `DB_TRX_ID`, and `DB_ROLL_PTR`).

3. Restart MySQL and query the `INNODB_TEMP_TABLE_INFO` table.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
Empty set (0.00 sec)
```

An empty set is returned because the `INNODB_TEMP_TABLE_INFO` table and the data within it are not persisted to disk on server shutdown.

4. Create a new temporary table.

```
mysql> CREATE TEMPORARY TABLE t1 (c1 INT PRIMARY KEY) ENGINE=INNODB;
Query OK, 0 rows affected (0.00 sec)
```

5. Query the `INNODB_TEMP_TABLE_INFO` table to view the temporary table's metadata.

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
***** 1. row *****
      TABLE_ID: 196
          NAME: #sql7b0e_1_0
         N_COLS: 4
          SPACE: 184
```

The `SPACE` ID is new because it is dynamically generated on server restart.

15.14.8 Retrieving InnoDB Tablespace Metadata from INFORMATION_SCHEMA.FILES

The `INFORMATION_SCHEMA.FILES` table provides metadata about all InnoDB tablespace types including [file-per-table tablespaces](#), [general tablespaces](#), the [system tablespace](#), [temporary table tablespaces](#), and [undo tablespaces](#) (if present).

This section provides InnoDB-specific usage examples. For more information about data provided by the `INFORMATION_SCHEMA.FILES` table, see [Section 24.9](#), “The INFORMATION_SCHEMA FILES Table”.

**Note**

The `INNODB_SYS_TABLESPACES` and `INNODB_SYS_DATAFILES` tables also provide metadata about InnoDB tablespaces, but data is limited to file-per-table and general tablespaces.

This query retrieves metadata about the InnoDB system tablespace from fields of the `INFORMATION_SCHEMA.FILES` table that are pertinent to InnoDB tablespaces. `INFORMATION_SCHEMA.FILES` fields that are not relevant to InnoDB always return NULL, and are excluded from the query.

```
mysql> SELECT FILE_ID, FILE_NAME, FILE_TYPE, TABLESPACE_NAME, FREE_EXTENTS,
TOTAL_EXTENTS, EXTENT_SIZE, INITIAL_SIZE, MAXIMUM_SIZE, AUTOEXTEND_SIZE, DATA_FREE, STATUS ENGINE
FROM INFORMATION_SCHEMA.FILES WHERE TABLESPACE_NAME LIKE 'innodb_system' \G
***** 1. row *****
      FILE_ID: 0
      FILE_NAME: ./ibdata1
      FILE_TYPE: TABLESPACE
TABLESPACE_NAME: innodb_system
      FREE_EXTENTS: 0
      TOTAL_EXTENTS: 12
      EXTENT_SIZE: 1048576
      INITIAL_SIZE: 12582912
      MAXIMUM_SIZE: NULL
      AUTOEXTEND_SIZE: 67108864
      DATA_FREE: 4194304
      ENGINE: NORMAL
```

This query retrieves the `FILE_ID` (equivalent to the space ID) and the `FILE_NAME` (which includes path information) for InnoDB file-per-table and general tablespaces. File-per-table and general tablespaces have a `.ibd` file extension.

```
mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME LIKE '%.ibd%' ORDER BY FILE_ID;
+-----+-----+
| FILE_ID | FILE_NAME |
+-----+-----+
|      2 | ./mysql/plugin.ibd |
|      3 | ./mysql/servers.ibd |
|      4 | ./mysql/help_topic.ibd |
|      5 | ./mysql/help_category.ibd |
|      6 | ./mysql/help_relation.ibd |
|      7 | ./mysql/help_keyword.ibd |
|      8 | ./mysql/time_zone_name.ibd |
|      9 | ./mysql/time_zone.ibd |
|     10 | ./mysql/time_zone_transition.ibd |
|     11 | ./mysql/time_zone_transition_type.ibd |
|     12 | ./mysql/time_zone_leap_second.ibd |
|     13 | ./mysql/innodb_table_stats.ibd |
|     14 | ./mysql/innodb_index_stats.ibd |
|     15 | ./mysql/slave_relay_log_info.ibd |
|     16 | ./mysql/slave_master_info.ibd |
|     17 | ./mysql/slave_worker_info.ibd |
|     18 | ./mysql/gtid_executed.ibd |
|     19 | ./mysql/server_cost.ibd |
|     20 | ./mysql/engine_cost.ibd |
|     21 | ./sys/sys_config.ibd |
|     23 | ./test/t1.ibd |
|     26 | /home/user/test/test/t2.ibd |
+-----+-----+
```

This query retrieves the `FILE_ID` and `FILE_NAME` for InnoDB temporary tablespaces. Temporary tablespace file names are prefixed by `ibtmp`.

```
mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME LIKE '%ibtmp%';
+-----+-----+
| FILE_ID | FILE_NAME |
+-----+-----+
|      22 | ./ibtmp1 |
+-----+-----+
```

Similarly, InnoDB undo tablespace file names are prefixed by `undo`. The following query returns the `FILE_ID` and `FILE_NAME` for InnoDB undo tablespaces, if separate undo tablespaces are configured.

```
mysql> SELECT FILE_ID, FILE_NAME FROM INFORMATION_SCHEMA.FILES
WHERE FILE_NAME LIKE '%undo%';
```

15.15 InnoDB Integration with MySQL Performance Schema

This section provides a brief introduction to InnoDB integration with Performance Schema. For comprehensive Performance Schema documentation, see [Chapter 25, MySQL Performance Schema](#).

You can profile certain internal InnoDB operations using the MySQL Performance Schema feature. This type of tuning is primarily for expert users who evaluate optimization strategies to overcome performance bottlenecks. DBAs can also use this feature for capacity planning, to see whether their typical workload encounters any performance bottlenecks with a particular combination of CPU, RAM, and disk storage; and if so, to judge whether performance can be improved by increasing the capacity of some part of the system.

To use this feature to examine InnoDB performance:

- You must be generally familiar with how to use the [Performance Schema feature](#). For example, you should know how to enable instruments and consumers, and how to query `performance_schema` tables to retrieve data. For an introductory overview, see [Section 25.1, “Performance Schema Quick Start”](#).
- You should be familiar with Performance Schema instruments that are available for InnoDB. To view InnoDB-related instruments, you can query the `setup_instruments` table for instrument names that contain `'innodb'`.

```
mysql> SELECT * FROM setup_instruments WHERE NAME LIKE '%innodb%';
```

NAME	ENABLED	TIMED
wait/synch/mutex/innodb/commit_cond_mutex	NO	NO
wait/synch/mutex/innodb/innobase_share_mutex	NO	NO
wait/synch/mutex/innodb/autoinc_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_zip_mutex	NO	NO
wait/synch/mutex/innodb/cache_last_read_mutex	NO	NO
wait/synch/mutex/innodb/dict_foreign_err_mutex	NO	NO
wait/synch/mutex/innodb/dict_sys_mutex	NO	NO
wait/synch/mutex/innodb/recalc_pool_mutex	NO	NO
...		
wait/io/file/innodb/innodb_data_file	YES	YES
wait/io/file/innodb/innodb_log_file	YES	YES
wait/io/file/innodb/innodb_temp_file	YES	YES
stage/innodb/alter table (end)	YES	YES
stage/innodb/alter table (flush)	YES	YES
stage/innodb/alter table (insert)	YES	YES
stage/innodb/alter table (log apply index)	YES	YES
stage/innodb/alter table (log apply table)	YES	YES
stage/innodb/alter table (merge sort)	YES	YES
stage/innodb/alter table (read PK and internal sort)	YES	YES
stage/innodb/buffer pool load	YES	YES
memory/innodb/buf_buf_pool	NO	NO
memory/innodb/dict_stats_bg_recalc_pool_t	NO	NO
memory/innodb/dict_stats_index_map_t	NO	NO
memory/innodb/dict_stats_n_diff_on_level	NO	NO
memory/innodb/other	NO	NO
memory/innodb/row_log_buf	NO	NO
memory/innodb/row_merge_sort	NO	NO
memory/innodb/std	NO	NO
memory/innodb/sync_debug_latches	NO	NO
memory/innodb/trx_sys_t::rw_trx_ids	NO	NO
...		

```
+-----+-----+-----+
155 rows in set (0.00 sec)
```

For additional information about the instrumented [InnoDB](#) objects, you can query Performance Schema [instances tables](#), which provide additional information about instrumented objects. Instance tables relevant to [InnoDB](#) include:

- The [mutex_instances](#) table
- The [rwlock_instances](#) table
- The [cond_instances](#) table
- The [file_instances](#) table

Note

Mutexes and RW-locks related to the [InnoDB](#) buffer pool are not included in this coverage; the same applies to the output of the `SHOW ENGINE INNODB MUTEX` command.

For example, to view information about instrumented [InnoDB](#) file objects seen by the Performance Schema when executing file I/O instrumentation, you might issue the following query:

```
mysql> SELECT * FROM file_instances WHERE EVENT_NAME LIKE '%innodb%' \G
***** 1. row *****
FILE_NAME: /path/to/mysql-8.0/data/ibdata1
EVENT_NAME: wait/io/file/innodb/innodb_data_file
OPEN_COUNT: 3
***** 2. row *****
FILE_NAME: /path/to/mysql-8.0/data/ib_logfile0
EVENT_NAME: wait/io/file/innodb/innodb_log_file
OPEN_COUNT: 2
***** 3. row *****
FILE_NAME: /path/to/mysql-8.0/data/ib_logfile1
EVENT_NAME: wait/io/file/innodb/innodb_log_file
OPEN_COUNT: 2
***** 4. row *****
FILE_NAME: /path/to/mysql-8.0/data/mysql/engine_cost.ibd
EVENT_NAME: wait/io/file/innodb/innodb_data_file
OPEN_COUNT: 3
...

```

- You should be familiar with [performance_schema](#) tables that store [InnoDB](#) event data. Tables relevant to [InnoDB](#)-related events include:
 - The [Wait Event](#) tables, which store wait events.
 - The [Summary](#) tables, which provide aggregated information for terminated events over time. Summary tables include [file I/O summary tables](#), which aggregate information about I/O operations.
 - [Stage Event](#) tables, which store event data for [InnoDB ALTER TABLE](#) and buffer pool load operations. For more information, see [Section 15.15.1, “Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema”](#), and [Monitoring Buffer Pool Load Progress Using Performance Schema](#).

If you are only interested in [InnoDB](#)-related objects, use the clause `WHERE EVENT_NAME LIKE '%innodb%'` or `WHERE NAME LIKE '%innodb%'` (as required) when querying these tables.

15.15.1 Monitoring ALTER TABLE Progress for InnoDB Tables Using Performance Schema

You can monitor `ALTER TABLE` progress for [InnoDB](#) tables using [Performance Schema](#).

There are seven stage events that represent different phases of `ALTER TABLE`. Each stage event reports a running total of `WORK_COMPLETED` and `WORK_ESTIMATED` for the overall `ALTER TABLE` operation as it progresses through its different phases. `WORK_ESTIMATED` is calculated using a formula that takes into account all of the work that `ALTER TABLE` performs, and may be revised during `ALTER TABLE` processing. `WORK_COMPLETED` and `WORK_ESTIMATED` values are an abstract representation of all of the work performed by `ALTER TABLE`.

In order of occurrence, `ALTER TABLE` stage events include:

- `stage/innodb/alter table (read PK and internal sort)`: This stage is active when `ALTER TABLE` is in the reading-primary-key phase. It starts with `WORK_COMPLETED=0` and `WORK_ESTIMATED` set to the estimated number of pages in the primary key. When the stage is completed, `WORK_ESTIMATED` is updated to the actual number of pages in the primary key.
- `stage/innodb/alter table (merge sort)`: This stage is repeated for each index added by the `ALTER TABLE` operation.
- `stage/innodb/alter table (insert)`: This stage is repeated for each index added by the `ALTER TABLE` operation.
- `stage/innodb/alter table (log apply index)`: This stage includes the application of DML log generated while `ALTER TABLE` was running.
- `stage/innodb/alter table (flush)`: Before this stage begins, `WORK_ESTIMATED` is updated with a more accurate estimate, based on the length of the flush list.
- `stage/innodb/alter table (log apply table)`: This stage includes the application of concurrent DML log generated while `ALTER TABLE` was running. The duration of this phase depends on the extent of table changes. This phase is instant if no concurrent DML was run on the table.
- `stage/innodb/alter table (end)`: Includes any remaining work that appeared after the flush phase, such as reapplying DML that was executed on the table while `ALTER TABLE` was running.

Note

InnoDB `ALTER TABLE` stage events do not currently account for the addition of spatial indexes.

ALTER TABLE Monitoring Example Using Performance Schema

The following example demonstrates how to enable the `stage/innodb/alter table%` stage event instruments and related consumer tables to monitor `ALTER TABLE` progress. For information about Performance Schema stage event instruments and related consumers, see [Section 25.11.5, “Performance Schema Stage Event Tables”](#).

1. Enable the `stage/innodb/alter%` instruments:

```
mysql> UPDATE setup_instruments SET ENABLED = 'YES' WHERE NAME LIKE 'stage/innodb/alter%';
Query OK, 7 rows affected (0.00 sec)
Rows matched: 7 Changed: 7 Warnings: 0
```

2. Enable the stage event consumer tables, which include `events_stages_current`, `events_stages_history`, and `events_stages_history_long`.

```
mysql> UPDATE setup_consumers SET ENABLED = 'YES' WHERE NAME LIKE '%stages%';
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3 Changed: 3 Warnings: 0
```

3. Run an `ALTER TABLE` operation. In this example, a `middle_name` column is added to the `employees` table of the `employees` sample database.

```
mysql> ALTER TABLE employees.employees ADD COLUMN middle_name varchar(14) AFTER first_name;
Query OK, 0 rows affected (9.27 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

- Check the progress of the `ALTER TABLE` operation by querying the Performance Schema `events_stages_current` table. The stage event shown differs depending on which `ALTER TABLE` phase is currently in progress. The `WORK_COMPLETED` column shows the work completed. The `WORK_ESTIMATED` column provides an estimate of the remaining work.

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED FROM events_stages_current;
```

EVENT_NAME	WORK_COMPLETED	WORK_ESTIMATED
stage/innodb/alter table (read PK and internal sort)	280	1245

1 row in set (0.01 sec)

The `events_stages_current` table returns an empty set if the `ALTER TABLE` operation has completed. In this case, you can check the `events_stages_history` table to view event data for the completed operation. For example:

```
mysql> SELECT EVENT_NAME, WORK_COMPLETED, WORK_ESTIMATED FROM events_stages_history;
```

EVENT_NAME	WORK_COMPLETED	WORK_ESTIMATED
stage/innodb/alter table (read PK and internal sort)	886	1213
stage/innodb/alter table (flush)	1213	1213
stage/innodb/alter table (log apply table)	1597	1597
stage/innodb/alter table (end)	1597	1597
stage/innodb/alter table (log apply table)	1981	1981

5 rows in set (0.00 sec)

As shown above, the `WORK_ESTIMATED` value was revised during `ALTER TABLE` processing. The estimated work after completion of the initial stage is 1213. When `ALTER TABLE` processing completed, `WORK_ESTIMATED` was set to the actual value, which is 1981.

15.15.2 Monitoring InnoDB Mutex Waits Using Performance Schema

A mutex is a synchronization mechanism used in the code to enforce that only one thread at a given time can have access to a common resource. When two or more threads executing in the server need to access the same resource, the threads compete against each other. The first thread to obtain a lock on the mutex causes the other threads to wait until the lock is released.

For InnoDB mutexes that are instrumented, mutex waits can be monitored using [Performance Schema](#). Wait event data collected in Performance Schema tables can help identify mutexes with the most waits or the greatest total wait time, for example.

The following example demonstrates how to enable InnoDB mutex wait instruments, how to enable associated consumers, and how to query wait event data.

- To view available InnoDB mutex wait instruments, query the Performance Schema `setup_instruments` table. All InnoDB mutex wait instruments are disabled by default.

```
mysql> SELECT * FROM performance_schema.setup_instruments
-> WHERE NAME LIKE '%wait/synch/mutex/innodb%';
```

NAME	ENABLED	TIMED
wait/synch/mutex/innodb/commit_cond_mutex	NO	NO
wait/synch/mutex/innodb/innobase_share_mutex	NO	NO
wait/synch/mutex/innodb/autoinc_mutex	NO	NO
wait/synch/mutex/innodb/autoinc_persisted_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_flush_state_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_LRU_list_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_free_list_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_zip_free_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_zip_hash_mutex	NO	NO
wait/synch/mutex/innodb/buf_pool_zip_mutex	NO	NO
wait/synch/mutex/innodb/cache_last_read_mutex	NO	NO
wait/synch/mutex/innodb/dict_foreign_err_mutex	NO	NO

wait/synch/mutex/innodb/dict_persist_dirty_tables_mutex	NO	NO
wait/synch/mutex/innodb/dict_sys_mutex	NO	NO
wait/synch/mutex/innodb/recalc_pool_mutex	NO	NO
wait/synch/mutex/innodb/fil_system_mutex	NO	NO
wait/synch/mutex/innodb/flush_list_mutex	NO	NO
wait/synch/mutex/innodb/fts_bg_threads_mutex	NO	NO
wait/synch/mutex/innodb/fts_delete_mutex	NO	NO
wait/synch/mutex/innodb/fts_optimize_mutex	NO	NO
wait/synch/mutex/innodb/fts_doc_id_mutex	NO	NO
wait/synch/mutex/innodb/log_flush_order_mutex	NO	NO
wait/synch/mutex/innodb/hash_table_mutex	NO	NO
wait/synch/mutex/innodb/ibuf_bitmap_mutex	NO	NO
wait/synch/mutex/innodb/ibuf_mutex	NO	NO
wait/synch/mutex/innodb/ibuf_pessimistic_insert_mutex	NO	NO
wait/synch/mutex/innodb/log_sys_mutex	NO	NO
wait/synch/mutex/innodb/log_sys_write_mutex	NO	NO
wait/synch/mutex/innodb/mutex_list_mutex	NO	NO
wait/synch/mutex/innodb/page_zip_stat_per_index_mutex	NO	NO
wait/synch/mutex/innodb/purge_sys_pq_mutex	NO	NO
wait/synch/mutex/innodb/recv_sys_mutex	NO	NO
wait/synch/mutex/innodb/recv_writer_mutex	NO	NO
wait/synch/mutex/innodb/redo_rseg_mutex	NO	NO
wait/synch/mutex/innodb/noredoreg_mutex	NO	NO
wait/synch/mutex/innodb/rw_lock_list_mutex	NO	NO
wait/synch/mutex/innodb/rw_lock_mutex	NO	NO
wait/synch/mutex/innodb/srv_dict_tmpfile_mutex	NO	NO
wait/synch/mutex/innodb/srv_innodb_monitor_mutex	NO	NO
wait/synch/mutex/innodb/srv_misc_tmpfile_mutex	NO	NO
wait/synch/mutex/innodb/srv_monitor_file_mutex	NO	NO
wait/synch/mutex/innodb/buf_dblwr_mutex	NO	NO
wait/synch/mutex/innodb/trx_undo_mutex	NO	NO
wait/synch/mutex/innodb/trx_pool_mutex	NO	NO
wait/synch/mutex/innodb/trx_pool_manager_mutex	NO	NO
wait/synch/mutex/innodb/srv_sys_mutex	NO	NO
wait/synch/mutex/innodb/lock_mutex	NO	NO
wait/synch/mutex/innodb/lock_wait_mutex	NO	NO
wait/synch/mutex/innodb/trx_mutex	NO	NO
wait/synch/mutex/innodb/srv_threads_mutex	NO	NO
wait/synch/mutex/innodb/rtr_active_mutex	NO	NO
wait/synch/mutex/innodb/rtr_match_mutex	NO	NO
wait/synch/mutex/innodb/rtr_path_mutex	NO	NO
wait/synch/mutex/innodb/rtr_ssn_mutex	NO	NO
wait/synch/mutex/innodb/trx_sys_mutex	NO	NO
wait/synch/mutex/innodb/zip_pad_mutex	NO	NO
wait/synch/mutex/innodb/master_key_id_mutex	NO	NO

- Some [InnoDB](#) mutex instances are created at server startup and are only instrumented if the associated instrument is also enabled at server startup. To ensure that all [InnoDB](#) mutex instances are instrumented and enabled, add the following [performance-schema-instrument](#) rule to your MySQL configuration file:

```
performance-schema-instrument='wait/synch/mutex/innodb/%=ON'
```

If you do not require wait event data for all [InnoDB](#) mutexes, you can disable specific instruments by adding additional [performance-schema-instrument](#) rules to your MySQL configuration file. For example, to disable [InnoDB](#) mutex wait event instruments related to full-text search, add the following rule:

```
performance-schema-instrument='wait/synch/mutex/innodb/fts%=OFF'
```

Note

Rules with a longer prefix such as `wait/synch/mutex/innodb/fts%` take precedence over rules with shorter prefixes such as `wait/synch/mutex/innodb/%`.

After adding the [performance-schema-instrument](#) rules to your configuration file, restart the server. All the [InnoDB](#) mutexes except for those related to full text search are enabled. To verify,

query the `setup_instruments` table. The `ENABLED` and `TIMED` columns should be set to `YES` for the instruments that you enabled.

```
mysql> SELECT * FROM performance_schema.setup_instruments
-> WHERE NAME LIKE '%wait/synch/mutex/innodb%';
+-----+-----+-----+
| NAME                                     | ENABLED | TIMED |
+-----+-----+-----+
| wait/synch/mutex/innodb/commit_cond_mutex | YES     | YES   |
| wait/synch/mutex/innodb/innobase_share_mutex | YES     | YES   |
| wait/synch/mutex/innodb/autoinc_mutex     | YES     | YES   |
| ...                                       |         |       |
| wait/synch/mutex/innodb/master_key_id_mutex | YES     | YES   |
+-----+-----+-----+
49 rows in set (0.00 sec)
```

3. Enable wait event consumers by updating the `setup_consumers` table. Wait event consumers are disabled by default.

```
mysql> UPDATE performance_schema.setup_consumers SET enabled = 'YES'
-> WHERE name like 'events_waits%';
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3 Changed: 3 Warnings: 0
```

You can verify that wait event consumers are enabled by querying the `setup_consumers` table. The `events_waits_current`, `events_waits_history`, and `events_waits_history_long` consumers should be enabled.

```
mysql> SELECT * FROM performance_schema.setup_consumers;
+-----+-----+
| NAME                                     | ENABLED |
+-----+-----+
| events_stages_current                   | NO      |
| events_stages_history                   | NO      |
| events_stages_history_long              | NO      |
| events_statements_current               | YES     |
| events_statements_history               | YES     |
| events_statements_history_long          | NO      |
| events_transactions_current             | YES     |
| events_transactions_history             | YES     |
| events_transactions_history_long        | NO      |
| events_waits_current                    | YES     |
| events_waits_history                    | YES     |
| events_waits_history_long               | YES     |
| global_instrumentation                  | YES     |
| thread_instrumentation                  | YES     |
| statements_digest                       | YES     |
+-----+-----+
15 rows in set (0.00 sec)
```

4. Once instruments and consumers are enabled, run the workload that you want to monitor. In this example, the `mysqlslap` load emulation client is used to simulate a workload.

```
shell> ./mysqlslap --auto-generate-sql --concurrency=100 --iterations=10
-> --number-of-queries=1000 --number-char-cols=6 --number-int-cols=6;
```

5. Query the wait event data. In this example, wait event data is queried from the `events_waits_summary_global_by_event_name` table which aggregates data found in the `events_waits_current`, `events_waits_history`, and `events_waits_history_long` tables. Data is summarized by event name (`EVENT_NAME`), which is the name of the instrument that produced the event. Summarized data includes:

- `COUNT_STAR`

The number of summarized wait events.

- [SUM_TIMER_WAIT](#)

The total wait time of the summarized timed wait events.

- [MIN_TIMER_WAIT](#)

The minimum wait time of the summarized timed wait events.

- [AVG_TIMER_WAIT](#)

The average wait time of the summarized timed wait events.

- [MAX_TIMER_WAIT](#)

The maximum wait time of the summarized timed wait events.

The following query returns the instrument name ([EVENT_NAME](#)), the number of wait events ([COUNT_STAR](#)), and the total wait time for the events for that instrument ([SUM_TIMER_WAIT](#)). Because waits are timed in picoseconds (trillionths of a second) by default, wait times are divided by 1000000000 to show wait times in milliseconds. Data is presented in descending order, by the number of summarized wait events ([COUNT_STAR](#)). You can adjust the [ORDER BY](#) clause to order the data by total wait time.

```
mysql> SELECT EVENT_NAME, COUNT_STAR, SUM_TIMER_WAIT/1000000000 SUM_TIMER_WAIT_MS
-> FROM performance_schema.events_waits_summary_global_by_event_name
-> WHERE SUM_TIMER_WAIT > 0 AND EVENT_NAME LIKE 'wait/synch/mutex/innodb/%'
-> ORDER BY COUNT_STAR DESC;
```

EVENT_NAME	COUNT_STAR	SUM_TIMER_WAIT_MS
wait/synch/mutex/innodb/trx_mutex	201111	23.4719
wait/synch/mutex/innodb/fil_system_mutex	62244	9.6426
wait/synch/mutex/innodb/redo_rseg_mutex	48238	3.1135

wait/synch/mutex/innodb/trx_sys_mutex	35134	1068.1588
wait/synch/mutex/innodb/lock_mutex	34872	1039.2589
wait/synch/mutex/innodb/log_sys_write_mutex	17805	1526.0490
wait/synch/mutex/innodb/dict_sys_mutex	14912	1606.7348
wait/synch/mutex/innodb/trx_undo_mutex	10634	1.1424
wait/synch/mutex/innodb/rw_lock_list_mutex	8538	0.1960
wait/synch/mutex/innodb/buf_pool_free_list_mutex	5961	0.6473
wait/synch/mutex/innodb/trx_pool_mutex	4885	8821.7496
wait/synch/mutex/innodb/buf_pool_LRU_list_mutex	4364	0.2077
wait/synch/mutex/innodb/innobase_share_mutex	3212	0.2650
wait/synch/mutex/innodb/flush_list_mutex	3178	0.2349
wait/synch/mutex/innodb/trx_pool_manager_mutex	2495	0.1310
wait/synch/mutex/innodb/buf_pool_flush_state_mutex	1318	0.2161
wait/synch/mutex/innodb/log_flush_order_mutex	1250	0.0893
wait/synch/mutex/innodb/buf_dblwr_mutex	951	0.0918
wait/synch/mutex/innodb/recalc_pool_mutex	670	0.0942
wait/synch/mutex/innodb/dict_persist_dirty_tables_mutex	345	0.0414
wait/synch/mutex/innodb/lock_wait_mutex	303	0.1565
wait/synch/mutex/innodb/autoinc_mutex	196	0.0213
wait/synch/mutex/innodb/autoinc_persisted_mutex	196	0.0175
wait/synch/mutex/innodb/purge_sys_pq_mutex	117	0.0308
wait/synch/mutex/innodb/srv_sys_mutex	94	0.0077
wait/synch/mutex/innodb/ibuf_mutex	22	0.0086
wait/synch/mutex/innodb/recv_sys_mutex	12	0.0008
wait/synch/mutex/innodb/srv_innodb_monitor_mutex	4	0.0009
wait/synch/mutex/innodb/recv_writer_mutex	1	0.0005

Note

The preceding result set includes wait event data produced during the startup process. To exclude this data, you can truncate the

`events_waits_summary_global_by_event_name` table immediately after startup and before running your workload. However, the truncate operation itself may produce a negligible amount wait event data.

```
mysql> TRUNCATE performance_schema.events_waits_summary_global_by_event_name;
```

15.16 InnoDB Monitors

InnoDB monitors provide information about the InnoDB internal state. This information is useful for performance tuning.

15.16.1 InnoDB Monitor Types

There are two types of InnoDB monitor:

- The standard InnoDB Monitor displays the following types of information:
 - Work done by the main background thread
 - Semaphore waits
 - Data about the most recent foreign key and deadlock errors
 - Lock waits for transactions
 - Table and record locks held by active transactions
 - Pending I/O operations and related statistics
 - Insert buffer and adaptive hash index statistics
 - Redo log data
 - Buffer pool statistics
 - Row operation data
- The InnoDB Lock Monitor prints additional lock information as part of the standard InnoDB Monitor output.

15.16.2 Enabling InnoDB Monitors

When you enable InnoDB monitors for periodic output, InnoDB writes the output to the `mysqld` server standard error output (`stderr`). In this case, no output is sent to clients. When switched on, InnoDB monitors print data about every 15 seconds. Server output usually is directed to the error log (see [Section 5.4.2, “The Error Log”](#)). This data is useful in performance tuning. On Windows, start the server from a command prompt in a console window with the `--console` option if you want to direct the output to the window rather than to the error log.

InnoDB sends diagnostic output to `stderr` or to files rather than to `stdout` or fixed-size memory buffers, to avoid potential buffer overflows. As a side effect, the output of `SHOW ENGINE INNODB STATUS` is written to a status file in the MySQL data directory every fifteen seconds. The name of the file is `innodb_status.pid`, where `pid` is the server process ID. InnoDB removes the file when the server is shut down normally. If abnormal shutdowns have occurred, instances of these status files may be present and must be removed manually. Before removing them, examine them to see if they contain useful information about the cause of abnormal shutdowns. The `innodb_status.pid` file is only created if the `innodb-status-file` configuration option is enabled. It is disabled by default.

InnoDB monitors should only be enabled when you actually want to see monitor information because output generation causes some performance decrement. Also, if you enable monitor output, your error log may become quite large if you forget to disable it later.

**Note**

To assist with troubleshooting, [InnoDB](#) temporarily enables standard [InnoDB](#) Monitor output under certain conditions. For more information, see [Section 15.20, “InnoDB Troubleshooting”](#).

[InnoDB](#) monitor output begins with a header containing a timestamp and the monitor name. For example:

```
=====
2014-10-16 18:37:29 0x7fc2a95c1700 INNODB MONITOR OUTPUT
=====
```

The header for the standard [InnoDB](#) Monitor (`INNODB MONITOR OUTPUT`) is also used for the Lock Monitor because the latter produces the same output with the addition of extra lock information.

The `innodb_status_output` and `innodb_status_output_locks` system variables are used to enable the standard [InnoDB](#) Monitor and [InnoDB](#) Lock Monitor.

The `PROCESS` privilege is required to enable and disable [InnoDB](#) Monitors.

Enabling the Standard InnoDB Monitor

Enable the standard [InnoDB](#) Monitor by setting the `innodb_status_output` system variable to `ON`.

```
set GLOBAL innodb_status_output=ON;
```

To disable the standard [InnoDB](#) Monitor, set `innodb_status_output` to `OFF`.

When you shut down the server, the `innodb_status_output` variable is set to the default `OFF` value.

Obtaining Standard InnoDB Monitor Output On Demand

As an alternative to enabling the standard [InnoDB](#) Monitor for periodic output, you can obtain standard [InnoDB](#) Monitor output on demand using the `SHOW ENGINE INNODB STATUS` SQL statement, which fetches the output to your client program. If you are using the `mysql` interactive client, the output is more readable if you replace the usual semicolon statement terminator with `\G`:

```
mysql> SHOW ENGINE INNODB STATUS\G
```

`SHOW ENGINE INNODB STATUS` output also includes [InnoDB](#) Lock Monitor data if the [InnoDB](#) Lock Monitor is enabled.

Enabling the InnoDB Lock Monitor

[InnoDB](#) Lock Monitor data is printed with the [InnoDB](#) Standard Monitor output. Both the [InnoDB](#) Standard Monitor and [InnoDB](#) Lock Monitor must be enabled to have [InnoDB](#) Lock Monitor data printed periodically.

To enable the [InnoDB](#) Lock Monitor, set the `innodb_status_output_locks` system variable to `ON`. Both the [InnoDB](#) standard Monitor and [InnoDB](#) Lock Monitor must be enabled to have [InnoDB](#) Lock Monitor data printed periodically:

```
set GLOBAL innodb_status_output=ON;
set GLOBAL innodb_status_output_locks=ON;
```

To disable the [InnoDB](#) Lock Monitor, set `innodb_status_output_locks` to `OFF`. Set `innodb_status_output` to `OFF` to also disable the [InnoDB](#) Standard Monitor.

When you shut down the server, the `innodb_status_output` and `innodb_status_output_locks` variables are set to the default `OFF` value.

**Note**

To enable the InnoDB Lock Monitor for `SHOW ENGINE INNODB STATUS` output, you are only required to enable `innodb_status_output_locks`.

15.16.3 InnoDB Standard Monitor and Lock Monitor Output

The Lock Monitor is the same as the Standard Monitor except that it includes additional lock information. Enabling either monitor for periodic output turns on the same output stream, but the stream includes extra information if the Lock Monitor is enabled. For example, if you enable the Standard Monitor and Lock Monitor, that turns on a single output stream. The stream includes extra lock information until you disable the Lock Monitor.

Standard Monitor output is limited to 1MB when produced using the `SHOW ENGINE INNODB STATUS` statement. This limit does not apply to output written to server standard error output (`stderr`).

Example Standard Monitor output:

```
mysql> SHOW ENGINE INNODB STATUS\G
***** 1. row *****
  Type: InnoDB
  Name:
  Status:
  =====

END OF INNODB MONITOR OUTPUT
=====

```

Standard Monitor Output Sections

For a description of each metric reported by the Standard Monitor, refer to the [Metrics](#) chapter in the [Oracle Enterprise Manager for MySQL Database User's Guide](#).

- [Status](#)

This section shows the timestamp, the monitor name, and the number of seconds that per-second averages are based on. The number of seconds is the elapsed time between the current time and the last time [InnoDB Monitor](#) output was printed.

- [BACKGROUND THREAD](#)

The `srv_master_thread` lines shows work done by the main background thread.

- [SEMAPHORES](#)

This section reports threads waiting for a semaphore and statistics on how many times threads have needed a spin or a wait on a mutex or a rw-lock semaphore. A large number of threads waiting for semaphores may be a result of disk I/O, or contention problems inside [InnoDB](#). Contention can be due to heavy parallelism of queries or problems in operating system thread scheduling. Setting the `innodb_thread_concurrency` system variable smaller than the default value might help in such

situations. The `Spin rounds per wait` line shows the number of spinlock rounds per OS wait for a mutex.

Mutex metrics are reported by `SHOW ENGINE INNODB MUTEX`.

- `LATEST FOREIGN KEY ERROR`

This section provides information about the most recent foreign key constraint error. It is not present if no such error has occurred. The contents include the statement that failed as well as information about the constraint that failed and the referenced and referencing tables.

- `LATEST DETECTED DEADLOCK`

This section provides information about the most recent deadlock. It is not present if no deadlock has occurred. The contents show which transactions are involved, the statement each was attempting to execute, the locks they have and need, and which transaction InnoDB decided to roll back to break the deadlock. The lock modes reported in this section are explained in [Section 15.5.1, “InnoDB Locking”](#).

- `TRANSACTIONS`

If this section reports lock waits, your applications might have lock contention. The output can also help to trace the reasons for transaction deadlocks.

- `FILE I/O`

This section provides information about threads that InnoDB uses to perform various types of I/O. The first few of these are dedicated to general InnoDB processing. The contents also display information for pending I/O operations and statistics for I/O performance.

The number of these threads are controlled by the `innodb_read_io_threads` and `innodb_write_io_threads` parameters. See [Section 15.13, “InnoDB Startup Options and System Variables”](#).

- `INSERT BUFFER AND ADAPTIVE HASH INDEX`

This section shows the status of the InnoDB insert buffer (also referred to as the [change buffer](#)) and the adaptive hash index.

For related information, see [Section 15.4.2, “Change Buffer”](#), and [Section 15.4.3, “Adaptive Hash Index”](#).

- `LOG`

This section displays information about the InnoDB log. The contents include the current log sequence number, how far the log has been flushed to disk, and the position at which InnoDB last took a checkpoint. (See [Section 15.11.3, “InnoDB Checkpoints”](#).) The section also displays information about pending writes and write performance statistics.

- `BUFFER POOL AND MEMORY`

This section gives you statistics on pages read and written. You can calculate from these numbers how many data file I/O operations your queries currently are doing.

For buffer pool statistics descriptions, see [Section 15.6.3.9, “Monitoring the Buffer Pool Using the InnoDB Standard Monitor”](#). For additional information about the operation of the buffer pool, see [Section 15.6.3.1, “The InnoDB Buffer Pool”](#).

- `ROW OPERATIONS`

This section shows what the main thread is doing, including the number and performance rate for each type of row operation.

15.17 InnoDB Backup and Recovery

This section covers topics related to [InnoDB](#) backup and recovery.

- For information about backup techniques applicable to [InnoDB](#), see [Section 15.17.1, “InnoDB Backup”](#).
- For information about point-in-time recovery, recovery from disk failure or corruption, and how [InnoDB](#) performs crash recovery, see [Section 15.17.2, “InnoDB Recovery”](#).

15.17.1 InnoDB Backup

The key to safe database management is making regular backups. Depending on your data volume, number of MySQL servers, and database workload, you can use these backup techniques, alone or in combination: [hot backup](#) with MySQL Enterprise Backup; [cold backup](#) by copying files while the MySQL server is shut down; [logical backup](#) with `mysqldump` for smaller data volumes or to record the structure of schema objects. Hot and cold backups are [physical backups](#) that copy actual data files, which can be used directly by the `mysqld` server for faster restore.

Hot Backups

The `mysqlbackup` command, part of the MySQL Enterprise Backup component, lets you back up a running MySQL instance, including [InnoDB](#) tables, with minimal disruption to operations while producing a consistent snapshot of the database. When `mysqlbackup` is copying [InnoDB](#) tables, reads and writes to [InnoDB](#) tables can continue. MySQL Enterprise Backup can also create compressed backup files, and back up subsets of tables and databases. In conjunction with the MySQL binary log, users can perform point-in-time recovery. MySQL Enterprise Backup is part of the MySQL Enterprise subscription. For more details, see [Section 29.2, “MySQL Enterprise Backup Overview”](#).

Cold Backups

If you can shut down the MySQL server, you can make a physical backup that consists of all files used by [InnoDB](#) to manage its tables. Use the following procedure:

1. Perform a [slow shutdown](#) of the MySQL server and make sure that it stops without errors.
2. Copy all [InnoDB](#) data files (`ibdata` files and `.ibd` files) into a safe place.
3. Copy all [InnoDB](#) log files (`ib_logfile` files) to a safe place.
4. Copy your `my.cnf` configuration file or files to a safe place.

Logical Backups Using `mysqldump`

In addition to physical backups, it is recommended that you regularly create logical backups by dumping your tables using `mysqldump`. A binary file might be corrupted without you noticing it. Dumped tables are stored into text files that are human-readable, so spotting table corruption becomes easier. Also, because the format is simpler, the chance for serious data corruption is smaller. `mysqldump` also has a `--single-transaction` option for making a consistent snapshot without locking out other clients. See [Section 7.3.1, “Establishing a Backup Policy”](#).

Replication works with [InnoDB](#) tables, so you can use MySQL replication capabilities to keep a copy of your database at database sites requiring high availability. See [Section 15.18, “InnoDB and MySQL Replication”](#).

15.17.2 InnoDB Recovery

This section describes [InnoDB](#) recovery. Topics include:

- [Point-in-Time Recovery](#)

- [Recovery from Data Corruption or Disk Failure](#)
- [InnoDB Crash Recovery](#)
- [Tablespace Discovery During Crash Recovery](#)
- [Lost or Corrupted Tablespace Map Files](#)

Point-in-Time Recovery

To recover an [InnoDB](#) database to the present from the time at which the physical backup was made, you must run MySQL server with binary logging enabled, even before taking the backup. To achieve point-in-time recovery after restoring a backup, you can apply changes from the binary log that occurred after the backup was made. See [Section 7.5, “Point-in-Time \(Incremental\) Recovery Using the Binary Log”](#).

Recovery from Data Corruption or Disk Failure

If your database becomes corrupted or disk failure occurs, you must perform the recovery using a backup. In the case of corruption, first find a backup that is not corrupted. After restoring the base backup, do a point-in-time recovery from the binary log files using `mysqlbinlog` and `mysql` to restore the changes that occurred after the backup was made.

In some cases of database corruption, it is enough to dump, drop, and re-create one or a few corrupt tables. You can use the `CHECK TABLE` statement to check whether a table is corrupt, although `CHECK TABLE` naturally cannot detect every possible kind of corruption.

In some cases, apparent database page corruption is actually due to the operating system corrupting its own file cache, and the data on disk may be okay. It is best to try restarting the computer first. Doing so may eliminate errors that appeared to be database page corruption. If MySQL still has trouble starting because of [InnoDB](#) consistency problems, see [Section 15.20.2, “Forcing InnoDB Recovery”](#) for steps to start the instance in recovery mode, which permits you to dump the data.

InnoDB Crash Recovery

To recover from a MySQL server crash, the only requirement is to restart the MySQL server. [InnoDB](#) automatically checks the logs and performs a roll-forward of the database to the present. [InnoDB](#) automatically rolls back uncommitted transactions that were present at the time of the crash. During recovery, `mysqld` displays output similar to this:

```
InnoDB: The log sequence number 664050266 in the system tablespace does not match
the log sequence number 685111586 in the ib_logfiles!
InnoDB: Database was not shutdown normally!
InnoDB: Starting crash recovery.
InnoDB: Using 'tablespaces.open.2' max LSN: 664075228
InnoDB: Doing recovery: scanned up to log sequence number 690354176
InnoDB: Doing recovery: scanned up to log sequence number 695597056
InnoDB: Doing recovery: scanned up to log sequence number 700839936
InnoDB: Doing recovery: scanned up to log sequence number 706082816
InnoDB: Doing recovery: scanned up to log sequence number 711325696
InnoDB: Doing recovery: scanned up to log sequence number 713458156
InnoDB: Applying a batch of 1467 redo log records ...
InnoDB: 10%
InnoDB: 20%
InnoDB: 30%
InnoDB: 40%
InnoDB: 50%
InnoDB: 60%
InnoDB: 70%
InnoDB: 80%
InnoDB: 90%
InnoDB: 100%
InnoDB: Apply batch completed!
```

```
InnoDB: 1 transaction(s) which must be rolled back or cleaned up in total 561887 row
operations to undo
InnoDB: Trx id counter is 4096
...
InnoDB: 8.0.1 started; log sequence number 713458156
InnoDB: Waiting for purge to start
InnoDB: Starting in background the rollback of uncommitted transactions
InnoDB: Rolling back trx with id 3596, 561887 rows to undo
...
./mysqld: ready for connections....
```

InnoDB crash recovery consists of several steps:

- **Tablespace discovery**

Tablespace discovery is the process that InnoDB uses to identify tablespaces that require redo log application. See [Tablespace Discovery During Crash Recovery](#).

- **Redo log application**

Redo log application is performed during initialization, before accepting any connections. If all changes are flushed from the [buffer pool](#) to the [tablespaces](#) (`ibdata*` and `*.ibd` files) at the time of the shutdown or crash, redo log application is skipped. InnoDB also skips redo log application if redo log files are missing at startup.

- The current maximum auto-increment counter value is written to the redo log each time the value changes, which makes it crash-safe. During recovery, InnoDB scans the redo log to collect counter value changes and applies the changes to the in-memory table object.

For more information about how InnoDB handles auto-increment values, see [Section 15.8.1.5, “AUTO_INCREMENT Handling in InnoDB”](#), and [InnoDB AUTO_INCREMENT Counter Initialization](#).

- When encountering index tree corruption, InnoDB writes a corruption flag to the redo log, which makes the corruption flag crash-safe. InnoDB also writes in-memory corruption flag data to an engine-private system table on each checkpoint. During recovery, InnoDB reads corruption flags from both locations and merges results before marking in-memory table and index objects as corrupt.
- Removing redo logs to speed up recovery is not recommended, even if some data loss is acceptable. Removing redo logs should only be considered after a clean shutdown, with `innodb_fast_shutdown` set to 0 or 1.
- **Roll back of incomplete transactions**

Incomplete transactions are any transactions that were active at the time of crash or [fast shutdown](#). The time it takes to roll back an incomplete transaction can be three or four times the amount of time a transaction is active before it is interrupted, depending on server load.

You cannot cancel transactions that are being rolled back. In extreme cases, when rolling back transactions is expected to take an exceptionally long time, it may be faster to start InnoDB with an `innodb_force_recovery` setting of 3 or greater. See [Section 15.20.2, “Forcing InnoDB Recovery”](#).

- **Change buffer merge**

Applying changes from the change buffer (part of the [system tablespace](#)) to leaf pages of secondary indexes, as the index pages are read to the buffer pool.

- **Purge**

Deleting delete-marked records that are no longer visible to active transactions.

The steps that follow redo log application do not depend on the redo log (other than for logging the writes) and are performed in parallel with normal processing. Of these, only rollback of incomplete transactions is special to crash recovery. The insert buffer merge and the purge are performed during normal processing.

After redo log application, InnoDB attempts to accept connections as early as possible, to reduce downtime. As part of crash recovery, InnoDB rolls back transactions that were not committed or in `XA PREPARE` state when the server crashed. The rollback is performed by a background thread, executed in parallel with transactions from new connections. Until the rollback operation is completed, new connections may encounter locking conflicts with recovered transactions.

In most situations, even if the MySQL server was killed unexpectedly in the middle of heavy activity, the recovery process happens automatically and no action is required of the DBA. If a hardware failure or severe system error corrupted InnoDB data, MySQL might refuse to start. In this case, see [Section 15.20.2, “Forcing InnoDB Recovery”](#).

For information about the binary log and InnoDB crash recovery, see [Section 5.4.4, “The Binary Log”](#).

Tablespace Discovery During Crash Recovery

If, during recovery, InnoDB encounters redo logs written since the last checkpoint, the redo logs must be applied to affected tablespaces. The process that identifies affected tablespaces during recovery is referred to as *tablespace discovery*.

In MySQL 8.0.1 and earlier, tablespace discovery is performed by scanning redo logs for `MLOG_FILE_NAME` records that contain tablespace ID and file name data. For information about this method of tablespace discovery, refer to [Tablespace Discovery During Crash Recovery](#) in the MySQL 5.7 Reference Manual.

As of MySQL 8.0.2, tablespace discovery is performed using tablespace map files that map tablespace IDs to tablespace file names. Tablespace map files are stored in the `innodb_data_home_dir` directory. If `innodb_data_home_dir` is not configured, the default location is the MySQL data directory (`datadir`).

There are two tablespace map files (`tablespaces.open.1` and `tablespaces.open.2`) that are written to in circular fashion. Tablespace map files are only used during recovery. The files are ignored during normal startup.

In case of lost or corrupted tablespace map files, see [Lost or Corrupted Tablespace Map Files](#).

Lost or Corrupted Tablespace Map Files

If tablespace map files, introduced in MySQL 8.0.2, are lost or corrupted, the `innodb_scan_directories` option can be used to specify tablespace file directories at startup. This option causes InnoDB to read the first page of each tablespace file in the specified directories and recreate tablespace map files so that the recovery process can apply redo logs.

This option can also be used to specify the directory path of a missing tablespace file. For example, if recovery reports an error due to a missing tablespace file, you can configure `innodb_scan_directories` to search for the tablespace file in a specific directory.

`innodb_scan_directories` may be specified as an option in a startup command or in a MySQL configuration file. Quotes are used around the argument value because otherwise a semicolon (;) is interpreted as a special character by some command interpreters. (Unix shells treat it as a command terminator, for example.)

Startup command:

```
mysqld --innodb-scan-directories="directory_path_1;directory_path_2"
```

MySQL configuration file:

```
[mysqld]
```

```
innodb_scan_directories="directory_path_1;directory_path_2"
```

When `innodb_scan_directories` is specified at startup, the InnoDB startup process prints messages similar to the following, reporting the directories that were scanned and the number of tablespace files found:

```
InnoDB: Directories to scan 'directory_path_1;directory_path_2'
InnoDB: Scanning 'directory_path_1'
InnoDB: Scanning 'directory_path_2'
InnoDB: Found 10 '.ibd' file(s)
```

15.18 InnoDB and MySQL Replication

MySQL replication works for InnoDB tables as it does for MyISAM tables. It is also possible to use replication in a way where the storage engine on the slave is not the same as the original storage engine on the master. For example, you can replicate modifications to an InnoDB table on the master to a MyISAM table on the slave. For more information see, [Section 18.3.4, “Using Replication with Different Master and Slave Storage Engines”](#).

For information about setting up a new slave for a master, see [Section 18.1.2.6, “Setting Up Replication Slaves”](#), and [Section 18.1.2.5, “Choosing a Method for Data Snapshots”](#). To make a new slave without taking down the master or an existing slave, use the [MySQL Enterprise Backup](#) product.

Transactions that fail on the master do not affect replication at all. MySQL replication is based on the binary log where MySQL writes SQL statements that modify data. A transaction that fails (for example, because of a foreign key violation, or because it is rolled back) is not written to the binary log, so it is not sent to slaves. See [Section 13.3.1, “START TRANSACTION, COMMIT, and ROLLBACK Syntax”](#).

Replication and CASCADE. Cascading actions for InnoDB tables on the master are replicated on the slave *only* if the tables sharing the foreign key relation use InnoDB on both the master and slave. This is true whether you are using statement-based or row-based replication. Suppose that you have started replication, and then create two tables on the master using the following `CREATE TABLE` statements:

```
CREATE TABLE fc1 (
  i INT PRIMARY KEY,
  j INT
) ENGINE = InnoDB;

CREATE TABLE fc2 (
  m INT PRIMARY KEY,
  n INT,
  FOREIGN KEY ni (n) REFERENCES fc1 (i)
  ON DELETE CASCADE
) ENGINE = InnoDB;
```

Suppose that the slave does not have InnoDB support enabled. If this is the case, then the tables on the slave are created, but they use the MyISAM storage engine, and the `FOREIGN KEY` option is ignored. Now we insert some rows into the tables on the master:

```
master> INSERT INTO fc1 VALUES (1, 1), (2, 2);
Query OK, 2 rows affected (0.09 sec)
Records: 2 Duplicates: 0 Warnings: 0

master> INSERT INTO fc2 VALUES (1, 1), (2, 2), (3, 1);
Query OK, 3 rows affected (0.19 sec)
Records: 3 Duplicates: 0 Warnings: 0
```

At this point, on both the master and the slave, table `fc1` contains 2 rows, and table `fc2` contains 3 rows, as shown here:

```
master> SELECT * FROM fc1;
```

```

+---+-----+
| i | j   |
+---+-----+
| 1 | 1   |
| 2 | 2   |
+---+-----+
2 rows in set (0.00 sec)

master> SELECT * FROM fc2;
+---+-----+
| m | n   |
+---+-----+
| 1 | 1   |
| 2 | 2   |
| 3 | 1   |
+---+-----+
3 rows in set (0.00 sec)

slave> SELECT * FROM fc1;
+---+-----+
| i | j   |
+---+-----+
| 1 | 1   |
| 2 | 2   |
+---+-----+
2 rows in set (0.00 sec)

slave> SELECT * FROM fc2;
+---+-----+
| m | n   |
+---+-----+
| 1 | 1   |
| 2 | 2   |
| 3 | 1   |
+---+-----+
3 rows in set (0.00 sec)

```

Now suppose that you perform the following `DELETE` statement on the master:

```

master> DELETE FROM fc1 WHERE i=1;
Query OK, 1 row affected (0.09 sec)

```

Due to the cascade, table `fc2` on the master now contains only 1 row:

```

master> SELECT * FROM fc2;
+---+-----+
| m | n   |
+---+-----+
| 2 | 2   |
+---+-----+
1 row in set (0.00 sec)

```

However, the cascade does not propagate on the slave because on the slave the `DELETE` for `fc1` deletes no rows from `fc2`. The slave's copy of `fc2` still contains all of the rows that were originally inserted:

```

slave> SELECT * FROM fc2;
+---+-----+
| m | n   |
+---+-----+
| 1 | 1   |
| 3 | 1   |
| 2 | 2   |
+---+-----+
3 rows in set (0.00 sec)

```

This difference is due to the fact that the cascading deletes are handled internally by the `InnoDB` storage engine, which means that none of the changes are logged.

15.19 InnoDB memcached Plugin

The `InnoDB memcached` plugin (`daemon_memcached`) provides an integrated `memcached` daemon that automatically stores and retrieves data from `InnoDB` tables, turning the MySQL server into a fast “key-value store”. Instead of formulating queries in SQL, you can use simple `get`, `set`, and `incr` operations that avoid the performance overhead associated with SQL parsing and constructing a query optimization plan. You can also access the same `InnoDB` tables through SQL for convenience, complex queries, bulk operations, and other strengths of traditional database software.

This “NoSQL-style” interface uses the `memcached` API to speed up database operations, letting `InnoDB` handle memory caching using its `buffer pool` mechanism. Data modified through `memcached` operations such as `add`, `set`, and `incr` are stored to disk, in `InnoDB` tables. The combination of `memcached` simplicity and `InnoDB` reliability and consistency provides users with the best of both worlds, as explained in [Section 15.19.1, “Benefits of the InnoDB memcached Plugin”](#). For an architectural overview, see [Section 15.19.2, “InnoDB memcached Architecture”](#).

15.19.1 Benefits of the InnoDB memcached Plugin

This section outlines advantages the `daemon_memcached` plugin. The combination of `InnoDB` tables and `memcached` offers advantages over using either by themselves.

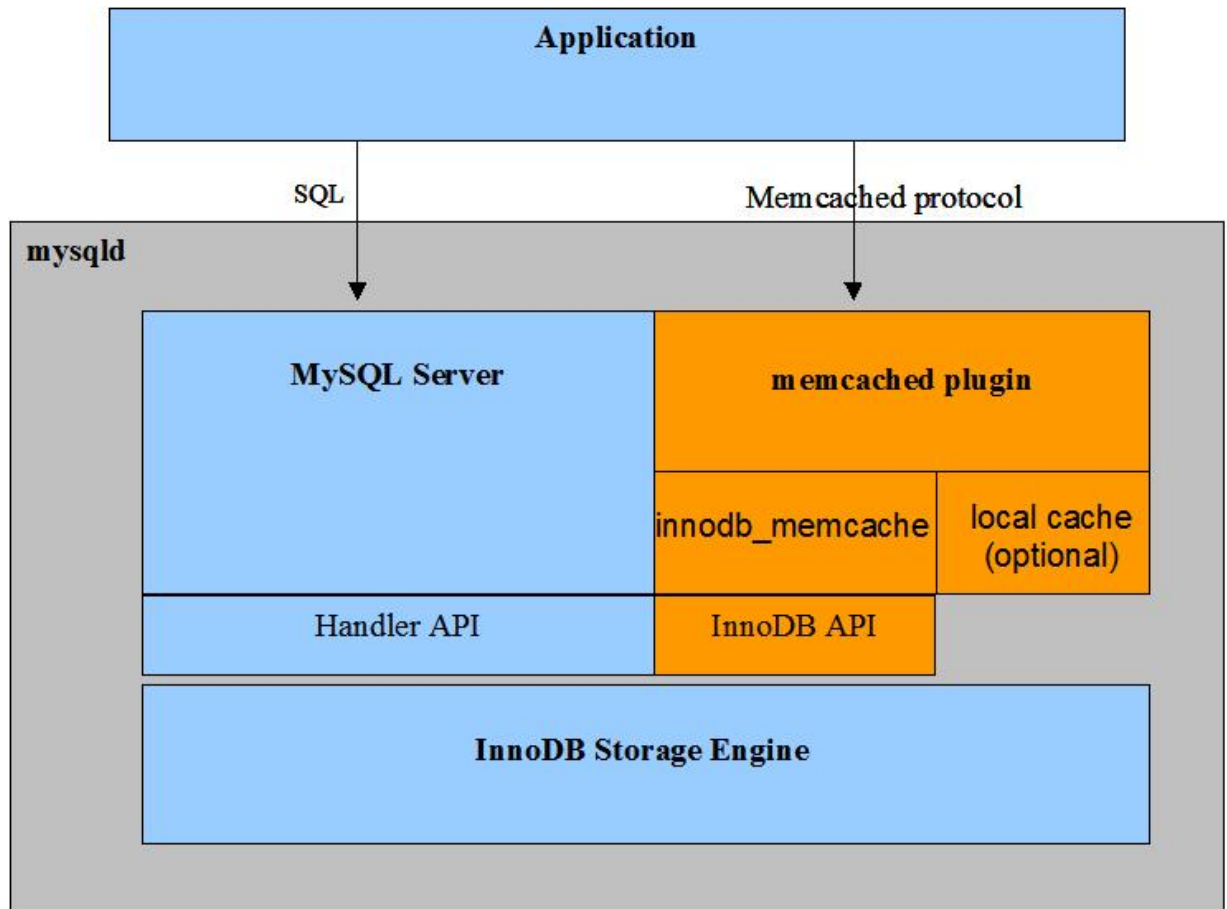

- Direct access to the `InnoDB` storage engine avoids the parsing and planning overhead of SQL.
- Running `memcached` in the same process space as the MySQL server avoids the network overhead of passing requests back and forth.
- Data written using the `memcached` protocol is transparently written to an `InnoDB` table, without going through the MySQL SQL layer. You can control frequency of writes to achieve higher raw performance when updating non-critical data.
- Data requested through the `memcached` protocol is transparently queried from an `InnoDB` table, without going through the MySQL SQL layer.
- Subsequent requests for the same data is served from the `InnoDB` buffer pool. The buffer pool handles the in-memory caching. You can tune performance of data-intensive operations using `InnoDB` configuration options.
- Data can be unstructured or structured, depending on the type of application. You can create a new table for data, or use existing tables.
- `InnoDB` can handle composing and decomposing multiple column values into a single `memcached` item value, reducing the amount of string parsing and concatenation required in your application. For example, you can store the string value `2 | 4 | 6 | 8` in the `memcached` cache, and have `InnoDB` split the value based on a separator character, then store the result in four numeric columns.
- The transfer between memory and disk is handled automatically, simplifying application logic.
- Data is stored in a MySQL database to protect against crashes, outages, and corruption.
- You can access the underlying `InnoDB` table through SQL for reporting, analysis, ad hoc queries, bulk loading, multi-step transactional computations, set operations such as union and intersection, and other operations suited to the expressiveness and flexibility of SQL.
- You can ensure high availability by using the `daemon_memcached` plugin on a `master server` in combination with MySQL replication.
- The integration of `memcached` with MySQL provides a way to make in-memory data persistent, so you can use it for more significant kinds of data. You can use more `add`, `incr`, and similar write operations in your application without concern that data could be lost. You can stop and start the `memcached` server without losing updates made to cached data. To guard against unexpected outages, you can take advantage of `InnoDB` crash recovery, replication, and backup capabilities.

- The way InnoDB does fast **primary key** lookups is a natural fit for memcached single-item queries. The direct, low-level database access path used by the `daemon_memcached` plugin is much more efficient for key-value lookups than equivalent SQL queries.
- The serialization features of memcached, which can turn complex data structures, binary files, or even code blocks into storable strings, offer a simple way to get such objects into a database.
- Because you can access the underlying data through SQL, you can produce reports, search or update across multiple keys, and call functions such as `AVG()` and `MAX()` on memcached data. All of these operations are expensive or complicated using memcached by itself.
- You do not need to manually load data into memcached at startup. As particular keys are requested by an application, values are retrieved from the database automatically, and cached in memory using the InnoDB **buffer pool**.
- Because memcached consumes relatively little CPU, and its memory footprint is easy to control, it can run comfortably alongside a MySQL instance on the same system.
- Because data consistency is enforced by mechanisms used for regular InnoDB tables, you do not have to worry about stale memcached data or fallback logic to query the database in the case of a missing key.

15.19.2 InnoDB memcached Architecture

The InnoDB memcached plugin implements memcached as a MySQL plugin daemon that accesses the InnoDB storage engine directly, bypassing the MySQL SQL layer.

The following diagram illustrates how an application accesses data through the `daemon_memcached` plugin, compared with SQL.

Features of the `daemon_memcached` plugin:

- `memcached` as a daemon plugin of `mysqld`. Both `mysqld` and `memcached` run in the same process space, with very low latency access to data.
- Direct access to `InnoDB` tables, bypassing the SQL parser, the optimizer, and even the Handler API layer.
- Standard `memcached` protocols, including the text-based protocol and the binary protocol. The `daemon_memcached` plugin passes all 55 compatibility tests of the `memcapable` command.
- Multi-column support. You can map multiple columns into the “value” part of the key/value store, with column values delimited by a user-specified separator character.
- By default, the `memcached` protocol is used to read and write data directly to `InnoDB`, letting MySQL manage in-memory caching using the `InnoDB` buffer pool. The default settings represent a combination of high reliability and the fewest surprises for database applications. For example, default settings avoid uncommitted data on the database side, or stale data returned for `memcached` `get` requests.
- Advanced users can configure the system as a traditional `memcached` server, with all data cached only in the `memcached` engine (memory caching), or use a combination of the “`memcached` engine” (memory caching) and the `InnoDB memcached` engine (`InnoDB` as back-end persistent storage).
- Control over how often data is passed back and forth between `InnoDB` and `memcached` operations through the `innodb_api_bk_commit_interval`, `daemon_memcached_r_batch_size`, and `daemon_memcached_w_batch_size` configuration options. Batch size options default to a value of 1 for maximum reliability.
- The ability to specify `memcached` options through the `daemon_memcached_option` configuration parameter. For example, you can change the port that `memcached` listens on, reduce the maximum number of simultaneous connections, change the maximum memory size for a key/value pair, or enable debugging messages for the error log.
- The `innodb_api_trx_level` configuration option controls the transaction `isolation level` on queries processed by `memcached`. Although `memcached` has no concept of `transactions`, you can use this option to control how soon `memcached` sees changes caused by SQL statements issued on the table used by the `daemon_memcached` plugin. By default, `innodb_api_trx_level` is set to `READ UNCOMMITTED`.
- The `innodb_api_enable_md` option can be used to lock the table at the MySQL level, so that the mapped table cannot be dropped or altered by `DDL` through the SQL interface. Without the lock, the table can be dropped from the MySQL layer, but kept in `InnoDB` storage until `memcached` or some other user stops using it. “MDL” stands for “metadata locking”.

Differences Between InnoDB memcached and Traditional memcached

You may already be familiar with using `memcached` with MySQL, as described in [Section 17.2, “Using MySQL with memcached”](#). This section describes how features of the integrated `InnoDB memcached` plugin differ from traditional `memcached`.

- Installation: The `memcached` library comes with the MySQL server, making installation and setup relatively easy. Installation involves running the `innodb_memcached_config.sql` script to create a `demo_test` table for `memcached` to use, issuing an `INSTALL PLUGIN` statement to enable the `daemon_memcached` plugin, and adding desired `memcached` options to a MySQL configuration file or startup script. You might still install the traditional `memcached` distribution for additional utilities such as `memcp`, `memcat`, and `memcapable`.

For comparison with traditional `memcached`, see [Section 17.2.1, “Installing memcached”](#).

- Deployment: With traditional `memcached`, it is typical to run large numbers of low-capacity `memcached` servers. A typical deployment of the `daemon_memcached` plugin, however, involves a smaller number of moderate or high-powered servers that are already running MySQL. The benefit of this configuration is in improving efficiency of individual database servers rather than

exploiting unused memory or distributing lookups across large numbers of servers. In the default configuration, very little memory is used for `memcached`, and in-memory lookups are served from the `InnoDB buffer pool`, which automatically caches the most recently and frequently used data. As with a traditional MySQL server instance, keep the value of the `innodb_buffer_pool_size` configuration option as high as practical (without causing paging at the OS level), so that as much work as possible is performed in memory.

For comparison with traditional `memcached`, see [Section 17.2.2.2, “memcached Deployment”](#).

- **Expiry:** By default (that is, using the `innodb_only` caching policy), the latest data from the `InnoDB` table is always returned, so the expiry options have no practical effect. If you change the caching policy to `caching` or `cache-only`, the expiry options work as usual, but requested data might be stale if it is updated in the underlying table before it expires from the memory cache.

For comparison with traditional `memcached`, see [Section 17.2.2.4, “Data Expiry”](#).

- **Namespaces:** `memcached` is like a large directory where you give files elaborate names with prefixes and suffixes to keep the files from conflicting. The `daemon_memcached` plugin lets you use similar naming conventions for keys, with one addition. Key names in the format `@@table_id.key.table_id` are decoded to reference a specific a table, using mapping data from the `innodb_memcache.containers` table. The `key` is looked up in or written to the specified table.

The `@@` notation only works for individual calls to `get`, `add`, and `set` functions, but not others such as `incr` or `delete`. To designate a default table for subsequent `memcached` operations within a session, perform a `get` request using the `@@` notation with a `table_id`, but without the key portion. For example:

```
get @@table_id
```

Subsequent `get`, `set`, `incr`, `delete`, and other operations use the table designated by `table_id` in the `innodb_memcache.containers.name` column.

For comparison with traditional `memcached`, see [Section 17.2.2.3, “Using Namespaces”](#).

- **Hashing and distribution:** The default configuration, which uses the `innodb_only` caching policy, is suitable for a traditional deployment configuration where all data is available on all servers, such as a set of replication slave servers.

If you physically divide data, as in a sharded configuration, you can split data across several machines running the `daemon_memcached` plugin, and use the traditional `memcached` hashing mechanism to route requests to a particular machine. On the MySQL side, you would typically let all data be inserted by `add` requests to `memcached` so that appropriate values are stored in the database on the appropriate server.

For comparison with traditional `memcached`, see [Section 17.2.2.5, “memcached Hashing/Distribution Types”](#).

- **Memory usage:** By default (with the `innodb_only` caching policy), the `memcached` protocol passes information back and forth with `InnoDB` tables, and the `InnoDB` buffer pool handles in-memory lookups instead of `memcached` memory usage growing and shrinking. Relatively little memory is used on the `memcached` side.

If you switch the caching policy to `caching` or `cache-only`, the normal rules of `memcached` memory usage apply. Memory for `memcached` data values is allocated in terms of “slabs”. You can control slab size and maximum memory used for `memcached`.

Either way, you can monitor and troubleshoot the `daemon_memcached` plugin using the familiar `statistics` system, accessed through the standard protocol, over a `telnet` session, for example. Extra utilities are not included with the `daemon_memcached` plugin. You can use the `memcached-tool` script to install a full `memcached` distribution.

For comparison with traditional `memcached`, see [Section 17.2.2.7, “Memory Allocation within memcached”](#).

- Thread usage: MySQL threads and `memcached` threads co-exist on the same server. Limits imposed on threads by the operating system apply to the total number of threads.

For comparison with traditional `memcached`, see [Section 17.2.2.8, “memcached Thread Support”](#).

- Log usage: Because the `memcached` daemon is run alongside the MySQL server and writes to `stderr`, the `-v`, `-vv`, and `-vvv` options for logging write output to the MySQL [error log](#).

For comparison with traditional `memcached`, see [Section 17.2.2.9, “memcached Logs”](#).

- `memcached` operations: Familiar `memcached` operations such as `get`, `set`, `add`, and `delete` are available. Serialization (that is, the exact string format representing complex data structures) depends on the language interface.

For comparison with traditional `memcached`, see [Section 17.2.3.1, “Basic memcached Operations”](#).

- Using `memcached` as a MySQL front end: This is the primary purpose of the `InnoDB memcached` plugin. An integrated `memcached` daemon improves application performance, and having `InnoDB` handle data transfers between memory and disk simplifies application logic.

For comparison with traditional `memcached`, see [Section 17.2.3.2, “Using memcached as a MySQL Caching Layer”](#).

- Utilities: The MySQL server includes the `libmemcached` library but not additional command-line utilities. To use commands such as `memcp`, `memcat`, and `memcapable` commands, install a full `memcached` distribution. When `memrm` and `memflush` remove items from the cache, the items are also removed from the underlying `InnoDB` table.

For comparison with traditional `memcached`, see [libmemcached Command-Line Utilities](#).

- Programming interfaces: You can access the MySQL server through the `daemon_memcached` plugin using all supported languages: [C and C++](#), [Java](#), [Perl](#), [Python](#), [PHP](#), and [Ruby](#). Specify the server hostname and port as with a traditional `memcached` server. By default, the `daemon_memcached` plugin listens on port `11211`. You can use both the [text and binary protocols](#). You can customize the [behavior](#) of `memcached` functions at runtime. Serialization (that is, the exact string format representing complex data structures) depends on the language interface.

For comparison with traditional `memcached`, see [Section 17.2.3, “Developing a memcached Application”](#).

- Frequently asked questions: MySQL has an extensive FAQ for traditional `memcached`. The FAQ is mostly applicable, except that using `InnoDB` tables as a storage medium for `memcached` data means that you can use `memcached` for more write-intensive applications than before, rather than as a read-only cache.

See [Section 17.2.5, “memcached FAQ”](#).

15.19.3 Setting Up the InnoDB memcached Plugin

This section describes how to set up the `daemon_memcached` plugin on a MySQL server. Because the `memcached` daemon is tightly integrated with the MySQL server to avoid network traffic and minimize latency, you perform this process on each MySQL instance that uses this feature.

Note

Before setting up the `daemon_memcached` plugin, consult [Section 15.19.5, “Security Considerations for the InnoDB memcached Plugin”](#) to understand the security procedures required to prevent unauthorized access.

Prerequisites

- The `daemon_memcached` plugin is only supported on Linux, Solaris, and OS X platforms. Other operating systems are not supported.
- When building MySQL from source, you must build with `-DWITH_INNODB_MEMCACHED=ON`. This build option generates two shared libraries in the MySQL plugin directory (`plugin_dir`) that are required to run the `daemon_memcached` plugin:
 - `libmemcached.so`: the `memcached` daemon plugin to MySQL.
 - `innodb_engine.so`: an InnoDB API plugin to `memcached`.
- `libevent` must be installed.
 - If you did not build MySQL from source, the `libevent` library is not included in your installation. Use the installation method for your operating system to install `libevent` 1.4.12 or later. For example, depending on the operating system, you might use `apt-get`, `yum`, or `port install`. For example, on Ubuntu Linux, use:

```
sudo apt-get install libevent-dev
```

- If you installed MySQL from a source code release, `libevent` 1.4.12 is bundled with the package and is located at the top level of the MySQL source code directory. If you use the bundled version of `libevent`, no action is required. If you want to use a local system version of `libevent`, you must build MySQL with the `-DWITH_LIBEVENT` build option set to `system` or `yes`.

Installing and Configuring the InnoDB memcached Plugin

1. Configure the `daemon_memcached` plugin so it can interact with InnoDB tables by running the `innodb_memcached_config.sql` configuration script, which is located in `MYSQL_HOME/share`. This script installs the `innodb_memcache` database with three required tables (`cache_policies`, `config_options`, and `containers`). It also installs the `demo_test` sample table in the `test` database.

```
mysql> source MYSQL_HOME/share/innodb_memcached_config.sql
```

Running the `innodb_memcached_config.sql` script is a one-time operation. The tables remain in place if you later uninstall and re-install the `daemon_memcached` plugin.

```
mysql> USE innodb_memcache;
mysql> SHOW TABLES;
+-----+
| Tables_in_innodb_memcache |
+-----+
| cache_policies            |
| config_options            |
| containers                 |
+-----+

mysql> USE test;
mysql> SHOW TABLES;
+-----+
| Tables_in_test |
+-----+
| demo_test      |
+-----+
```

Of these tables, the `innodb_memcache.containers` table is the most important. Entries in the `containers` table provide a mapping to InnoDB table columns. Each InnoDB table used with the `daemon_memcached` plugin requires an entry in the `containers` table.

The `innodb_memcached_config.sql` script inserts a single entry in the `containers` table that provides a mapping for the `demo_test` table. It also inserts a single row of data into the

`demo_test` table. This data allows you to immediately verify the installation after the setup is completed.

```
mysql> SELECT * FROM innodb_memcache.containers\G
***** 1. row *****
      name: aaa
      db_schema: test
      db_table: demo_test
      key_columns: c1
      value_columns: c2
      flags: c3
      cas_column: c4
      expire_time_column: c5
      unique_idx_name_on_key: PRIMARY

mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+-----+
| c1 | c2 | c3 | c4 | c5 |
+-----+-----+-----+-----+
| AA | HELLO, HELLO | 8 | 0 | 0 |
+-----+-----+-----+-----+
```

For more information about `innodb_memcache` tables and the `demo_test` sample table, see [Section 15.19.8, “InnoDB memcached Plugin Internals”](#).

2. Activate the `daemon_memcached` plugin by running the `INSTALL PLUGIN` statement:

```
mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

Once the plugin is installed, it is automatically activated each time the MySQL server is restarted.

Verifying the InnoDB and memcached Setup

To verify the `daemon_memcached` plugin setup, use a `telnet` session to issue `memcached` commands. By default, the `memcached` daemon listens on port 11211.

1. Retrieve data from the `test.demo_test` table. The single row of data in the `demo_test` table has a key value of `AA`.

```
telnet localhost 11211
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
get AA
VALUE AA 8 12
HELLO, HELLO
END
```

2. Insert data using a `set` command.

```
set BB 10 0 16
GOODBYE, GOODBYE
STORED
```

where:

- `set` is the command to store a value
- `BB` is the key
- `10` is a flag for the operation; ignored by `memcached` but may be used by the client to indicate any type of information; specify `0` if unused
- `0` is the expiration time (TTL); specify `0` if unused
- `16` is the length of the supplied value block in bytes

- `GOODBYE`, `GOODBYE` is the value that is stored
3. Verify that the data inserted is stored in MySQL by connecting to the MySQL server and querying the `test.demo_test` table.

```
mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+-----+
| c1 | c2 | c3 | c4 | c5 |
+-----+-----+-----+-----+
| AA | HELLO, HELLO | 8 | 0 | 0 |
| BB | GOODBYE, GOODBYE | 10 | 1 | 0 |
+-----+-----+-----+-----+
```

4. Return to the telnet session and retrieve the data that you inserted earlier using key `BB`.

```
get BB
VALUE BB 10 16
GOODBYE, GOODBYE
END
quit
```

If you shut down the MySQL server, which also shuts off the integrated `memcached` server, further attempts to access the `memcached` data fail with a connection error. Normally, the `memcached` data also disappears at this point, and you would require application logic to load the data back into memory when `memcached` is restarted. However, the `InnoDB memcached` plugin automates this process for you.

When you restart MySQL, `get` operations once again return the key/value pairs you stored in the earlier `memcached` session. When a key is requested and the associated value is not already in the memory cache, the value is automatically queried from the MySQL `test.demo_test` table.

Creating a New Table and Column Mapping

This example shows how to setup your own `InnoDB` table with the `daemon_memcached` plugin.

1. Create an `InnoDB` table. The table must have a key column with a unique index. The key column of the city table is `city_id`, which is defined as the primary key. The table must also include columns for `flags`, `cas`, and `expiry` values. There may be one or more value columns. The `city` table has three value columns (`name`, `state`, `country`).

Note

There is no special requirement with respect to column names as long as a valid mapping is added to the `innodb_memcache.containers` table.

```
mysql> CREATE TABLE city (
  city_id VARCHAR(32),
  name VARCHAR(1024),
  state VARCHAR(1024),
  country VARCHAR(1024),
  flags INT,
  cas BIGINT UNSIGNED,
  expiry INT,
  primary key(city_id)
) ENGINE=InnoDB;
```

2. Add an entry to the `innodb_memcache.containers` table so that the `daemon_memcached` plugin knows how to access the `InnoDB` table. The entry must satisfy the `innodb_memcache.containers` table definition. For a description of each field, see [Section 15.19.8, “InnoDB memcached Plugin Internals”](#).

```
mysql> DESCRIBE innodb_memcache.containers;
+-----+-----+-----+-----+-----+-----+
| Field | Type | Null | Key | Default | Extra |
+-----+-----+-----+-----+-----+-----+
```

name	varchar(50)	NO	PRI	NULL		
db_schema	varchar(250)	NO		NULL		
db_table	varchar(250)	NO		NULL		
key_columns	varchar(250)	NO		NULL		
value_columns	varchar(250)	YES		NULL		
flags	varchar(250)	NO		0		
cas_column	varchar(250)	YES		NULL		
expire_time_column	varchar(250)	YES		NULL		
unique_idx_name_on_key	varchar(250)	NO		NULL		

The `innodb_memcache.containers` table entry for the `city` table is defined as:

```
mysql> INSERT INTO `innodb_memcache`.`containers` (
`name`, `db_schema`, `db_table`, `key_columns`, `value_columns`,
`flags`, `cas_column`, `expire_time_column`, `unique_idx_name_on_key`)
VALUES ('default', 'test', 'city', 'city_id', 'name|state|country',
'flags','cas','expiry','PRIMARY');
```

- `default` is specified for the `containers.name` column to configure the `city` table as the default InnoDB table to be used with the `daemon_memcached` plugin.
 - Multiple InnoDB table columns (`name`, `state`, `country`) are mapped to `containers.value_columns` using a “|” delimiter.
 - The `flags`, `cas_column`, and `expire_time_column` fields of the `innodb_memcache.containers` table are typically not significant in applications using the `daemon_memcached` plugin. However, a designated InnoDB table column is required for each. When inserting data, specify `0` for these columns if they are unused.
3. After updating the `innodb_memcache.containers` table, restart the `daemon_memcache` plugin to apply the changes.

```
mysql> UNINSTALL PLUGIN daemon_memcached;
mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

4. Using telnet, insert data into the `city` table using a `memcached set` command.

```
telnet localhost 11211
Trying 127.0.0.1...
Connected to localhost.
Escape character is '^]'.
set B 0 0 22
BANGALORE|BANGALORE|IN
STORED
```

5. Using MySQL, query the `test.city` table to verify that the data you inserted was stored.

```
mysql> SELECT * FROM test.city;
+-----+-----+-----+-----+-----+-----+-----+
| city_id | name      | state      | country | flags | cas | expiry |
+-----+-----+-----+-----+-----+-----+-----+
| B       | BANGALORE | BANGALORE | IN      |      | 3   | 0       |
+-----+-----+-----+-----+-----+-----+-----+
```

6. Using MySQL, insert additional data into the `test.city` table.

```
mysql> INSERT INTO city VALUES ('C','CHENNAI','TAMIL NADU','IN', 0, 0 ,0);
mysql> INSERT INTO city VALUES ('D','DELHI','DELHI','IN', 0, 0, 0);
mysql> INSERT INTO city VALUES ('H','HYDERABAD','TELANGANA','IN', 0, 0, 0);
mysql> INSERT INTO city VALUES ('M','MUMBAI','MAHARASHTRA','IN', 0, 0, 0);
```

**Note**

It is recommended that you specify a value of 0 for the `flags`, `cas_column`, and `expire_time_column` fields if they are unused.

- Using telnet, issue a `memcached get` command to retrieve data you inserted using MySQL.

```
get H
VALUE H 0 22
HYDERABAD | TELANGANA | IN
END
```

Configuring the InnoDB memcached Plugin

Traditional `memcached` configuration options may be specified in a MySQL configuration file or a `mysqld` startup string, encoded in the argument of the `daemon_memcached_option` configuration parameter. `memcached` configuration options take effect when the plugin is loaded, which occurs each time the MySQL server is started.

For example, to make `memcached` listen on port 11222 instead of the default port 11211, specify `-p11222` as an argument of the `daemon_memcached_option` configuration option:

```
mysqld ... --daemon_memcached_option="-p11222"
```

Other `memcached` options can be encoded in the `daemon_memcached_option` string. For example, you can specify options to reduce the maximum number of simultaneous connections, change the maximum memory size for a key/value pair, or enable debugging messages for the error log, and so on.

There are also configuration options specific to the `daemon_memcached` plugin. These include:

- `daemon_memcached_engine_lib_name`: Specifies the shared library that implements the InnoDB `memcached` plugin. The default setting is `innodb_engine.so`.
- `daemon_memcached_engine_lib_path`: The path of the directory containing the shared library that implements the InnoDB `memcached` plugin. The default is NULL, representing the plugin directory.
- `daemon_memcached_r_batch_size`: Defines the batch commit size for read operations (`get`). It specifies the number of `memcached` read operations after which a `commit` occurs. `daemon_memcached_r_batch_size` is set to 1 by default so that every `get` request accesses the most recently committed data in the InnoDB table, whether the data was updated through `memcached` or by SQL. When the value is greater than 1, the counter for read operations is incremented with each `get` call. A `flush_all` call resets both read and write counters.
- `daemon_memcached_w_batch_size`: Defines the batch commit size for write operations (`set`, `replace`, `append`, `prepend`, `incr`, `decr`, and so on). `daemon_memcached_w_batch_size` is set to 1 by default so that no uncommitted data is lost in case of an outage, and so that SQL queries on the underlying table access the most recent data. When the value is greater than 1, the counter for write operations is incremented for each `add`, `set`, `incr`, `decr`, and `delete` call. A `flush_all` call resets both read and write counters.

By default, you do not need to modify `daemon_memcached_engine_lib_name` or `daemon_memcached_engine_lib_path`. You might configure these options if, for example, you want to use a different storage engine for `memcached` (such as the NDB `memcached` engine).

`daemon_memcached` plugin configuration parameters may be specified in the MySQL configuration file or in a `mysqld` startup string. They take effect when you load the `daemon_memcached` plugin.

When making changes to `daemon_memcached` plugin configuration, reload the plugin to apply the changes. To do so, issue the following statements:

```
mysql> UNINSTALL PLUGIN daemon_memcached;
mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

Configuration settings, required tables, and data are preserved when the plugin is restarted.

For additional information about enabling and disabling plugins, see [Section 5.6.2, “Installing and Uninstalling Plugins”](#).

15.19.4 InnoDB memcached Multiple get and Range Query Support

The `daemon_memcached` plugin supports multiple get operations (fetching multiple key/value pairs in a single `memcached` query) and range queries.

Multiple get Operations

The ability to fetch multiple key/value pairs in a single `memcached` query improves read performance by reducing communication traffic between the client and server. For `InnoDB`, it means fewer transactions and open-table operations.

The following example demonstrates multiple-get support. The example uses the `test.city` table described in [Creating a New Table and Column Mapping](#).

```
mysql> USE test;
mysql> SELECT * FROM test.city;
```

city_id	name	state	country	flags	cas	expiry
B	BANGALORE	BANGALORE	IN	0	1	0
C	CHENNAI	TAMIL NADU	IN	0	0	0
D	DELHI	DELHI	IN	0	0	0
H	HYDERABAD	TELANGANA	IN	0	0	0
M	MUMBAI	MAHARASHTRA	IN	0	0	0

Run a `get` command to retrieve all values from the `city` table. The results are returned in a key/value pair sequence.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
get B C D H M
VALUE B 0 22
BANGALORE|BANGALORE|IN
VALUE C 0 21
CHENNAI|TAMIL NADU|IN
VALUE D 0 14
DELHI|DELHI|IN
VALUE H 0 22
HYDERABAD|TELANGANA|IN
VALUE M 0 21
MUMBAI|MAHARASHTRA|IN
END
```

When retrieving multiple values in a single `get` command, you can switch tables (using `@@containers.name` notation) to retrieve the value for the first key, but you cannot switch tables for subsequent keys. For example, the table switch in this example is valid:

```
get @@aaa.AA BB
VALUE @@aaa.AA 8 12
```

```
HELLO, HELLO
VALUE BB 10 16
GOODBYE, GOODBYE
END
```

Attempting to switch tables again in the same `get` command to retrieve a key value from a different table is not supported.

Range Queries

For range queries, the `daemon_memcached` plugin supports the following comparison operators: `<`, `>`, `<=`, `>=`. An operator must be preceded by an `@` symbol. When a range query finds multiple matching key/value pairs, results are returned in a key/value pair sequence.

The following examples demonstrate range query support. The examples use the `test.city` table described in [Creating a New Table and Column Mapping](#).

```
mysql> SELECT * FROM test.city;
+-----+-----+-----+-----+-----+-----+-----+
| city_id | name      | state      | country | flags | cas  | expiry |
+-----+-----+-----+-----+-----+-----+-----+
| B       | BANGALORE | BANGALORE  | IN      | 0     | 1    | 0       |
| C       | CHENNAI   | TAMIL NADU | IN      | 0     | 0    | 0       |
| D       | DELHI     | DELHI      | IN      | 0     | 0    | 0       |
| H       | HYDERABAD | TELANGANA  | IN      | 0     | 0    | 0       |
| M       | MUMBAI    | MAHARASHTRA | IN     | 0     | 0    | 0       |
+-----+-----+-----+-----+-----+-----+-----+
```

Open a telnet session:

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
```

To get all values greater than `B`, enter `get @>B`:

```
get @>B
VALUE C 0 21
CHENNAI|TAMIL NADU|IN
VALUE D 0 14
DELHI|DELHI|IN
VALUE H 0 22
HYDERABAD|TELANGANA|IN
VALUE M 0 21
MUMBAI|MAHARASHTRA|IN
END
```

To get all values less than `M`, enter `get @<M`:

```
get @<M
VALUE B 0 22
BANGALORE|BANGALORE|IN
VALUE C 0 21
CHENNAI|TAMIL NADU|IN
VALUE D 0 14
DELHI|DELHI|IN
VALUE H 0 22
HYDERABAD|TELANGANA|IN
END
```

To get all values less than and including `M`, enter `get @<=M`:

```
get @<=M
VALUE B 0 22
BANGALORE|BANGALORE|IN
VALUE C 0 21
CHENNAI|TAMIL NADU|IN
VALUE D 0 14
DELHI|DELHI|IN
VALUE H 0 22
HYDERABAD|TELANGANA|IN
VALUE M 0 21
MUMBAI|MAHARASHTRA|IN
```

To get values greater than **B** but less than **M**, enter `get @>B@<M`:

```
get @>B@<M
VALUE C 0 21
CHENNAI|TAMIL NADU|IN
VALUE D 0 14
DELHI|DELHI|IN
VALUE H 0 22
HYDERABAD|TELANGANA|IN
END
```

A maximum of two comparison operators can be parsed, one being either a 'less than' (`@<`) or 'less than or equal to' (`@<=`) operator, and the other being either a 'greater than' (`@>`) or 'greater than or equal to' (`@>=`) operator. Any additional operators are assumed to be part of the key. For example, if you issue a `get` command with three operators, the third operator (`@>C`) is treated as part of the key, and the `get` command searches for values smaller than **M** and greater than `B@>C`.

```
get @<M@>B@>C
VALUE C 0 21
CHENNAI|TAMIL NADU|IN
VALUE D 0 14
DELHI|DELHI|IN
VALUE H 0 22
HYDERABAD|TELANGANA|IN
```

15.19.5 Security Considerations for the InnoDB memcached Plugin

Caution

Consult this section before deploying the `daemon_memcached` plugin on a production server, or even on a test server if the MySQL instance contains sensitive data.

Because `memcached` does not use an authentication mechanism by default, and the optional SASL authentication is not as strong as traditional DBMS security measures, only keep non-sensitive data in the MySQL instance that uses the `daemon_memcached` plugin, and wall off any servers that use this configuration from potential intruders. Do not allow `memcached` access to these servers from the Internet; only allow access from within a firewalled intranet, ideally from a subnet whose membership you can restrict.

Password-Protecting memcached Using SASL

SASL support provides the capability to protect your MySQL database from unauthenticated access through `memcached` clients. This section explains how to enable SASL with the `daemon_memcached` plugin. The steps are almost identical to those performed to enable SASL for a traditional `memcached` server.

SASL stands for “Simple Authentication and Security Layer”, a standard for adding authentication support to connection-based protocols. `memcached` added SASL support in version 1.4.3.

SASL authentication is only supported with the binary protocol.

`memcached` clients are only able to access `InnoDB` tables that are registered in the `innodb_memcache.containers` table. Even though a DBA can place access restrictions on such tables, access through `memcached` applications cannot be controlled. For this reason, SASL support is provided to control access to `InnoDB` tables associated with the `daemon_memcached` plugin.

The following section shows how to build, enable, and test an SASL-enabled `daemon_memcached` plugin.

Building and Enabling SASL with the InnoDB memcached Plugin

By default, an SASL-enabled `daemon_memcached` plugin is not included in MySQL release packages, since an SASL-enabled `daemon_memcached` plugin requires building `memcached` with SASL libraries. To enable SASL support, download the MySQL source and rebuild the `daemon_memcached` plugin after downloading the SASL libraries:

1. Install the SASL development and utility libraries. For example, on Ubuntu, use `apt-get` to obtain the libraries:

```
sudo apt-get -f install libsasl2-2 sasl2-bin libsasl2-2 libsasl2-dev libsasl2-modules
```

2. Build the `daemon_memcached` plugin shared libraries with SASL capability by adding `ENABLE_MEMCACHED_SASL=1` to your `cmake` options. `memcached` also provides *simple cleartext password support*, which facilitates testing. To enable simple cleartext password support, specify the `ENABLE_MEMCACHED_SASL_PWDB=1` `cmake` option.

In summary, add following three `cmake` options:

```
cmake ... -DWITH_INNODB_MEMCACHED=1 -DENABLE_MEMCACHED_SASL=1 -DENABLE_MEMCACHED_SASL_PWDB=1
```

3. Install the `daemon_memcached` plugin, as described in [Section 15.19.3, "Setting Up the InnoDB memcached Plugin"](#).
4. Configure a user name and password file. (This example uses `memcached` simple cleartext password support.)
 - a. In a file, create a user named `testname` and define the password as `testpasswd`:

```
echo "testname:testpasswd:::::::::" >/home/jy/memcached-sasl-db
```

- b. Configure the `MEMCACHED_SASL_PWDB` environment variable to inform `memcached` of the user name and password file:

```
export MEMCACHED_SASL_PWDB=/home/jy/memcached-sasl-db
```

- c. Inform `memcached` that a cleartext password is used:

```
echo "mech_list: plain" > /home/jy/work2/msasl/clients/memcached.conf
export SASL_CONF_PATH=/home/jy/work2/msasl/clients
```

5. Enable SASL by restarting the MySQL server with the `memcached -S` option encoded in the `daemon_memcached_option` configuration parameter:

```
mysqld ... --daemon_memcached_option="-S"
```

6. To test the setup, use an SASL-enabled client such as [SASL-enabled libmemcached](#).

```
memcp --servers=localhost:11211 --binary --username=testname
--password=testpasswd myfile.txt
```

```
memcat --servers=localhost:11211 --binary --username=testname
      --password=testpasswd myfile.txt
```

If you specify an incorrect user name or password, the operation is rejected with a `memcache error AUTHENTICATION FAILURE` message. In this case, examine the cleartext password set in the `memcached-sasl-db` file to verify that the credentials you supplied are correct.

There are other methods to test SASL authentication with `memcached`, but the method described above is the most straightforward.

15.19.6 Writing Applications for the InnoDB memcached Plugin

Typically, writing an application for the `InnoDB memcached` plugin involves some degree of rewriting or adapting existing code that uses MySQL or the `memcached` API.

- With the `daemon_memcached` plugin, instead of many traditional `memcached` servers running on low-powered machines, you have the same number of `memcached` servers as MySQL servers, running on relatively high-powered machines with substantial disk storage and memory. You might reuse some existing code that works with the `memcached` API, but adaptation is likely required due to the different server configuration.
- The data stored through the `daemon_memcached` plugin goes into `VARCHAR`, `TEXT`, or `BLOB` columns, and must be converted to do numeric operations. You can perform the conversion on the application side, or by using the `CAST()` function in queries.
- Coming from a database background, you might be used to general-purpose SQL tables with many columns. The tables accessed by `memcached` code likely have only a few or even a single column holding data values.
- You might adapt parts of your application that perform single-row queries, inserts, updates, or deletes, to improve performance in critical sections of code. Both `queries` (read) and `DML` (write) operations can be substantially faster when performed through the `InnoDB memcached` interface. The performance improvement for writes is typically greater than the performance improvement for reads, so you might focus on adapting code that performs logging or records interactive choices on a web site.

The following sections explore these points in more detail.

15.19.6.1 Adapting an Existing MySQL Schema for the InnoDB memcached Plugin

Consider these aspects of `memcached` applications when adapting an existing MySQL schema or application to use the `daemon_memcached` plugin:

- `memcached` keys cannot contain spaces or newlines, because these characters are used as separators in the ASCII protocol. If you are using lookup values that contain spaces, transform or hash them into values without spaces before using them as keys in calls to `add()`, `set()`, `get()`, and so on. Although theoretically these characters are allowed in keys in programs that use the binary protocol, you should restrict the characters used in keys to ensure compatibility with a broad range of clients.
- If there is a short numeric `primary key` column in an `InnoDB` table, use it as the unique lookup key for `memcached` by converting the integer to a string value. If the `memcached` server is used for multiple applications, or with more than one `InnoDB` table, consider modifying the name to ensure that it is unique. For example, prepend the table name, or the database name and the table name, before the numeric value.

Note

The `daemon_memcached` plugin supports inserts and reads on mapped `InnoDB` tables that have an `INTEGER` defined as the primary key.

- You cannot use a partitioned table for data queried or stored using `memcached`.
- The `memcached` protocol passes numeric values around as strings. To store numeric values in the underlying InnoDB table, to implement counters that can be used in SQL functions such as `SUM()` or `AVG()`, for example:
 - Use `VARCHAR` columns with enough characters to hold all the digits of the largest expected number (and additional characters if appropriate for the negative sign, decimal point, or both).
 - In any query that performs arithmetic using column values, use the `CAST()` function to convert the values from string to integer, or to some other numeric type. For example:

```
-- Alphabetic entries are returned as zero.
select cast(c2 as unsigned integer) from demo_test;
-- Since there could be numeric values of 0, can't disqualify them.
-- Test the string values to find the ones that are integers, and average only those.
select avg(cast(c2 as unsigned integer)) from demo_test
  where c2 between '0' and '9999999999';
-- Views let you hide the complexity of queries. The results are already converted;
-- no need to repeat conversion functions and WHERE clauses each time.
create view numbers as select c1 key, cast(c2 as unsigned integer) val
  from demo_test where c2 between '0' and '9999999999';
select sum(val) from numbers;
```

Note

Any alphabetic values in the result set are converted into 0 by the call to `CAST()`. When using functions such as `AVG()`, which depend on the number of rows in the result set, include `WHERE` clauses to filter out non-numeric values.

- If the InnoDB column used as a key could have values longer than 250 bytes, hash the value to less than 250 bytes.
- To use an existing table with the `daemon_memcached` plugin, define an entry for it in the `innodb_memcache.containers` table. To make that table the default for all `memcached` requests, specify a value of `default` in the `name` column, then restart the MySQL server to make the change take effect. If you use multiple tables for different classes of `memcached` data, set up multiple entries in the `innodb_memcache.containers` table with `name` values of your choice, then issue a `memcached` request in the form of `get @@name` or `set @@name` within the application to specify the table to be used for subsequent `memcached` requests.

For an example of using a table other than the predefined `test.demo_test` table, see [Example 15.13, “Using Your Own Table with an InnoDB memcached Application”](#). For the required table layout, see [Section 15.19.8, “InnoDB memcached Plugin Internals”](#).

- To use multiple InnoDB table column values with `memcached` key/value pairs, specify column names separated by comma, semicolon, space, or pipe characters in the `value_columns` field of the `innodb_memcache.containers` entry for the InnoDB table. For example, specify `col1,col2,col3` or `col1|col2|col3` in the `value_columns` field.

Concatenate the column values into a single string using the pipe character as a separator before passing the string to `memcached add` or `set` calls. The string is unpacked automatically into the correct column. Each `get` call returns a single string containing the column values that is also delimited by the pipe character. You can unpack the values using the appropriate application language syntax.

Example 15.13 Using Your Own Table with an InnoDB memcached Application

This example shows how to use your own table with a sample Python application that uses `memcached` for data manipulation.

The example assumes that the `daemon_memcached` plugin is installed as described in [Section 15.19.3, “Setting Up the InnoDB memcached Plugin”](#). It also assumes that your system is configured to run a Python script that uses the `python-memcache` module.

1. Create the `multicol` table which stores country information including population, area, and driver side data ('R' for right and 'L' for left).

```
mysql> USE test;

mysql> CREATE TABLE `multicol` (
  `country` varchar(128) NOT NULL DEFAULT '',
  `population` varchar(10) DEFAULT NULL,
  `area_sq_km` varchar(9) DEFAULT NULL,
  `drive_side` varchar(1) DEFAULT NULL,
  `c3` int(11) DEFAULT NULL,
  `c4` bigint(20) unsigned DEFAULT NULL,
  `c5` int(11) DEFAULT NULL,
  PRIMARY KEY (`country`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;
```

2. Insert a record into the `innodb_memcache.containers` table so that the `daemon_memcached` plugin can access the `multicol` table.

```
mysql> INSERT INTO innodb_memcache.containers
  (name,db_schema,db_table,key_columns,value_columns,flags,cas_column,
  expire_time_column,unique_idx_name_on_key)
VALUES
  ('bbb','test','multicol','country','population,area_sq_km,drive_side',
  'c3','c4','c5','PRIMARY');

mysql> COMMIT;
```

- The `innodb_memcache.containers` record for the `multicol` table specifies a `name` value of 'bbb', which is the table identifier.

Note

If a single InnoDB table is used for all memcached applications, the `name` value can be set to `default` to avoid using `@@` notation to switch tables.

- The `db_schema` column is set to `test`, which is the name of the database where the `multicol` table resides.
- The `db_table` column is set to `multicol`, which is the name of the InnoDB table.
- `key_columns` is set to the unique `country` column. The `country` column is defined as the primary key in the `multicol` table definition.
- Rather than a single InnoDB table column to hold a composite data value, data is divided among three table columns (`population`, `area_sq_km`, and `drive_side`). To accommodate multiple value columns, a comma-separated list of columns is specified in the `value_columns` field. The columns defined in the `value_columns` field are the columns used when storing or retrieving values.
- Values for the `flags`, `expire_time`, and `cas_column` fields are based on values used in the `demo.test` sample table. These fields are typically not significant in applications that use the `daemon_memcached` plugin because MySQL keeps data synchronized, and there is no need to worry about data expiring or becoming stale.
- The `unique_idx_name_on_key` field is set to `PRIMARY`, which refers to the primary index defined on the unique `country` column in the `multicol` table.

- Copy the sample Python application into a file. In this example, the sample script is copied to a file named `multicol.py`.

The sample Python application inserts data into the `multicol` table and retrieves data for all keys, demonstrating how to access an InnoDB table through the `daemon_memcached` plugin.

```
import sys, os
import memcache

def connect_to_memcached():
    memc = memcache.Client(['127.0.0.1:11211'], debug=0);
    print "Connected to memcached."
    return memc

        (m_population, m_area, m_drive_side) = result.split("|")
        print "Unpacked population value: " + m_population
        print "Unpacked area value      : " + m_area
        print "Unpacked drive side value: " + m_drive_side

if __name__ == '__main__':
```

```

memc = connect_to_memcached()
switch_table(memc, "bbb")
insert_country_data(memc)
query_country_data(memc)

sys.exit(0)

```

Sample Python application notes:

- No database authorization is required to run the application, since data manipulation is performed through the `memcached` interface. The only required information is the port number on the local system where the `memcached` daemon listens.
- To make sure the application uses the `multicol` table, the `switch_table()` function is called, which performs a dummy `get` or `set` request using `@@` notation. The `name` value in the request is `bbb`, which is the `multicol` table identifier defined in the `innodb_memcache.containers.name` field.

A more descriptive `name` value might be used in a real-world application. This example simply illustrates that a table identifier is specified rather than the table name in `get @@...` requests.

- The utility functions used to insert and query data demonstrate how to turn a Python data structure into pipe-separated values for sending data to MySQL with `add` or `set` requests, and how to unpack the pipe-separated values returned by `get` requests. This extra processing is only required when mapping a single `memcached` value to multiple MySQL table columns.

4. Run the sample Python application.

```
shell> python multicol.py
```

If successful, the sample application returns this output:

```

Connected to memcached.
Switching default table to 'bbb' by issuing GET for '@@bbb'.

```

5. Query the `innodb_memcache.containers` table to view the record you inserted earlier for the `multicol` table. The first record is the sample entry for the `demo_test` table that is created during the initial `daemon_memcached` plugin setup. The second record is the entry you inserted for the `multicol` table.

```

mysql> SELECT * FROM innodb_memcache.containers\G
***** 1. row *****
      name: aaa
    db_schema: test
      db_table: demo_test
  key_columns: c1
value_columns: c2
         flags: c3
    cas_column: c4

```

```

    expire_time_column: c5
unique_idx_name_on_key: PRIMARY
***** 2. row *****
    name: bbb
    db_schema: test
    db_table: multicol
    key_columns: country
    value_columns: population,area_sq_km,drive_side
    flags: c3
    cas_column: c4
    expire_time_column: c5
unique_idx_name_on_key: PRIMARY

```

6. Query the `multicol` table to view data inserted by the sample Python application. The data is available for MySQL [queries](#), which demonstrates how the same data can be accessed using SQL or through applications (using the appropriate [MySQL Connector or API](#)).

```

mysql> SELECT * FROM test.multicol;
+-----+-----+-----+-----+-----+-----+
| country | population | area_sq_km | drive_side | c3 | c4 | c5 |
+-----+-----+-----+-----+-----+-----+
| Canada | 34820000 | 9984670 | R | 0 | 11 | 0 |
| China | 1347350000 | 9640821 | R | 0 | 20 | 0 |
| Denmark | 5543453 | 43094 | R | 0 | 16 | 0 |
| India | 1210193422 | 3287263 | L | 0 | 19 | 0 |
| Ireland | 6399152 | 84421 | L | 0 | 13 | 0 |
| Mexico | 113910608 | 1972550 | R | 0 | 15 | 0 |
| Norway | 5002942 | 385252 | R | 0 | 17 | 0 |
| UAE | 8264070 | 83600 | R | 0 | 18 | 0 |
| UK | 62262000 | 243610 | L | 0 | 14 | 0 |
| USA | 314242000 | 9826675 | R | 0 | 12 | 0 |
+-----+-----+-----+-----+-----+-----+

```

Note

Always allow sufficient size to hold necessary digits, decimal points, sign characters, leading zeros, and so on when defining the length for columns that are treated as numbers. Too-long values in a string column such as a `VARCHAR` are truncated by removing some characters, which could produce nonsensical numeric values.

7. Optionally, run report-type queries on the `InnoDB` table that stores the `memcached` data.

You can produce reports through SQL queries, performing calculations and tests across any columns, not just the `country` key column. (Because the following examples use data from only a few countries, the numbers are for illustration purposes only.) The following queries return the average population of countries where people drive on the right, and the average size of countries whose names start with “U”:

```

mysql> SELECT AVG(population) FROM multicol WHERE drive_side = 'R';
+-----+
| avg(population) |
+-----+
| 261304724.7142857 |
+-----+

mysql> SELECT SUM(area_sq_km) FROM multicol WHERE country LIKE 'U%';
+-----+
| sum(area_sq_km) |
+-----+
| 10153885 |
+-----+

```

Because the `population` and `area_sq_km` columns store character data rather than strongly typed numeric data, functions such as `AVG()` and `SUM()` work by converting each value to a number first. This approach *does not work* for operators such as `<` or `>`, for example, when

comparing character-based values, `9 > 1000`, which is not expected from a clause such as `ORDER BY population DESC`. For the most accurate type treatment, perform queries against views that cast numeric columns to the appropriate types. This technique lets you issue simple `SELECT *` queries from database applications, while ensuring that casting, filtering, and ordering is correct. The following example shows a view that can be queried to find the top three countries in descending order of population, with the results reflecting the latest data in the `multicol` table, and with population and area figures treated as numbers:

```
mysql> CREATE VIEW populous_countries AS
SELECT
    country,
    cast(population as unsigned integer) population,
    cast(area_sq_km as unsigned integer) area_sq_km,
    drive_side FROM multicol
ORDER BY CAST(population as unsigned integer) DESC
LIMIT 3;
```

```
mysql> SELECT * FROM populous_countries;
```

country	population	area_sq_km	drive_side
China	1347350000	9640821	R
India	1210193422	3287263	L
USA	314242000	9826675	R

```
mysql> DESC populous_countries;
```

Field	Type	Null	Key	Default	Extra
country	varchar(128)	NO			
population	bigint(10) unsigned	YES		NULL	
area_sq_km	int(9) unsigned	YES		NULL	
drive_side	varchar(1)	YES		NULL	

15.19.6.2 Adapting a memcached Application for the InnoDB memcached Plugin

Consider these aspects of MySQL and InnoDB tables when adapting existing memcached applications to use the `daemon_memcached` plugin:

- If there are key values longer than a few bytes, it may be more efficient to use a numeric auto-increment column as the **primary key** of the InnoDB table, and to create a unique **secondary index** on the column that contains the memcached key values. This is because InnoDB performs best for large-scale insertions if primary key values are added in sorted order (as they are with auto-increment values). Primary key values are included in secondary indexes, which takes up unnecessary space if the primary key is a long string value.
- If you store several different classes of information using memcached, consider setting up a separate InnoDB table for each type of data. Define additional table identifiers in the `innodb_memcache.containers` table, and use the `@@table_id.key` notation to store and retrieve items from different tables. Physically dividing different types of information allows you tune the characteristics of each table for optimum space utilization, performance, and reliability. For example, you might enable **compression** for a table that holds blog posts, but not for a table that holds thumbnail images. You might back up one table more frequently than another because it holds critical data. You might create additional **secondary indexes** on tables that are frequently used to generate reports using SQL.
- Preferably, configure a stable set of table definitions for use with the `daemon_memcached` plugin, and leave the tables in place permanently. Changes to the `innodb_memcache.containers` table take effect the next time the `innodb_memcache.containers` table is queried. Entries in the containers table are processed at startup, and are consulted whenever an unrecognized table identifier (as defined by `containers.name`) is requested using `@@` notation. Thus, new entries are

visible as soon as you use the associated table identifier, but changes to existing entries require a server restart before they take effect.

- When you use the default `innodb_only` caching policy, calls to `add()`, `set()`, `incr()`, and so on can succeed but still trigger debugging messages such as `while expecting 'STORED', got unexpected response 'NOT_STORED'`. Debug messages occur because new and updated values are sent directly to the InnoDB table without being saved in the memory cache, due to the `innodb_only` caching policy.

15.19.6.3 Tuning InnoDB memcached Plugin Performance

Because using InnoDB in combination with memcached involves writing all data to disk, whether immediately or sometime later, raw performance is expected to be somewhat slower than using memcached by itself. When using the InnoDB memcached plugin, focus tuning goals for memcached operations on achieving better performance than equivalent SQL operations.

Benchmarks suggest that queries and DML operations (inserts, updates, and deletes) that use the memcached interface are faster than traditional SQL. DML operations typically see a larger improvements. Therefore, consider adapting write-intensive applications to use the memcached interface first. Also consider prioritizing adaptation of write-intensive applications that use fast, lightweight mechanisms that lack reliability.

Adapting SQL Queries

The types of queries that are most suited to simple GET requests are those with a single clause or a set of AND conditions in the WHERE clause:

```
SQL:
SELECT col FROM tbl WHERE key = 'key_value';

memcached:
GET key_value

SQL:
SELECT col FROM tbl WHERE col1 = val1 and col2 = val2 and col3 = val3;

memcached:
# Since you must always know these 3 values to look up the key,
# combine them into a unique string and use that as the key
# for all ADD, SET, and GET operations.
key_value = val1 + ":" + val2 + ":" + val3
GET key_value

SQL:
SELECT 'key exists!' FROM tbl
  WHERE EXISTS (SELECT col1 FROM tbl WHERE KEY = 'key_value') LIMIT 1;

memcached:
# Test for existence of key by asking for its value and checking if the call succeeds,
# ignoring the value itself. For existence checking, you typically only store a very
# short value such as "1".
GET key_value
```

Using System Memory

For best performance, deploy the `daemon_memcached` plugin on machines that are configured as typical database servers, where the majority of system RAM is devoted to the InnoDB buffer pool, through the `innodb_buffer_pool_size` configuration option. For systems with multi-gigabyte buffer pools, consider raising the value of `innodb_buffer_pool_instances` for maximum throughput when most operations involve data that is already cached in memory.

Reducing Redundant I/O

InnoDB has a number of settings that let you choose the balance between high reliability, in case of a crash, and the amount of I/O overhead during high write workloads. For example, consider setting the `innodb_doublewrite` to 0 and `innodb_flush_log_at_trx_commit` to 2. Measure performance with different `innodb_flush_method` settings.

For other ways to reduce or tune I/O for table operations, see [Section 8.5.8, “Optimizing InnoDB Disk I/O”](#).

Reducing Transactional Overhead

A default value of 1 for `daemon_memcached_r_batch_size` and `daemon_memcached_w_batch_size` is intended for maximum reliability of results and safety of stored or updated data.

Depending on the type of application, you might increase one or both of these settings to reduce the overhead of frequent `commit` operations. On a busy system, you might increase `daemon_memcached_r_batch_size`, knowing that changes to data made through SQL may not become visible to `memcached` immediately (that is, until N more `get` operations are processed). When processing data where every write operation must be reliably stored, leave `daemon_memcached_w_batch_size` set to 1. Increase the setting when processing large numbers of updates intended only for statistical analysis, where losing the last N updates in a crash is an acceptable risk.

For example, imagine a system that monitors traffic crossing a busy bridge, recording data for approximately 100,000 vehicles each day. If the application counts different types of vehicles to analyze traffic patterns, changing `daemon_memcached_w_batch_size` from 1 to 100 reduces I/O overhead for commit operations by 99%. In case of an outage, a maximum of 100 records are lost, which may be an acceptable margin of error. If instead the application performed automated toll collection for each car, you would set `daemon_memcached_w_batch_size` to 1 to ensure that each toll record is immediately saved to disk.

Because of the way InnoDB organizes `memcached` key values on disk, if you have a large number of keys to create, it may be faster to sort the data items by key value in the application and `add` them in sorted order, rather than create keys in arbitrary order.

The `memslap` command, which is part of the regular `memcached` distribution but not included with the `daemon_memcached` plugin, can be useful for benchmarking different configurations. It can also be used to generate sample key/value pairs to use in your own benchmarks. See [libmemcached Command-Line Utilities](#) for details.

15.19.6.4 Controlling Transactional Behavior of the InnoDB memcached Plugin

Unlike traditional `memcached`, the `daemon_memcached` plugin allows you to control durability of data values produced through calls to `add`, `set`, `incr`, and so on. By default, data written through the `memcached` interface is stored to disk, and calls to `get` return the most recent value from disk. Although the default behavior does not offer the best possible raw performance, it is still fast compared to the SQL interface for InnoDB tables.

As you gain experience using the `daemon_memcached` plugin, you can consider relaxing durability settings for non-critical classes of data, at the risk of losing some updated values in the event of an outage, or returning data that is slightly out-of-date.

Frequency of Commits

One tradeoff between durability and raw performance is how frequently new and changed data is `committed`. If data is critical, it should be committed immediately so that it is safe in case of a crash or

outage. If data is less critical, such as counters that are reset after a crash or logging data that you can afford to lose, you might prefer higher raw throughput that is available with less frequent commits.

When a `memcached` operation inserts, updates, or deletes data in the underlying InnoDB table, the change might be committed to the InnoDB table instantly (if `daemon_memcached_w_batch_size=1`) or some time later (if the `daemon_memcached_w_batch_size` value is greater than 1). In either case, the change cannot be rolled back. If you increase the value of `daemon_memcached_w_batch_size` to avoid high I/O overhead during busy times, commits could become infrequent when the workload decreases. As a safety measure, a background thread automatically commits changes made through the `memcached` API at regular intervals. The interval is controlled by the `innodb_api_bk_commit_interval` configuration option, which has a default setting of 5 seconds.

When a `memcached` operation inserts or updates data in the underlying InnoDB table, the changed data is immediately visible to other `memcached` requests because the new value remains in the memory cache, even if it is not yet committed on the MySQL side.

Transaction Isolation

When a `memcached` operation such as `get` or `incr` causes a query or DML operation on the underlying InnoDB table, you can control whether the operation sees the very latest data written to the table, only data that has been committed, or other variations of transaction [isolation level](#). Use the `innodb_api_trx_level` configuration option to control this feature. The numeric values specified for this option correspond to isolation levels such as `REPEATABLE READ`. See the description of the `innodb_api_trx_level` option for information about other settings.

A strict isolation level ensures that data you retrieve is not rolled back or changed suddenly causing subsequent queries to return different values. However, strict isolation levels require greater [locking](#) overhead, which can cause waits. For a NoSQL-style application that does not use long-running transactions, you can typically use the default isolation level or switch to a less strict isolation level.

Disabling Row Locks for memcached DML Operations

The `innodb_api_disable_rowlock` option can be used to disable row locks when `memcached` requests through the `daemon_memcached` plugin cause DML operations. By default, `innodb_api_disable_rowlock` is set to `OFF` which means that `memcached` requests row locks for `get` and `set` operations. When `innodb_api_disable_rowlock` is set to `ON`, `memcached` requests a table lock instead of row locks.

The `innodb_api_disable_rowlock` option is not dynamic. It must be specified at startup on the `mysqld` command line or entered in a MySQL configuration file.

Allowing or Disallowing DDL

By default, you can perform [DDL](#) operations such as `ALTER TABLE` on tables used by the `daemon_memcached` plugin. To avoid potential slowdowns when these tables are used for high-throughput applications, disable DDL operations on these tables by enabling `innodb_api_enable_mdl` at startup. This option is less appropriate when accessing the same tables through both `memcached` and SQL, because it blocks `CREATE INDEX` statements on the tables, which could be important for running reporting queries.

Storing Data on Disk, in Memory, or Both

The `innodb_memcache.cache_policies` table specifies whether to store data written through the `memcached` interface to disk (`innodb_only`, the default); in memory only, as with traditional `memcached` (`cache-only`); or both (`caching`).

With the `caching` setting, if `memcached` cannot find a key in memory, it searches for the value in an InnoDB table. Values returned from `get` calls under the `caching` setting could be out-of-date if the values were updated on disk in the InnoDB table but are not yet expired from the memory cache.

The caching policy can be set independently for `get`, `set` (including `incr` and `decr`), `delete`, and `flush` operations.

For example, you might allow `get` and `set` operations to query or update a table and the `memcached` memory cache at the same time (using the `caching` setting), while making `delete`, `flush`, or both operate only on the in-memory copy (using the `cache_only` setting). That way, deleting or flushing an item only expires the item from the cache, and the latest value is returned from the InnoDB table the next time the item is requested.

```
mysql> SELECT * FROM innodb_memcache.cache_policies;
+-----+-----+-----+-----+-----+
| policy_name | get_policy | set_policy | delete_policy | flush_policy |
+-----+-----+-----+-----+-----+
| cache_policy | innodb_only | innodb_only | innodb_only | innodb_only |
+-----+-----+-----+-----+-----+

mysql> UPDATE innodb_memcache.cache_policies SET set_policy = 'caching'
        WHERE policy_name = 'cache_policy';
```

`innodb_memcache.cache_policies` values are only read at startup. After changing values in this table, uninstall and reinstall the `daemon_memcached` plugin to ensure that changes take effect.

```
mysql> UNINSTALL PLUGIN daemon_memcached;
mysql> INSTALL PLUGIN daemon_memcached soname "libmemcached.so";
```

15.19.6.5 Adapting DML Statements to memcached Operations

Benchmarks suggest that the `daemon_memcached` plugin speeds up DML operations (inserts, updates, and deletes) more than it speeds up queries. Therefore, consider focussing initial development efforts on write-intensive applications that are I/O-bound, and look for opportunities to use MySQL with the `daemon_memcached` plugin for new write-intensive applications.

Single-row DML statements are the easiest types of statements to turn into `memcached` operations. `INSERT` becomes `add`, `UPDATE` becomes `set`, `incr` or `decr`, and `DELETE` becomes `delete`. These operations are guaranteed to only affect one row when issued through the `memcached` interface, because the `key` is unique within the table.

In the following SQL examples, `t1` refers to the table used for `memcached` operations, based on the configuration in the `innodb_memcache.containers` table. `key` refers to the column listed under `key_columns`, and `val` refers to the column listed under `value_columns`.

```
INSERT INTO t1 (key,val) VALUES (some_key,some_value);
SELECT val FROM t1 WHERE key = some_key;
UPDATE t1 SET val = new_value WHERE key = some_key;
UPDATE t1 SET val = val + x WHERE key = some_key;
DELETE FROM t1 WHERE key = some_key;
```

The following `TRUNCATE TABLE` and `DELETE` statements, which remove all rows from the table, correspond to the `flush_all` operation, where `t1` is configured as the table for `memcached` operations, as in the previous example.

```
TRUNCATE TABLE t1;
DELETE FROM t1;
```

15.19.6.6 Performing DML and DDL Statements on the Underlying InnoDB Table

You can access the underlying InnoDB table (which is `test.demo_test` by default) through standard SQL interfaces. However, there are some restrictions:

- When querying a table that is also accessed through the `memcached` interface, remember that `memcached` operations can be configured to be committed periodically rather than after every write operation. This behavior is controlled by the `daemon_memcached_w_batch_size` option. If this

option is set to a value greater than 1, use `READ UNCOMMITTED` queries to find rows that were just inserted.

```
mysql> SET SESSION TRANSACTION ISOLATION LEVEL READ UNCOMMITTED;

mysql> SELECT * FROM demo_test;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| cx   | cy   | c1   | cz   | c2   | ca   | CB   | c3   | cu   | c4   | C5   |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| NULL | NULL | a11  | NULL | 123456789 | NULL | NULL | 10  | NULL | 3   | NULL |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+

```

- When modifying a table using SQL that is also accessed through the `memcached` interface, you can configure `memcached` operations to start a new transaction periodically rather than for every read operation. This behavior is controlled by the `daemon_memcached_r_batch_size` option. If this option is set to a value greater than 1, changes made to the table using SQL are not immediately visible to `memcached` operations.
- The InnoDB table is either IS (intention shared) or IX (intention exclusive) locked for all operations in a transaction. If you increase `daemon_memcached_r_batch_size` and `daemon_memcached_w_batch_size` substantially from their default value of 1, the table is most likely locked between each operation, preventing DDL statements on the table.

15.19.7 The InnoDB memcached Plugin and Replication

Because the `daemon_memcached` plugin supports the MySQL `binary log`, updates made on a `master server` through the `memcached` interface can be replicated for backup, balancing intensive read workloads, and high availability. All `memcached` commands are supported with binary logging.

You do not need to set up the `daemon_memcached` plugin on `slave servers`. The primary advantage of this configuration is increased write throughput on the master. The speed of the replication mechanism is not affected.

The following sections show how to use the binary log capability when using the `daemon_memcached` plugin with MySQL replication. It is assumed that you have completed the setup described in [Section 15.19.3, “Setting Up the InnoDB memcached Plugin”](#).

Enabling the InnoDB memcached Binary Log

1. To use the `daemon_memcached` plugin with the MySQL `binary log`, enable the `innodb_api_enable_binlog` configuration option on the `master server`. This option can only be set at server startup. You must also enable the MySQL binary log on the master server using the `--log-bin` option. You can add these options to the MySQL configuration file, or on the `mysqld` command line.

```
mysqld ... --log-bin --innodb_api_enable_binlog=1
```

2. Configure the master and slave server, as described in [Section 18.1.2, “Setting Up Binary Log File Position Based Replication”](#).
3. Use `mysqldump` to create a master data snapshot, and sync the snapshot to the slave server.

```
master shell> mysqldump --all-databases --lock-all-tables > dbdump.db
slave shell> mysql < dbdump.db
```

4. On the master server, issue `SHOW MASTER STATUS` to obtain the master binary log coordinates.

```
mysql> SHOW MASTER STATUS;
```

5. On the slave server, use a `CHANGE MASTER TO` statement to set up a slave server using the master binary log coordinates.

```
mysql> CHANGE MASTER TO
      MASTER_HOST='localhost',
      MASTER_USER='root',
      MASTER_PASSWORD='',
      MASTER_PORT = 13000,
      MASTER_LOG_FILE='0.000001',
      MASTER_LOG_POS=114;
```

6. Start the slave.

```
mysql> START SLAVE;
```

If the error log prints output similar to the following, the slave is ready for replication.

```
2013-09-24T13:04:38.639684Z 49 [Note] Slave I/O thread: connected to
master 'root@localhost:13000', replication started in log '0.000001'
at position 114
```

Testing the InnoDB memcached Replication Configuration

This example demonstrates how to test the `InnoDB memcached` replication configuration using the `memcached` and `telnet` to insert, update, and delete data. A MySQL client is used to verify results on the master and slave servers.

The example uses the `demo_test` table, which was created by the `innodb_memcached_config.sql` configuration script during the initial setup of the `daemon_memcached` plugin. The `demo_test` table contains a single example record.

1. Use the `set` command to insert a record with a key of `test1`, a flag value of `10`, an expiration value of `0`, a cas value of `1`, and a value of `t1`.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
set test1 10 0 1
t1
STORED
```

2. On the master server, check that the record was inserted into the `demo_test` table. Assuming the `demo_test` table was not previously modified, there should be two records. The example record with a key of `AA`, and the record you just inserted, with a key of `test1`. The `c1` column maps to the key, the `c2` column to the value, the `c3` column to the flag value, the `c4` column to the cas value, and the `c5` column to the expiration time. The expiration time was set to `0`, since it is unused.

```
mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+-----+
| c1    | c2          | c3    | c4    | c5    |
+-----+-----+-----+-----+-----+
| AA    | HELLO, HELLO | 8     | 0     | 0     |
| test1 | t1          | 10    | 1     | 0     |
+-----+-----+-----+-----+-----+
```

3. Check to verify that the same record was replicated to the slave server.

```
mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+-----+
| c1    | c2          | c3    | c4    | c5    |
+-----+-----+-----+-----+-----+
| AA    | HELLO, HELLO | 8     | 0     | 0     |
| test1 | t1          | 10    | 1     | 0     |
+-----+-----+-----+-----+-----+
```

4. Use the `set` command to update the key to a value of `new`.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
set test1 10 0 2
new
STORED
```

The update is replicated to the slave server (notice that the `cas` value is also updated).

```
mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+-----+
| c1 | c2 | c3 | c4 | c5 |
+-----+-----+-----+-----+-----+
| AA | HELLO, HELLO | 8 | 0 | 0 |
| test1 | new | 10 | 2 | 0 |
+-----+-----+-----+-----+-----+
```

5. Delete the `test1` record using a `delete` command.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
delete test1
DELETED
```

When the `delete` operation is replicated to the slave, the `test1` record on the slave is also deleted.

```
mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+-----+
| c1 | c2 | c3 | c4 | c5 |
+-----+-----+-----+-----+-----+
| AA | HELLO, HELLO | 8 | 0 | 0 |
+-----+-----+-----+-----+-----+
```

6. Remove all rows from the table using the `flush_all` command.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
flush_all
OK
```

```
mysql> SELECT * FROM test.demo_test;
Empty set (0.00 sec)
```

7. Telnet to the master server and enter two new records.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
set test2 10 0 4
again
STORED
set test3 10 0 5
again1
STORED
```

8. Confirm that the two records were replicated to the slave server.

```
mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+-----+
```

c1	c2	c3	c4	c5
test2	again	10	4	0
test3	again1	10	5	0

9. Remove all rows from the table using the `flush_all` command.

```
telnet 127.0.0.1 11211
Trying 127.0.0.1...
Connected to 127.0.0.1.
Escape character is '^]'.
flush_all
OK
```

10. Check to ensure that the `flush_all` operation was replicated on the slave server.

```
mysql> SELECT * FROM test.demo_test;
Empty set (0.00 sec)
```

InnoDB memcached Binary Log Notes

Binary Log Format:

- Most `memcached` operations are mapped to `DML` statements (analogous to insert, delete, update). Since there is no actual SQL statement being processed by the MySQL server, all `memcached` commands (except for `flush_all`) use Row-Based Replication (RBR) logging, which is independent of any server `binlog_format` setting.
- The `memcached flush_all` command is mapped to the `TRUNCATE TABLE` command in MySQL 5.7 and earlier. Since `DDL` commands can only use statement-based logging, the `flush_all` command is replicated by sending a `TRUNCATE TABLE` statement. In MySQL 8.0 and later, `flush_all` is mapped to `DELETE` but is still replicated by sending a `TRUNCATE TABLE` statement.

Transactions:

- The concept of `transactions` has not typically been part of `memcached` applications. For performance considerations, `daemon_memcached_r_batch_size` and `daemon_memcached_w_batch_size` are used to control the batch size for read and write transactions. These settings do not affect replication. Each SQL operation on the underlying `InnoDB` table is replicated after successful completion.
- The default value of `daemon_memcached_w_batch_size` is `1`, which means that each `memcached` write operation is committed immediately. This default setting incurs a certain amount of performance overhead to avoid inconsistencies in the data that is visible on the master and slave servers. The replicated records are always available immediately on the slave server. If you set `daemon_memcached_w_batch_size` to a value greater than `1`, records inserted or updated through `memcached` are not immediately visible on the master server; to view the records on the master server before they are committed, issue `SET TRANSACTION ISOLATION LEVEL READ UNCOMMITTED`.

15.19.8 InnoDB memcached Plugin Internals

InnoDB API for the InnoDB memcached Plugin

The `InnoDB memcached` engine accesses `InnoDB` through `InnoDB` APIs, most of which are directly adopted from embedded `InnoDB`. `InnoDB` API functions are passed to the `InnoDB memcached` engine as callback functions. `InnoDB` API functions access the `InnoDB` tables directly, and are mostly `DML` operations with the exception of `TRUNCATE TABLE`.

`memcached` commands are implemented through the `InnoDB memcached` API. The following table outlines how `memcached` commands are mapped to `DML` or `DDL` operations.

Table 15.15 memcached Commands and Associated DML or DDL Operations

memcached Command	DML or DDL Operations
<code>get</code>	a read/fetch command
<code>set</code>	a search followed by an <code>INSERT</code> or <code>UPDATE</code> (depending on whether or not a key exists)
<code>add</code>	a search followed by an <code>INSERT</code> or <code>UPDATE</code>
<code>replace</code>	a search followed by an <code>UPDATE</code>
<code>append</code>	a search followed by an <code>UPDATE</code> (appends data to the result before <code>UPDATE</code>)
<code>prepend</code>	a search followed by an <code>UPDATE</code> (prepends data to the result before <code>UPDATE</code>)
<code>incr</code>	a search followed by an <code>UPDATE</code>
<code>decr</code>	a search followed by an <code>UPDATE</code>
<code>delete</code>	a search followed by a <code>DELETE</code>
<code>flush_all</code>	<code>TRUNCATE TABLE</code> (DDL)

InnoDB memcached Plugin Configuration Tables

This section describes configuration tables used by the `daemon_memcached` plugin. The `cache_policies` table, `config_options` table, and `containers` table are created by the `innodb_memcached_config.sql` configuration script in the `innodb_memcache` database.

```
mysql> USE innodb_memcache;
Database changed
mysql> SHOW TABLES;
+-----+
| Tables_in_innodb_memcache |
+-----+
| cache_policies            |
| config_options           |
| containers                |
+-----+
```

cache_policies Table

The `cache_policies` table defines a cache policy for the InnoDB memcached installation. You can specify individual policies for `get`, `set`, `delete`, and `flush` operations, within a single cache policy. The default setting for all operations is `innodb_only`.

- `innodb_only`: Use InnoDB as the data store.
- `cache-only`: Use the memcached engine as the data store.
- `caching`: Use both InnoDB and the memcached engine as data stores. In this case, if memcached cannot find a key in memory, it searches for the value in an InnoDB table.
- `disable`: Disable caching.

Table 15.16 cache_policies Columns

Column	Description
<code>policy_name</code>	Name of the cache policy. The default cache policy name is <code>cache_policy</code> .
<code>get_policy</code>	The cache policy for get operations. Valid values are <code>innodb_only</code> , <code>cache-only</code> , <code>caching</code> , or <code>disabled</code> . The default setting is <code>innodb_only</code> .

Column	Description
<code>set_policy</code>	The cache policy for set operations. Valid values are <code>innodb_only</code> , <code>cache-only</code> , <code>caching</code> , or <code>disabled</code> . The default setting is <code>innodb_only</code> .
<code>delete_policy</code>	The cache policy for delete operations. Valid values are <code>innodb_only</code> , <code>cache-only</code> , <code>caching</code> , or <code>disabled</code> . The default setting is <code>innodb_only</code> .
<code>flush_policy</code>	The cache policy for flush operations. Valid values are <code>innodb_only</code> , <code>cache-only</code> , <code>caching</code> , or <code>disabled</code> . The default setting is <code>innodb_only</code> .

config_options Table

The `config_options` table stores `memcached`-related settings that can be changed at runtime using SQL. Supported configuration options are `separator` and `table_map_delimiter`.

Table 15.17 config_options Columns

Column	Description
Name	<p>Name of the <code>memcached</code>-related configuration option. The following configuration options are supported by the <code>config_options</code> table:</p> <ul style="list-style-type: none"> <code>separator</code>: Used to separate values of a long string into separate values when there are multiple <code>value_columns</code> defined. By default, the <code>separator</code> is a <code> </code> character. For example, if you define <code>col1</code>, <code>col2</code> as value columns, and you define <code> </code> as the separator, you can issue the following <code>memcached</code> command to insert values into <code>col1</code> and <code>col2</code>, respectively: <pre>set keyx 10 0 19 valuecolx valuecoly</pre> <p><code>valuecol1x</code> is stored in <code>col1</code> and <code>valuecoly</code> is stored in <code>col2</code>.</p> <code>table_map_delimiter</code>: The character separating the schema name and the table name when you use the <code>@@</code> notation in a key name to access a key in a specific table. For example, <code>@@t1.some_key</code> and <code>@@t2.some_key</code> have the same key value, but are stored in different tables.
Value	The value assigned to the <code>memcached</code> -related configuration option.

containers Table

The `containers` table is the most important of the three configuration tables. Each `InnoDB` table that is used to store `memcached` values must have an entry in the `containers` table. The entry provides a mapping between `InnoDB` table columns and container table columns, which is required for `memcached` to work with `InnoDB` tables.

The `containers` table contains a default entry for the `test.demo_test` table, which is created by the `innodb_memcached_config.sql` configuration script. To use the `daemon_memcached` plugin with your own `InnoDB` table, you must create an entry in the `containers` table.

Table 15.18 containers Columns

Column	Description
<code>name</code>	The name given to the container. If an <code>InnoDB</code> table is not requested by name using <code>@@</code> notation, the <code>daemon_memcached</code> plugin uses the <code>InnoDB</code> table with a <code>containers.name</code> value of <code>default</code> . If there is no such entry, the first entry in the <code>containers</code> table, ordered alphabetically by <code>name</code> (ascending), determines the default <code>InnoDB</code> table.
<code>db_schema</code>	The name of the database where the <code>InnoDB</code> table resides. This is a required value.
<code>db_table</code>	The name of the <code>InnoDB</code> table that stores <code>memcached</code> values. This is a required value.
<code>key_columns</code>	The column in the <code>InnoDB</code> table that contains lookup key values for <code>memcached</code> operations. This is a required value.
<code>value_columns</code>	The <code>InnoDB</code> table columns (one or more) that store <code>memcached</code> data. Multiple columns can be specified using the separator character specified in the <code>innodb_memcached.config_options</code> table. By default, the separator is a pipe character (<code> </code>). To specify multiple columns, separate them with the defined separator character. For example: <code>col1 col2 col3</code> . This is a required value.
<code>flags</code>	The <code>InnoDB</code> table columns that are used as flags (a user-defined numeric value that is stored and retrieved along with the main value) for <code>memcached</code> . A flag value can be used as a column specifier for some operations (such as <code>incr</code> , <code>prepend</code>) if a <code>memcached</code> value is mapped to multiple columns, so that an operation is performed on a specified column. For example, if you have mapped a <code>value_columns</code> to three <code>InnoDB</code> table columns, and only want the increment operation performed on one columns, use the <code>flags</code> column to specify the column. If you do not use the <code>flags</code> column, set a value of <code>0</code> to indicate that it is unused.
<code>cas_column</code>	The <code>InnoDB</code> table column that stores compare-and-swap (cas) values. The <code>cas_column</code> value is related to the way <code>memcached</code> hashes requests to different servers and caches data in memory. Because the <code>InnoDB memcached</code> plugin is tightly integrated with a single <code>memcached</code> daemon, and the in-memory caching mechanism is handled by MySQL and the <code>InnoDB buffer pool</code> , this column is rarely needed. If you do not use this column, set a value of <code>0</code> to indicate that it is unused.
<code>expire_time_column</code>	The <code>InnoDB</code> table column that stores expiration values. The <code>expire_time_column</code> value is related to the way <code>memcached</code> hashes requests to different servers and caches data in memory. Because the <code>InnoDB memcached</code> plugin is tightly

Column	Description
	integrated with a single <code>memcached</code> daemon, and the in-memory caching mechanism is handled by MySQL and the <code>InnoDB buffer pool</code> , this column is rarely needed. If you do not use this column, set a value of <code>0</code> to indicate that the column is unused. The maximum expire time is defined as <code>INT_MAX32</code> or 2147483647 seconds (approximately 68 years).
<code>unique_idx_name_on_key</code>	The name of the index on the key column. It must be a unique index. It can be the <code>primary key</code> or a <code>secondary index</code> . Preferably, use the primary key of the <code>InnoDB</code> table. Using the primary key avoids a lookup that is performed when using a secondary index. You cannot make a <code>covering index</code> for <code>memcached</code> lookups; <code>InnoDB</code> returns an error if you try to define a composite secondary index over both the key and value columns.

containers Table Column Constraints

- You must supply a value for `db_schema`, `db_name`, `key_columns`, `value_columns` and `unique_idx_name_on_key`. Specify `0` for `flags`, `cas_column`, and `expire_time_column` if they are unused. Failing to do so could cause your setup to fail.
- `key_columns`: The maximum limit for a `memcached` key is 250 characters, which is enforced by `memcached`. The mapped key must be a non-Null `CHAR` or `VARCHAR` type.
- `value_columns`: Must be mapped to a `CHAR`, `VARCHAR`, or `BLOB` column. There is no length restriction and the value can be NULL.
- `cas_column`: The `cas` value is a 64 bit integer. It must be mapped to a `BIGINT` of at least 8 bytes. If you do not use this column, set a value of `0` to indicate that it is unused.
- `expiration_time_column`: Must mapped to an `INTEGER` of at least 4 bytes. Expiration time is defined as a 32-bit integer for Unix time (the number of seconds since January 1, 1970, as a 32-bit value), or the number of seconds starting from the current time. For the latter, the number of seconds may not exceed $60*60*24*30$ (the number of seconds in 30 days). If the number sent by a client is larger, the server considers it to be a real Unix time value rather than an offset from the current time. If you do not use this column, set a value of `0` to indicate that it is unused.
