- `flags`: Must be mapped to an `INTEGER` of at least 32-bits and can be NULL. If you do not use this column, set a value of `0` to indicate that it is unused.

A pre-check is performed at plugin load time to enforce column constraints. If mismatches are found, the plugin is not loaded.

Multiple Value Column Mapping

- During plugin initialization, when `InnoDB memcached` is configured with information defined in the `containers` table, each mapped column defined in `containers.value_columns` is verified against the mapped `InnoDB` table. If multiple `InnoDB` table columns are mapped, there is a check to ensure that each column exists and is the right type.
- At run-time, for `memcached` insert operations, if there are more delimited values than the number of mapped columns, only the number of mapped values are taken. For example, if there are six mapped columns, and seven delimited values are provided, only the first six delimited values are taken. The seventh delimited value is ignored.

- If there are fewer delimited values than mapped columns, unfilled columns are set to NULL. If an unfilled column cannot be set to NULL, insert operations fail.
- If a table has more columns than mapped values, the extra columns do not affect results.

The demo_test Example Table

The `innodb_memcached_config.sql` configuration script creates a `demo_test` table in the `test` database, which can be used to verify InnoDB memcached plugin installation immediately after setup.

The `innodb_memcached_config.sql` configuration script also creates an entry for the `demo_test` table in the `innodb_memcache.containers` table.

```
mysql> SELECT * FROM innodb_memcache.containers\G
***** 1. row *****
      name: aaa
    db_schema: test
    db_table: demo_test
  key_columns: c1
value_columns: c2
      flags: c3
    cas_column: c4
  expire_time_column: c5
unique_idx_name_on_key: PRIMARY

mysql> SELECT * FROM test.demo_test;
+-----+-----+-----+-----+-----+
| c1 | c2          | c3 | c4 | c5 |
+-----+-----+-----+-----+
| AA | HELLO, HELLO | 8  | 0  | 0  |
+-----+-----+-----+-----+
```

15.19.9 Troubleshooting the InnoDB memcached Plugin

This section describes issues that you may encounter when using the InnoDB memcached plugin.

- If you encounter the following error in the MySQL error log, the server might fail to start:

```
failed to set rlimit for open files. Try running as root or requesting
smaller maxconns value.
```

The error message is from the `memcached` daemon. One solution is to raise the OS limit for the number of open files. The commands for checking and increasing the open file limit varies by operating system. This example shows commands for Linux and OS X:

```
# Linux
shell> ulimit -n
1024
shell> ulimit -n 4096
shell> ulimit -n
4096

# OS X
shell> ulimit -n
256
shell> ulimit -n 4096
shell> ulimit -n
4096
```

The other solution is to reduce the number of concurrent connections permitted for the `memcached` daemon. To do so, encode the `-c memcached` option in the `daemon_memcached_option` configuration parameter in the MySQL configuration file. The `-c` option has a default value of 1024.

```
[mysqld]
...
loose-daemon_memcached_option='-c 64'
```

- To troubleshoot problems where the `memcached` daemon is unable to store or retrieve InnoDB table data, encode the `-vvv memcached` option in the `daemon_memcached_option` configuration parameter in the MySQL configuration file. Examine the MySQL error log for debug output related to `memcached` operations.

```
[mysqld]
...
loose-daemon_memcached_option='-vvv'
```

- If columns specified to hold `memcached` values are the wrong data type, such as a numeric type instead of a string type, attempts to store key/value pairs fail with no specific error code or message.
- If the `daemon_memcached` plugin causes MySQL server startup issues, you can temporarily disable the `daemon_memcached` plugin while troubleshooting by adding this line under the `[mysqld]` group in the MySQL configuration file:

```
daemon_memcached=OFF
```

For example, if you run the `INSTALL PLUGIN` statement before running the `innodb_memcached_config.sql` configuration script to set up the necessary database and tables, the server might crash and fail to start. The server could also fail to start if you incorrectly configure an entry in the `innodb_memcache.containers` table.

To uninstall the `memcached` plugin for a MySQL instance, issue the following statement:

```
mysql> UNINSTALL PLUGIN daemon_memcached;
```

- If you run more than one instance of MySQL on the same machine with the `daemon_memcached` plugin enabled in each instance, use the `daemon_memcached_option` configuration parameter to specify a unique `memcached` port for each `daemon_memcached` plugin.
- If an SQL statement cannot find the InnoDB table or finds no data in the table, but `memcached` API calls retrieve the expected data, you may be missing an entry for the InnoDB table in the `innodb_memcache.containers` table, or you may have not switched to the correct InnoDB table by issuing a `get` or `set` request using `@table_id` notation. This problem could also occur if you change an existing entry in the `innodb_memcache.containers` table without restarting the MySQL server afterward. The free-form storage mechanism is flexible enough that your requests to store or retrieve a multi-column value such as `col1|col2|col3` may still work, even if the daemon is using the `test.demo_test` table which stores values in a single column.
- When defining your own InnoDB table for use with the `daemon_memcached` plugin, and columns in the table are defined as `NOT NULL`, ensure that values are supplied for the `NOT NULL` columns when inserting a record for the table into the `innodb_memcache.containers` table. If the `INSERT` statement for the `innodb_memcache.containers` record contains fewer delimited values than there are mapped columns, unfilled columns are set to `NULL`. Attempting to insert a `NULL` value into a `NOT NULL` column causes the `INSERT` to fail, which may only become evident after you reinitialize the `daemon_memcached` plugin to apply changes to the `innodb_memcache.containers` table.
- If `cas_column` and `expire_time_column` fields of the `innodb_memcached.containers` table are set to `NULL`, the following error is returned when attempting to load the `memcached` plugin:

```
InnoDB_Memcached: column 6 in the entry for config table 'containers' in
database 'innodb_memcache' has an invalid NULL value.
```

The `memcached` plugin rejects usage of `NULL` in the `cas_column` and `expire_time_column` columns. Set the value of these columns to `0` when the columns are unused.

- As the length of the `memcached` key and values increase, you might encounter size and length limits.

- When the key exceeds 250 bytes, `memcached` operations return an error. This is currently a fixed limit within `memcached`.
- `InnoDB` table limits may be encountered if values exceed 768 bytes in size, 3072 bytes in size, or half of the `innodb_page_size` value. These limits primarily apply if you intend to create an index on a value column to run report-generating queries on that column using SQL. See [Section 15.8.1.7, “Limits on InnoDB Tables”](#) for details.
- The maximum size for the key-value combination is 1 MB.
- If you share configuration files across MySQL servers of different versions, using the latest configuration options for the `daemon_memcached` plugin could cause startup errors on older MySQL versions. To avoid compatibility problems, use the `loose` prefix with option names. For example, use `loose-daemon_memcached_option='-c 64'` instead of `daemon_memcached_option='-c 64'`.
- There is no restriction or check in place to validate character set settings. `memcached` stores and retrieves keys and values in bytes and is therefore not character set sensitive. However, you must ensure that the `memcached` client and the MySQL table use the same character set.
- `memcached` connections are blocked from accessing tables that contain an indexed virtual column. Accessing an indexed virtual column requires a callback to the server, but a `memcached` connection does not have access to the server code.

15.20 InnoDB Troubleshooting

The following general guidelines apply to troubleshooting `InnoDB` problems:

- When an operation fails or you suspect a bug, look at the MySQL server error log (see [Section 5.4.2, “The Error Log”](#)). [Section B.3, “Server Error Codes and Messages”](#) provides troubleshooting information for some of the common `InnoDB`-specific errors that you may encounter.
- If the failure is related to a `deadlock`, run with the `innodb_print_all_deadlocks` option enabled so that details about each deadlock are printed to the MySQL server error log. For information about deadlocks, see [Section 15.5.5, “Deadlocks in InnoDB”](#).
- If the issue is related to the `InnoDB` data dictionary, see [Section 15.20.3, “Troubleshooting InnoDB Data Dictionary Operations”](#).
- When troubleshooting, it is usually best to run the MySQL server from the command prompt, rather than through `mysqld_safe` or as a Windows service. You can then see what `mysqld` prints to the console, and so have a better grasp of what is going on. On Windows, start `mysqld` with the `--console` option to direct the output to the console window.
- Enable the `InnoDB` Monitors to obtain information about a problem (see [Section 15.16, “InnoDB Monitors”](#)). If the problem is performance-related, or your server appears to be hung, you should enable the standard Monitor to print information about the internal state of `InnoDB`. If the problem is with locks, enable the Lock Monitor. If the problem is with table creation, tablespaces, or data dictionary operations, refer to the [InnoDB Information Schema system tables](#) to examine contents of the `InnoDB` internal data dictionary.

`InnoDB` temporarily enables standard `InnoDB` Monitor output under the following conditions:

- A long semaphore wait
- `InnoDB` cannot find free blocks in the buffer pool
- Over 67% of the buffer pool is occupied by lock heaps or the adaptive hash index
- If you suspect that a table is corrupt, run `CHECK TABLE` on that table.

15.20.1 Troubleshooting InnoDB I/O Problems

The troubleshooting steps for InnoDB I/O problems depend on when the problem occurs: during startup of the MySQL server, or during normal operations when a DML or DDL statement fails due to problems at the file system level.

Initialization Problems

If something goes wrong when InnoDB attempts to initialize its tablespace or its log files, delete all files created by InnoDB: all `ibdata` files and all `ib_logfile` files. If you already created some InnoDB tables, also delete any `.ibd` files from the MySQL database directories. Then try the InnoDB database creation again. For easiest troubleshooting, start the MySQL server from a command prompt so that you see what is happening.

Runtime Problems

If InnoDB prints an operating system error during a file operation, usually the problem has one of the following solutions:

- Make sure the InnoDB data file directory and the InnoDB log directory exist.
- Make sure `mysqld` has access rights to create files in those directories.
- Make sure `mysqld` can read the proper `my.cnf` or `my.ini` option file, so that it starts with the options that you specified.
- Make sure the disk is not full and you are not exceeding any disk quota.
- Make sure that the names you specify for subdirectories and data files do not clash.
- Doublecheck the syntax of the `innodb_data_home_dir` and `innodb_data_file_path` values. In particular, any `MAX` value in the `innodb_data_file_path` option is a hard limit, and exceeding that limit causes a fatal error.

15.20.2 Forcing InnoDB Recovery

To investigate database page corruption, you might dump your tables from the database with `SELECT ... INTO OUTFILE`. Usually, most of the data obtained in this way is intact. Serious corruption might cause `SELECT * FROM tbl_name` statements or InnoDB background operations to crash or assert, or even cause InnoDB roll-forward recovery to crash. In such cases, you can use the `innodb_force_recovery` option to force the InnoDB storage engine to start up while preventing background operations from running, so that you can dump your tables. For example, you can add the following line to the `[mysqld]` section of your option file before restarting the server:

```
[mysqld]
innodb_force_recovery = 1
```

Warning

Only set `innodb_force_recovery` to a value greater than 0 in an emergency situation, so that you can start InnoDB and dump your tables. Before doing so, ensure that you have a backup copy of your database in case you need to recreate it. Values of 4 or greater can permanently corrupt data files. Only use an `innodb_force_recovery` setting of 4 or greater on a production server instance after you have successfully tested the setting on a separate physical copy of your database. When forcing InnoDB recovery, you should always start with `innodb_force_recovery=1` and only increase the value incrementally, as necessary.

`innodb_force_recovery` is 0 by default (normal startup without forced recovery). The permissible nonzero values for `innodb_force_recovery` are 1 to 6. A larger value includes the functionality of lesser values. For example, a value of 3 includes all of the functionality of values 1 and 2.

If you are able to dump your tables with an `innodb_force_recovery` value of 3 or less, then you are relatively safe that only some data on corrupt individual pages is lost. A value of 4 or greater is considered dangerous because data files can be permanently corrupted. A value of 6 is considered drastic because database pages are left in an obsolete state, which in turn may introduce more corruption into **B-trees** and other database structures.

As a safety measure, InnoDB prevents `INSERT`, `UPDATE`, or `DELETE` operations when `innodb_force_recovery` is greater than 0. An `innodb_force_recovery` setting of 4 or greater places InnoDB in read-only mode.

- 1 (`SRV_FORCE_IGNORE_CORRUPT`)

Lets the server run even if it detects a corrupt **page**. Tries to make `SELECT * FROM tbl_name` jump over corrupt index records and pages, which helps in dumping tables.

- 2 (`SRV_FORCE_NO_BACKGROUND`)

Prevents the **master thread** and any **purge threads** from running. If a crash would occur during the **purge** operation, this recovery value prevents it.

- 3 (`SRV_FORCE_NO_TRX_UNDO`)

Does not run transaction **rollbacks** after **crash recovery**.

- 4 (`SRV_FORCE_NO_IBUF_MERGE`)

Prevents **insert buffer** merge operations. If they would cause a crash, does not do them. Does not calculate table **statistics**. This value can permanently corrupt data files. After using this value, be prepared to drop and recreate all secondary indexes. Sets InnoDB to read-only.

- 5 (`SRV_FORCE_NO_UNDO_LOG_SCAN`)

Does not look at **undo logs** when starting the database: InnoDB treats even incomplete transactions as committed. This value can permanently corrupt data files. Sets InnoDB to read-only.

- 6 (`SRV_FORCE_NO_LOG_REDO`)

Does not do the **redo log** roll-forward in connection with recovery. This value can permanently corrupt data files. Leaves database pages in an obsolete state, which in turn may introduce more corruption into B-trees and other database structures. Sets InnoDB to read-only.

You can `SELECT` from tables to dump them. With an `innodb_force_recovery` value of 3 or less you can `DROP` or `CREATE` tables. `DROP TABLE` is also supported with an `innodb_force_recovery` value greater than 3. `DROP TABLE` is not permitted with an `innodb_force_recovery` value greater than 4.

If you know that a given table is causing a crash on rollback, you can drop it. If you encounter a runaway rollback caused by a failing mass import or `ALTER TABLE`, you can kill the `mysqld` process and set `innodb_force_recovery` to 3 to bring the database up without the rollback, and then `DROP` the table that is causing the runaway rollback.

If corruption within the table data prevents you from dumping the entire table contents, a query with an `ORDER BY primary_key DESC` clause might be able to dump the portion of the table after the corrupted part.

If a high `innodb_force_recovery` value is required to start InnoDB, there may be corrupted data structures that could cause complex queries (queries containing `WHERE`, `ORDER BY`, or other clauses) to fail. In this case, you may only be able to run basic `SELECT * FROM t` queries.

15.20.3 Troubleshooting InnoDB Data Dictionary Operations

Information about table definitions is stored in the InnoDB [data dictionary](#). If you move data files around, or if the server crashes in the middle of a data dictionary operation, dictionary data can become inconsistent.

If a data dictionary corruption or consistency issue prevents you from starting [InnoDB](#), see [Section 15.20.2, “Forcing InnoDB Recovery”](#) for information about manual recovery.

Cannot Open Datafile

With `innodb_file_per_table` enabled (the default), the following messages may appear at startup if a [file-per-table](#) tablespace file (`.ibd` file) is missing:

```
[ERROR] InnoDB: Operating system error number 2 in a file operation.
[ERROR] InnoDB: The error means the system cannot find the path specified.
[ERROR] InnoDB: Cannot open datafile for read-only: './test/t1.ibd' OS error: 71
[Warning] InnoDB: Ignoring tablespace `test/t1` because it could not be opened.
```

To address these messages, issue `DROP TABLE` statement to remove data about the missing table from the data dictionary.

Restoring Orphan File-Per-Table `ibd` Files

This procedure describes how to restore orphan [file-per-table](#) `.ibd` files to another MySQL instance. You might use this procedure if the system tablespace is lost or unrecoverable and you want to restore `.ibd` file backups on a new MySQL instance.

The procedure is not supported for [general tablespace](#) `.ibd` files.

The procedure assumes that you only have `.ibd` file backups, you are recovering to the same version of MySQL that initially created the orphan `.ibd` files, and that `.ibd` file backups are clean. See [Section 15.8.1.3, “Moving or Copying InnoDB Tables”](#) for information about creating clean backups.

Tablespace copying limitations outlined in [Section 15.7.6, “Copying File-Per-Table Tablespaces to Another Instance”](#) are applicable to this procedure.

1. On the new MySQL instance, recreate the table in a database of the same name.

```
mysql> CREATE DATABASE sakila;

mysql> USE sakila;

mysql> CREATE TABLE actor (
->   actor_id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT,
->   first_name VARCHAR(45) NOT NULL,
->   last_name VARCHAR(45) NOT NULL,
->   last_update TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
->   PRIMARY KEY (actor_id),
->   KEY idx_actor_last_name (last_name)
-> )ENGINE=InnoDB DEFAULT CHARSET=utf8;
```

2. Discard the tablespace of the newly created table.

```
mysql> ALTER TABLE sakila.actor DISCARD TABLESPACE;
```

3. Copy the orphan `.ibd` file from your backup directory to the new database directory.

```
shell> cp /backup_directory/actor.ibd path/to/mysql-5.7/data/sakila/
```

4. Ensure that the `.ibd` file has the necessary file permissions.
5. Import the orphan `.ibd` file. A warning is issued indicating that [InnoDB](#) will attempt to import the file without schema verification.

```
mysql> ALTER TABLE sakila.actor IMPORT TABLESPACE; SHOW WARNINGS;
Query OK, 0 rows affected, 1 warning (0.15 sec)

Warning | 1810 | InnoDB: IO Read error: (2, No such file or directory)
Error opening './sakila/actor.cfg', will attempt to import
without schema verification
```

6. Query the table to verify that the `.ibd` file was successfully restored.

```
mysql> SELECT COUNT(*) FROM sakila.actor;
+-----+
| count(*) |
+-----+
|         200 |
+-----+
```

15.20.4 InnoDB Error Handling

The following items describe how `InnoDB` performs error handling. `InnoDB` sometimes rolls back only the statement that failed, other times it rolls back the entire transaction.

- If you run out of file space in a `tablespace`, a MySQL `Table is full` error occurs and `InnoDB` rolls back the SQL statement.
- A transaction `deadlock` causes `InnoDB` to `roll back` the entire `transaction`. Retry the whole transaction when this happens.

A lock wait timeout causes `InnoDB` to roll back only the single statement that was waiting for the lock and encountered the timeout. (To have the entire transaction roll back, start the server with the `--innodb_rollback_on_timeout` option.) Retry the statement if using the current behavior, or the entire transaction if using `--innodb_rollback_on_timeout`.

Both deadlocks and lock wait timeouts are normal on busy servers and it is necessary for applications to be aware that they may happen and handle them by retrying. You can make them less likely by doing as little work as possible between the first change to data during a transaction and the commit, so the locks are held for the shortest possible time and for the smallest possible number of rows. Sometimes splitting work between different transactions may be practical and helpful.

When a transaction rollback occurs due to a deadlock or lock wait timeout, it cancels the effect of the statements within the transaction. But if the start-transaction statement was `START TRANSACTION` or `BEGIN` statement, rollback does not cancel that statement. Further SQL statements become part of the transaction until the occurrence of `COMMIT`, `ROLLBACK`, or some SQL statement that causes an implicit commit.

- A duplicate-key error rolls back the SQL statement, if you have not specified the `IGNORE` option in your statement.
- A `row too long error` rolls back the SQL statement.
- Other errors are mostly detected by the MySQL layer of code (above the `InnoDB` storage engine level), and they roll back the corresponding SQL statement. Locks are not released in a rollback of a single SQL statement.

During implicit rollbacks, as well as during the execution of an explicit `ROLLBACK` SQL statement, `SHOW PROCESSLIST` displays `Rolling back` in the `State` column for the relevant connection.

16.11.1	Pluggable Storage Engine Architecture	2338
16.11.2	The Common Database Server Layer	2338

Storage engines are MySQL components that handle the SQL operations for different table types. [InnoDB](#) is the default and most general-purpose storage engine, and Oracle recommends using it for tables except for specialized use cases. (The [CREATE TABLE](#) statement in MySQL 8.0 creates [InnoDB](#) tables by default.)

MySQL Server uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

To determine which storage engines your server supports, use the [SHOW ENGINES](#) statement. The value in the [Support](#) column indicates whether an engine can be used. A value of [YES](#), [NO](#), or [DEFAULT](#) indicates that an engine is available, not available, or available and currently set as the default storage engine.

```
mysql> SHOW ENGINES\G
***** 1. row *****
  Engine: PERFORMANCE_SCHEMA
  Support: YES
  Comment: Performance Schema
Transactions: NO
  XA: NO
  Savepoints: NO
***** 2. row *****
  Engine: InnoDB
  Support: DEFAULT
  Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
  XA: YES
```

```

Savepoints: YES
***** 3. row *****
  Engine: MRG_MYISAM

  XA: NO
  Savepoints: NO
...

```

This chapter covers use cases for special-purpose MySQL storage engines. It does not cover the default [InnoDB](#) storage engine or the [NDB](#) storage engine which are covered in [Chapter 15, The InnoDB Storage Engine](#) and [MySQL NDB Cluster 7.5 and NDB Cluster 7.6](#). For advanced users, it also contains a description of the pluggable storage engine architecture (see [Section 16.11, “Overview of MySQL Storage Engine Architecture”](#)).

For information about storage engine support offered in commercial MySQL Server binaries, see [MySQL Enterprise Server 5.7](#), on the MySQL Web site. The storage engines available might depend on which edition of Enterprise Server you are using.

For answers to commonly asked questions about MySQL storage engines, see [Section A.2, “MySQL 8.0 FAQ: Storage Engines”](#).

MySQL 8.0 Supported Storage Engines

- [InnoDB](#): The default storage engine in MySQL 8.0. [InnoDB](#) is a transaction-safe (ACID compliant) storage engine for MySQL that has commit, rollback, and crash-recovery capabilities to protect user data. [InnoDB](#) row-level locking (without escalation to coarser granularity locks) and Oracle-style consistent nonlocking reads increase multi-user concurrency and performance. [InnoDB](#) stores user data in clustered indexes to reduce I/O for common queries based on primary keys. To maintain data integrity, [InnoDB](#) also supports [FOREIGN KEY](#) referential-integrity constraints. For more information about [InnoDB](#), see [Chapter 15, The InnoDB Storage Engine](#).
- [MyISAM](#): These tables have a small footprint. [Table-level locking](#) limits the performance in read/write workloads, so it is often used in read-only or read-mostly workloads in Web and data warehousing configurations.
- [Memory](#): Stores all data in RAM, for fast access in environments that require quick lookups of non-critical data. This engine was formerly known as the [HEAP](#) engine. Its use cases are decreasing; [InnoDB](#) with its buffer pool memory area provides a general-purpose and durable way to keep most or all data in memory, and [NDBCLUSTER](#) provides fast key-value lookups for huge distributed data sets.
- [CSV](#): Its tables are really text files with comma-separated values. CSV tables let you import or dump data in CSV format, to exchange data with scripts and applications that read and write that same format. Because CSV tables are not indexed, you typically keep the data in [InnoDB](#) tables during normal operation, and only use CSV tables during the import or export stage.
- [Archive](#): These compact, unindexed tables are intended for storing and retrieving large amounts of seldom-referenced historical, archived, or security audit information.

- **Blackhole**: The Blackhole storage engine accepts but does not store data, similar to the Unix /dev/null device. Queries always return an empty set. These tables can be used in replication configurations where DML statements are sent to slave servers, but the master server does not keep its own copy of the data.
- **Merge**: Enables a MySQL DBA or developer to logically group a series of identical MyISAM tables and reference them as one object. Good for VLDB environments such as data warehousing.
- **Federated**: Offers the ability to link separate MySQL servers to create one logical database from many physical servers. Very good for distributed or data mart environments.
- **Example**: This engine serves as an example in the MySQL source code that illustrates how to begin writing new storage engines. It is primarily of interest to developers. The storage engine is a “stub” that does nothing. You can create tables with this engine, but no data can be stored in them or retrieved from them.

You are not restricted to using the same storage engine for an entire server or schema. You can specify the storage engine for any table. For example, an application might use mostly InnoDB tables, with one CSV table for exporting data to a spreadsheet and a few MEMORY tables for temporary workspaces.

Choosing a Storage Engine

The various storage engines provided with MySQL are designed with different use cases in mind. The following table provides an overview of some storage engines provided with MySQL:

Table 16.1 Storage Engines Feature Summary

Feature	MyISAM	Memory	InnoDB	Archive	NDB
Storage limits	256TB	RAM	64TB	None	384EB
Transactions	No	No	Yes	No	Yes
Locking granularity	Table	Table	Row	Row	Row
MVCC	No	No	Yes	No	No
Geospatial data type support	Yes	No	Yes	Yes	Yes
Geospatial indexing support	Yes	No	Yes ^a	No	No
B-tree indexes	Yes	Yes	Yes	No	No
T-tree indexes	No	No	No	No	Yes
Hash indexes	No	Yes	No ^b	No	Yes
Full-text search indexes	Yes	No	Yes ^c	No	No
Clustered indexes	No	No	Yes	No	No
Data caches	No	N/A	Yes	No	Yes

Feature	MyISAM	Memory	InnoDB	Archive	NDB
Index caches	Yes	N/A	Yes	No	Yes
Compressed data	Yes ^d	No	Yes ^e	Yes	No
Encrypted data ^f	Yes	Yes	Yes	Yes	Yes
Cluster database support	No	No	No	No	Yes
Replication support ^g	Yes	Yes	Yes	Yes	Yes
Foreign key support	No	No	Yes	No	Yes ^h
Backup / point-in-time recovery ⁱ	Yes	Yes	Yes	Yes	Yes
Query cache support	Yes	Yes	Yes	Yes	Yes
Update statistics for data dictionary	Yes	Yes	Yes	Yes	Yes

^aInnoDB support for geospatial indexing is available in MySQL 5.7.5 and later.

^bInnoDB utilizes hash indexes internally for its Adaptive Hash Index feature.

^cInnoDB support for FULLTEXT indexes is available in MySQL 5.6.4 and later.

^dCompressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.

^eCompressed InnoDB tables require the InnoDB Barracuda file format.

^fImplemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and later.

^gImplemented in the server, rather than in the storage engine.

^hSupport for foreign keys is available in MySQL Cluster NDB 7.3 and later.

ⁱImplemented in the server, rather than in the storage engine.

16.1 Setting the Storage Engine

When you create a new table, you can specify which storage engine to use by adding an `ENGINE` table option to the `CREATE TABLE` statement:

```
-- ENGINE=INNODB not needed unless you have set a different
-- default storage engine.
CREATE TABLE t1 (i INT) ENGINE = INNODB;
-- Simple table definitions can be switched from one to another.
CREATE TABLE t2 (i INT) ENGINE = CSV;
CREATE TABLE t3 (i INT) ENGINE = MEMORY;
```

When you omit the `ENGINE` option, the default storage engine is used. The default engine is `InnoDB` in MySQL 8.0. You can specify the default engine by using the `--default-storage-engine` server startup option, or by setting the `default-storage-engine` option in the `my.cnf` configuration file.

You can set the default storage engine for the current session by setting the `default_storage_engine` variable:

```
SET default_storage_engine=NDBCLUSTER;
```

The storage engine for `TEMPORARY` tables created with `CREATE TEMPORARY TABLE` can be set separately from the engine for permanent tables by setting the `default_tmp_storage_engine`, either at startup or at runtime.

To convert a table from one storage engine to another, use an `ALTER TABLE` statement that indicates the new engine:

```
ALTER TABLE t ENGINE = InnoDB;
```

See [Section 13.1.15, “CREATE TABLE Syntax”](#), and [Section 13.1.7, “ALTER TABLE Syntax”](#).

If you try to use a storage engine that is not compiled in or that is compiled in but deactivated, MySQL instead creates a table using the default storage engine. For example, in a replication setup, perhaps your master server uses `InnoDB` tables for maximum safety, but the slave servers use other storage engines for speed at the expense of durability or concurrency.

By default, a warning is generated whenever `CREATE TABLE` or `ALTER TABLE` cannot use the default storage engine. To prevent confusing, unintended behavior if the desired engine is unavailable, enable the `NO_ENGINE_SUBSTITUTION` SQL mode. If the desired engine is unavailable, this setting produces an error instead of a warning, and the table is not created or altered. See [Section 5.1.8, “Server SQL Modes”](#).

MySQL may store a table's index and data in one or more other files, depending on the storage engine. Table and column definitions are stored in the MySQL data dictionary. Individual storage engines create any additional files required for the tables that they manage. If a table name contains special characters, the names for the table files contain encoded versions of those characters as described in [Section 9.2.3, “Mapping of Identifiers to File Names”](#).

16.2 The MyISAM Storage Engine

`MyISAM` is based on the older (and no longer available) `ISAM` storage engine but has many useful extensions.

Table 16.2 MyISAM Storage Engine Features

Storage limits	256TB	Transactions	No	Locking granularity	Table
MVCC	No	Geospatial data type support	Yes	Geospatial indexing support	Yes
B-tree indexes	Yes	T-tree indexes	No	Hash indexes	No
Full-text search indexes	Yes	Clustered indexes	No	Data caches	No
Index caches	Yes	Compressed data	Yes ^a	Encrypted data^b	Yes
Cluster database support	No	Replication support^c	Yes	Foreign key support	No
Backup / point-in-time recovery^d	Yes	Query cache support	Yes	Update statistics for data dictionary	Yes

^aCompressed MyISAM tables are supported only when using the compressed row format. Tables using the compressed row format with MyISAM are read only.

^bImplemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and later.

^cImplemented in the server, rather than in the storage engine.

^dImplemented in the server, rather than in the storage engine.

Each `MyISAM` table is stored on disk in two files. The files have names that begin with the table name and have an extension to indicate the file type. The data file has an `.MYD` (`MYData`) extension.

The index file has an `.MYI` (`MYIndex`) extension. The table definition is stored in the MySQL data dictionary.

To specify explicitly that you want a `MyISAM` table, indicate that with an `ENGINE` table option:

```
CREATE TABLE t (i INT) ENGINE = MYISAM;
```

In MySQL 8.0, it is normally necessary to use `ENGINE` to specify the `MyISAM` storage engine because `InnoDB` is the default engine.

You can check or repair `MyISAM` tables with the `mysqlcheck` client or `myisamchk` utility. You can also compress `MyISAM` tables with `myisampack` to take up much less space. See [Section 4.5.3, “mysqlcheck — A Table Maintenance Program”](#), [Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#), and [Section 4.6.6, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#).

In MySQL 8.0, the `MyISAM` storage engine provides no partitioning support. *Partitioned MyISAM tables created in previous versions of MySQL cannot be used in MySQL 8.0.* For more information, see [Section 22.6.2, “Partitioning Limitations Relating to Storage Engines”](#). For help with upgrading such tables so that they can be used in MySQL 8.0, see [Section 2.10.1.1, “Changes Affecting Upgrades to MySQL 8.0”](#).

`MyISAM` tables have the following characteristics:

- All data values are stored with the low byte first. This makes the data machine and operating system independent. The only requirements for binary portability are that the machine uses two's-complement signed integers and IEEE floating-point format. These requirements are widely used among mainstream machines. Binary compatibility might not be applicable to embedded systems, which sometimes have peculiar processors.

There is no significant speed penalty for storing data low byte first; the bytes in a table row normally are unaligned and it takes little more processing to read an unaligned byte in order than in reverse order. Also, the code in the server that fetches column values is not time critical compared to other code.

- All numeric key values are stored with the high byte first to permit better index compression.
- Large files (up to 63-bit file length) are supported on file systems and operating systems that support large files.
- There is a limit of $(2^{32})^2$ (1.844E+19) rows in a `MyISAM` table.
- The maximum number of indexes per `MyISAM` table is 64.

The maximum number of columns per index is 16.

- The maximum key length is 1000 bytes. This can also be changed by changing the source and recompiling. For the case of a key longer than 250 bytes, a larger key block size than the default of 1024 bytes is used.
- When rows are inserted in sorted order (as when you are using an `AUTO_INCREMENT` column), the index tree is split so that the high node only contains one key. This improves space utilization in the index tree.
- Internal handling of one `AUTO_INCREMENT` column per table is supported. `MyISAM` automatically updates this column for `INSERT` and `UPDATE` operations. This makes `AUTO_INCREMENT` columns faster (at least 10%). Values at the top of the sequence are not reused after being deleted. (When an `AUTO_INCREMENT` column is defined as the last column of a multiple-column index, reuse of values deleted from the top of a sequence does occur.) The `AUTO_INCREMENT` value can be reset with `ALTER TABLE` or `myisamchk`.

- Dynamic-sized rows are much less fragmented when mixing deletes with updates and inserts. This is done by automatically combining adjacent deleted blocks and by extending blocks if the next block is deleted.
- `MyISAM` supports concurrent inserts: If a table has no free blocks in the middle of the data file, you can `INSERT` new rows into it at the same time that other threads are reading from the table. A free block can occur as a result of deleting rows or an update of a dynamic length row with more data than its current contents. When all free blocks are used up (filled in), future inserts become concurrent again. See [Section 8.11.3, “Concurrent Inserts”](#).
- You can put the data file and index file in different directories on different physical devices to get more speed with the `DATA DIRECTORY` and `INDEX DIRECTORY` table options to `CREATE TABLE`. See [Section 13.1.15, “CREATE TABLE Syntax”](#).
- `BLOB` and `TEXT` columns can be indexed.
- `NULL` values are permitted in indexed columns. This takes 0 to 1 bytes per key.
- Each character column can have a different character set. See [Section 10.1, “Character Set Support”](#).
- There is a flag in the `MyISAM` index file that indicates whether the table was closed correctly. If `mysqld` is started with the `--myisam-recover-options` option, `MyISAM` tables are automatically checked when opened, and are repaired if the table wasn't closed properly.
- `myisamchk` marks tables as checked if you run it with the `--update-state` option. `myisamchk --fast` checks only those tables that don't have this mark.
- `myisamchk --analyze` stores statistics for portions of keys, as well as for entire keys.
- `myisampack` can pack `BLOB` and `VARCHAR` columns.

`MyISAM` also supports the following features:

- Support for a true `VARCHAR` type; a `VARCHAR` column starts with a length stored in one or two bytes.
- Tables with `VARCHAR` columns may have fixed or dynamic row length.
- The sum of the lengths of the `VARCHAR` and `CHAR` columns in a table may be up to 64KB.
- Arbitrary length `UNIQUE` constraints.

Additional Resources

- A forum dedicated to the `MyISAM` storage engine is available at <http://forums.mysql.com/list.php?21>.

16.2.1 MyISAM Startup Options

The following options to `mysqld` can be used to change the behavior of `MyISAM` tables. For additional information, see [Section 5.1.4, “Server Command Options”](#).

Table 16.3 `MyISAM` Option/Variable Reference

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynamic
<code>bulk_insert_buffer</code>	Yes	Yes	Yes		Both	Yes
<code>concurrent_insert</code>	Yes	Yes	Yes		Global	Yes
<code>delay-key-write</code>	Yes	Yes			Global	Yes
- Variable: <code>delay_key_write</code>			Yes		Global	Yes
<code>have_rtree_keys</code>			Yes		Global	No
<code>key_buffer_size</code>	Yes	Yes	Yes		Global	Yes

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynamic
log-isam	Yes	Yes				
myisam-block-size	Yes	Yes				
myisam_data_pointer_size	Yes	Yes	Yes		Global	Yes
myisam_max_sort_file_size	Yes	Yes	Yes		Global	Yes
myisam_mmap_size	Yes	Yes	Yes		Global	No
myisam-recover-options	Yes	Yes				
- Variable: myisam_recover_options						
myisam_recover_options			Yes		Global	No
myisam_repair_threads	Yes	Yes	Yes		Both	Yes
myisam_sort_buffer_size	Yes	Yes	Yes	Yes	Both	Yes
myisam_stats_method	Yes	Yes	Yes		Both	Yes
myisam_use_mmap	Yes	Yes	Yes		Global	Yes
skip-concurrent-insert	Yes	Yes				
- Variable: concurrent_insert						
tmp_table_size	Yes	Yes	Yes		Both	Yes

- `--myisam-recover-options=mode`

Set the mode for automatic recovery of crashed [MyISAM](#) tables.

- `--delay-key-write=ALL`

Don't flush key buffers between writes for any [MyISAM](#) table.

Note

If you do this, you should not access [MyISAM](#) tables from another program (such as from another MySQL server or with `myisamchk`) when the tables are in use. Doing so risks index corruption. Using `--external-locking` does not eliminate this risk.

The following system variables affect the behavior of [MyISAM](#) tables. For additional information, see [Section 5.1.5, "Server System Variables"](#).

- `bulk_insert_buffer_size`

The size of the tree cache used in bulk insert optimization.

Note

This is a limit *per thread*!

- `myisam_max_sort_file_size`

The maximum size of the temporary file that MySQL is permitted to use while re-creating a [MyISAM](#) index (during `REPAIR TABLE`, `ALTER TABLE`, or `LOAD DATA INFILE`). If the file size would be larger than this value, the index is created using the key cache instead, which is slower. The value is given in bytes.

- `myisam_sort_buffer_size`

Set the size of the buffer used when recovering tables.

Automatic recovery is activated if you start `mysqld` with the `--myisam-recover-options` option. In this case, when the server opens a `MyISAM` table, it checks whether the table is marked as crashed or whether the open count variable for the table is not 0 and you are running the server with external locking disabled. If either of these conditions is true, the following happens:

- The server checks the table for errors.
- If the server finds an error, it tries to do a fast table repair (with sorting and without re-creating the data file).
- If the repair fails because of an error in the data file (for example, a duplicate-key error), the server tries again, this time re-creating the data file.
- If the repair still fails, the server tries once more with the old repair option method (write row by row without sorting). This method should be able to repair any type of error and has low disk space requirements.

If the recovery wouldn't be able to recover all rows from previously completed statements and you didn't specify `FORCE` in the value of the `--myisam-recover-options` option, automatic repair aborts with an error message in the error log:

```
Error: Couldn't repair table: test.g00pages
```

If you specify `FORCE`, a warning like this is written instead:

```
Warning: Found 344 of 354 rows when repairing ./test/g00pages
```

If the automatic recovery value includes `BACKUP`, the recovery process creates files with names of the form `tbl_name-datetime.BAK`. You should have a `cron` script that automatically moves these files from the database directories to backup media.

16.2.2 Space Needed for Keys

`MyISAM` tables use B-tree indexes. You can roughly calculate the size for the index file as $(key_length+4)/0.67$, summed over all keys. This is for the worst case when all keys are inserted in sorted order and the table doesn't have any compressed keys.

String indexes are space compressed. If the first index part is a string, it is also prefix compressed. Space compression makes the index file smaller than the worst-case figure if a string column has a lot of trailing space or is a `VARCHAR` column that is not always used to the full length. Prefix compression is used on keys that start with a string. Prefix compression helps if there are many strings with an identical prefix.

In `MyISAM` tables, you can also prefix compress numbers by specifying the `PACK_KEYS=1` table option when you create the table. Numbers are stored with the high byte first, so this helps when you have many integer keys that have an identical prefix.

16.2.3 MyISAM Table Storage Formats

`MyISAM` supports three different storage formats. Two of them, fixed and dynamic format, are chosen automatically depending on the type of columns you are using. The third, compressed format, can be created only with the `myisampack` utility (see [Section 4.6.6, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#)).

When you use `CREATE TABLE` or `ALTER TABLE` for a table that has no `BLOB` or `TEXT` columns, you can force the table format to `FIXED` or `DYNAMIC` with the `ROW_FORMAT` table option.

See [Section 13.1.15, “CREATE TABLE Syntax”](#), for information about `ROW_FORMAT`.

You can decompress (unpack) compressed MyISAM tables using `myisamchk --unpack`; see [Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#), for more information.

16.2.3.1 Static (Fixed-Length) Table Characteristics

Static format is the default for MyISAM tables. It is used when the table contains no variable-length columns (`VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT`). Each row is stored using a fixed number of bytes.

Of the three MyISAM storage formats, static format is the simplest and most secure (least subject to corruption). It is also the fastest of the on-disk formats due to the ease with which rows in the data file can be found on disk: To look up a row based on a row number in the index, multiply the row number by the row length to calculate the row position. Also, when scanning a table, it is very easy to read a constant number of rows with each disk read operation.

The security is evidenced if your computer crashes while the MySQL server is writing to a fixed-format MyISAM file. In this case, `myisamchk` can easily determine where each row starts and ends, so it can usually reclaim all rows except the partially written one. MyISAM table indexes can always be reconstructed based on the data rows.

Note

Fixed-length row format is only available for tables without `BLOB` or `TEXT` columns. Creating a table with these columns with an explicit `ROW_FORMAT` clause will not raise an error or warning; the format specification will be ignored.

Static-format tables have these characteristics:

- `CHAR` and `VARCHAR` columns are space-padded to the specified column width, although the column type is not altered. `BINARY` and `VARBINARY` columns are padded with `0x00` bytes to the column width.
- `NULL` columns require additional space in the row to record whether their values are `NULL`. Each `NULL` column takes one bit extra, rounded up to the nearest byte.
- Very quick.
- Easy to cache.
- Easy to reconstruct after a crash, because rows are located in fixed positions.
- Reorganization is unnecessary unless you delete a huge number of rows and want to return free disk space to the operating system. To do this, use `OPTIMIZE TABLE` or `myisamchk -r`.
- Usually require more disk space than dynamic-format tables.
- The expected row length in bytes for static-sized rows is calculated using the following expression:

```
row length = 1
             + (sum of column lengths)
             + (number of NULL columns + delete_flag + 7)/8
             + (number of variable-length columns)
```

`delete_flag` is 1 for tables with static row format. Static tables use a bit in the row record for a flag that indicates whether the row has been deleted. `delete_flag` is 0 for dynamic tables because the flag is stored in the dynamic row header.

16.2.3.2 Dynamic Table Characteristics

Dynamic storage format is used if a MyISAM table contains any variable-length columns (`VARCHAR`, `VARBINARY`, `BLOB`, or `TEXT`), or if the table was created with the `ROW_FORMAT=DYNAMIC` table option.

Dynamic format is a little more complex than static format because each row has a header that indicates how long it is. A row can become fragmented (stored in noncontiguous pieces) when it is made longer as a result of an update.

You can use `OPTIMIZE TABLE` or `myisamchk -r` to defragment a table. If you have fixed-length columns that you access or change frequently in a table that also contains some variable-length columns, it might be a good idea to move the variable-length columns to other tables just to avoid fragmentation.

Dynamic-format tables have these characteristics:

- All string columns are dynamic except those with a length less than four.
- Each row is preceded by a bitmap that indicates which columns contain the empty string (for string columns) or zero (for numeric columns). This does not include columns that contain `NULL` values. If a string column has a length of zero after trailing space removal, or a numeric column has a value of zero, it is marked in the bitmap and not saved to disk. Nonempty strings are saved as a length byte plus the string contents.
- `NULL` columns require additional space in the row to record whether their values are `NULL`. Each `NULL` column takes one bit extra, rounded up to the nearest byte.
- Much less disk space usually is required than for fixed-length tables.
- Each row uses only as much space as is required. However, if a row becomes larger, it is split into as many pieces as are required, resulting in row fragmentation. For example, if you update a row with information that extends the row length, the row becomes fragmented. In this case, you may have to run `OPTIMIZE TABLE` or `myisamchk -r` from time to time to improve performance. Use `myisamchk -ei` to obtain table statistics.
- More difficult than static-format tables to reconstruct after a crash, because rows may be fragmented into many pieces and links (fragments) may be missing.
- The expected row length for dynamic-sized rows is calculated using the following expression:

```

3
+ (number of columns + 7) / 8
+ (number of char columns)
+ (packed size of numeric columns)
+ (length of strings)
+ (number of NULL columns + 7) / 8

```

There is a penalty of 6 bytes for each link. A dynamic row is linked whenever an update causes an enlargement of the row. Each new link is at least 20 bytes, so the next enlargement probably goes in the same link. If not, another link is created. You can find the number of links using `myisamchk -ed`. All links may be removed with `OPTIMIZE TABLE` or `myisamchk -r`.

16.2.3.3 Compressed Table Characteristics

Compressed storage format is a read-only format that is generated with the `myisampack` tool. Compressed tables can be uncompressed with `myisamchk`.

Compressed tables have the following characteristics:

- Compressed tables take very little disk space. This minimizes disk usage, which is helpful when using slow disks (such as CD-ROMs).
- Each row is compressed separately, so there is very little access overhead. The header for a row takes up one to three bytes depending on the biggest row in the table. Each column is compressed differently. There is usually a different Huffman tree for each column. Some of the compression types are:

- Suffix space compression.
- Prefix space compression.
- Numbers with a value of zero are stored using one bit.
- If values in an integer column have a small range, the column is stored using the smallest possible type. For example, a `BIGINT` column (eight bytes) can be stored as a `TINYINT` column (one byte) if all its values are in the range from `-128` to `127`.
- If a column has only a small set of possible values, the data type is converted to `ENUM`.
- A column may use any combination of the preceding compression types.
- Can be used for fixed-length or dynamic-length rows.

Note

While a compressed table is read only, and you cannot therefore update or add rows in the table, DDL (Data Definition Language) operations are still valid. For example, you may still use `DROP` to drop the table, and `TRUNCATE TABLE` to empty the table.

16.2.4 MyISAM Table Problems

The file format that MySQL uses to store data has been extensively tested, but there are always circumstances that may cause database tables to become corrupted. The following discussion describes how this can happen and how to handle it.

16.2.4.1 Corrupted MyISAM Tables

Even though the `MyISAM` table format is very reliable (all changes to a table made by an SQL statement are written before the statement returns), you can still get corrupted tables if any of the following events occur:

- The `mysqld` process is killed in the middle of a write.
- An unexpected computer shutdown occurs (for example, the computer is turned off).
- Hardware failures.
- You are using an external program (such as `myisamchk`) to modify a table that is being modified by the server at the same time.
- A software bug in the MySQL or `MyISAM` code.

Typical symptoms of a corrupt table are:

- You get the following error while selecting data from the table:

```
Incorrect key file for table: '...'. Try to repair it
```

- Queries don't find rows in the table or return incomplete results.

You can check the health of a `MyISAM` table using the `CHECK TABLE` statement, and repair a corrupted `MyISAM` table with `REPAIR TABLE`. When `mysqld` is not running, you can also check or repair a table with the `myisamchk` command. See [Section 13.7.2.2, “CHECK TABLE Syntax”](#), [Section 13.7.2.5, “REPAIR TABLE Syntax”](#), and [Section 4.6.4, “myisamchk — MyISAM Table-Maintenance Utility”](#).

If your tables become corrupted frequently, you should try to determine why this is happening. The most important thing to know is whether the table became corrupted as a result of a server crash. You can verify this easily by looking for a recent `restarted mysqld` message in the error log. If there is such a message, it is likely that table corruption is a result of the server dying. Otherwise, corruption may have occurred during normal operation. This is a bug. You should try to create a reproducible test case that demonstrates the problem. See [Section B.5.3.3, “What to Do If MySQL Keeps Crashing”](#), and [Section 28.5, “Debugging and Porting MySQL”](#).

16.2.4.2 Problems from Tables Not Being Closed Properly

Each `MyISAM` index file (`.MYI` file) has a counter in the header that can be used to check whether a table has been closed properly. If you get the following warning from `CHECK TABLE` or `myisamchk`, it means that this counter has gone out of sync:

```
clients are using or haven't closed the table properly
```

This warning doesn't necessarily mean that the table is corrupted, but you should at least check the table.

The counter works as follows:

- The first time a table is updated in MySQL, a counter in the header of the index files is incremented.
- The counter is not changed during further updates.
- When the last instance of a table is closed (because a `FLUSH TABLES` operation was performed or because there is no room in the table cache), the counter is decremented if the table has been updated at any point.
- When you repair the table or check the table and it is found to be okay, the counter is reset to zero.
- To avoid problems with interaction with other processes that might check the table, the counter is not decremented on close if it was zero.

In other words, the counter can become incorrect only under these conditions:

- A `MyISAM` table is copied without first issuing `LOCK TABLES` and `FLUSH TABLES`.
- MySQL has crashed between an update and the final close. (The table may still be okay because MySQL always issues writes for everything between each statement.)
- A table was modified by `myisamchk --recover` or `myisamchk --update-state` at the same time that it was in use by `mysqld`.
- Multiple `mysqld` servers are using the table and one server performed a `REPAIR TABLE` or `CHECK TABLE` on the table while it was in use by another server. In this setup, it is safe to use `CHECK TABLE`, although you might get the warning from other servers. However, `REPAIR TABLE` should be avoided because when one server replaces the data file with a new one, this is not known to the other servers.

In general, it is a bad idea to share a data directory among multiple servers. See [Section 5.7, “Running Multiple MySQL Instances on One Machine”](#), for additional discussion.

16.3 The MEMORY Storage Engine

The `MEMORY` storage engine (formerly known as `HEAP`) creates special-purpose tables with contents that are stored in memory. Because the data is vulnerable to crashes, hardware issues, or power outages, only use these tables as temporary work areas or read-only caches for data pulled from other tables.

Table 16.4 MEMORY Storage Engine Features

Storage limits	RAM	Transactions	No	Locking granularity	Table
MVCC	No	Geospatial data type support	No	Geospatial indexing support	No
B-tree indexes	Yes	T-tree indexes	No	Hash indexes	Yes
Full-text search indexes	No	Clustered indexes	No	Data caches	N/A
Index caches	N/A	Compressed data	No	Encrypted data^a	Yes
Cluster database support	No	Replication support^b	Yes	Foreign key support	No
Backup / point-in-time recovery^c	Yes	Query cache support	Yes	Update statistics for data dictionary	Yes

^aImplemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and later.

^bImplemented in the server, rather than in the storage engine.

^cImplemented in the server, rather than in the storage engine.

When to Use MEMORY or MySQL Cluster. Developers looking to deploy applications that use the MEMORY storage engine for important, highly available, or frequently updated data should consider whether MySQL Cluster is a better choice. A typical use case for the MEMORY engine involves these characteristics:

- Operations involving transient, non-critical data such as session management or caching. When the MySQL server halts or restarts, the data in MEMORY tables is lost.
- In-memory storage for fast access and low latency. Data volume can fit entirely in memory without causing the operating system to swap out virtual memory pages.
- A read-only or read-mostly data access pattern (limited updates).

MySQL Cluster offers the same features as the MEMORY engine with higher performance levels, and provides additional features not available with MEMORY:

- Row-level locking and multiple-thread operation for low contention between clients.
- Scalability even with statement mixes that include writes.
- Optional disk-backed operation for data durability.
- Shared-nothing architecture and multiple-host operation with no single point of failure, enabling 99.999% availability.
- Automatic data distribution across nodes; application developers need not craft custom sharding or partitioning solutions.
- Support for variable-length data types (including BLOB and TEXT) not supported by MEMORY.

MEMORY tables cannot be partitioned.

Performance Characteristics

MEMORY performance is constrained by contention resulting from single-thread execution and table lock overhead when processing updates. This limits scalability when load increases, particularly for statement mixes that include writes.

Despite the in-memory processing for MEMORY tables, they are not necessarily faster than InnoDB tables on a busy server, for general-purpose queries, or under a read/write workload. In particular, the table locking involved with performing updates can slow down concurrent usage of MEMORY tables from multiple sessions.

Depending on the kinds of queries performed on a `MEMORY` table, you might create indexes as either the default hash data structure (for looking up single values based on a unique key), or a general-purpose B-tree data structure (for all kinds of queries involving equality, inequality, or range operators such as less than or greater than). The following sections illustrate the syntax for creating both kinds of indexes. A common performance issue is using the default hash indexes in workloads where B-tree indexes are more efficient.

Characteristics of MEMORY Tables

The `MEMORY` storage engine does not create any files on disk. The table definition is stored in the MySQL data dictionary.

`MEMORY` tables have the following characteristics:

- Space for `MEMORY` tables is allocated in small blocks. Tables use 100% dynamic hashing for inserts. No overflow area or extra key space is needed. No extra space is needed for free lists. Deleted rows are put in a linked list and are reused when you insert new data into the table. `MEMORY` tables also have none of the problems commonly associated with deletes plus inserts in hashed tables.
- `MEMORY` tables use a fixed-length row-storage format. Variable-length types such as `VARCHAR` are stored using a fixed length.
- `MEMORY` tables cannot contain `BLOB` or `TEXT` columns.
- `MEMORY` includes support for `AUTO_INCREMENT` columns.
- Non-`TEMPORARY MEMORY` tables are shared among all clients, just like any other non-`TEMPORARY` table.

DDL Operations for MEMORY Tables

To create a `MEMORY` table, specify the clause `ENGINE=MEMORY` on the `CREATE TABLE` statement.

```
CREATE TABLE t (i INT) ENGINE = MEMORY;
```

As indicated by the engine name, `MEMORY` tables are stored in memory. They use hash indexes by default, which makes them very fast for single-value lookups, and very useful for creating temporary tables. However, when the server shuts down, all rows stored in `MEMORY` tables are lost. The tables themselves continue to exist because their definitions are stored in MySQL data dictionary, but they are empty when the server restarts.

This example shows how you might create, use, and remove a `MEMORY` table:

```
mysql> CREATE TABLE test ENGINE=MEMORY
-> SELECT ip,SUM(downloads) AS down
-> FROM log_table GROUP BY ip;
mysql> SELECT COUNT(ip),AVG(down) FROM test;
mysql> DROP TABLE test;
```

The maximum size of `MEMORY` tables is limited by the `max_heap_table_size` system variable, which has a default value of 16MB. To enforce different size limits for `MEMORY` tables, change the value of this variable. The value in effect for `CREATE TABLE`, or a subsequent `ALTER TABLE` or `TRUNCATE TABLE`, is the value used for the life of the table. A server restart also sets the maximum size of existing `MEMORY` tables to the global `max_heap_table_size` value. You can set the size for individual tables as described later in this section.

Indexes

The `MEMORY` storage engine supports both `HASH` and `BTREE` indexes. You can specify one or the other for a given index by adding a `USING` clause as shown here:

```
CREATE TABLE lookup
  (id INT, INDEX USING HASH (id))
ENGINE = MEMORY;
CREATE TABLE lookup
  (id INT, INDEX USING BTREE (id))
ENGINE = MEMORY;
```

For general characteristics of B-tree and hash indexes, see [Section 8.3.1, “How MySQL Uses Indexes”](#).

`MEMORY` tables can have up to 64 indexes per table, 16 columns per index and a maximum key length of 3072 bytes.

If a `MEMORY` table hash index has a high degree of key duplication (many index entries containing the same value), updates to the table that affect key values and all deletes are significantly slower. The degree of this slowdown is proportional to the degree of duplication (or, inversely proportional to the index cardinality). You can use a `BTREE` index to avoid this problem.

`MEMORY` tables can have nonunique keys. (This is an uncommon feature for implementations of hash indexes.)

Columns that are indexed can contain `NULL` values.

User-Created and Temporary Tables

`MEMORY` table contents are stored in memory, which is a property that `MEMORY` tables share with internal temporary tables that the server creates on the fly while processing queries. However, the two types of tables differ in that `MEMORY` tables are not subject to storage conversion, whereas internal temporary tables are:

- If an internal temporary table becomes too large, the server automatically converts it to on-disk storage, as described in [Section 8.4.4, “Internal Temporary Table Use in MySQL”](#).
- User-created `MEMORY` tables are never converted to disk tables.

Loading Data

To populate a `MEMORY` table when the MySQL server starts, you can use the `--init-file` option. For example, you can put statements such as `INSERT INTO ... SELECT` or `LOAD DATA INFILE` into this file to load the table from a persistent data source. See [Section 5.1.4, “Server Command Options”](#), and [Section 13.2.7, “LOAD DATA INFILE Syntax”](#).

MEMORY Tables and Replication

A server's `MEMORY` tables become empty when it is shut down and restarted. If the server is a replication master, its slaves are not aware that these tables have become empty, so you see out-of-date content if you select data from the tables on the slaves. To synchronize master and slave `MEMORY` tables, when a `MEMORY` table is used on a master for the first time since it was started, a `DELETE` statement is written to the master's binary log, to empty the table on the slaves also. The slave still has outdated data in the table during the interval between the master's restart and its first use of the table. To avoid this interval when a direct query to the slave could return stale data, use the `--init-file` option to populate the `MEMORY` table on the master at startup.

Managing Memory Use

The server needs sufficient memory to maintain all `MEMORY` tables that are in use at the same time.

Memory is not reclaimed if you delete individual rows from a `MEMORY` table. Memory is reclaimed only when the entire table is deleted. Memory that was previously used for deleted rows is re-used for new rows within the same table. To free all the memory used by a `MEMORY` table when you no longer require its contents, execute `DELETE` or `TRUNCATE TABLE` to remove all rows, or remove the table

altogether using `DROP TABLE`. To free up the memory used by deleted rows, use `ALTER TABLE ENGINE=MEMORY` to force a table rebuild.

The memory needed for one row in a `MEMORY` table is calculated using the following expression:

```
SUM_OVER_ALL_BTREE_KEYS(max_length_of_key + sizeof(char*) * 4)
+ SUM_OVER_ALL_HASH_KEYS(sizeof(char*) * 2)
+ ALIGN(length_of_row+1, sizeof(char*))
```

`ALIGN()` represents a round-up factor to cause the row length to be an exact multiple of the `char` pointer size. `sizeof(char*)` is 4 on 32-bit machines and 8 on 64-bit machines.

As mentioned earlier, the `max_heap_table_size` system variable sets the limit on the maximum size of `MEMORY` tables. To control the maximum size for individual tables, set the session value of this variable before creating each table. (Do not change the global `max_heap_table_size` value unless you intend the value to be used for `MEMORY` tables created by all clients.) The following example creates two `MEMORY` tables, with a maximum size of 1MB and 2MB, respectively:

```
mysql> SET max_heap_table_size = 1024*1024;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t1 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.01 sec)

mysql> SET max_heap_table_size = 1024*1024*2;
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t2 (id INT, UNIQUE(id)) ENGINE = MEMORY;
Query OK, 0 rows affected (0.00 sec)
```

Both tables revert to the server's global `max_heap_table_size` value if the server restarts.

You can also specify a `MAX_ROWS` table option in `CREATE TABLE` statements for `MEMORY` tables to provide a hint about the number of rows you plan to store in them. This does not enable the table to grow beyond the `max_heap_table_size` value, which still acts as a constraint on maximum table size. For maximum flexibility in being able to use `MAX_ROWS`, set `max_heap_table_size` at least as high as the value to which you want each `MEMORY` table to be able to grow.

Additional Resources

A forum dedicated to the `MEMORY` storage engine is available at <http://forums.mysql.com/list.php?92>.

16.4 The CSV Storage Engine

The `CSV` storage engine stores data in text files using comma-separated values format.

The `CSV` storage engine is always compiled into the MySQL server.

To examine the source for the `CSV` engine, look in the `storage/csv` directory of a MySQL source distribution.

When you create a `CSV` table, the server creates a data file. The data file name begins with the table name and has a `.CSV` extension. The data file is a plain text file. When you store data into the table, the storage engine saves it into the data file in comma-separated values format.

```
mysql> CREATE TABLE test (i INT NOT NULL, c CHAR(10) NOT NULL)
-> ENGINE = CSV;
Query OK, 0 rows affected (0.12 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0
```

```
mysql> SELECT * FROM test;
+-----+-----+
| i     | c     |
+-----+-----+
| 1    | record one |
| 2    | record two |
+-----+-----+
2 rows in set (0.00 sec)
```

Creating a CSV table also creates a corresponding Metafile that stores the state of the table and the number of rows that exist in the table. The name of this file is the same as the name of the table with the extension `CSM`.

If you examine the `test.CSV` file in the database directory created by executing the preceding statements, its contents should look like this:

```
"1","record one"
"2","record two"
```

This format can be read, and even written, by spreadsheet applications such as Microsoft Excel or StarOffice Calc.

16.4.1 Repairing and Checking CSV Tables

The CSV storage engines supports the `CHECK` and `REPAIR` statements to verify and if possible repair a damaged CSV table.

When running the `CHECK` statement, the CSV file will be checked for validity by looking for the correct field separators, escaped fields (matching or missing quotation marks), the correct number of fields compared to the table definition and the existence of a corresponding CSV metafile. The first invalid row discovered will report an error. Checking a valid table produces output like that shown below:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table          | Op    | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest  | check | status   | OK       |
+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

A check on a corrupted table returns a fault:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table          | Op    | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest  | check | error    | Corrupt  |
+-----+-----+-----+-----+
1 row in set (0.01 sec)
```

If the check fails, the table is marked as crashed (corrupt). Once a table has been marked as corrupt, it is automatically repaired when you next run `CHECK` or execute a `SELECT` statement. The corresponding corrupt status and new status will be displayed when running `CHECK`:

```
mysql> check table csvtest;
+-----+-----+-----+-----+
| Table          | Op    | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest  | check | warning  | Table is marked as crashed |
| test.csvtest  | check | status   | OK       |
+-----+-----+-----+-----+
2 rows in set (0.08 sec)
```

To repair a table you can use `REPAIR`, this copies as many valid rows from the existing CSV data as possible, and then replaces the existing CSV file with the recovered rows. Any rows beyond the corrupted data are lost.

```
mysql> repair table csvtest;
+-----+-----+-----+-----+
| Table      | Op      | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.csvtest | repair  | status   | OK       |
+-----+-----+-----+-----+
1 row in set (0.02 sec)
```

Warning

During repair, only the rows from the CSV file up to the first damaged row are copied to the new table. All other rows from the first damaged row to the end of the table are removed, even valid rows.

16.4.2 CSV Limitations

The [CSV](#) storage engine does not support indexing.

The [CSV](#) storage engine does not support partitioning.

All tables that you create using the [CSV](#) storage engine must have the [NOT NULL](#) attribute on all columns. However, for backward compatibility, you can continue to use tables with nullable columns that were created in previous MySQL releases. (Bug #32050)

16.5 The ARCHIVE Storage Engine

The [ARCHIVE](#) storage engine produces special-purpose tables that store large amounts of unindexed data in a very small footprint.

Table 16.5 ARCHIVE Storage Engine Features

Storage limits	None	Transactions	No	Locking granularity	Row
MVCC	No	Geospatial data type support	Yes	Geospatial indexing support	No
B-tree indexes	No	T-tree indexes	No	Hash indexes	No
Full-text search indexes	No	Clustered indexes	No	Data caches	No
Index caches	No	Compressed data	Yes	Encrypted data^a	Yes
Cluster database support	No	Replication support^b	Yes	Foreign key support	No
Backup / point-in-time recovery^c	Yes	Query cache support	Yes	Update statistics for data dictionary	Yes

^aImplemented in the server (via encryption functions). Data-at-rest tablespace encryption is available in MySQL 5.7 and later.

^bImplemented in the server, rather than in the storage engine.

^cImplemented in the server, rather than in the storage engine.

The [ARCHIVE](#) storage engine is included in MySQL binary distributions. To enable this storage engine if you build MySQL from source, invoke [CMake](#) with the `-DWITH_ARCHIVE_STORAGE_ENGINE` option.

To examine the source for the [ARCHIVE](#) engine, look in the `storage/archive` directory of a MySQL source distribution.

You can check whether the [ARCHIVE](#) storage engine is available with the `SHOW ENGINES` statement.

When you create an [ARCHIVE](#) table, the storage engine creates files with names that begin with the table name. The data file has an extension of `.ARZ`. An `.ARN` file may appear during optimization operations.

The `ARCHIVE` engine supports `INSERT`, `REPLACE`, and `SELECT`, but not `DELETE` or `UPDATE`. It does support `ORDER BY` operations, `BLOB` columns, and basically all but spatial data types (see [Section 11.5.1, “Spatial Data Types”](#)). The `ARCHIVE` engine uses row-level locking.

The `ARCHIVE` engine supports the `AUTO_INCREMENT` column attribute. The `AUTO_INCREMENT` column can have either a unique or nonunique index. Attempting to create an index on any other column results in an error. The `ARCHIVE` engine also supports the `AUTO_INCREMENT` table option in `CREATE TABLE` statements to specify the initial sequence value for a new table or reset the sequence value for an existing table, respectively.

`ARCHIVE` does not support inserting a value into an `AUTO_INCREMENT` column less than the current maximum column value. Attempts to do so result in an `ER_DUP_KEY` error.

The `ARCHIVE` engine ignores `BLOB` columns if they are not requested and scans past them while reading.

The `ARCHIVE` storage engine does not support partitioning.

Storage: Rows are compressed as they are inserted. The `ARCHIVE` engine uses `zlib` lossless data compression (see <http://www.zlib.net/>). You can use `OPTIMIZE TABLE` to analyze the table and pack it into a smaller format (for a reason to use `OPTIMIZE TABLE`, see later in this section). The engine also supports `CHECK TABLE`. There are several types of insertions that are used:

- An `INSERT` statement just pushes rows into a compression buffer, and that buffer flushes as necessary. The insertion into the buffer is protected by a lock. A `SELECT` forces a flush to occur.
- A bulk insert is visible only after it completes, unless other inserts occur at the same time, in which case it can be seen partially. A `SELECT` never causes a flush of a bulk insert unless a normal insert occurs while it is loading.

Retrieval: On retrieval, rows are uncompressed on demand; there is no row cache. A `SELECT` operation performs a complete table scan: When a `SELECT` occurs, it finds out how many rows are currently available and reads that number of rows. `SELECT` is performed as a consistent read. Note that lots of `SELECT` statements during insertion can deteriorate the compression, unless only bulk or delayed inserts are used. To achieve better compression, you can use `OPTIMIZE TABLE` or `REPAIR TABLE`. The number of rows in `ARCHIVE` tables reported by `SHOW TABLE STATUS` is always accurate. See [Section 13.7.2.4, “OPTIMIZE TABLE Syntax”](#), [Section 13.7.2.5, “REPAIR TABLE Syntax”](#), and [Section 13.7.5.36, “SHOW TABLE STATUS Syntax”](#).

Additional Resources

- A forum dedicated to the `ARCHIVE` storage engine is available at <http://forums.mysql.com/list.php?112>.

16.6 The BLACKHOLE Storage Engine

The `BLACKHOLE` storage engine acts as a “black hole” that accepts data but throws it away and does not store it. Retrievals always return an empty result:

```
mysql> CREATE TABLE test(i INT, c CHAR(10)) ENGINE = BLACKHOLE;
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO test VALUES(1,'record one'),(2,'record two');
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM test;
Empty set (0.00 sec)
```

To enable the `BLACKHOLE` storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_BLACKHOLE_STORAGE_ENGINE` option.

To examine the source for the `BLACKHOLE` engine, look in the `sql` directory of a MySQL source distribution.

When you create a `BLACKHOLE` table, the server creates the table definition in the global data dictionary. There are no files associated with the table.

The `BLACKHOLE` storage engine supports all kinds of indexes. That is, you can include index declarations in the table definition.

The `BLACKHOLE` storage engine does not support partitioning.

You can check whether the `BLACKHOLE` storage engine is available with the `SHOW ENGINES` statement.

Inserts into a `BLACKHOLE` table do not store any data, but if statement based binary logging is enabled, the SQL statements are logged and replicated to slave servers. This can be useful as a repeater or filter mechanism.

Suppose that your application requires slave-side filtering rules, but transferring all binary log data to the slave first results in too much traffic. In such a case, it is possible to set up on the master host a “dummy” slave process whose default storage engine is `BLACKHOLE`, depicted as follows:

The master writes to its binary log. The “dummy” `mysqld` process acts as a slave, applying the desired combination of `replicate-do-*` and `replicate-ignore-*` rules, and writes a new, filtered binary log of its own. (See [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).) This filtered log is provided to the slave.

The dummy process does not actually store any data, so there is little processing overhead incurred by running the additional `mysqld` process on the replication master host. This type of setup can be repeated with additional replication slaves.

`INSERT` triggers for `BLACKHOLE` tables work as expected. However, because the `BLACKHOLE` table does not actually store any data, `UPDATE` and `DELETE` triggers are not activated: The `FOR EACH ROW` clause in the trigger definition does not apply because there are no rows.

Other possible uses for the `BLACKHOLE` storage engine include:

- Verification of dump file syntax.
- Measurement of the overhead from binary logging, by comparing performance using `BLACKHOLE` with and without binary logging enabled.

- `BLACKHOLE` is essentially a “no-op” storage engine, so it could be used for finding performance bottlenecks not related to the storage engine itself.

The `BLACKHOLE` engine is transaction-aware, in the sense that committed transactions are written to the binary log and rolled-back transactions are not.

Blackhole Engine and Auto Increment Columns

The Blackhole engine is a no-op engine. Any operations performed on a table using Blackhole will have no effect. This should be born in mind when considering the behavior of primary key columns that auto increment. The engine will not automatically increment field values, and does not retain auto increment field state. This has important implications in replication.

Consider the following replication scenario where all three of the following conditions apply:

1. On a master server there is a blackhole table with an auto increment field that is a primary key.
2. On a slave the same table exists but using the MyISAM engine.
3. Inserts are performed into the master's table without explicitly setting the auto increment value in the `INSERT` statement itself or through using a `SET INSERT_ID` statement.

In this scenario replication will fail with a duplicate entry error on the primary key column.

In statement based replication, the value of `INSERT_ID` in the context event will always be the same. Replication will therefore fail due to trying insert a row with a duplicate value for a primary key column.

In row based replication, the value that the engine returns for the row always be the same for each insert. This will result in the slave attempting to replay two insert log entries using the same value for the primary key column, and so replication will fail.

Column Filtering

When using row-based replication, (`binlog_format=ROW`), a slave where the last columns are missing from a table is supported, as described in the section [Section 18.4.1.10, “Replication with Differing Table Definitions on Master and Slave”](#).

This filtering works on the slave side, that is, the columns are copied to the slave before they are filtered out. There are at least two cases where it is not desirable to copy the columns to the slave:

1. If the data is confidential, so the slave server should not have access to it.
2. If the master has many slaves, filtering before sending to the slaves may reduce network traffic.

Master column filtering can be achieved using the `BLACKHOLE` engine. This is carried out in a way similar to how master table filtering is achieved - by using the `BLACKHOLE` engine and the `--replicate-do-table` or `--replicate-ignore-table` option.

The setup for the master is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N,
                 secret_col_1, ..., secret_col_M) ENGINE=MyISAM;
```

The setup for the trusted slave is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=BLACKHOLE;
```

The setup for the untrusted slave is:

```
CREATE TABLE t1 (public_col_1, ..., public_col_N) ENGINE=MyISAM;
```

16.7 The MERGE Storage Engine

The `MERGE` storage engine, also known as the `MRG_MyISAM` engine, is a collection of identical `MyISAM` tables that can be used as one. “Identical” means that all tables have identical column and index information. You cannot merge `MyISAM` tables in which the columns are listed in a different order, do not have exactly the same columns, or have the indexes in different order. However, any or all of the `MyISAM` tables can be compressed with `myisampack`. See [Section 4.6.6, “myisampack — Generate Compressed, Read-Only MyISAM Tables”](#). Differences in table options such as `AVG_ROW_LENGTH`, `MAX_ROWS`, or `PACK_KEYS` do not matter.

An alternative to a `MERGE` table is a partitioned table, which stores partitions of a single table in separate files and enables some operations to be performed more efficiently. For more information, see [Chapter 22, Partitioning](#).

When you create a `MERGE` table, MySQL creates a `.MRG` file on disk that contains the names of the underlying `MyISAM` tables that should be used as one. The table format of the `MERGE` table is stored in the MySQL data dictionary. The underlying tables do not have to be in the same database as the `MERGE` table.

You can use `SELECT`, `DELETE`, `UPDATE`, and `INSERT` on `MERGE` tables. You must have `SELECT`, `DELETE`, and `UPDATE` privileges on the `MyISAM` tables that you map to a `MERGE` table.

Note

The use of `MERGE` tables entails the following security issue: If a user has access to `MyISAM` table `t`, that user can create a `MERGE` table `m` that accesses `t`. However, if the user's privileges on `t` are subsequently revoked, the user can continue to access `t` by doing so through `m`.

Use of `DROP TABLE` with a `MERGE` table drops only the `MERGE` specification. The underlying tables are not affected.

To create a `MERGE` table, you must specify a `UNION=(list-of-tables)` option that indicates which `MyISAM` tables to use. You can optionally specify an `INSERT_METHOD` option to control how inserts into the `MERGE` table take place. Use a value of `FIRST` or `LAST` to cause inserts to be made in the first or last underlying table, respectively. If you specify no `INSERT_METHOD` option or if you specify it with a value of `NO`, inserts into the `MERGE` table are not permitted and attempts to do so result in an error.

The following example shows how to create a `MERGE` table:

```
mysql> CREATE TABLE t1 (
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   message CHAR(20)) ENGINE=MyISAM;
mysql> CREATE TABLE t2 (
->   a INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   message CHAR(20)) ENGINE=MyISAM;
mysql> INSERT INTO t1 (message) VALUES ('Testing'),('table'),('t1');
mysql> INSERT INTO t2 (message) VALUES ('Testing'),('table'),('t2');
mysql> CREATE TABLE total (
->   a INT NOT NULL AUTO_INCREMENT,
->   message CHAR(20), INDEX(a))
->   ENGINE=MERGE UNION=(t1,t2) INSERT_METHOD=LAST;
```

Column `a` is indexed as a `PRIMARY KEY` in the underlying `MyISAM` tables, but not in the `MERGE` table. There it is indexed but not as a `PRIMARY KEY` because a `MERGE` table cannot enforce uniqueness over the set of underlying tables. (Similarly, a column with a `UNIQUE` index in the underlying tables should be indexed in the `MERGE` table but not as a `UNIQUE` index.)

After creating the `MERGE` table, you can use it to issue queries that operate on the group of tables as a whole:

```
mysql> SELECT * FROM total;
+---+-----+
```

```

| a | message |
+---+-----+
| 1 | Testing |
| 2 | table   |
| 3 | t1      |
| 1 | Testing |
| 2 | table   |
| 3 | t2      |
+---+-----+

```

To remap a `MERGE` table to a different collection of `MyISAM` tables, you can use one of the following methods:

- `DROP` the `MERGE` table and re-create it.
- Use `ALTER TABLE tbl_name UNION=(...)` to change the list of underlying tables.

It is also possible to use `ALTER TABLE ... UNION=()` (that is, with an empty `UNION` clause) to remove all of the underlying tables. However, in this case, the table is effectively empty and inserts fail because there is no underlying table to take new rows. Such a table might be useful as a template for creating new `MERGE` tables with `CREATE TABLE ... LIKE`.

The underlying table definitions and indexes must conform closely to the definition of the `MERGE` table. Conformance is checked when a table that is part of a `MERGE` table is opened, not when the `MERGE` table is created. If any table fails the conformance checks, the operation that triggered the opening of the table fails. This means that changes to the definitions of tables within a `MERGE` may cause a failure when the `MERGE` table is accessed. The conformance checks applied to each table are:

- The underlying table and the `MERGE` table must have the same number of columns.
- The column order in the underlying table and the `MERGE` table must match.
- Additionally, the specification for each corresponding column in the parent `MERGE` table and the underlying tables are compared and must satisfy these checks:
 - The column type in the underlying table and the `MERGE` table must be equal.
 - The column length in the underlying table and the `MERGE` table must be equal.
 - The column of the underlying table and the `MERGE` table can be `NULL`.
- The underlying table must have at least as many indexes as the `MERGE` table. The underlying table may have more indexes than the `MERGE` table, but cannot have fewer.

Note

A known issue exists where indexes on the same columns must be in identical order, in both the `MERGE` table and the underlying `MyISAM` table. See Bug #33653.

Each index must satisfy these checks:

- The index type of the underlying table and the `MERGE` table must be the same.
- The number of index parts (that is, multiple columns within a compound index) in the index definition for the underlying table and the `MERGE` table must be the same.
- For each index part:
 - Index part lengths must be equal.
 - Index part types must be equal.
 - Index part languages must be equal.

- Check whether index parts can be `NULL`.

If a `MERGE` table cannot be opened or used because of a problem with an underlying table, `CHECK TABLE` displays information about which table caused the problem.

Additional Resources

- A forum dedicated to the `MERGE` storage engine is available at <http://forums.mysql.com/list.php?93>.

16.7.1 MERGE Table Advantages and Disadvantages

`MERGE` tables can help you solve the following problems:

- Easily manage a set of log tables. For example, you can put data from different months into separate tables, compress some of them with `myisampack`, and then create a `MERGE` table to use them as one.
- Obtain more speed. You can split a large read-only table based on some criteria, and then put individual tables on different disks. A `MERGE` table structured this way could be much faster than using a single large table.
- Perform more efficient searches. If you know exactly what you are looking for, you can search in just one of the underlying tables for some queries and use a `MERGE` table for others. You can even have many different `MERGE` tables that use overlapping sets of tables.
- Perform more efficient repairs. It is easier to repair individual smaller tables that are mapped to a `MERGE` table than to repair a single large table.
- Instantly map many tables as one. A `MERGE` table need not maintain an index of its own because it uses the indexes of the individual tables. As a result, `MERGE` table collections are very fast to create or remap. (You must still specify the index definitions when you create a `MERGE` table, even though no indexes are created.)
- If you have a set of tables from which you create a large table on demand, you can instead create a `MERGE` table from them on demand. This is much faster and saves a lot of disk space.
- Exceed the file size limit for the operating system. Each `MyISAM` table is bound by this limit, but a collection of `MyISAM` tables is not.
- You can create an alias or synonym for a `MyISAM` table by defining a `MERGE` table that maps to that single table. There should be no really notable performance impact from doing this (only a couple of indirect calls and `memcpy()` calls for each read).

The disadvantages of `MERGE` tables are:

- You can use only identical `MyISAM` tables for a `MERGE` table.
- Some `MyISAM` features are unavailable in `MERGE` tables. For example, you cannot create `FULLTEXT` indexes on `MERGE` tables. (You can create `FULLTEXT` indexes on the underlying `MyISAM` tables, but you cannot search the `MERGE` table with a full-text search.)
- If the `MERGE` table is nontemporary, all underlying `MyISAM` tables must be nontemporary. If the `MERGE` table is temporary, the `MyISAM` tables can be any mix of temporary and nontemporary.
- `MERGE` tables use more file descriptors than `MyISAM` tables. If 10 clients are using a `MERGE` table that maps to 10 tables, the server uses $(10 \times 10) + 10$ file descriptors. (10 data file descriptors for each of the 10 clients, and 10 index file descriptors shared among the clients.)
- Index reads are slower. When you read an index, the `MERGE` storage engine needs to issue a read on all underlying tables to check which one most closely matches a given index value. To read

the next index value, the `MERGE` storage engine needs to search the read buffers to find the next value. Only when one index buffer is used up does the storage engine need to read the next index block. This makes `MERGE` indexes much slower on `eq_ref` searches, but not much slower on `ref` searches. For more information about `eq_ref` and `ref`, see [Section 13.8.2, “EXPLAIN Syntax”](#).

16.7.2 MERGE Table Problems

The following are known problems with `MERGE` tables:

- In versions of MySQL Server prior to 5.1.23, it was possible to create temporary merge tables with nontemporary child `MyISAM` tables.

From versions 5.1.23, `MERGE` children were locked through the parent table. If the parent was temporary, it was not locked and so the children were not locked either. Parallel use of the `MyISAM` tables corrupted them.

- If you use `ALTER TABLE` to change a `MERGE` table to another storage engine, the mapping to the underlying tables is lost. Instead, the rows from the underlying `MyISAM` tables are copied into the altered table, which then uses the specified storage engine.
- The `INSERT_METHOD` table option for a `MERGE` table indicates which underlying `MyISAM` table to use for inserts into the `MERGE` table. However, use of the `AUTO_INCREMENT` table option for that `MyISAM` table has no effect for inserts into the `MERGE` table until at least one row has been inserted directly into the `MyISAM` table.
- A `MERGE` table cannot maintain uniqueness constraints over the entire table. When you perform an `INSERT`, the data goes into the first or last `MyISAM` table (as determined by the `INSERT_METHOD` option). MySQL ensures that unique key values remain unique within that `MyISAM` table, but not over all the underlying tables in the collection.
- Because the `MERGE` engine cannot enforce uniqueness over the set of underlying tables, `REPLACE` does not work as expected. The two key facts are:
 - `REPLACE` can detect unique key violations only in the underlying table to which it is going to write (which is determined by the `INSERT_METHOD` option). This differs from violations in the `MERGE` table itself.
 - If `REPLACE` detects a unique key violation, it will change only the corresponding row in the underlying table it is writing to; that is, the first or last table, as determined by the `INSERT_METHOD` option.

Similar considerations apply for `INSERT ... ON DUPLICATE KEY UPDATE`.

- `MERGE` tables do not support partitioning. That is, you cannot partition a `MERGE` table, nor can any of a `MERGE` table's underlying `MyISAM` tables be partitioned.
- You should not use `ANALYZE TABLE`, `REPAIR TABLE`, `OPTIMIZE TABLE`, `ALTER TABLE`, `DROP TABLE`, `DELETE` without a `WHERE` clause, or `TRUNCATE TABLE` on any of the tables that are mapped into an open `MERGE` table. If you do so, the `MERGE` table may still refer to the original table and yield unexpected results. To work around this problem, ensure that no `MERGE` tables remain open by issuing a `FLUSH TABLES` statement prior to performing any of the named operations.

The unexpected results include the possibility that the operation on the `MERGE` table will report table corruption. If this occurs after one of the named operations on the underlying `MyISAM` tables, the corruption message is spurious. To deal with this, issue a `FLUSH TABLES` statement after modifying the `MyISAM` tables.

- `DROP TABLE` on a table that is in use by a `MERGE` table does not work on Windows because the `MERGE` storage engine's table mapping is hidden from the upper layer of MySQL. Windows does not permit open files to be deleted, so you first must flush all `MERGE` tables (with `FLUSH TABLES`) or drop the `MERGE` table before dropping the table.

- The definition of the [MyISAM](#) tables and the [MERGE](#) table are checked when the tables are accessed (for example, as part of a [SELECT](#) or [INSERT](#) statement). The checks ensure that the definitions of the tables and the parent [MERGE](#) table definition match by comparing column order, types, sizes and associated indexes. If there is a difference between the tables, an error is returned and the statement fails. Because these checks take place when the tables are opened, any changes to the definition of a single table, including column changes, column ordering, and engine alterations will cause the statement to fail.
- The order of indexes in the [MERGE](#) table and its underlying tables should be the same. If you use [ALTER TABLE](#) to add a [UNIQUE](#) index to a table used in a [MERGE](#) table, and then use [ALTER TABLE](#) to add a nonunique index on the [MERGE](#) table, the index ordering is different for the tables if there was already a nonunique index in the underlying table. (This happens because [ALTER TABLE](#) puts [UNIQUE](#) indexes before nonunique indexes to facilitate rapid detection of duplicate keys.) Consequently, queries on tables with such indexes may return unexpected results.
- If you encounter an error message similar to `ERROR 1017 (HY000): Can't find file: 'tbl_name.MRG' (errno: 2)`, it generally indicates that some of the underlying tables do not use the [MyISAM](#) storage engine. Confirm that all of these tables are [MyISAM](#).
- The maximum number of rows in a [MERGE](#) table is 2^{64} (~1.844E+19; the same as for a [MyISAM](#) table). It is not possible to merge multiple [MyISAM](#) tables into a single [MERGE](#) table that would have more than this number of rows.
- Use of underlying [MyISAM](#) tables of differing row formats with a parent [MERGE](#) table is currently known to fail. See Bug #32364.
- You cannot change the union list of a nontemporary [MERGE](#) table when [LOCK TABLES](#) is in effect. The following does *not* work:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ...;
LOCK TABLES t1 WRITE, t2 WRITE, m1 WRITE;
ALTER TABLE m1 ... UNION=(t1,t2) ...;
```

However, you can do this with a temporary [MERGE](#) table.

- You cannot create a [MERGE](#) table with [CREATE ... SELECT](#), neither as a temporary [MERGE](#) table, nor as a nontemporary [MERGE](#) table. For example:

```
CREATE TABLE m1 ... ENGINE=MRG_MYISAM ... SELECT ...;
```

Attempts to do this result in an error: `tbl_name` is not [BASE TABLE](#).

- In some cases, differing [PACK_KEYS](#) table option values among the [MERGE](#) and underlying tables cause unexpected results if the underlying tables contain [CHAR](#) or [BINARY](#) columns. As a workaround, use [ALTER TABLE](#) to ensure that all involved tables have the same [PACK_KEYS](#) value. (Bug #50646)

16.8 The FEDERATED Storage Engine

The [FEDERATED](#) storage engine lets you access data from a remote MySQL database without using replication or cluster technology. Querying a local [FEDERATED](#) table automatically pulls the data from the remote (federated) tables. No data is stored on the local tables.

To include the [FEDERATED](#) storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_FEDERATED_STORAGE_ENGINE` option.

The [FEDERATED](#) storage engine is not enabled by default in the running server; to enable [FEDERATED](#), you must start the MySQL server binary using the `--federated` option.

To examine the source for the [FEDERATED](#) engine, look in the `storage/federated` directory of a MySQL source distribution.

16.8.1 FEDERATED Storage Engine Overview

When you create a table using one of the standard storage engines (such as [MyISAM](#), [CSV](#) or [InnoDB](#)), the table consists of the table definition and the associated data. When you create a [FEDERATED](#) table, the table definition is the same, but the physical storage of the data is handled on a remote server.

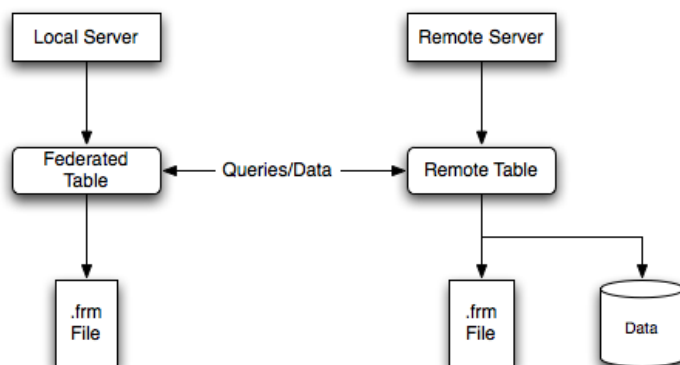

A [FEDERATED](#) table consists of two elements:

- A *remote server* with a database table, which in turn consists of the table definition (stored in the MySQL data dictionary) and the associated table. The table type of the remote table may be any type supported by the remote `mysqld` server, including [MyISAM](#) or [InnoDB](#).
- A *local server* with a database table, where the table definition matches that of the corresponding table on the remote server. The table definition is stored in the data dictionary. There is no data file on the local server. Instead, the table definition includes a connection string that points to the remote table.

When executing queries and statements on a [FEDERATED](#) table on the local server, the operations that would normally insert, update or delete information from a local data file are instead sent to the remote server for execution, where they update the data file on the remote server or return matching rows from the remote server.

The basic structure of a [FEDERATED](#) table setup is shown in [Figure 16.1, “FEDERATED Table Structure”](#).

Figure 16.1 FEDERATED Table Structure

When a client issues an SQL statement that refers to a [FEDERATED](#) table, the flow of information between the local server (where the SQL statement is executed) and the remote server (where the data is physically stored) is as follows:

1. The storage engine looks through each column that the [FEDERATED](#) table has and constructs an appropriate SQL statement that refers to the remote table.
2. The statement is sent to the remote server using the MySQL client API.
3. The remote server processes the statement and the local server retrieves any result that the statement produces (an affected-rows count or a result set).
4. If the statement produces a result set, each column is converted to internal storage engine format that the [FEDERATED](#) engine expects and can use to display the result to the client that issued the original statement.

The local server communicates with the remote server using MySQL client C API functions. It invokes `mysql_real_query()` to send the statement. To read a result set, it uses `mysql_store_result()` and fetches rows one at a time using `mysql_fetch_row()`.

16.8.2 How to Create FEDERATED Tables

To create a [FEDERATED](#) table you should follow these steps:

1. Create the table on the remote server. Alternatively, make a note of the table definition of an existing table, perhaps using the [SHOW CREATE TABLE](#) statement.
2. Create the table on the local server with an identical table definition, but adding the connection information that links the local table to the remote table.

For example, you could create the following table on the remote server:

```
CREATE TABLE test_table (
  id      INT(20) NOT NULL AUTO_INCREMENT,
  name    VARCHAR(32) NOT NULL DEFAULT '',
  other   INT(20) NOT NULL DEFAULT '0',
  PRIMARY KEY (id),
  INDEX name (name),
  INDEX other_key (other)
)
ENGINE=MyISAM
DEFAULT CHARSET=utf8mb4;
```

To create the local table that will be federated to the remote table, there are two options available. You can either create the local table and specify the connection string (containing the server name, login, password) to be used to connect to the remote table using the [CONNECTION](#), or you can use an existing connection that you have previously created using the [CREATE SERVER](#) statement.

Important

When you create the local table it *must* have an identical field definition to the remote table.

Note

You can improve the performance of a [FEDERATED](#) table by adding indexes to the table on the host. The optimization will occur because the query sent to the remote server will include the contents of the [WHERE](#) clause and will be sent to the remote server and subsequently executed locally. This reduces the network traffic that would otherwise request the entire table from the server for local processing.

16.8.2.1 Creating a FEDERATED Table Using CONNECTION

To use the first method, you must specify the [CONNECTION](#) string after the engine type in a [CREATE TABLE](#) statement. For example:

```
CREATE TABLE federated_table (
  id      INT(20) NOT NULL AUTO_INCREMENT,
  name    VARCHAR(32) NOT NULL DEFAULT '',
  other   INT(20) NOT NULL DEFAULT '0',
  PRIMARY KEY (id),
  INDEX name (name),
  INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=utf8mb4
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

Note

[CONNECTION](#) replaces the [COMMENT](#) used in some previous versions of MySQL.

The `CONNECTION` string contains the information required to connect to the remote server containing the table that will be used to physically store the data. The connection string specifies the server name, login credentials, port number and database/table information. In the example, the remote table is on the server `remote_host`, using port 9306. The name and port number should match the host name (or IP address) and port number of the remote MySQL server instance you want to use as your remote table.

The format of the connection string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

Where:

- `scheme`: A recognized connection protocol. Only `mysql` is supported as the `scheme` value at this point.
- `user_name`: The user name for the connection. This user must have been created on the remote server, and must have suitable privileges to perform the required actions (`SELECT`, `INSERT`, `UPDATE`, and so forth) on the remote table.
- `password`: (Optional) The corresponding password for `user_name`.
- `host_name`: The host name or IP address of the remote server.
- `port_num`: (Optional) The port number for the remote server. The default is 3306.
- `db_name`: The name of the database holding the remote table.
- `tbl_name`: The name of the remote table. The name of the local and the remote table do not have to match.

Sample connection strings:

```
CONNECTION='mysql://username:password@hostname:port/database/tablename'
CONNECTION='mysql://username@hostname/database/tablename'
CONNECTION='mysql://username:password@hostname/database/tablename'
```

16.8.2.2 Creating a FEDERATED Table Using CREATE SERVER

If you are creating a number of `FEDERATED` tables on the same server, or if you want to simplify the process of creating `FEDERATED` tables, you can use the `CREATE SERVER` statement to define the server connection parameters, just as you would with the `CONNECTION` string.

The format of the `CREATE SERVER` statement is:

```
CREATE SERVER
server_name
FOREIGN DATA WRAPPER wrapper_name
OPTIONS (option [, option] ...)
```

The `server_name` is used in the connection string when creating a new `FEDERATED` table.

For example, to create a server connection identical to the `CONNECTION` string:

```
CONNECTION='mysql://fed_user@remote_host:9306/federated/test_table';
```

You would use the following statement:

```
CREATE SERVER fedlink
FOREIGN DATA WRAPPER mysql
OPTIONS (USER 'fed_user', HOST 'remote_host', PORT 9306, DATABASE 'federated');
```

To create a `FEDERATED` table that uses this connection, you still use the `CONNECTION` keyword, but specify the name you used in the `CREATE SERVER` statement.

```
CREATE TABLE test_table (
  id      INT(20) NOT NULL AUTO_INCREMENT,
  name    VARCHAR(32) NOT NULL DEFAULT '',
  other   INT(20) NOT NULL DEFAULT '0',
  PRIMARY KEY (id),
  INDEX name (name),
  INDEX other_key (other)
)
ENGINE=FEDERATED
DEFAULT CHARSET=utf8mb4
CONNECTION='fedlink/test_table';
```

The connection name in this example contains the name of the connection (`fedlink`) and the name of the table (`test_table`) to link to, separated by a slash. If you specify only the connection name without a table name, the table name of the local table is used instead.

For more information on `CREATE SERVER`, see [Section 13.1.14, “CREATE SERVER Syntax”](#).

The `CREATE SERVER` statement accepts the same arguments as the `CONNECTION` string. The `CREATE SERVER` statement updates the rows in the `mysql.servers` table. See the following table for information on the correspondence between parameters in a connection string, options in the `CREATE SERVER` statement, and the columns in the `mysql.servers` table. For reference, the format of the `CONNECTION` string is as follows:

```
scheme://user_name[:password]@host_name[:port_num]/db_name/tbl_name
```

Description	CONNECTION string	CREATE SERVER option	mysql.servers column
Connection scheme	<i>scheme</i>	wrapper_name	Wrapper
Remote user	<i>user_name</i>	USER	Username
Remote password	<i>password</i>	PASSWORD	Password
Remote host	<i>host_name</i>	HOST	Host
Remote port	<i>port_num</i>	PORT	Port
Remote database	<i>db_name</i>	DATABASE	Db

16.8.3 FEDERATED Storage Engine Notes and Tips

You should be aware of the following points when using the `FEDERATED` storage engine:

- `FEDERATED` tables may be replicated to other slaves, but you must ensure that the slave servers are able to use the user/password combination that is defined in the `CONNECTION` string (or the row in the `mysql.servers` table) to connect to the remote server.

The following items indicate features that the `FEDERATED` storage engine does and does not support:

- The remote server must be a MySQL server.
- The remote table that a `FEDERATED` table points to *must* exist before you try to access the table through the `FEDERATED` table.
- It is possible for one `FEDERATED` table to point to another, but you must be careful not to create a loop.
- A `FEDERATED` table does not support indexes in the usual sense; because access to the table data is handled remotely, it is actually the remote table that makes use of indexes. This means that, for a query that cannot use any indexes and so requires a full table scan, the server fetches all rows from the remote table and filters them locally. This occurs regardless of any `WHERE` or `LIMIT` used with this `SELECT` statement; these clauses are applied locally to the returned rows.

Queries that fail to use indexes can thus cause poor performance and network overload. In addition, since returned rows must be stored in memory, such a query can also lead to the local server swapping, or even hanging.

- Care should be taken when creating a [FEDERATED](#) table since the index definition from an equivalent [MyISAM](#) or other table may not be supported. For example, creating a [FEDERATED](#) table with an index prefix on [VARCHAR](#), [TEXT](#) or [BLOB](#) columns will fail. The following definition in [MyISAM](#) is valid:

```
CREATE TABLE `T1` (`A` VARCHAR(100), UNIQUE KEY(`A`(30))) ENGINE=MYISAM;
```

The key prefix in this example is incompatible with the [FEDERATED](#) engine, and the equivalent statement will fail:

```
CREATE TABLE `T1` (`A` VARCHAR(100), UNIQUE KEY(`A`(30))) ENGINE=FEDERATED
CONNECTION='MYSQL://127.0.0.1:3306/TEST/T1';
```

If possible, you should try to separate the column and index definition when creating tables on both the remote server and the local server to avoid these index issues.

- Internally, the implementation uses [SELECT](#), [INSERT](#), [UPDATE](#), and [DELETE](#), but not [HANDLER](#).
- The [FEDERATED](#) storage engine supports [SELECT](#), [INSERT](#), [UPDATE](#), [DELETE](#), [TRUNCATE TABLE](#), and indexes. It does not support [ALTER TABLE](#), or any Data Definition Language statements that directly affect the structure of the table, other than [DROP TABLE](#). The current implementation does not use prepared statements.
- [FEDERATED](#) accepts [INSERT ... ON DUPLICATE KEY UPDATE](#) statements, but if a duplicate-key violation occurs, the statement fails with an error.
- Performance on a [FEDERATED](#) table when performing bulk inserts (for example, on a [INSERT INTO ... SELECT ...](#) statement) is slower than with other table types because each selected row is treated as an individual [INSERT](#) statement on the [FEDERATED](#) table.
- Transactions are not supported.
- [FEDERATED](#) performs bulk-insert handling such that multiple rows are sent to the remote table in a batch. This provides a performance improvement and enables the remote table to perform improvement. Also, if the remote table is transactional, it enables the remote storage engine to perform statement rollback properly should an error occur. This capability has the following limitations:
 - The size of the insert cannot exceed the maximum packet size between servers. If the insert exceeds this size, it is broken into multiple packets and the rollback problem can occur.
 - Bulk-insert handling does not occur for [INSERT ... ON DUPLICATE KEY UPDATE](#).
- There is no way for the [FEDERATED](#) engine to know if the remote table has changed. The reason for this is that this table must work like a data file that would never be written to by anything other than the database system. The integrity of the data in the local table could be breached if there was any change to the remote database.
- When using a [CONNECTION](#) string, you cannot use an '@' character in the password. You can get round this limitation by using the [CREATE SERVER](#) statement to create a server connection.
- The [insert_id](#) and [timestamp](#) options are not propagated to the data provider.
- Any [DROP TABLE](#) statement issued against a [FEDERATED](#) table drops only the local table, not the remote table.
- [FEDERATED](#) tables do not work with the query cache.
- User-defined partitioning is not supported for [FEDERATED](#) tables.

16.8.4 FEDERATED Storage Engine Resources

The following additional resources are available for the `FEDERATED` storage engine:

- A forum dedicated to the `FEDERATED` storage engine is available at <http://forums.mysql.com/list.php?105>.

16.9 The EXAMPLE Storage Engine

The `EXAMPLE` storage engine is a stub engine that does nothing. Its purpose is to serve as an example in the MySQL source code that illustrates how to begin writing new storage engines. As such, it is primarily of interest to developers.

To enable the `EXAMPLE` storage engine if you build MySQL from source, invoke `CMake` with the `-DWITH_EXAMPLE_STORAGE_ENGINE` option.

To examine the source for the `EXAMPLE` engine, look in the `storage/example` directory of a MySQL source distribution.

When you create an `EXAMPLE` table, no files are created. No data can be stored into the table. Retrievals return an empty result.

```
mysql> CREATE TABLE test (i INT) ENGINE = EXAMPLE;
Query OK, 0 rows affected (0.78 sec)

mysql> INSERT INTO test VALUES(1),(2),(3);
ERROR 1031 (HY000): Table storage engine for 'test' doesn't »
      have this option

mysql> SELECT * FROM test;
Empty set (0.31 sec)
```

The `EXAMPLE` storage engine does not support indexing.

The `EXAMPLE` storage engine does not support partitioning.

16.10 Other Storage Engines

Other storage engines may be available from third parties and community members that have used the Custom Storage Engine interface.

Third party engines are not supported by MySQL. For further information, documentation, installation guides, bug reporting or for any help or assistance with these engines, please contact the developer of the engine directly.

For more information on developing a customer storage engine that can be used with the Pluggable Storage Engine Architecture, see [MySQL Internals: Writing a Custom Storage Engine](#).

16.11 Overview of MySQL Storage Engine Architecture

The MySQL pluggable storage engine architecture enables a database professional to select a specialized storage engine for a particular application need while being completely shielded from the need to manage any specific application coding requirements. The MySQL server architecture isolates the application programmer and DBA from all of the low-level implementation details at the storage level, providing a consistent and easy application model and API. Thus, although there are different capabilities across different storage engines, the application is shielded from these differences.

The pluggable storage engine architecture provides a standard set of management and support services that are common among all underlying storage engines. The storage engines themselves

are the components of the database server that actually perform actions on the underlying data that is maintained at the physical server level.

This efficient and modular architecture provides huge benefits for those wishing to specifically target a particular application need—such as data warehousing, transaction processing, or high availability situations—while enjoying the advantage of utilizing a set of interfaces and services that are independent of any one storage engine.

The application programmer and DBA interact with the MySQL database through Connector APIs and service layers that are above the storage engines. If application changes bring about requirements that demand the underlying storage engine change, or that one or more storage engines be added to support new needs, no significant coding or process changes are required to make things work. The MySQL server architecture shields the application from the underlying complexity of the storage engine by presenting a consistent and easy-to-use API that applies across storage engines.

16.11.1 Pluggable Storage Engine Architecture

MySQL Server uses a pluggable storage engine architecture that enables storage engines to be loaded into and unloaded from a running MySQL server.

Plugging in a Storage Engine

Before a storage engine can be used, the storage engine plugin shared library must be loaded into MySQL using the `INSTALL PLUGIN` statement. For example, if the `EXAMPLE` engine plugin is named `example` and the shared library is named `ha_example.so`, you load it with the following statement:

```
mysql> INSTALL PLUGIN example SONAME 'ha_example.so';
```

To install a pluggable storage engine, the plugin file must be located in the MySQL plugin directory, and the user issuing the `INSTALL PLUGIN` statement must have `INSERT` privilege for the `mysql.plugin` table.

The shared library must be located in the MySQL server plugin directory, the location of which is given by the `plugin_dir` system variable.

Unplugging a Storage Engine

To unplug a storage engine, use the `UNINSTALL PLUGIN` statement:

```
mysql> UNINSTALL PLUGIN example;
```

If you unplug a storage engine that is needed by existing tables, those tables become inaccessible, but will still be present on disk (where applicable). Ensure that there are no tables using a storage engine before you unplug the storage engine.

16.11.2 The Common Database Server Layer

A MySQL pluggable storage engine is the component in the MySQL database server that is responsible for performing the actual data I/O operations for a database as well as enabling and enforcing certain feature sets that target a specific application need. A major benefit of using specific storage engines is that you are only delivered the features needed for a particular application, and therefore you have less system overhead in the database, with the end result being more efficient and higher database performance. This is one of the reasons that MySQL has always been known to have such high performance, matching or beating proprietary monolithic databases in industry standard benchmarks.

From a technical perspective, what are some of the unique supporting infrastructure components that are in a storage engine? Some of the key feature differentiations include:

- *Concurrency*: Some applications have more granular lock requirements (such as row-level locks) than others. Choosing the right locking strategy can reduce overhead and therefore improve overall performance. This area also includes support for capabilities such as multi-version concurrency control or “snapshot” read.
- *Transaction Support*: Not every application needs transactions, but for those that do, there are very well defined requirements such as ACID compliance and more.
- *Referential Integrity*: The need to have the server enforce relational database referential integrity through DDL defined foreign keys.
- *Physical Storage*: This involves everything from the overall page size for tables and indexes as well as the format used for storing data to physical disk.
- *Index Support*: Different application scenarios tend to benefit from different index strategies. Each storage engine generally has its own indexing methods, although some (such as B-tree indexes) are common to nearly all engines.
- *Memory Caches*: Different applications respond better to some memory caching strategies than others, so although some memory caches are common to all storage engines (such as those used for user connections or MySQL's high-speed Query Cache), others are uniquely defined only when a particular storage engine is put in play.
- *Performance Aids*: This includes multiple I/O threads for parallel operations, thread concurrency, database checkpointing, bulk insert handling, and more.
- *Miscellaneous Target Features*: This may include support for geospatial operations, security restrictions for certain data manipulation operations, and other similar features.

Each set of the pluggable storage engine infrastructure components are designed to offer a selective set of benefits for a particular application. Conversely, avoiding a set of component features helps reduce unnecessary overhead. It stands to reason that understanding a particular application's set of requirements and selecting the proper MySQL storage engine can have a dramatic impact on overall system efficiency and performance.

Data is the currency of today's web, mobile, social, enterprise and cloud applications. Ensuring data is always available is a top priority for any organization. Minutes of downtime can result in significant loss of revenue and reputation.

There is no “one size fits all” approach to delivering High Availability (HA). Unique application attributes, business requirements, operational capabilities and legacy infrastructure can all influence HA technology selection. And technology is only one element in delivering HA: people and processes are just as critical as the technology itself.

MySQL is deployed into many applications demanding availability and scalability. **Availability** refers to the ability to cope with, and if necessary recover from, failures on the host, including failures of MySQL, the operating system, or the hardware and maintenance activity that may otherwise cause downtime. **Scalability** refers to the ability to spread both the database and the load of your application queries across multiple MySQL servers.

Because each application has different operational and availability requirements, MySQL offers a range of certified and supported solutions, delivering the appropriate levels of High Availability (HA) and scalability to meet service level requirements. Such solutions extend from replication, through virtualization and geographically redundant, multi-data center solutions delivering 99.999% uptime.

Selecting the right high availability solution for an application largely depends on:

- The level of availability required.
- The type of application being deployed.
- Accepted best practices within your own environment.

The primary solutions supported by MySQL include:

- MySQL Replication. Learn more: [Chapter 18, Replication](#).
- MySQL Cluster. Learn more: [MySQL NDB Cluster 7.5 and NDB Cluster 7.6](#).
- Oracle MySQL Cloud Service. [Learn more about MySQL Cloud Service](#).
- Oracle Clusterware Agent for MySQL. [Learn more about Oracle Clusterware](#).
- MySQL with Solaris Cluster. [Learn more about Solaris Cluster](#).

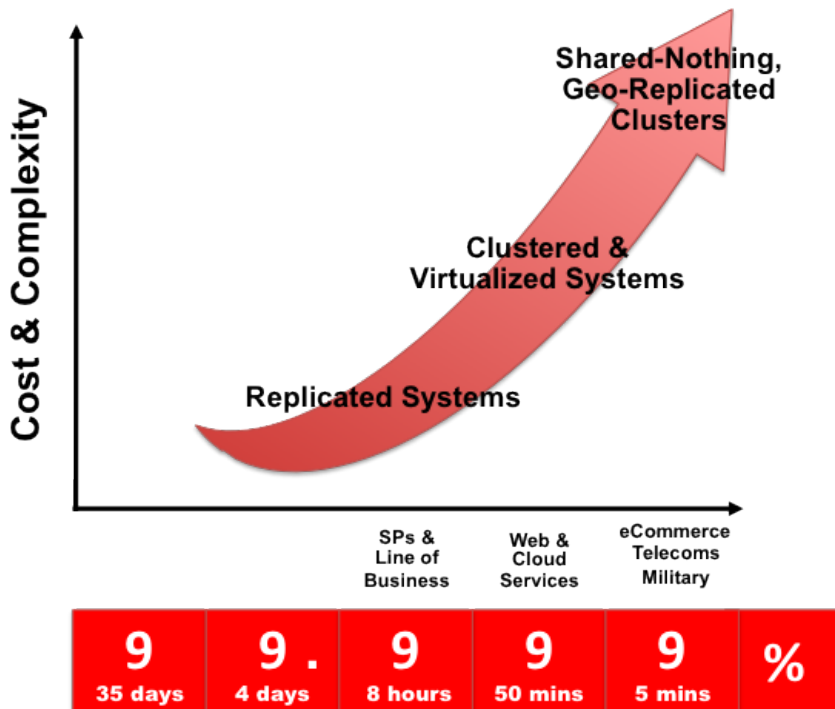

Further options are available using third-party solutions.

Each architecture used to achieve highly available database services is differentiated by the levels of uptime it offers. These architectures can be grouped into three main categories:

- Data Replication.
- Clustered & Virtualized Systems.
- Shared-Nothing, Geographically-Replicated Clusters.

As illustrated in the following figure, each of these architectures offers progressively higher levels of uptime, which must be balanced against potentially greater levels of cost and complexity that each can incur. Simply deploying a high availability architecture is not a guarantee of actually delivering HA. In fact, a poorly implemented and maintained shared-nothing cluster could easily deliver lower levels of availability than a simple data replication solution.

Figure 17.1 Tradeoffs: Cost and Complexity versus Availability

The following table compares the HA and Scalability capabilities of the various MySQL solutions:

Table 17.1 Feature Comparison of MySQL HA Solutions

Requirement	MySQL Replication	MySQL Cluster
Availability		
Platform Support	All Supported by MySQL Server (http://www.mysql.com/support/supportedplatforms/database.html)	All Supported by MySQL Cluster (http://www.mysql.com/support/supportedplatforms/cluster.html)
Automated IP Failover	No	Depends on Connector and Configuration
Automated Database Failover	No	Yes
Automatic Data Resynchronization	No	Yes
Typical Failover Time	User / Script Dependent	1 Second and Less
Synchronous Replication	No, Asynchronous and Semisynchronous	Yes
Shared Storage	No, Distributed	No, Distributed

Requirement	MySQL Replication	MySQL Cluster
Geographic redundancy support	Yes	Yes, via MySQL Replication
Update Schema On-Line	No	Yes
Scalability		
Number of Nodes	One Master, Multiple Slaves	255
Built-in Load Balancing	Reads, via MySQL Replication	Yes, Reads and Writes
Supports Read-Intensive Workloads	Yes	Yes
Supports Write-Intensive Workloads	Yes, via Application-Level Sharding	Yes, via Auto-Sharding
Scale On-Line (add nodes, repartition, etc.)	No	Yes

17.1 Using ZFS Replication

To support high availability environments, providing an instant copy of the information on both the currently active machine and the hot backup is a critical part of the HA solution. There are many solutions to this problem, such as [Chapter 18, Replication](#).

The ZFS file system provides functionality to create a snapshot of the file system contents, transfer the snapshot to another machine, and extract the snapshot to recreate the file system. You can create a snapshot at any time, and you can create as many snapshots as you like. By continually creating, transferring, and restoring snapshots, you can provide synchronization between one or more machines in a fashion similar to DRBD.

The following example shows a simple Solaris system running with a single ZFS pool, mounted at `/scratchpool`:

```

Filesystem                size  used  avail capacity  Mounted on
/dev/dsk/c0d0s0          4.6G  3.7G   886M    82%      /
/devices                  0K    0K    0K     0%      /devices
ctfs                      0K    0K    0K     0%      /system/contract
proc                     0K    0K    0K     0%      /proc
mnttab                   0K    0K    0K     0%      /etc/mnttab
swap                    1.4G   892K   1.4G     1%      /etc/svc/volatile
objfs                    0K    0K    0K     0%      /system/object
/usr/lib/libc/libc_hwcap1.so.1
                          4.6G  3.7G   886M    82%      /lib/libc.so.1
fd                        0K    0K    0K     0%      /dev/fd
swap                    1.4G   40K   1.4G     1%      /tmp
swap                    1.4G   28K   1.4G     1%      /var/run
/dev/dsk/c0d0s7          26G   913M   25G     4%      /export/home
scratchpool              16G   24K   16G     1%      /scratchpool

```

The MySQL data is stored in a directory on `/scratchpool`. To help demonstrate some of the basic replication functionality, there are also other items stored in `/scratchpool` as well:

```

total 17
drwxr-xr-x  31 root    bin           50 Jul 21 07:32 DTT/
drwxr-xr-x   4 root    bin           5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x  14 root    sys          16 Nov  5 09:56 SUNWspro/
drwxrwxrwx  19 1000   1000         40 Nov  6 19:16 emacs-22.1/

```

To create a snapshot of the file system, you use `zfs snapshot`, specifying the pool and the snapshot name:

```
root-shell> zfs snapshot scratchpool@snap1
```

To list the snapshots already taken:

```
root-shell> zfs list -t snapshot
NAME                USED  AVAIL  REFER  MOUNTPOINT
scratchpool@snap1    0      -   24.5K  -
scratchpool@snap2    0      -   24.5K  -
```

The snapshots themselves are stored within the file system metadata, and the space required to keep them varies as time goes on because of the way the snapshots are created. The initial creation of a snapshot is very quick, because instead of taking an entire copy of the data and metadata required to hold the entire snapshot, ZFS records only the point in time and metadata of when the snapshot was created.

As more changes to the original file system are made, the size of the snapshot increases because more space is required to keep the record of the old blocks. If you create lots of snapshots, say one per day, and then delete the snapshots from earlier in the week, the size of the newer snapshots might also increase, as the changes that make up the newer state have to be included in the more recent snapshots, rather than being spread over the seven snapshots that make up the week.

You cannot directly back up the snapshots because they exist within the file system metadata rather than as regular files. To get the snapshot into a format that you can copy to another file system, tape, and so on, you use the `zfs send` command to create a stream version of the snapshot.

For example, to write the snapshot out to a file:

```
root-shell> zfs send scratchpool@snap1 >/backup/scratchpool-snap1
```

Or tape:

```
root-shell> zfs send scratchpool@snap1 >/dev/rmt/0
```

You can also write out the incremental changes between two snapshots using `zfs send`:

```
root-shell> zfs send scratchpool@snap1 scratchpool@snap2 >/backup/scratchpool-changes
```

To recover a snapshot, you use `zfs recv`, which applies the snapshot information either to a new file system, or to an existing one.

17.1.1 Using ZFS for File System Replication

Because `zfs send` and `zfs recv` use streams to exchange data, you can use them to replicate information from one system to another by combining `zfs send`, `ssh`, and `zfs recv`.

For example, to copy a snapshot of the `scratchpool` file system to a new file system called `slavepool` on a new server, you would use the following command. This sequence combines the snapshot of `scratchpool`, the transmission to the slave machine (using `ssh` with login credentials), and the recovery of the snapshot on the slave using `zfs recv`:

```
root-shell> zfs send scratchpool@snap1 |ssh id@host pfexec zfs recv -F slavepool
```

The first part of the pipeline, `zfs send scratchpool@snap1`, streams the snapshot. The `ssh` command, and the command that it executes on the other server, `pfexec zfs recv -F slavepool`, receives the streamed snapshot data and writes it to `slavepool`. In this instance, I've specified the `-F` option which forces the snapshot data to be applied, and is therefore destructive. This is fine, as I'm creating the first version of my replicated file system.

On the slave machine, the replicated file system contains the exact same content:

```
root-shell> ls -al /slavepool/
total 23
drwxr-xr-x  6 root    root          7 Nov  8 09:13 ./
drwxr-xr-x 29 root    root          34 Nov  9 07:06 ../
drwxr-xr-x 31 root    bin           50 Jul 21 07:32 DTT/
drwxr-xr-x  4 root    bin           5 Jul 21 07:32 SUNWmlib/
drwxr-xr-x 14 root    sys          16 Nov  5 09:56 SUNWspro/
drwxrwxrwx 19 1000   1000        40 Nov  6 19:16 emacs-22.1/
```

Once a snapshot has been created, to synchronize the file system again, you create a new snapshot and then use the incremental snapshot feature of `zfs send` to send the changes between the two snapshots to the slave machine again:

```
root-shell> zfs send -i scratchpool@snapshot1 scratchpool@snapshot2 |ssh id@host pfexec zfs recv slavepool
```

This operation only succeeds if the file system on the slave machine has not been modified at all. You cannot apply the incremental changes to a destination file system that has changed. In the example above, the `ls` command would cause problems by changing the metadata, such as the last access time for files or directories.

To prevent changes on the slave file system, set the file system on the slave to be read-only:

```
root-shell> zfs set readonly=on slavepool
```

Setting `readonly` means that you cannot change the file system on the slave by normal means, including the file system metadata. Operations that would normally update metadata (like our `ls`) silently perform their function without attempting to update the file system state.

In essence, the slave file system is nothing but a static copy of the original file system. However, even when configured to be read-only, a file system can have snapshots applied to it. With the file system set to read only, re-run the initial copy:

```
root-shell> zfs send scratchpool@snap1 |ssh id@host pfexec zfs recv -F slavepool
```

Now you can make changes to the original file system and replicate them to the slave.

17.1.2 Configuring MySQL for ZFS Replication

Configuring MySQL on the source file system is a case of creating the data on the file system that you intend to replicate. The configuration file in the example below has been updated to use `/scratchpool/mysql-data` as the data directory, and now you can initialize the tables:

```
root-shell> mysql_install_db --defaults-file=/etc/mysql/5.5/my.cnf --user=mysql
```

To synchronize the initial information, perform a new snapshot and then send an incremental snapshot to the slave using `zfs send`:

```
root-shell> zfs snapshot scratchpool@snap2
root-shell> zfs send -i scratchpool@snap1 scratchpool@snap2|ssh id@host pfexec zfs recv slavepool
```

Doublecheck that the slave has the data by looking at the MySQL data directory on the `slavepool`:

```
root-shell> ls -al /slavepool/mysql-data/
```

Now you can start up MySQL, create some data, and then replicate the changes using `zfs send/zfs recv` to the slave to synchronize the changes.

The rate at which you perform the synchronization depends on your application and environment. The limitation is the speed required to perform the snapshot and then to send the changes over the network.

To automate the process, create a script that performs the snapshot, send, and receive operation, and use `cron` to synchronize the changes at set times or intervals.

17.1.3 Handling MySQL Recovery with ZFS

When using ZFS replication to provide a constant copy of your data, ensure that you can recover your tables, either manually or automatically, in the event of a failure of the original system.

In the event of a failure, follow this sequence:

1. Stop the script on the master, if it is still up and running.
2. Set the slave file system to be read/write:

```
root-shell> zfs set readonly=off slavepool
```

3. Start up `mysqld` on the slave. If you are using `InnoDB`, you get auto-recovery, if it is needed, to make sure the table data is correct, as shown here when I started up from our mid-INSERT snapshot:

```
InnoDB: The log sequence number in ibdata files does not match
InnoDB: the log sequence number in the ib_logfiles!
081109 15:59:59 InnoDB: Database was not shut down normally!
InnoDB: Starting crash recovery.
InnoDB: Reading tablespace information from the .ibd files...
InnoDB: Restoring possible half-written data pages from the doublewrite
InnoDB: buffer...
081109 16:00:03 InnoDB: Started; log sequence number 0 1142807951
081109 16:00:03 [Note] /slavepool/mysql-5.0.67-solaris10-i386/bin/mysqld: ready for connections.
Version: '5.0.67' socket: '/tmp/mysql.sock' port: 3306 MySQL Community Server (GPL)
```

Use `InnoDB` tables and a regular synchronization schedule to reduce the risk for significant data loss. On `MyISAM` tables, you might need to run `REPAIR TABLE`, and you might even have lost some information.

17.2 Using MySQL with `memcached`

`memcached` is a simple, highly scalable key-based cache that stores data and objects wherever dedicated or spare RAM is available for quick access by applications, without going through layers of parsing or disk I/O. To use, you run the `memcached` command on one or more hosts and then use the shared cache to store objects. For more usage instructions, see [Section 17.2.2, “Using `memcached`”](#)

Benefits of using `memcached` include:

- Because all information is stored in RAM, the access speed is faster than loading the information each time from disk.
- Because the “value” portion of the key-value pair does not have any data type restrictions, you can cache data such as complex structures, documents, images, or a mixture of such things.
- If you use the in-memory cache to hold transient information, or as a read-only cache for information also stored in a database, the failure of any `memcached` server is not critical. For persistent data, you can fall back to an alternative lookup method using database queries, and reload the data into RAM on a different server.

The typical usage environment is to modify your application so that information is read from the cache provided by `memcached`. If the information is not in `memcached`, then the data is loaded from the MySQL database and written into the cache so that future requests for the same object benefit from the cached data.

For a typical deployment layout, see [Figure 17.2, “`memcached` Architecture Overview”](#).

Figure 17.2 memcached Architecture Overview

In the example structure, any of the clients can contact one of the `memcached` servers to request a given key. Each client is configured to talk to all of the servers shown in the illustration. Within the client, when the request is made to store the information, the key used to reference the data is hashed and this hash is then used to select one of the `memcached` servers. The selection of the `memcached` server takes place on the client before the server is contacted, keeping the process lightweight.

The same algorithm is used again when a client requests the same key. The same key generates the same hash, and the same `memcached` server is selected as the source for the data. Using this method, the cached data is spread among all of the `memcached` servers, and the cached information is accessible from any client. The result is a distributed, memory-based, cache that can return information, particularly complex data and structures, much faster than natively reading the information from the database.

The data held within a traditional `memcached` server is never stored on disk (only in RAM, which means there is no persistence of data), and the RAM cache is always populated from the backing store (a MySQL database). If a `memcached` server fails, the data can always be recovered from the MySQL database.

17.2.1 Installing memcached

You can build and install `memcached` from the source code directly, or you can use an existing operating system package or installation.

Installing memcached from a Binary Distribution

To install `memcached` on a Red Hat, or Fedora host, use `yum`:

```
root-shell> yum install memcached
```

Note

On CentOS, you may be able to obtain a suitable RPM from another source, or use the source tarball.

To install `memcached` on a Debian or Ubuntu host, use `apt-get`:

```
root-shell> apt-get install memcached
```

To install `memcached` on a Gentoo host, use `emerge`:

```
root-shell> emerge install memcached
```

Building memcached from Source

On other Unix-based platforms, including Solaris, AIX, HP-UX and OS X, and Linux distributions not mentioned already, you must install from source. For Linux, make sure you have a 2.6-based kernel, which includes the improved `epoll` interface. For all platforms, ensure that you have `libevent` 1.1 or higher installed. You can obtain `libevent` from [libevent web page](#).

You can obtain the source for `memcached` from [memcached Web site](#).

To build `memcached`, follow these steps:

1. Extract the `memcached` source package:

```
shell> gunzip -c memcached-1.2.5.tar.gz | tar xf -
```

2. Change to the `memcached-1.2.5` directory:

```
shell> cd memcached-1.2.5
```

3. Run `configure`

```
shell> ./configure
```

Some additional options you might specify to the `configure`:

- `--prefix`

To specify a different installation directory, use the `--prefix` option:

```
shell> ./configure --prefix=/opt
```

The default is to use the `/usr/local` directory.

- `--with-libevent`

If you have installed `libevent` and `configure` cannot find the library, use the `--with-libevent` option to specify the location of the installed library.

- `--enable-64bit`

To build a 64-bit version of `memcached` (which enables you to use a single instance with a large RAM allocation), use `--enable-64bit`.

- `--enable-threads`

To enable multi-threading support in `memcached`, which improves the response times on servers with a heavy load, use `--enable-threads`. You must have support for the POSIX threads within your operating system to enable thread support. For more information on the threading support, see [Section 17.2.2.8, “memcached Thread Support”](#).

- `--enable-dtrace`

`memcached` includes a range of DTrace threads that can be used to monitor and benchmark a `memcached` instance. For more information, see [Section 17.2.2.6, “Using memcached and DTrace”](#).

4. Run `make` to build `memcached`:

```
shell> make
```

5. Run `make install` to install `memcached`:

```
shell> make install
```

17.2.2 Using `memcached`

To start using `memcached`, start the `memcached` service on one or more servers. Running `memcached` sets up the server, allocates the memory and starts listening for connections from clients.

Note

You do not need to be a privileged user (`root`) to run `memcached` except to listen on one of the privileged TCP/IP ports (below 1024). You must, however, use a user that has not had their memory limits restricted using `setrlimit` or similar.

To start the server, run `memcached` as a nonprivileged (that is, non-`root`) user:

```
shell> memcached
```

By default, `memcached` uses the following settings:

- Memory allocation of 64MB
- Listens for connections on all network interfaces, using port 11211
- Supports a maximum of 1024 simultaneous connections

Typically, you would specify the full combination of options that you want when starting `memcached`, and normally provide a startup script to handle the initialization of `memcached`. For example, the following line starts `memcached` with a maximum of 1024MB RAM for the cache, listening on port 11211 on the IP address 192.168.0.110, running as a background daemon:

```
shell> memcached -d -m 1024 -p 11211 -l 192.168.0.110
```

To ensure that `memcached` is started up on boot, check the init script and configuration parameters.

17.2.2.1 `memcached` Command-Line Options

`memcached` supports the following options:

- `-u user`

If you start `memcached` as `root`, use the `-u` option to specify the user for executing `memcached`:

```
shell> memcached -u memcache
```

- `-m memory`

Set the amount of memory allocated to `memcached` for object storage. Default is 64MB.

To increase the amount of memory allocated for the cache, use the `-m` option to specify the amount of RAM to be allocated (in megabytes). The more RAM you allocate, the more data you can store and therefore the more effective your cache is.

Warning

Do not specify a memory allocation larger than your available RAM. If you specify too large a value, then some RAM allocated for `memcached` uses swap space, and not physical RAM. This may lead to delays when storing

and retrieving values, because data is swapped to disk, instead of storing the data directly in RAM.

You can use the output of the `vmstat` command to get the free memory, as shown in `free` column:

```
shell> vmstat
kthr      memory          page        disk          faults        cpu
r  b  w     swap free  re  mf  pi  po  fr  de  sr  sl  s2  --  --  in  sy  cs  us  sy  id
0  0  0  5170504 3450392 2   7   2  0  0  0  4  0  0  0  0  296  54  199  0  0  100
```

For example, to allocate 3GB of RAM:

```
shell> memcached -m 3072
```

On 32-bit x86 systems where you are using PAE to access memory above the 4GB limit, you cannot allocate RAM beyond the maximum process size. You can get around this by running multiple instances of `memcached`, each listening on a different port:

```
shell> memcached -m 1024 -p11211
shell> memcached -m 1024 -p11212
shell> memcached -m 1024 -p11213
```

Note

On all systems, particularly 32-bit, ensure that you leave enough room for both `memcached` application in addition to the memory setting. For example, if you have a dedicated `memcached` host with 4GB of RAM, do not set the memory size above 3500MB. Failure to do this may cause either a crash or severe performance issues.

- `-l interface`

Specify a network interface/address to listen for connections. The default is to listen on all available address (`INADDR_ANY`).

```
shell> memcached -l 192.168.0.110
```

Support for IPv6 address support was added in `memcached` 1.2.5.

- `-p port`

Specify the TCP port to use for connections. Default is 18080.

```
shell> memcached -p 18080
```

- `-U port`

Specify the UDP port to use for connections. Default is 11211, 0 switches UDP off.

```
shell> memcached -U 18080
```

- `-s socket`

Specify a Unix socket to listen on.

If you are running `memcached` on the same server as the clients, you can disable the network interface and use a local Unix socket using the `-s` option:

```
shell> memcached -s /tmp/memcached
```

Using a Unix socket automatically disables network support, and saves network ports (allowing more ports to be used by your web server or other process).

- `-a mask`

Specify the access mask to be used for the Unix socket, in octal. Default is 0700.

- `-c connections`

Specify the maximum number of simultaneous connections to the `memcached` service. The default is 1024.

```
shell> memcached -c 2048
```

Use this option, either to reduce the number of connections (to prevent overloading `memcached` service) or to increase the number to make more effective use of the server running `memcached` server.

- `-t threads`

Specify the number of threads to use when processing incoming requests.

By default, `memcached` is configured to use 4 concurrent threads. The threading improves the performance of storing and retrieving data in the cache, using a locking system to prevent different threads overwriting or updating the same values. To increase or decrease the number of threads, use the `-t` option:

```
shell> memcached -t 8
```

- `-d`

Run `memcached` as a daemon (background) process:

```
shell> memcached -d
```

- `-r`

Maximize the size of the core file limit. In the event of a failure, this attempts to dump the entire memory space to disk as a core file, up to any limits imposed by `setrlimit`.

- `-M`

Return an error to the client when the memory has been exhausted. This replaces the normal behavior of removing older items from the cache to make way for new items.

- `-k`

Lock down all paged memory. This reserves the memory before use, instead of allocating new slabs of memory as new items are stored in the cache.

Note

There is a user-level limit on how much memory you can lock. Trying to allocate more than the available memory fails. You can set the limit for the user you started the daemon with (not for the `-u user` user) within the shell by using `ulimit -S -l NUM_KB`

Verbose mode. Prints errors and warnings while executing the main event loop.

- `-vv`

Very verbose mode. In addition to information printed by `-v`, also prints each client command and the response.

- `-vvv`

Extremely verbose mode. In addition to information printed by `-vv`, also show the internal state transitions.

- `-h`

Print the help message and exit.

- `-i`

Print the `memcached` and `libevent` license.

- `-I mem`

Specify the maximum size permitted for storing an object within the `memcached` instance. The size supports a unit postfix (`k` for kilobytes, `m` for megabytes). For example, to increase the maximum supported object size to 32MB:

```
shell> memcached -I 32m
```

The maximum object size you can specify is 128MB, the default remains at 1MB.

This option was added in 1.4.2.

- `-b`

Set the backlog queue limit. The backlog queue configures how many network connections can be waiting to be processed by `memcached`. Increasing this limit may reduce errors received by the client that it is not able to connect to the `memcached` instance, but does not improve the performance of the server. The default is 1024.

- `-P pidfile`

Save the process ID of the `memcached` instance into `file`.

- `-f`

Set the chunk size growth factor. When allocating new memory chunks, the allocated size of new chunks is determined by multiplying the default slab size by this factor.

To see the effects of this option without extensive testing, use the `-vv` command-line option to show the calculated slab sizes. For more information, see [Section 17.2.2.9, “memcached Logs”](#).

- `-n bytes`

The minimum space allocated for the key+value+flags information. The default is 48 bytes.

- `-L`

On systems that support large memory pages, enables large memory page use. Using large memory pages enables `memcached` to allocate the item cache in one large chunk, which can improve the performance by reducing the number misses when accessing memory.

- `-C`

Disable the use of compare and swap (CAS) operations.

This option was added in `memcached` 1.3.x.

- `-D char`

Set the default character to be used as a delimiter between the key prefixes and IDs. This is used for the per-prefix statistics reporting (see [Section 17.2.4, “Getting `memcached` Statistics”](#)). The default is the colon (:). If this option is used, statistics collection is turned on automatically. If not used, you can enable stats collection by sending the `stats detail on` command to the server.

This option was added in `memcached` 1.3.x.

- `-R num`

Sets the maximum number of requests per event process. The default is 20.

- `-B protocol`

Set the binding protocol, that is, the default `memcached` protocol support for client connections. Options are `ascii`, `binary` or `auto`. Automatic (`auto`) is the default.

This option was added in `memcached` 1.4.0.

17.2.2.2 `memcached` Deployment

When using `memcached` you can use a number of different potential deployment strategies and topologies. The exact strategy to use depends on your application and environment. When developing a system for deploying `memcached` within your system, keep in mind the following points:

- `memcached` is only a caching mechanism. It shouldn't be used to store information that you cannot otherwise afford to lose and then load from a different location.
- There is no security built into the `memcached` protocol. At a minimum, make sure that the servers running `memcached` are only accessible from inside your network, and that the network ports being used are blocked (using a firewall or similar). If the information on the `memcached` servers that is being stored is any sensitive, then encrypt the information before storing it in `memcached`.
- `memcached` does not provide any sort of failover. Because there is no communication between different `memcached` instances. If an instance fails, your application must be capable of removing it from the list, reloading the data and then writing data to another `memcached` instance.
- Latency between the clients and the `memcached` can be a problem if you are using different physical machines for these tasks. If you find that the latency is a problem, move the `memcached` instances to be on the clients.
- Key length is determined by the `memcached` server. The default maximum key size is 250 bytes.
- Try to use at least two `memcached` instances, especially for multiple clients, to avoid having a single point of failure. Ideally, create as many `memcached` nodes as possible. When adding and removing `memcached` instances from a pool, the hashing and distribution of key/value pairs may be affected. For information on how to avoid problems, see [Section 17.2.2.5, “`memcached` Hashing/Distribution Types”](#).

17.2.2.3 Using Namespaces

The `memcached` cache is a very simple massive key/value storage system, and as such there is no way of compartmentalizing data automatically into different sections. For example, if you are storing information by the unique ID returned from a MySQL database, then storing the data from two different tables could run into issues because the same ID might be valid in both tables.

Some interfaces provide an automated mechanism for creating *namespaces* when storing information into the cache. In practice, these namespaces are merely a prefix before a given ID that is applied every time a value is stored or retrieve from the cache.

You can implement the same basic principle by using keys that describe the object and the unique identifier within the key that you supply when the object is stored. For example, when storing user data, prefix the ID of the user with `user:` or `user-`.

**Note**

Using namespaces or prefixes only controls the keys stored/retrieved. There is no security within `memcached`, and therefore no way to enforce that a particular client only accesses keys with a particular namespace. Namespaces are only useful as a method of identifying data and preventing corruption of key/value pairs.

17.2.2.4 Data Expiry

There are two types of data expiry within a `memcached` instance. The first type is applied at the point when you store a new key/value pair into the `memcached` instance. If there is not enough space within a suitable slab to store the value, then an existing least recently used (LRU) object is removed (evicted) from the cache to make room for the new item.

The LRU algorithm ensures that the object that is removed is one that is either no longer in active use or that was used so long ago that its data is potentially out of date or of little value. However, in a system where the memory allocated to `memcached` is smaller than the number of regularly used objects required in the cache, a lot of expired items could be removed from the cache even though they are in active use. You use the statistics mechanism to get a better idea of the level of evictions (expired objects). For more information, see [Section 17.2.4, “Getting `memcached` Statistics”](#).

You can change this eviction behavior by setting the `-M` command-line option when starting `memcached`. This option forces an error to be returned when the memory has been exhausted, instead of automatically evicting older data.

The second type of expiry system is an explicit mechanism that you can set when a key/value pair is inserted into the cache, or when deleting an item from the cache. Using an expiration time can be a useful way of ensuring that the data in the cache is up to date and in line with your application needs and requirements.

A typical scenario for explicitly setting the expiry time might include caching session data for a user when accessing a Web site. `memcached` uses a lazy expiry mechanism where the explicit expiry time that has been set is compared with the current time when the object is requested. Only objects that have not expired are returned.

You can also set the expiry time when explicitly deleting an object from the cache. In this case, the expiry time is really a timeout and indicates the period when any attempts to set the value for a given key are rejected.

17.2.2.5 `memcached` Hashing/Distribution Types

The `memcached` client interface supports a number of different distribution algorithms that are used in multi-server configurations to determine which host should be used when setting or getting data from a given `memcached` instance. When you get or set a value, a hash is constructed from the supplied key and then used to select a host from the list of configured servers. Because the hashing mechanism uses the supplied key as the basis for the hash, the same server is selected during both set and get operations.

You can think of this process as follows. Given an array of servers (a, b, and c), the client uses a hashing algorithm that returns an integer based on the key being stored or retrieved. The resulting value is then used to select a server from the list of servers configured in the client. Most standard

client hashing within `memcache` clients uses a simple modulus calculation on the value against the number of configured `memcached` servers. You can summarize the process in pseudocode as:

```
@memcservers = ['a.memc', 'b.memc', 'c.memc'];
$value = hash($key);
$chosen = $value % length(@memcservers);
```

Replacing the above with values:

```
@memcservers = ['a.memc', 'b.memc', 'c.memc'];
$value = hash('myid');
$chosen = 7009 % 3;
```

In the above example, the client hashing algorithm chooses the server at index 1 ($7009 \% 3 = 1$), and store or retrieve the key and value with that server.

Note

This selection and hashing process is handled automatically by the `memcached` client you are using; you need only provide the list of `memcached` servers to use.

You can see a graphical representation of this below in [Figure 17.3, “memcached Hash Selection”](#).

Figure 17.3 `memcached` Hash Selection

The same hashing and selection process takes place during any operation on the specified key within the `memcached` client.

Using this method provides a number of advantages:

- The hashing and selection of the server to contact is handled entirely within the client. This eliminates the need to perform network communication to determine the right machine to contact.
- Because the determination of the `memcached` server occurs entirely within the client, the server can be selected automatically regardless of the operation being executed (set, get, increment, etc.).
- Because the determination is handled within the client, the hashing algorithm returns the same value for a given key; values are not affected or reset by differences in the server environment.
- Selection is very fast. The hashing algorithm on the key value is quick and the resulting selection of the server is from a simple array of available machines.
- Using client-side hashing simplifies the distribution of data over each `memcached` server. Natural distribution of the values returned by the hashing algorithm means that keys are automatically spread over the available servers.

Providing that the list of servers configured within the client remains the same, the same stored key returns the same value, and therefore selects the same server.

However, if you do not use the same hashing mechanism then the same data may be recorded on different servers by different interfaces, both wasting space on your `memcached` and leading to potential differences in the information.

Note

One way to use a multi-interface compatible hashing mechanism is to use the `libmemcached` library and the associated interfaces. Because the interfaces for the different languages (including C, Ruby, Perl and Python) use the same client library interface, they always generate the same hash code from the ID.

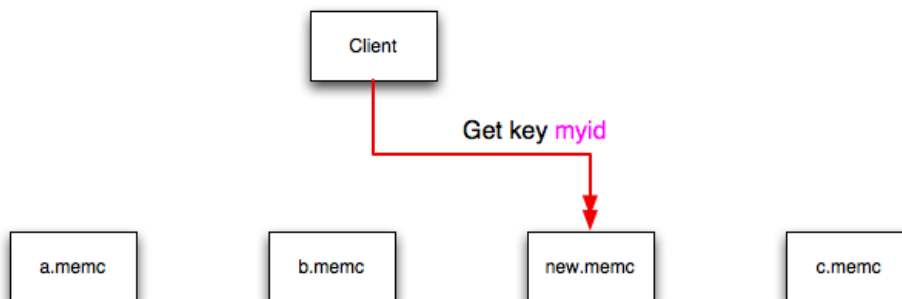

The problem with client-side selection of the server is that the list of the servers (including their sequential order) *must* remain consistent on each client using the `memcached` servers, and the servers must be available. If you try to perform an operation on a key when:

- A new `memcached` instance has been added to the list of available instances
- A `memcached` instance has been removed from the list of available instances
- The order of the `memcached` instances has changed

When the hashing algorithm is used on the given key, but with a different list of servers, the hash calculation may choose a different server from the list.

If a new `memcached` instance is added into the list of servers, as `new.memc` is in the example below, then a GET operation using the same key, `myid`, can result in a cache-miss. This is because the same value is computed from the key, which selects the same index from the array of servers, but index 2 now points to the new server, not the server `c.memc` where the data was originally stored. This would result in a cache miss, even though the key exists within the cache on another `memcached` instance.

Figure 17.4 `memcached` Hash Selection with New `memcached` instance

This means that servers `c.memc` and `new.memc` both contain the information for key `myid`, but the information stored against the key in each server may be different in each instance. A more significant problem is a much higher number of cache-misses when retrieving data, as the addition of a new server changes the distribution of keys, and this in turn requires rebuilding the cached data on the `memcached` instances, causing an increase in database reads.

The same effect can occur if you actively manage the list of servers configured in your clients, adding and removing the configured `memcached` instances as each instance is identified as being available. For example, removing a `memcached` instance when the client notices that the instance can no longer be contacted can cause the server selection to fail as described here.

To prevent this causing significant problems and invalidating your cache, you can select the hashing algorithm used to select the server. There are two common types of hashing algorithm, *consistent* and *modula*.

With *consistent* hashing algorithms, the same key when applied to a list of servers always uses the same server to store or retrieve the keys, even if the list of configured servers changes. This means

that you can add and remove servers from the configure list and always use the same server for a given key. There are two types of consistent hashing algorithms available, Ketama and Wheel. Both types are supported by `libmemcached`, and implementations are available for PHP and Java.

Any consistent hashing algorithm has some limitations. When you add servers to an existing list of configured servers, keys are distributed to the new servers as part of the normal distribution. When you remove servers from the list, the keys are re-allocated to another server within the list, meaning that the cache needs to be re-populated with the information. Also, a consistent hashing algorithm does not resolve the issue where you want consistent selection of a server across multiple clients, but where each client contains a different list of servers. The consistency is enforced only within a single client.

With a *modula* hashing algorithm, the client selects a server by first computing the hash and then choosing a server from the list of configured servers. As the list of servers changes, so the server selected when using a modula hashing algorithm also changes. The result is the behavior described above; changes to the list of servers mean that different servers are selected when retrieving data, leading to cache misses and increase in database load as the cache is re-seeded with information.

If you use only a single `memcached` instance for each client, or your list of `memcached` servers configured for a client never changes, then the selection of a hashing algorithm is irrelevant, as it has no noticeable effect.

If you change your servers regularly, or you use a common set of servers that are shared among a large number of clients, then using a consistent hashing algorithm should help to ensure that your cache data is not duplicated and the data is evenly distributed.

17.2.2.6 Using `memcached` and DTrace

`memcached` includes a number of different DTrace probes that can be used to monitor the operation of the server. The probes included can monitor individual connections, slab allocations, and modifications to the hash table when a key/value pair is added, updated, or removed.

For more information on DTrace and writing DTrace scripts, read the [DTrace User Guide](#).

Support for DTrace probes was added to `memcached` 1.2.6 includes a number of DTrace probes that can be used to help monitor your application. DTrace is supported on Solaris 10, OpenSolaris, OS X 10.5 and FreeBSD. To enable the DTrace probes in `memcached`, build from source and use the `--enable-dtrace` option. For more information, see [Section 17.2.1, "Installing `memcached`"](#).

The probes supported by `memcached` are:

- `conn-allocate(connid)`

Fired when a connection object is allocated from the connection pool.

- `connid`: The connection ID.

- `conn-release(connid)`

Fired when a connection object is released back to the connection pool.

Arguments:

- `connid`: The connection ID.

- `conn-create(ptr)`

Fired when a new connection object is being created (that is, there are no free connection objects in the connection pool).

Arguments:

- `ptr`: A pointer to the connection. object

- `conn-destroy(ptr)`

Fired when a connection object is being destroyed.

Arguments:

- `ptr`: A pointer to the connection object.

- `conn-dispatch(connid, threadid)`

Fired when a connection is dispatched from the main or connection-management thread to a worker thread.

Arguments:

- `connid`: The connection ID.
- `threadid`: The thread ID.

- `slabs-allocate(size, slabclass, slabsize, ptr)`

Allocate memory from the slab allocator.

Arguments:

- `size`: The requested size.
- `slabclass`: The allocation is fulfilled in this class.
- `slabsize`: The size of each item in this class.
- `ptr`: A pointer to allocated memory.

- `slabs-allocate-failed(size, slabclass)`

Failed to allocate memory (out of memory).

Arguments:

- `size`: The requested size.
- `slabclass`: The class that failed to fulfill the request.

- `slabs-slabclass-allocate(slabclass)`

Fired when a slab class needs more space.

Arguments:

- `slabclass`: The class that needs more memory.

- `slabs-slabclass-allocate-failed(slabclass)`

Failed to allocate memory (out of memory).

Arguments:

- `slabclass`: The class that failed to grab more memory.

- `slabs-free(size, slabclass, ptr)`

Release memory.

Arguments:

- `size`: The amount of memory to release, in bytes.
- `slabclass`: The class the memory belongs to.
- `ptr`: A pointer to the memory to release.
- `assoc-find(key, depth)`

Fired when we have searched the hash table for a named key. These two elements provide an insight into how well the hash function operates. Traversals are a sign of a less optimal function, wasting CPU capacity.

Arguments:

- `key`: The key searched for.
- `depth`: The depth in the list of hash table.
- `assoc-insert(key, nokeys)`

Fired when a new item has been inserted.

Arguments:

- `key`: The key just inserted.
- `nokeys`: The total number of keys currently being stored, including the key for which insert was called.
- `assoc-delete(key, nokeys)`

Fired when a new item has been removed.

Arguments:

- `key`: The key just deleted.
- `nokeys`: The total number of keys currently being stored, excluding the key for which delete was called.
- `item-link(key, size)`

Fired when an item is being linked in the cache.

Arguments:

- `key`: The items key.
- `size`: The size of the data.
- `item-unlink(key, size)`

Fired when an item is being deleted.

Arguments:

- `key`: The items key.
- `size`: The size of the data.
- `item-remove(key, size)`

Fired when the refcount for an item is reduced.

Arguments:

- `key`: The item's key.
- `size`: The size of the data.
- `item-update(key, size)`

Fired when the "last referenced" time is updated.

Arguments:

- `key`: The item's key.
- `size`: The size of the data.
- `item-replace(oldkey, oldsize, newkey, newsize)`

Fired when an item is being replaced with another item.

Arguments:

- `oldkey`: The key of the item to replace.
- `oldsize`: The size of the old item.
- `newkey`: The key of the new item.
- `newsize`: The size of the new item.
- `process-command-start(connid, request, size)`

Fired when the processing of a command starts.

Arguments:

- `connid`: The connection ID.
- `request`: The incoming request.
- `size`: The size of the request.
- `process-command-end(connid, response, size)`

Fired when the processing of a command is done.

Arguments:

- `connid`: The connection ID.
- `response`: The response to send back to the client.
- `size`: The size of the response.
- `command-get(connid, key, size)`

Fired for a `get` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.

- `size`: The size of the key's data (or -1 if not found).

- `command-gets(connid, key, size, casid)`

Fired for a `gets` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The size of the key's data (or -1 if not found).
- `casid`: The casid for the item.

- `command-add(connid, key, size)`

Fired for a `add` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The new size of the key's data (or -1 if not found).

- `command-set(connid, key, size)`

Fired for a `set` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The new size of the key's data (or -1 if not found).

- `command-replace(connid, key, size)`

Fired for a `replace` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The new size of the key's data (or -1 if not found).

- `command-prepend(connid, key, size)`

Fired for a `prepend` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `size`: The new size of the key's data (or -1 if not found).

- `command-append(connid, key, size)`

Fired for a `append` command.

Arguments:

- `connid`: The connection ID.
 - `key`: The requested key.
 - `size`: The new size of the key's data (or -1 if not found).
- `command-cas(connid, key, size, casid)`

Fired for a `cas` command.

Arguments:

- `connid`: The connection ID.
 - `key`: The requested key.
 - `size`: The size of the key's data (or -1 if not found).
 - `casid`: The cas ID requested.
- `command-incr(connid, key, val)`

Fired for `incr` command.

Arguments:

- `connid`: The connection ID.
 - `key`: The requested key.
 - `val`: The new value.
- `command-decr(connid, key, val)`

Fired for `decr` command.

Arguments:

- `connid`: The connection ID.
 - `key`: The requested key.
 - `val`: The new value.
- `command-delete(connid, key, exptime)`

Fired for a `delete` command.

Arguments:

- `connid`: The connection ID.
- `key`: The requested key.
- `exptime`: The expiry time.

17.2.2.7 Memory Allocation within memcached

When you first start `memcached`, the memory that you have configured is not automatically allocated. Instead, `memcached` only starts allocating and reserving physical memory once you start saving information into the cache.

When you start to store data into the cache, `memcached` does not allocate the memory for the data on an item by item basis. Instead, a slab allocation is used to optimize memory usage and prevent memory fragmentation when information expires from the cache.

With slab allocation, memory is reserved in blocks of 1MB. The slab is divided up into a number of blocks of equal size. When you try to store a value into the cache, `memcached` checks the size of the value that you are adding to the cache and determines which slab contains the right size allocation for the item. If a slab with the item size already exists, the item is written to the block within the slab.

If the new item is bigger than the size of any existing blocks, then a new slab is created, divided up into blocks of a suitable size. If an existing slab with the right block size already exists, but there are no free blocks, a new slab is created. If you update an existing item with data that is larger than the existing block allocation for that key, then the key is re-allocated into a suitable slab.

For example, the default size for the smallest block is 88 bytes (40 bytes of value, and the default 48 bytes for the key and flag data). If the size of the first item you store into the cache is less than 40 bytes, then a slab with a block size of 88 bytes is created and the value stored.

If the size of the data that you intend to store is larger than this value, then the block size is increased by the chunk size factor until a block size large enough to hold the value is determined. The block size is always a function of the scale factor, rounded up to a block size which is exactly divisible into the chunk size.

For a sample of the structure, see [Figure 17.5, “Memory Allocation in memcached”](#).

Figure 17.5 Memory Allocation in memcached

The result is that you have multiple pages allocated within the range of memory allocated to `memcached`. Each page is 1MB in size (by default), and is split into a different number of chunks, according to the chunk size required to store the key/value pairs. Each instance has multiple pages allocated, and a page is always created when a new item needs to be created requiring a chunk of a particular size. A slab may consist of multiple pages, and each page within a slab contains an equal number of chunks.

The chunk size of a new slab is determined by the base chunk size combined with the chunk size growth factor. For example, if the initial chunks are 104 bytes in size, and the default chunk size growth factor is used (1.25), then the next chunk size allocated would be the best power of 2 fit for 104×1.25 , or 136 bytes.

Allocating the pages in this way ensures that memory does not get fragmented. However, depending on the distribution of the objects that you store, it may lead to an inefficient distribution of the slabs and chunks if you have significantly different sized items. For example, having a relatively small number of items within each chunk size may waste a lot of memory with just few chunks in each allocated page.

You can tune the growth factor to reduce this effect by using the `-f` command line option, which adapts the growth factor applied to make more effective use of the chunks and slabs allocated. For information on how to determine the current slab allocation statistics, see [Section 17.2.4.2, “memcached Slabs Statistics”](#).

If your operating system supports it, you can also start `memcached` with the `-L` command line option. This option preallocates all the memory during startup using large memory pages. This can improve performance by reducing the number of misses in the CPU memory cache.

17.2.2.8 `memcached` Thread Support

If you enable the thread implementation within when building `memcached` from source, then `memcached` uses multiple threads in addition to the `libevent` system to handle requests.

When enabled, the threading implementation operates as follows:

- Threading is handled by wrapping functions within the code to provide basic protection from updating the same global structures at the same time.
- Each thread uses its own instance of the `libevent` to help improve performance.
- TCP/IP connections are handled with a single thread listening on the TCP/IP socket. Each connection is then distributed to one of the active threads on a simple round-robin basis. Each connection then operates solely within this thread while the connection remains open.
- For UDP connections, all the threads listen to a single UDP socket for incoming requests. Threads that are not currently dealing with another request ignore the incoming packet. One of the remaining, nonbusy, threads reads the request and sends the response. This implementation can lead to increased CPU load as threads wake from sleep to potentially process the request.

Using threads can increase the performance on servers that have multiple CPU cores available, as the requests to update the hash table can be spread between the individual threads. To minimize overhead from the locking mechanism employed, experiment with different thread values to achieve the best performance based on the number and type of requests within your given workload.

17.2.2.9 `memcached` Logs

If you enable verbose mode, using the `-v`, `-vv`, or `-vvv` options, then the information output by `memcached` includes details of the operations being performed.

Without the verbose options, `memcached` normally produces no output during normal operating.

- **Output when using `-v`**

The lowest verbosity level shows you:

- Errors and warnings
- Transient errors
- Protocol and socket errors, including exhausting available connections
- Each registered client connection, including the socket descriptor number and the protocol used.

For example:

```
32: Client using the ascii protocol
33: Client using the ascii protocol
```

The socket descriptor is only valid while the client remains connected. Non-persistent connections may not be effectively represented.

Examples of the error messages output at this level include:

```

<%d send buffer was %d, now %d
Can't listen for events on fd %d
Can't read from libevent pipe
Catastrophic: event fd doesn't match conn fd!
Couldn't build response
Couldn't realloc input buffer
Couldn't update event
Failed to build UDP headers
Failed to read, and not due to blocking
Too many open connections
Unexpected state %d

```

- **Output when using `-vv`**

When using the second level of verbosity, you get more detailed information about protocol operations, keys updated, chunk and network operations and details.

During the initial start-up of `memcached` with this level of verbosity, you are shown the sizes of the individual slab classes, the chunk sizes, and the number of entries per slab. These do not show the allocation of the slabs, just the slabs that would be created when data is added. You are also given information about the listen queues and buffers used to send information. A sample of the output generated for a TCP/IP based system with the default memory and growth factors is given below:

```

shell> memcached -vv
slab class 1: chunk size      80 perslab 13107
slab class 2: chunk size     104 perslab 10082
slab class 3: chunk size     136 perslab  7710
slab class 4: chunk size     176 perslab  5957
slab class 5: chunk size     224 perslab  4681
slab class 6: chunk size     280 perslab  3744
slab class 7: chunk size     352 perslab  2978
slab class 8: chunk size     440 perslab  2383
slab class 9: chunk size     552 perslab  1899
slab class 10: chunk size    696 perslab  1506
slab class 11: chunk size    872 perslab  1202
slab class 12: chunk size   1096 perslab   956
slab class 13: chunk size   1376 perslab   762
slab class 14: chunk size   1720 perslab   609
slab class 15: chunk size   2152 perslab   487
slab class 16: chunk size   2696 perslab   388
slab class 17: chunk size   3376 perslab   310
slab class 18: chunk size   4224 perslab   248
slab class 19: chunk size   5280 perslab   198
slab class 20: chunk size   6600 perslab   158
slab class 21: chunk size   8256 perslab   127
slab class 22: chunk size  10320 perslab   101
slab class 23: chunk size  12904 perslab    81
slab class 24: chunk size  16136 perslab    64
slab class 25: chunk size  20176 perslab    51
slab class 26: chunk size  25224 perslab    41
slab class 27: chunk size  31536 perslab    33
slab class 28: chunk size  39424 perslab    26
slab class 29: chunk size  49280 perslab    21
slab class 30: chunk size  61600 perslab    17
slab class 31: chunk size  77000 perslab    13
slab class 32: chunk size  96256 perslab    10
slab class 33: chunk size 120320 perslab    8
slab class 34: chunk size 150400 perslab    6
slab class 35: chunk size 188000 perslab    5
slab class 36: chunk size 235000 perslab    4
slab class 37: chunk size 293752 perslab    3
slab class 38: chunk size 367192 perslab    2
slab class 39: chunk size 458992 perslab    2
<26 server listening (auto-negotiate)
<29 server listening (auto-negotiate)
<30 send buffer was 57344, now 2097152
<31 send buffer was 57344, now 2097152

```

```
<30 server listening (udp)
<30 server listening (udp)
<31 server listening (udp)
<30 server listening (udp)
<30 server listening (udp)
<31 server listening (udp)
<31 server listening (udp)
<31 server listening (udp)
```

Using this verbosity level can be a useful way to check the effects of the growth factor used on slabs with different memory allocations, which in turn can be used to better tune the growth factor to suit the data you are storing in the cache. For example, if you set the growth factor to 4 (quadrupling the size of each slab):

```
shell> memcached -f 4 -m 1g -vv
slab class 1: chunk size 80 perslab 13107
slab class 2: chunk size 320 perslab 3276
slab class 3: chunk size 1280 perslab 819
slab class 4: chunk size 5120 perslab 204
slab class 5: chunk size 20480 perslab 51
slab class 6: chunk size 81920 perslab 12
slab class 7: chunk size 327680 perslab 3
...
```

During use of the cache, this verbosity level also prints out detailed information on the storage and recovery of keys and other information. An example of the output during a typical set/get and increment/decrement operation is shown below.

```
32: Client using the ascii protocol
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key
>32 sending key my_key
>32 END
<32 get object_key
>32 sending key object_key
>32 END
<32 set key 0 0 6
>32 STORED
<32 incr key 1
>32 789544
<32 decr key 1
>32 789543
<32 incr key 2
>32 789545
<32 set my_key 0 0 10
>32 STORED
<32 set object_key 1 0 36
>32 STORED
<32 get my_key

>32 789543
<32 incr key 2
>32 789545
```

During client communication, for each line, the initial character shows the direction of flow of the information. The `<` for communication from the client to the `memcached` server and `>` for communication back to the client. The number is the numeric socket descriptor for the connection.

- **Output when using `-vvv`**

This level of verbosity includes the transitions of connections between different states in the event library while reading and writing content to/from the clients. It should be used to diagnose and identify issues in client communication. For example, you can use this information to determine if `memcached` is taking a long time to return information to the client, during the read of the client operation or before returning and completing the operation. An example of the typical sequence for a set operation is provided below:

```
<32 new auto-negotiating client connection
32: going from conn_new_cmd to conn_waiting
32: going from conn_waiting to conn_read
32: going from conn_read to conn_parse_cmd
32: Client using the ascii protocol
<32 set my_key 0 0 10
32: going from conn_parse_cmd to conn_nread
> NOT FOUND my_key
>32 STORED
32: going from conn_nread to conn_write
32: going from conn_write to conn_new_cmd
32: going from conn_new_cmd to conn_waiting
32: going from conn_waiting to conn_read
32: going from conn_read to conn_closing
<32 connection closed.
```

All of the verbosity levels in `memcached` are designed to be used during debugging or examination of issues. The quantity of information generated, particularly when using `-vvv`, is significant, particularly on a busy server. Also be aware that writing the error information out, especially to disk, may negate some of the performance gains you achieve by using `memcached`. Therefore, use in production or deployment environments is not recommended.

17.2.3 Developing a `memcached` Application

A number of language interfaces let applications store and retrieve information with `memcached` servers. You can write `memcached` applications in popular languages such as Perl, PHP, Python, Ruby, C, and Java.

Data stored into a `memcached` server is referred to by a single string (the key), with storage into the cache and retrieval from the cache using the key as the reference. The cache therefore operates like a large associative array or hash table. It is not possible to structure or otherwise organize the information stored in the cache. To emulate database notions such as multiple tables or composite key values, you must encode the extra information into the strings used as keys. For example, to store or look up the address corresponding to a specific latitude and longitude, you might turn those two numeric values into a single comma-separated string to use as a key.

17.2.3.1 Basic `memcached` Operations

The interface to `memcached` supports the following methods for storing and retrieving information in the cache, and these are consistent across all the different APIs, although the language specific mechanics might be different:

- `get(key)`: Retrieves information from the cache. Returns the value associated with the key if the specified key exists. Returns `NULL`, `nil`, `undefined`, or the closest equivalent in the corresponding language, if the specified key does not exist.
- `set(key, value [, expiry])`: Sets the item associated with a key in the cache to the specified value. This either updates an existing item if the key already exists, or adds a new key/value pair if

the key doesn't exist. If the expiry time is specified, then the item expires (and is deleted) when the expiry time is reached. The time is specified in seconds, and is taken as a relative time if the value is less than 30 days ($30 \times 24 \times 60 \times 60$), or an absolute time (epoch) if larger than this value.

- `add(key, value [, expiry])`: Adds the key and associated value to the cache, if the specified key does not already exist.
- `replace(key, value [, expiry])`: Replaces the item associated with the specified `key`, only if the key already exists. The new value is given by the `value` parameter.
- `delete(key [, time])`: Deletes the `key` and its associated item from the cache. If you supply a `time`, then adding another item with the specified `key` is blocked for the specified period.
- `incr(key , value)`: Increments the item associated with the `key` by the specified `value`.
- `decr(key , value)`: Decrements the item associated with the `key` by the specified `value`.
- `flush_all`: Invalidates (or expires) all the current items in the cache. Technically they still exist (they are not deleted), but they are silently destroyed the next time you try to access them.

In all implementations, most or all of these functions are duplicated through the corresponding native language interface.

When practical, use `memcached` to store full items, rather than caching a single column value from the database. For example, when displaying a record about an object (invoice, user history, or blog post), load all the data for the associated entry from the database, and compile it into the internal structure that would normally be required by the application. Save the complete object in the cache.

Complex data structures cannot be stored directly. Most interfaces serialize the data for you, that is, put it in a textual form that can reconstruct the original pointers and nesting. Perl uses `Storable`, PHP uses `serialize`, Python uses `cPickle` (or `Pickle`) and Java uses the `Serializable` interface. In most cases, the serialization interface used is customizable. To share data stored in `memcached` instances between different language interfaces, consider using a common serialization solution such as JSON (Javascript Object Notation).

17.2.3.2 Using `memcached` as a MySQL Caching Layer

When using `memcached` to cache MySQL data, your application must retrieve data from the database and load the appropriate key-value pairs into the cache. Then, subsequent lookups can be done directly from the cache.

Because MySQL has its own in-memory caching mechanisms for queried data, such as the `InnoDB buffer pool` and the MySQL query cache, look for opportunities beyond loading individual column values or rows into the cache. Prefer to cache composite values, such as those retrieved from multiple tables through a join query, or result sets assembled from multiple rows.

Caution

Limit the information in the cache to non-sensitive data, because there is no security required to access or update the information within a `memcached` instance. Anybody with access to the machine has the ability to read, view and potentially update the information. To keep the data secure, encrypt the information before caching it. To restrict the users capable of connecting to the server, either disable network access, or use `IPTables` or similar techniques to restrict access to the `memcached` ports to a select set of hosts.

You can introduce `memcached` to an existing application, even if caching was not part of the original design. In many languages and environments the changes to the application will be just a few lines, first to attempt to read from the cache when loading data, fall back to the old method if the information is not cached, and to update the cache with information once the data has been read.

The general sequence for using `memcached` in any language as a caching solution for MySQL is as follows:

1. Request the item from the cache.
2. If the item exists, use the item data.
3. If the item does not exist, load the data from MySQL, and store the value into the cache. This means the value is available to the next client that requests it from the cache.

For a flow diagram of this sequence, see [Figure 17.6, “Typical `memcached` Application Flowchart”](#).

Figure 17.6 Typical `memcached` Application Flowchart

Adapting Database Best Practices to `memcached` Applications

The most direct way to cache MySQL data is to use a 2-column table, where the first column is a [primary key](#). Because of the uniqueness requirements for `memcached` keys, make sure your database schema makes appropriate use of primary keys and [unique constraints](#).

If you combine multiple column values into a single `memcached` item value, choose data types to make it easy to parse the value back into its components, for example by using a separator character between numeric values.

The queries that map most easily to `memcached` lookups are those with a single [WHERE](#) clause, using an `=` or `IN` operator. For complicated [WHERE](#) clauses, or those using operators such as `<`, `>`, [BETWEEN](#), or [LIKE](#), `memcached` does not provide a simple or efficient way to scan through or filter the keys or associated values, so typically you perform those operations as SQL queries on the underlying database.

17.2.3.3 Using `libmemcached` with C and C++

The `libmemcached` library provides both C and C++ interfaces to `memcached` and is also the basis for a number of different additional API implementations, including Perl, Python and Ruby. Understanding the core `libmemcached` functions can help when using these other interfaces.

The C library is the most comprehensive interface library for `memcached` and provides functions and operational systems not always exposed in interfaces not based on the `libmemcached` library.

The different functions can be divided up according to their basic operation. In addition to functions that interface to the core API, a number of utility functions provide extended functionality, such as appending and prepending data.

To build and install `libmemcached`, download the `libmemcached` package, run `configure`, and then build and install:

```
shell> tar xjf libmemcached-0.21.tar.gz
shell> cd libmemcached-0.21
shell> ./configure
shell> make
shell> make install
```

On many Linux operating systems, you can install the corresponding `libmemcached` package through the usual `yum`, `apt-get`, or similar commands.

To build an application that uses the library, first set the list of servers. Either directly manipulate the servers configured within the main `memcached_st` structure, or separately populate a list of servers, and then add this list to the `memcached_st` structure. The latter method is used in the following example. Once the server list has been set, you can call the functions to store or retrieve data. A simple application for setting a preset value to `localhost` is provided here:

```
#include <stdio.h>
#include <string.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
{
    memcached_server_st *servers = NULL;
    memcached_st *memc;
    memcached_return rc;
    char *key= "keystring";
    char *value= "keyvalue";

    memcached_server_st *memcached_servers_parse (char *server_strings);
    memc= memcached_create(NULL);

    servers= memcached_server_list_append(servers, "localhost", 11211, &rc);
    rc= memcached_server_push(memc, servers);

    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr, "Added server successfully\n");
    else
        fprintf(stderr, "Couldn't add server: %s\n", memcached_strerror(memc, rc));

    rc= memcached_set(memc, key, strlen(key), value, strlen(value), (time_t)0, (uint32_t)0);

    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr, "Key stored successfully\n");
    else
        fprintf(stderr, "Couldn't store key: %s\n", memcached_strerror(memc, rc));

    return 0;
}
```

To test the success of an operation, use the return value, or populated result code, for a given function. The value is always set to `MEMCACHED_SUCCESS` if the operation succeeded. In the event of a failure, use the `memcached_strerror()` function to translate the result code into a printable string.

To build the application, specify the `memcached` library:

```
shell> gcc -o memc_basic memc_basic.c -lmemcached
```

Running the above sample application, after starting a `memcached` server, should return a success message:

```
shell> memc_basic
Added server successfully
Key stored successfully
```

libmemcached Base Functions

The base `libmemcached` functions let you create, destroy and clone the main `memcached_st` structure that is used to interface with the `memcached` servers. The main functions are defined below:

```
memcached_st *memcached_create (memcached_st *ptr);
```

Creates a new `memcached_st` structure for use with the other `libmemcached` API functions. You can supply an existing, static, `memcached_st` structure, or `NULL` to have a new structured allocated. Returns a pointer to the created structure, or `NULL` on failure.

```
void memcached_free (memcached_st *ptr);
```

Frees the structure and memory allocated to a previously created `memcached_st` structure.

```
memcached_st *memcached_clone(memcached_st *clone, memcached_st *source);
```

Clones an existing `memcached` structure from the specified `source`, copying the defaults and list of servers defined in the structure.

libmemcached Server Functions

The `libmemcached` API uses a list of servers, stored within the `memcached_server_st` structure, to act as the list of servers used by the rest of the functions. To use `memcached`, you first create the server list, and then apply the list of servers to a valid `libmemcached` object.

Because the list of servers, and the list of servers within an active `libmemcached` object can be manipulated separately, you can update and manage server lists while an active `libmemcached` interface is running.

The functions for manipulating the list of servers within a `memcached_st` structure are:

```
memcached_return
memcached_server_add (memcached_st *ptr,
                    char *hostname,
                    unsigned int port);
```

Adds a server, using the given `hostname` and `port` into the `memcached_st` structure given in `ptr`.

```
memcached_return
memcached_server_add_unix_socket (memcached_st *ptr,
                                char *socket);
```

Adds a Unix socket to the list of servers configured in the `memcached_st` structure.

```
unsigned int memcached_server_count (memcached_st *ptr);
```

Returns a count of the number of configured servers within the `memcached_st` structure.

```
memcached_server_st *
memcached_server_list (memcached_st *ptr);
```

Returns an array of all the defined hosts within a `memcached_st` structure.

```
memcached_return
memcached_server_push (memcached_st *ptr,
                      memcached_server_st *list);
```

Pushes an existing list of servers onto list of servers configured for a current `memcached_st` structure. This adds servers to the end of the existing list, and duplicates are not checked.

The `memcached_server_st` structure can be used to create a list of `memcached` servers which can then be applied individually to `memcached_st` structures.

```
memcached_server_st *
memcached_server_list_append (memcached_server_st *ptr,
                             char *hostname,
                             unsigned int port,
                             memcached_return *error);
```

Adds a server, with `hostname` and `port`, to the server list in `ptr`. The result code is handled by the `error` argument, which should point to an existing `memcached_return` variable. The function returns a pointer to the returned list.

```
unsigned int memcached_server_list_count (memcached_server_st *ptr);
```

Returns the number of the servers in the server list.

```
void memcached_server_list_free (memcached_server_st *ptr);
```

Frees the memory associated with a server list.

```
memcached_server_st *memcached_servers_parse (char *server_strings);
```

Parses a string containing a list of servers, where individual servers are separated by a comma, space, or both, and where individual servers are of the form `server[:port]`. The return value is a server list structure.

`libmemcached` Set Functions

The set-related functions within `libmemcached` provide the same functionality as the core functions supported by the `memcached` protocol. The full definition for the different functions is the same for all the base functions (`add`, `replace`, `prepend`, `append`). For example, the function definition for `memcached_set()` is:

```
memcached_return
memcached_set (memcached_st *ptr,
              const char *key,
              size_t key_length,
              const char *value,
              size_t value_length,
              time_t expiration,
              uint32_t flags);
```

The `ptr` is the `memcached_st` structure. The `key` and `key_length` define the key name and length, and `value` and `value_length` the corresponding value and length. You can also set the expiration and optional flags. For more information, see [Controlling `libmemcached` Behaviors](#).

This table outlines the remainder of the set-related `libmemcached` functions and the equivalent core functions supported by the `memcached` protocol.

libmemcached Function	Equivalent Core Function
<code>memcached_set(memc, key, key_length, value, value_length, expiration, flags)</code>	Generic <code>set()</code> operation.
<code>memcached_add(memc, key, key_length, value, value_length, expiration, flags)</code>	Generic <code>add()</code> function.
<code>memcached_replace(memc, key, key_length, value, value_length, expiration, flags)</code>	Generic <code>replace()</code> .
<code>memcached_prepend(memc, key, key_length, value, value_length, expiration, flags)</code>	Prepends the specified <code>value</code> before the current value of the specified <code>key</code> .
<code>memcached_append(memc, key, key_length, value, value_length, expiration, flags)</code>	Appends the specified <code>value</code> after the current value of the specified <code>key</code> .
<code>memcached_cas(memc, key, key_length, value, value_length, expiration, flags, cas)</code>	Overwrites the data for a given key as long as the corresponding <code>cas</code> value is still the same within the server.
<code>memcached_set_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the generic <code>set()</code> , but has the option of an additional master key that can be used to identify an individual server.
<code>memcached_add_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the generic <code>add()</code> , but has the option of an additional master key that can be used to identify an individual server.
<code>memcached_replace_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the generic <code>replace()</code> , but has the option of an additional master key that can be used to identify an individual server.
<code>memcached_prepend_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the <code>memcached_prepend()</code> , but has the option of an additional master key that can be used to identify an individual server.
<code>memcached_append_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the <code>memcached_append()</code> , but has the option of an additional master key that can be used to identify an individual server.
<code>memcached_cas_by_key(memc, master_key, master_key_length, key, key_length, value, value_length, expiration, flags)</code>	Similar to the <code>memcached_cas()</code> , but has the option of an additional master key that can be used to identify an individual server.

The `by_key` methods add two further arguments that define the master key, to be used and applied during the hashing stage for selecting the servers. You can see this in the following definition:

```
memcached_return
memcached_set_by_key(memcached_st *ptr,
                    const char *master_key,
                    size_t master_key_length,
                    const char *key,
                    size_t key_length,
                    const char *value,
```

```
size_t value_length,
time_t expiration,
uint32_t flags);
```

All the functions return a value of type `memcached_return`, which you can compare against the `MEMCACHED_SUCCESS` constant.

libmemcached Get Functions

The `libmemcached` functions provide both direct access to a single item, and a multiple-key request mechanism that provides much faster responses when fetching a large number of keys simultaneously.

The main get-style function, which is equivalent to the generic `get()` is `memcached_get()`. This function returns a string pointer, pointing to the value associated with the specified key.

```
char *memcached_get (memcached_st *ptr,
                    const char *key, size_t key_length,
                    size_t *value_length,
                    uint32_t *flags,
                    memcached_return *error);
```

A multi-key get, `memcached_mget()`, is also available. Using a multiple key get operation is much quicker to do in one block than retrieving the key values with individual calls to `memcached_get()`. To start the multi-key get, call `memcached_mget()`:

```
memcached_return
memcached_mget (memcached_st *ptr,
               char **keys, size_t *key_length,
               unsigned int number_of_keys);
```

The return value is the success of the operation. The `keys` parameter should be an array of strings containing the keys, and `key_length` an array containing the length of each corresponding key. `number_of_keys` is the number of keys supplied in the array.

To fetch the individual values, use `memcached_fetch()` to get each corresponding value.

```
char *memcached_fetch (memcached_st *ptr,
                      const char *key, size_t *key_length,
                      size_t *value_length,
                      uint32_t *flags,
                      memcached_return *error);
```

The function returns the key value, with the `key`, `key_length` and `value_length` parameters being populated with the corresponding key and length information. The function returns `NULL` when there are no more values to be returned. A full example, including the populating of the key data and the return of the information is provided here.

```
#include <stdio.h>
#include <sstring.h>
#include <unistd.h>
#include <libmemcached/memcached.h>

int main(int argc, char *argv[])
{
    memcached_server_st *servers = NULL;
    memcached_st *memc;
    memcached_return rc;
    char *keys[] = {"huey", "dewey", "louie"};
    size_t key_length[3];
    char *values[] = {"red", "blue", "green"};
    size_t value_length[3];
    unsigned int x;
    uint32_t flags;
```

```

char return_key[MEMCACHED_MAX_KEY];
size_t return_key_length;
char *return_value;
size_t return_value_length;

memc= memcached_create(NULL);

servers= memcached_server_list_append(servers, "localhost", 11211, &rc);
rc= memcached_server_push(memc, servers);

if (rc == MEMCACHED_SUCCESS)
    fprintf(stderr,"Added server successfully\n");
else
    fprintf(stderr,"Couldn't add server: %s\n",memcached_strerror(memc, rc));

for(x= 0; x < 3; x++)
    {
    key_length[x] = strlen(keys[x]);
    value_length[x] = strlen(values[x]);

    rc= memcached_set(memc, keys[x], key_length[x], values[x],
                      value_length[x], (time_t)0, (uint32_t)0);
    if (rc == MEMCACHED_SUCCESS)
        fprintf(stderr,"Key %s stored successfully\n",keys[x]);
    else
        fprintf(stderr,"Couldn't store key: %s\n",memcached_strerror(memc, rc));
    }

rc= memcached_mget(memc, keys, key_length, 3);

if (rc == MEMCACHED_SUCCESS)
    {
    while ((return_value= memcached_fetch(memc, return_key, &return_key_length,
                                         &return_value_length, &flags, &rc)) != NULL)
        {
        if (rc == MEMCACHED_SUCCESS)
            {
            fprintf(stderr,"Key %s returned %s\n",return_key, return_value);
            }
        }
    }

return 0;
}

```

Running the above application produces the following output:

```

shell> memc_multi_fetch
Added server successfully
Key huey stored successfully
Key dewey stored successfully
Key louie stored successfully
Key huey returned red
Key dewey returned blue
Key louie returned green

```

Controlling libmemcached Behaviors

The behavior of `libmemcached` can be modified by setting one or more behavior flags. These can either be set globally, or they can be applied during the call to individual functions. Some behaviors also accept an additional setting, such as the hashing mechanism used when selecting servers.

To set global behaviors:

```

memcached_return
    memcached_behavior_set (memcached_st *ptr,
                           memcached_behavior flag,
                           uint64_t data);

```

To get the current behavior setting:

```
uint64_t
memcached_behavior_get (memcached_st *ptr,
                       memcached_behavior flag);
```

The following table describes libmemcached behavior flags.

Behavior	Description
MEMCACHED_BEHAVIOR_NO_BLOCK	Caused libmemcached to use asynchronous I/O.
MEMCACHED_BEHAVIOR_TCP_NODELAY	Turns on no-delay for network sockets.
MEMCACHED_BEHAVIOR_HASH	Without a value, sets the default hashing algorithm for keys to use MD5. Other valid values include MEMCACHED_HASH_DEFAULT, MEMCACHED_HASH_MD5, MEMCACHED_HASH_CRC, MEMCACHED_HASH_FNV1_64, MEMCACHED_HASH_FNV1A_64, MEMCACHED_HASH_FNV1_32, and MEMCACHED_HASH_FNV1A_32.
MEMCACHED_BEHAVIOR_DISTRIBUTION	Changes the method of selecting the server used to store a given value. The default method is MEMCACHED_DISTRIBUTION_MODULA. You can enable consistent hashing by setting MEMCACHED_DISTRIBUTION_CONSISTENT. MEMCACHED_DISTRIBUTION_CONSISTENT is an alias for the value MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA.
MEMCACHED_BEHAVIOR_CACHE_LOOKUPS	Cache the lookups made to the DNS service. This can improve the performance if you are using names instead of IP addresses for individual hosts.
MEMCACHED_BEHAVIOR_SUPPORT_CAS	Support CAS operations. By default, this is disabled because it imposes a performance penalty.
MEMCACHED_BEHAVIOR_KETAMA	Sets the default distribution to MEMCACHED_DISTRIBUTION_CONSISTENT_KETAMA and the hash to MEMCACHED_HASH_MD5.
MEMCACHED_BEHAVIOR_POLL_TIMEOUT	Modify the timeout value used by poll(). Supply a signed int pointer for the timeout value.
MEMCACHED_BEHAVIOR_BUFFER_REQUESTS	Buffers IO requests instead of them being sent. A get operation, or closing the connection causes the data to be flushed.
MEMCACHED_BEHAVIOR_VERIFY_KEY	Forces libmemcached to verify that a specified key is valid.
MEMCACHED_BEHAVIOR_SORT_HOSTS	If set, hosts added to the list of configured hosts for a memcached_st structure are placed into the host list in sorted order. This breaks consistent hashing if that behavior has been enabled.
MEMCACHED_BEHAVIOR_CONNECT_TIMEOUT	In nonblocking mode this changes the value of the timeout during socket connection.

libmemcached Command-Line Utilities

In addition to the main C library interface, libmemcached also includes a number of command-line utilities that can be useful when working with and debugging memcached applications.

All of the command-line tools accept a number of arguments, the most critical of which is servers, which specifies the list of servers to connect to when returning information.

The main tools are:

- `memcat`: Display the value for each ID given on the command line:

```
shell> memcat --servers=localhost hwkey
Hello world
```

- `memcp`: Copy the contents of a file into the cache, using the file name as the key:

```
shell> echo "Hello World" > hwkey
shell> memcp --servers=localhost hwkey
shell> memcat --servers=localhost hwkey
Hello world
```

- `memrm`: Remove an item from the cache:

```
shell> memcat --servers=localhost hwkey
Hello world
shell> memrm --servers=localhost hwkey
shell> memcat --servers=localhost hwkey
```

- `memslap`: Test the load on one or more `memcached` servers, simulating get/set and multiple client operations. For example, you can simulate the load of 100 clients performing get operations:

```
shell> memslap --servers=localhost --concurrency=100 --flush --test=get
memslap --servers=localhost --concurrency=100 --flush --test=get Threads connecting to servers 100
Took 13.571 seconds to read data
```

- `memflush`: Flush (empty) the contents of the `memcached` cache.

```
shell> memflush --servers=localhost
```

17.2.3.4 Using MySQL and `memcached` with Perl

The `Cache::Memcached` module provides a native interface to the Memcache protocol, and provides support for the core functions offered by `memcached`. Install the module using your operating system's package management system, or using [CPAN](#):

```
root-shell> perl -MCPAN -e 'install Cache::Memcached'
```

To use `memcached` from Perl through the `Cache::Memcached` module, first create a new `Cache::Memcached` object that defines the list of servers and other parameters for the connection. The only argument is a hash containing the options for the cache interface. For example, to create a new instance that uses three `memcached` servers:

```
use Cache::Memcached;

my $cache = new Cache::Memcached {
    'servers' => [
        '192.168.0.100:11211',
        '192.168.0.101:11211',
        '192.168.0.102:11211',
    ],
};
```

Note

When using the `Cache::Memcached` interface with multiple servers, the API automatically performs certain operations across all the servers in the group. For example, getting statistical information through `Cache::Memcached`

returns a hash that contains data on a host-by-host basis, as well as generalized statistics for all the servers in the group.

You can set additional properties on the cache object instance when it is created by specifying the option as part of the option hash. Alternatively, you can use a corresponding method on the instance:

- `servers` or method `set_servers()`: Specifies the list of the servers to be used. The servers list should be a reference to an array of servers, with each element as the address and port number combination (separated by a colon). You can also specify a local connection through a Unix socket (for example `/tmp/sock/memcached`). To specify the server with a weight (indicating how much more frequently the server should be used during hashing), specify an array reference with the `memcached` server instance and a weight number. Higher numbers give higher priority.
- `compress_threshold` or method `set_compress_threshold()`: Specifies the threshold when values are compressed. Values larger than the specified number are automatically compressed (using `zlib`) during storage and retrieval.
- `no_rehash` or method `set_norehash()`: Disables finding a new server if the original choice is unavailable.
- `readonly` or method `set_readonly()`: Disables writes to the `memcached` servers.

Once the `Cache::Memcached` object instance has been configured, you can use the `set()` and `get()` methods to store and retrieve information from the `memcached` servers. Objects stored in the cache are automatically serialized and deserialized using the `Storable` module.

The `Cache::Memcached` interface supports the following methods for storing/retrieving data, and relate to the generic methods as shown in the table.

Cache::Memcached Function	Equivalent Generic Method
<code>get()</code>	Generic <code>get()</code> .
<code>get_multi(keys)</code>	Gets multiple <code>keys</code> from memcache using just one query. Returns a hash reference of key/value pairs.
<code>set()</code>	Generic <code>set()</code> .
<code>add()</code>	Generic <code>add()</code> .
<code>replace()</code>	Generic <code>replace()</code> .
<code>delete()</code>	Generic <code>delete()</code> .
<code>incr()</code>	Generic <code>incr()</code> .
<code>decr()</code>	Generic <code>decr()</code> .

Below is a complete example for using `memcached` with Perl and the `Cache::Memcached` module:

```
#!/usr/bin/perl

use Cache::Memcached;
use DBI;
use Data::Dumper;

# Configure the memcached server

my $cache = new Cache::Memcached {
    'servers' => [
        'localhost:11211',
    ],
};
```

```

# Get the film name from the command line
# memcached keys must not contain spaces, so create
# a key name by replacing spaces with underscores

my $filmmame = shift or die "Must specify the film name\n";
my $filmkey = $filmmame;
$filmkey =~ s/ /_/;

# Load the data from the cache

my $filmdata = $cache->get($filmkey);

# If the data wasn't in the cache, then we load it from the database

if (!defined($filmdata))
{
    $filmdata = load_filmdata($filmmame);

    if (defined($filmdata))
    {
# Set the data into the cache, using the key

        if ($cache->set($filmkey,$filmdata))
            {
                print STDERR "Film data loaded from database and cached\n";
            }
        else
            {
                print STDERR "Couldn't store to cache\n";
            }
    }
}
else
{
    print STDERR "Film data loaded from Memcached\n";
}

sub load_filmdata
{
    my ($filmmame) = @_ ;

    my $dsn = "DBI:mysql:database=sakila;host=localhost;port=3306";

    $dbh = DBI->connect($dsn, 'sakila','password');

    my ($filmbase) = $dbh->selectrow_hashref(sprintf('select * from film where title = %s',
                                                    $dbh->quote($filmmame)));

    if (!defined($filmmame))
    {
        return (undef);
    }

    $filmbase->{stars} =
    $dbh->selectall_arrayref(sprintf('select concat(first_name," ",last_name) ' .
                                    'from film_actor left join (actor) ' .
                                    'on (film_actor.actor_id = actor.actor_id) ' .
                                    'where film_id=%s',
                                    $dbh->quote($filmbase->{film_id})));

    return($filmbase);
}

```

The example uses the Sakila database, obtaining film data from the database and writing a composite record of the film and actors to `memcached`. When calling it for a film does not exist, you get this result:

```
shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from database and cached
```

When accessing a film that has already been added to the cache:

```
shell> memcached-sakila.pl "ROCK INSTINCT"
Film data loaded from Memcached
```

17.2.3.5 Using MySQL and `memcached` with Python

The Python `memcache` module interfaces to `memcached` servers, and is written in pure Python (that is, without using one of the C APIs). You can download and install a copy from [Python Memcached](#).

To install, download the package and then run the Python installer:

```
python setup.py install
running install
running bdist_egg
running egg_info
creating python_memcached.egg-info
...
removing 'build/bdist.linux-x86_64/egg' (and everything under it)
Processing python_memcached-1.43-py2.4.egg
creating /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Extracting python_memcached-1.43-py2.4.egg to /usr/lib64/python2.4/site-packages
Adding python-memcached 1.43 to easy-install.pth file

Installed /usr/lib64/python2.4/site-packages/python_memcached-1.43-py2.4.egg
Processing dependencies for python-memcached==1.43
Finished processing dependencies for python-memcached==1.43
```

Once installed, the `memcache` module provides a class-based interface to your `memcached` servers. When you store Python data structures as `memcached` items, they are automatically serialized (turned into string values) using the Python `cPickle` or `pickle` modules.

To create a new `memcache` interface, import the `memcache` module and create a new instance of the `memcache.Client` class. For example, if the `memcached` daemon is running on localhost using the default port:

```
import memcache
memc = memcache.Client(['127.0.0.1:11211'])
```

The first argument is an array of strings containing the server and port number for each `memcached` instance to use. To enable debugging, set the optional `debug` parameter to 1.

By default, the hashing mechanism used to divide the items among multiple servers is `crc32`. To change the function used, set the value of `memcache.serverHashFunction` to the alternate function to use. For example:

```
from zlib import Adler32
memcache.serverHashFunction = Adler32
```

Once you have defined the servers to use within the `memcache` instance, the core functions provide the same functionality as in the generic interface specification. The following table provides a summary of the supported functions:

Python <code>memcache</code> Function	Equivalent Generic Function
<code>get()</code>	Generic <code>get()</code> .

Python <code>memcache</code> Function	Equivalent Generic Function
<code>get_multi(keys)</code>	Gets multiple values from the supplied array of <code>keys</code> . Returns a hash reference of key/value pairs.
<code>set()</code>	Generic <code>set()</code> .
<code>set_multi(dict [, expiry [, key_prefix]])</code>	Sets multiple key/value pairs from the supplied <code>dict</code> .
<code>add()</code>	Generic <code>add()</code> .
<code>replace()</code>	Generic <code>replace()</code> .
<code>prepend(key, value [, expiry])</code>	Prepends the supplied <code>value</code> to the value of the existing <code>key</code> .
<code>append(key, value [, expiry])</code>	Appends the supplied <code>value</code> to the value of the existing <code>key</code> .
<code>delete()</code>	Generic <code>delete()</code> .
<code>delete_multi(keys [, expiry [, key_prefix]])</code>	Deletes all the keys from the hash matching each string in the array <code>keys</code> .
<code>incr()</code>	Generic <code>incr()</code> .
<code>decr()</code>	Generic <code>decr()</code> .

Note

Within the Python `memcache` module, all the `*_multi()` functions support an optional `key_prefix` parameter. If supplied, then the string is used as a prefix to all key lookups. For example, if you call:

```
memc.get_multi(['a','b'], key_prefix='users:')
```

The function retrieves the keys `users:a` and `users:b` from the servers.

Here is an example showing the storage and retrieval of information to a `memcache` instance, loading the raw data from MySQL:

```
import sys
import MySQLdb
import memcache

memc = memcache.Client(['127.0.0.1:11211'], debug=1);

try:
    conn = MySQLdb.connect (host = "localhost",
                            user = "sakila",
                            passwd = "password",
                            db = "sakila")
except MySQLdb.Error, e:
    print "Error %d: %s" % (e.args[0], e.args[1])
    sys.exit (1)

popularfilms = memc.get('top5films')

if not popularfilms:
    cursor = conn.cursor()
    cursor.execute('select film_id,title from film order by rental_rate desc limit 5')
    rows = cursor.fetchall()
    memc.set('top5films',rows,60)
    print "Updated memcached with MySQL data"
else:
    print "Loaded data from memcached"
    for row in popularfilms:
        print "%s, %s" % (row[0], row[1])
```

When executed for the first time, the data is loaded from the MySQL database and stored to the `memcached` server.

```
shell> python memc_python.py
Updated memcached with MySQL data
```

Because the data is automatically serialized using `cPickle/pickle`, when you load the data back from `memcached`, you can use the object directly. In the example above, the information stored to `memcached` is in the form of rows from a Python DB cursor. When accessing the information (within the 60 second expiry time), the data is loaded from `memcached` and dumped:

```
shell> python memc_python.py
Loaded data from memcached
2, ACE GOLDFINGER
7, AIRPLANE SIERRA
8, AIRPORT POLLOCK
10, ALADDIN CALENDAR
13, ALI FOREVER
```

The serialization and deserialization happens automatically. Because serialization of Python data may be incompatible with other interfaces and languages, you can change the serialization module used during initialization. For example, you might use JSON format when you store complex data structures using a script written in one language, and access them in a script written in a different language.

17.2.3.6 Using MySQL and `memcached` with PHP

PHP provides support for the Memcache functions through a PECL extension. To enable the PHP `memcache` extensions, build PHP using the `--enable-memcache` option to `configure` when building from source.

If you are installing on a Red Hat-based server, you can install the `php-pecl-memcache` RPM:

```
root-shell> yum --install php-pecl-memcache
```

On Debian-based distributions, use the `php-memcache` package.

To set global runtime configuration options, specify the configuration option values within your `php.ini` file. The following table provides the name, default value, and a description for each global runtime configuration option.

Configuration option	Default	Description
<code>memcache.allow_failover</code>	1	Specifies whether another server in the list should be queried if the first server selected fails.
<code>memcache.max_failover_attempts</code>	20	Specifies the number of servers to try before returning a failure.
<code>memcache.chunk_size</code>	8192	Defines the size of network chunks used to exchange data with the <code>memcached</code> server.
<code>memcache.default_port</code>	11211	Defines the default port to use when communicating with the <code>memcached</code> servers.
<code>memcache.hash_strategy</code>	standard	Specifies which hash strategy to use. Set to <code>consistent</code> to enable servers to be added or removed from the pool without causing the keys to be remapped to other servers. When set to <code>standard</code> , an older (modula) strategy

Configuration option	Default	Description
		is used that potentially uses different servers for storage.
<code>memcache.hash_function</code>	<code>crc32</code>	Specifies which function to use when mapping keys to servers. <code>crc32</code> uses the standard CRC32 hash. <code>fnv</code> uses the FNV-1a hashing algorithm.

To create a connection to a `memcached` server, create a new `Memcache` object and then specify the connection options. For example:

```
<?php
$cache = new Memcache;
$cache->connect('localhost',11211);
?>
```

This opens an immediate connection to the specified server.

To use multiple `memcached` servers, you need to add servers to the `memcache` object using `addServer()`:

```
bool Memcache::addServer ( string $host [, int $port [, bool $persistent
                        [, int $weight [, int $timeout [, int $retry_interval
                        [, bool $status [, callback $failure_callback
                        ]]]]] ] )
```

The server management mechanism within the `php-memcache` module is a critical part of the interface as it controls the main interface to the `memcached` instances and how the different instances are selected through the hashing mechanism.

To create a simple connection to two `memcached` instances:

```
<?php
$cache = new Memcache;
$cache->addServer('192.168.0.100',11211);
$cache->addServer('192.168.0.101',11211);
?>
```

In this scenario, the instance connection is not explicitly opened, but only opened when you try to store or retrieve a value. To enable persistent connections to `memcached` instances, set the `$persistent` argument to true. This is the default setting, and causes the connections to remain open.

To help control the distribution of keys to different instances, use the global `memcache.hash_strategy` setting. This sets the hashing mechanism used to select. You can also add another weight to each server, which effectively increases the number of times the instance entry appears in the instance list, therefore increasing the likelihood of the instance being chosen over other instances. To set the weight, set the value of the `$weight` argument to more than one.

The functions for setting and retrieving information are identical to the generic functional interface offered by `memcached`, as shown in this table:

PECL <code>memcache</code> Function	Generic Function
<code>get()</code>	Generic <code>get()</code> .
<code>set()</code>	Generic <code>set()</code> .
<code>add()</code>	Generic <code>add()</code> .

PECL <code>memcache</code> Function	Generic Function
<code>replace()</code>	Generic <code>replace()</code> .
<code>delete()</code>	Generic <code>delete()</code> .
<code>increment()</code>	Generic <code>incr()</code> .
<code>decrement()</code>	Generic <code>decr()</code> .

A full example of the PECL `memcache` interface is provided below. The code loads film data from the Sakila database when the user provides a film name. The data stored into the `memcached` instance is recorded as a `mysqli` result row, and the API automatically serializes the information for you.

```
<?php

$memc = new Memcache;
$memc->addServer('localhost', '11211');

if(empty($_POST['film'])) {
?>
<html xmlns="http://www.w3.org/1999/xhtml" xml:lang="en" lang="en">
<head>
<meta http-equiv="Content-Type" content="text/html; charset=utf-8" />
<title>Simple Memcache Lookup</title>
</head>
<body>
<form method="post">
<p><b>Film</b>: <input type="text" size="20" name="film"></p>
<input type="submit">
</form>
<hr/>
<?php

} else {

    echo "Loading data...\n";

    $film = htmlspecialchars($_POST['film'], ENT_QUOTES, 'UTF-8');
    $mfilms = $memc->get($film);

    if ($mfilms) {

        printf("<p>Film data for %s loaded from memcache</p>", $mfilms['title']);

        foreach (array_keys($mfilms) as $key) {
            printf("<p><b>%s</b>: %s</p>", $key, $mfilms[$key]);
        }

    } else {

        $mysqli = mysqli('localhost', 'sakila', 'password', 'sakila');

        if (mysqli_connect_error()) {
            printf("Database error: (%d) %s", mysqli_connect_errno(), mysqli_connect_error());
            exit;
        }

        $sql = sprintf('SELECT * FROM film WHERE title="%s"', $mysqli->real_escape_string($film));

        $result = $mysqli->query($sql);

        if (!$result) {
            printf("Database error: (%d) %s", $mysqli->errno, $mysqli->error);
            exit;
        }

        $row = $result->fetch_assoc();

        $memc->set($row['title'], $row);
    }
}
```

```

        printf("<p>Loaded (%s) from MySQL</p>", htmlspecialchars($row['title'], ENT_QUOTES, 'UTF-8'));
    }
}
?>
</body>
</html>

```

With PHP, the connections to the `memcached` instances are kept open as long as the PHP and associated Apache instance remain running. When adding or removing servers from the list in a running instance (for example, when starting another script that mentions additional servers), the connections are shared, but the script only selects among the instances explicitly configured within the script.

To ensure that changes to the server list within a script do not cause problems, make sure to use the consistent hashing mechanism.

17.2.3.7 Using MySQL and `memcached` with Ruby

There are a number of different modules for interfacing to `memcached` within Ruby. The `Ruby-MemCache` client library provides a native interface to `memcached` that does not require any external libraries, such as `libmemcached`. You can obtain the installer package from <http://www.deveiate.org/projects/RMemCache>.

To install, extract the package and then run `install.rb`:

```
shell> install.rb
```

If you have RubyGems, you can install the `Ruby-MemCache` gem:

```

shell> gem install Ruby-MemCache
Bulk updating Gem source index for: http://gems.rubyforge.org
Install required dependency io-reactor? [Yn] y
Successfully installed Ruby-MemCache-0.0.1
Successfully installed io-reactor-0.05
Installing ri documentation for io-reactor-0.05...
Installing RDoc documentation for io-reactor-0.05...

```

To use a `memcached` instance from within Ruby, create a new instance of the `MemCache` object.

```

require 'memcache'
memc = MemCache::new '192.168.0.100:11211'

```

You can add a weight to each server to increase the likelihood of the server being selected during hashing by appending the weight count to the server host name/port string:

```

require 'memcache'
memc = MemCache::new '192.168.0.100:11211:3'

```

To add servers to an existing list, you can append them directly to the `MemCache` object:

```
memc += ["192.168.0.101:11211"]
```

To set data into the cache, you can just assign a value to a key within the new cache object, which works just like a standard Ruby hash object:

```
memc["key"] = "value"
```

Or to retrieve the value:

```
print memc["key"]
```

For more explicit actions, you can use the method interface, which mimics the main `memcached` API functions, as summarized in the following table:

Ruby <code>MemCache</code> Method	Equivalent <code>memcached</code> API Functions
<code>get()</code>	Generic <code>get()</code> .
<code>get_hash(keys)</code>	Get the values of multiple <code>keys</code> , returning the information as a hash of the keys and their values.
<code>set()</code>	Generic <code>set()</code> .
<code>set_many(pairs)</code>	Set the values of the keys and values in the hash <code>pairs</code> .
<code>add()</code>	Generic <code>add()</code> .
<code>replace()</code>	Generic <code>replace()</code> .
<code>delete()</code>	Generic <code>delete()</code> .
<code>incr()</code>	Generic <code>incr()</code> .
<code>decr()</code>	Generic <code>decr()</code> .

17.2.3.8 Using MySQL and `memcached` with Java

The `com.danga.MemCached` class within Java provides a native interface to `memcached` instances. You can obtain the client from <https://github.com/gwhalin/Memcached-Java-Client/downloads>. The Java class uses hashes that are compatible with `libmemcached`, so you can mix and match Java and `libmemcached` applications accessing the same `memcached` instances. The serialization between Java and other interfaces are not compatible. If this is a problem, use JSON or a similar nonbinary serialization format.

On most systems, you can download the package and use the `jar` directly.

To use the `com.danga.MemCached` interface, you create a `MemCachedClient` instance and then configure the list of servers by configuring the `SockIOPool`. Through the pool specification you set up the server list, weighting, and the connection parameters to optimized the connections between your client and the `memcached` instances that you configure.

Generally, you can configure the `memcached` interface once within a single class, then use this interface throughout the rest of your application.

For example, to create a basic interface, first configure the `MemCachedClient` and base `SockIOPool` settings:

```
public class MyClass {

    protected static MemCachedClient mcc = new MemCachedClient();

    static {

        String[] servers =
            {
                "localhost:11211",
            };

        Integer[] weights = { 1 };

        SockIOPool pool = SockIOPool.getInstance();
    }
}
```

```
pool.setServers( servers );
pool.setWeights( weights );
```

In the above sample, the list of servers is configured by creating an array of the `memcached` instances to use. You can then configure individual weights for each server.

The remainder of the properties for the connection are optional, but you can set the connection numbers (initial connections, minimum connections, maximum connections, and the idle timeout) by setting the pool parameters:

```
pool.setInitConn( 5 );
pool.setMinConn( 5 );
pool.setMaxConn( 250 );
pool.setMaxIdle( 1000 * 60 * 60 * 6
```

Once the parameters have been configured, initialize the connection pool:

```
pool.initialize();
```

The pool, and the connection to your `memcached` instances should now be ready to use.

To set the hashing algorithm used to select the server used when storing a given key, use `pool.setHashingAlg()`:

```
pool.setHashingAlg( SockIOPool.NEW_COMPAT_HASH );
```

Valid values are `NEW_COMPAT_HASH`, `OLD_COMPAT_HASH` and `NATIVE_HASH` are also basic modular hashing algorithms. For a consistent hashing algorithm, use `CONSISTENT_HASH`. These constants are equivalent to the corresponding hash settings within `libmemcached`.

The following table outlines the Java `com.danga.MemCached` methods and the equivalent generic methods in the `memcached` interface specification.

Java <code>com.danga.MemCached</code> Method	Equivalent Generic Method
<code>get()</code>	Generic <code>get()</code> .
<code>getMulti(keys)</code>	Get the values of multiple <code>keys</code> , returning the information as Hash map using <code>java.lang.String</code> for the keys and <code>java.lang.Object</code> for the corresponding values.
<code>set()</code>	Generic <code>set()</code> .
<code>add()</code>	Generic <code>add()</code> .
<code>replace()</code>	Generic <code>replace()</code> .
<code>delete()</code>	Generic <code>delete()</code> .
<code>incr()</code>	Generic <code>incr()</code> .
<code>decr()</code>	Generic <code>decr()</code> .

17.2.3.9 Using the `memcached` TCP Text Protocol

Communicating with a `memcached` server can be achieved through either the TCP or UDP protocols. When using the TCP protocol, you can use a simple text based interface for the exchange of information.

When communicating with `memcached`, you can connect to the server using the port configured for the server. You can open a connection with the server without requiring authorization or login. As soon as you have connected, you can start to send commands to the server. When you have finished, you can terminate the connection without sending any specific disconnection command. Clients are encouraged to keep their connections open to decrease latency and improve performance.

Data is sent to the `memcached` server in two forms:

- Text lines, which are used to send commands to the server, and receive responses from the server.
- Unstructured data, which is used to receive or send the value information for a given key. Data is returned to the client in exactly the format it was provided.

Both text lines (commands and responses) and unstructured data are always terminated with the string `\r\n`. Because the data being stored may contain this sequence, the length of the data (returned by the client before the unstructured data is transmitted) should be used to determine the end of the data.

Commands to the server are structured according to their operation:

- **Storage commands:** `set`, `add`, `replace`, `append`, `prepend`, `cas`

Storage commands to the server take the form:

```
command key [flags] [exptime] length [noreply]
```

Or when using compare and swap (`cas`):

```
cas key [flags] [exptime] length [casunique] [noreply]
```

Where:

- `command`: The command name.
 - `set`: Store value against key
 - `add`: Store this value against key if the key does not already exist
 - `replace`: Store this value against key if the key already exists
 - `append`: Append the supplied value to the end of the value for the specified key. The `flags` and `exptime` arguments should not be used.
 - `prepend`: Append value currently in the cache to the end of the supplied value for the specified key. The `flags` and `exptime` arguments should not be used.
 - `cas`: Set the specified key to the supplied value, only if the supplied `casunique` matches. This is effectively the equivalent of change the information if nobody has updated it since I last fetched it.
- `key`: The key. All data is stored using a the specific key. The key cannot contain control characters or whitespace, and can be up to 250 characters in size.
- `flags`: The flags for the operation (as an integer). Flags in `memcached` are transparent. The `memcached` server ignores the contents of the flags. They can be used by the client to indicate any type of information. In `memcached` 1.2.0 and lower the value is a 16-bit integer value. In `memcached` 1.2.1 and higher the value is a 32-bit integer.
- `exptime`: The expiry time, or zero for no expiry.
- `length`: The length of the supplied value block in bytes, excluding the terminating `\r\n` characters.

- **casunique**: A unique 64-bit value of an existing entry. This is used to compare against the existing value. Use the value returned by the `gets` command when issuing `cas` updates.
- **noreply**: Tells the server not to reply to the command.

For example, to store the value `abcdef` into the key `xyzkey`, you would use:

```
set xyzkey 0 0 6\r\nabcdef\r\n
```

The return value from the server is one line, specifying the status or error information. For more information, see [Table 17.3, “memcached Protocol Responses”](#).

- **Retrieval commands**: `get`, `gets`

Retrieval commands take the form:

```
get key1 [key2 ... keyn]
gets key1 [key2 ... keyn]
```

You can supply multiple keys to the commands, with each requested key separated by whitespace.

The server responds with an information line of the form:

```
VALUE key flags bytes [casunique]
```

Where:

- **key**: The key name.
- **flags**: The value of the flag integer supplied to the `memcached` server when the value was stored.
- **bytes**: The size (excluding the terminating `\r\n` character sequence) of the stored value.
- **casunique**: The unique 64-bit integer that identifies the item.

The information line is immediately followed by the value data block. For example:

```
get xyzkey\r\n
VALUE xyzkey 0 6\r\n
abcdef\r\n
```

If you have requested multiple keys, an information line and data block is returned for each key found. If a requested key does not exist in the cache, no information is returned.

- **Delete commands**: `delete`

Deletion commands take the form:

```
delete key [time] [noreply]
```

Where:

- **key**: The key name.
- **time**: The time in seconds (or a specific Unix time) for which the client wishes the server to refuse `add` or `replace` commands on this key. All `add`, `replace`, `get`, and `gets` commands fail during this period. `set` operations succeed. After this period, the key is deleted permanently and all commands are accepted.

If not supplied, the value is assumed to be zero (delete immediately).

- `noreply`: Tells the server not to reply to the command.

Responses to the command are either `DELETED` to indicate that the key was successfully removed, or `NOT_FOUND` to indicate that the specified key could not be found.

- **Increment/Decrement:** `incr`, `decr`

The increment and decrement commands change the value of a key within the server without performing a separate get/set sequence. The operations assume that the currently stored value is a 64-bit integer. If the stored value is not a 64-bit integer, then the value is assumed to be zero before the increment or decrement operation is applied.

Increment and decrement commands take the form:

```
incr key value [noreply]
decr key value [noreply]
```

Where:

- `key`: The key name.
- `value`: An integer to be used as the increment or decrement value.
- `noreply`: Tells the server not to reply to the command.

The response is:

- `NOT_FOUND`: The specified key could not be located.
- `value`: The new value associated with the specified key.

Values are assumed to be unsigned. For `decr` operations, the value is never decremented below 0. For `incr` operations, the value wraps around the 64-bit maximum.

- **Statistics commands:** `stats`

The `stats` command provides detailed statistical information about the current status of the `memcached` instance and the data it is storing.

Statistics commands take the form:

```
STAT [name] [value]
```

Where:

- `name`: The optional name of the statistics to return. If not specified, the general statistics are returned.
- `value`: A specific value to be used when performing certain statistics operations.

The return value is a list of statistics data, formatted as follows:

```
STAT name value
```

The statistics are terminated with a single line, `END`.

For more information, see [Section 17.2.4, “Getting `memcached` Statistics”](#).

For reference, a list of the different commands supported and their formats is provided below.

Table 17.2 memcached Command Reference

Command	Command Formats
set	set key flags exptime length, set key flags exptime length noreply
add	add key flags exptime length, add key flags exptime length noreply
replace	replace key flags exptime length, replace key flags exptime length noreply
append	append key length, append key length noreply
prepend	prepend key length, prepend key length noreply
cas	cas key flags exptime length casunique, cas key flags exptime length casunique noreply
get	get key1 [key2 ... keyn]
gets	
delete	delete key, delete key noreply, delete key expiry, delete key expiry noreply
incr	incr key, incr key noreply, incr key value, incr key value noreply
decr	decr key, decr key noreply, decr key value, decr key value noreply
stat	stat, stat name, stat name value

When sending a command to the server, the response from the server is one of the settings in the following table. All response values from the server are terminated by `\r\n`:

Table 17.3 memcached Protocol Responses

String	Description
STORED	Value has successfully been stored.
NOT_STORED	The value was not stored, but not because of an error. For commands where you are adding a or updating a value if it exists (such as <code>add</code> and <code>replace</code>), or where the item has already been set to be deleted.
EXISTS	When using a <code>cas</code> command, the item you are trying to store already exists and has been modified since you last checked it.
NOT_FOUND	The item you are trying to store, update or delete does not exist or has already been deleted.
ERROR	You submitted a nonexistent command name.
CLIENT_ERROR errorstring	There was an error in the input line, the detail is contained in <code>errorstring</code> .
SERVER_ERROR errorstring	There was an error in the server that prevents it from returning the information. In extreme conditions, the server may disconnect the client after this error occurs.
VALUE key flags length	The requested key has been found, and the stored <code>key</code> , <code>flags</code> and data block are returned, of the specified <code>length</code> .
DELETED	The requested key was deleted from the server.
STAT name value	A line of statistics data.

String	Description
<code>END</code>	The end of the statistics data.

17.2.4 Getting `memcached` Statistics

The `memcached` system has a built-in statistics system that collects information about the data being stored into the cache, cache hit ratios, and detailed information on the memory usage and distribution of information through the slab allocation used to store individual items. Statistics are provided at both a basic level that provide the core statistics, and more specific statistics for specific areas of the `memcached` server.

This information can be useful to ensure that you are getting the correct level of cache and memory usage, and that your slab allocation and configuration properties are set at an optimal level.

The stats interface is available through the standard `memcached` protocol, so the reports can be accessed by using `telnet` to connect to the `memcached`. The supplied `memcached-tool` includes support for obtaining the [Section 17.2.4.2, “memcached Slabs Statistics”](#) and [Section 17.2.4.1, “memcached General Statistics”](#) information. For more information, see [Section 17.2.4.6, “Using memcached-tool”](#).

Alternatively, most of the language API interfaces provide a function for obtaining the statistics from the server.

For example, to get the basic stats using `telnet`:

```
shell> telnet localhost 11211
Trying ::1...
Connected to localhost.
Escape character is '^]'.
stats
STAT pid 23599
STAT uptime 675
STAT time 1211439587
STAT version 1.2.5
STAT pointer_size 32
STAT rusage_user 1.404992
STAT rusage_system 4.694685
STAT curr_items 32
STAT total_items 56361
STAT bytes 2642
STAT curr_connections 53
STAT total_connections 438
STAT connection_structures 55
STAT cmd_get 113482
STAT cmd_set 80519
STAT get_hits 78926
STAT get_misses 34556
STAT evictions 0
STAT bytes_read 6379783
STAT bytes_written 4860179
STAT limit_maxbytes 67108864
STAT threads 1
END
```

When using Perl and the `Cache::Memcached` module, the `stats()` function returns information about all the servers currently configured in the connection object, and total statistics for all the `memcached` servers as a whole.

For example, the following Perl script obtains the stats and dumps the hash reference that is returned:

```
use Cache::Memcached;
use Data::Dumper;

my $memc = new Cache::Memcached;
```

```
$memc->set_servers(\@ARGV);

print Dumper($memc->stats());
```

When executed on the same `memcached` as used in the `Telnet` example above we get a hash reference with the host by host and total statistics:

```
$VAR1 = {
  'hosts' => {
    'localhost:11211' => {
      'misc' => {
        'bytes' => '2421',
        'curr_connections' => '3',
        'connection_structures' => '56',
        'pointer_size' => '32',
        'time' => '1211440166',
        'total_items' => '410956',
        'cmd_set' => '588167',
        'bytes_written' => '35715151',
        'evictions' => '0',
        'curr_items' => '31',
        'pid' => '23599',
        'limit_maxbytes' => '67108864',
        'uptime' => '1254',
        'rusage_user' => '9.857805',
        'cmd_get' => '838451',
        'rusage_system' => '34.096988',
        'version' => '1.2.5',
        'get_hits' => '581511',
        'bytes_read' => '46665716',
        'threads' => '1',
        'total_connections' => '3104',
        'get_misses' => '256940'
      },
      'sizes' => {
        '128' => '16',
        '64' => '15'
      }
    }
  },
  'self' => {},
  'total' => {
    'cmd_get' => 838451,
    'bytes' => 2421,
    'get_hits' => 581511,
    'connection_structures' => 56,
    'bytes_read' => 46665716,
    'total_items' => 410956,
    'total_connections' => 3104,
    'cmd_set' => 588167,
    'bytes_written' => 35715151,
    'curr_items' => 31,
    'get_misses' => 256940
  }
};
```

The statistics are divided up into a number of distinct sections, and then can be requested by adding the type to the `stats` command. Each statistics output is covered in more detail in the following sections.

- General statistics, see [Section 17.2.4.1, “memcached General Statistics”](#).
- Slab statistics (`slabs`), see [Section 17.2.4.2, “memcached Slabs Statistics”](#).
- Item statistics (`items`), see [Section 17.2.4.3, “memcached Item Statistics”](#).
- Size statistics (`sizes`), see [Section 17.2.4.4, “memcached Size Statistics”](#).
- Detailed status (`detail`), see [Section 17.2.4.5, “memcached Detail Statistics”](#).

17.2.4.1 `memcached` General Statistics

The output of the general statistics provides an overview of the performance and use of the `memcached` instance. The statistics returned by the command and their meaning is shown in the following table.

The following terms are used to define the value type for each statistics value:

- `32u`: 32-bit unsigned integer
- `64u`: 64-bit unsigned integer
- `32u:32u`: Two 32-bit unsigned integers separated by a colon
- `String`: Character string

Statistic	Data type	Description	Version
<code>pid</code>	<code>32u</code>	Process ID of the <code>memcached</code> instance.	
<code>uptime</code>	<code>32u</code>	Uptime (in seconds) for this <code>memcached</code> instance.	
<code>time</code>	<code>32u</code>	Current time (as epoch).	
<code>version</code>	string	Version string of this instance.	
<code>pointer_size</code>	string	Size of pointers for this host specified in bits (32 or 64).	
<code>rusage_user</code>	<code>32u:32u</code>	Total user time for this instance (seconds:microseconds).	
<code>rusage_system</code>	<code>32u:32u</code>	Total system time for this instance (seconds:microseconds).	
<code>curr_items</code>	<code>32u</code>	Current number of items stored by this instance.	
<code>total_items</code>	<code>32u</code>	Total number of items stored during the life of this instance.	
<code>bytes</code>	<code>64u</code>	Current number of bytes used by this server to store items.	
<code>curr_connections</code>	<code>32u</code>	Current number of open connections.	
<code>total_connections</code>	<code>32u</code>	Total number of connections opened since the server started running.	
<code>connection_structures</code>	<code>32u</code>	Number of connection structures allocated by the server.	
<code>cmd_get</code>	<code>64u</code>	Total number of retrieval requests (<code>get</code> operations).	
<code>cmd_set</code>	<code>64u</code>	Total number of storage requests (<code>set</code> operations).	
<code>get_hits</code>	<code>64u</code>	Number of keys that have been requested and found present.	
<code>get_misses</code>	<code>64u</code>	Number of items that have been requested and not found.	
<code>delete_hits</code>	<code>64u</code>	Number of keys that have been deleted and found present.	1.3.x
<code>delete_misses</code>	<code>64u</code>	Number of items that have been delete and not found.	1.3.x
<code>incr_hits</code>	<code>64u</code>	Number of keys that have been incremented and found present.	1.3.x
<code>incr_misses</code>	<code>64u</code>	Number of items that have been incremented and not found.	1.3.x
<code>decr_hits</code>	<code>64u</code>	Number of keys that have been decremented and found present.	1.3.x

Statistic	Data type	Description	Version
<code>decr_misses</code>	64u	Number of items that have been decremented and not found.	1.3.x
<code>cas_hits</code>	64u	Number of keys that have been compared and swapped and found present.	1.3.x
<code>cas_misses</code>	64u	Number of items that have been compared and swapped and not found.	1.3.x
<code>cas_badvalue</code>	64u	Number of keys that have been compared and swapped, but the comparison (original) value did not match the supplied value.	1.3.x
<code>evictions</code>	64u	Number of valid items removed from cache to free memory for new items.	
<code>bytes_read</code>	64u	Total number of bytes read by this server from network.	
<code>bytes_written</code>	64u	Total number of bytes sent by this server to network.	
<code>limit_maxbytes</code>	32u	Number of bytes this server is permitted to use for storage.	
<code>threads</code>	32u	Number of worker threads requested.	
<code>conn_yields</code>	64u	Number of yields for connections (related to the <code>-R</code> option).	1.4.0

The most useful statistics from those given here are the number of cache hits, misses, and evictions.

A large number of `get_misses` may just be an indication that the cache is still being populated with information. The number should, over time, decrease in comparison to the number of cache `get_hits`. If, however, you have a large number of cache misses compared to cache hits after an extended period of execution, it may be an indication that the size of the cache is too small and you either need to increase the total memory size, or increase the number of the `memcached` instances to improve the hit ratio.

A large number of `evictions` from the cache, particularly in comparison to the number of items stored is a sign that your cache is too small to hold the amount of information that you regularly want to keep cached. Instead of items being retained in the cache, items are being evicted to make way for new items keeping the turnover of items in the cache high, reducing the efficiency of the cache.

17.2.4.2 `memcached` Slabs Statistics

To get the `slabs` statistics, use the `stats slabs` command, or the API equivalent.

The slab statistics provide you with information about the slabs that have created and allocated for storing information within the cache. You get information both on each individual slab-class and total statistics for the whole slab.

```
STAT 1:chunk_size 104
STAT 1:chunks_per_page 10082
STAT 1:total_pages 1
STAT 1:total_chunks 10082
STAT 1:used_chunks 10081
STAT 1:free_chunks 1
STAT 1:free_chunks_end 10079
STAT 9:chunk_size 696
STAT 9:chunks_per_page 1506
STAT 9:total_pages 63
STAT 9:total_chunks 94878
STAT 9:used_chunks 94878
STAT 9:free_chunks 0
STAT 9:free_chunks_end 0
STAT active_slabs 2
```

```
STAT total_malloced 67083616
END
```

Individual stats for each slab class are prefixed with the slab ID. A unique ID is given to each allocated slab from the smallest size up to the largest. The prefix number indicates the slab class number in relation to the calculated chunk from the specified growth factor. Hence in the example, 1 is the first chunk size and 9 is the 9th chunk allocated size.

The parameters returned for each chunk size and a description of each parameter are provided in the following table.

Statistic	Description	Version
<code>chunk_size</code>	Space allocated to each chunk within this slab class.	
<code>chunks_per_page</code>	Number of chunks within a single page for this slab class.	
<code>total_pages</code>	Number of pages allocated to this slab class.	
<code>total_chunks</code>	Number of chunks allocated to the slab class.	
<code>used_chunks</code>	Number of chunks allocated to an item..	
<code>free_chunks</code>	Number of chunks not yet allocated to items.	
<code>free_chunks_end</code>	Number of free chunks at the end of the last allocated page.	
<code>get_hits</code>	Number of get hits to this chunk	1.3.x
<code>cmd_set</code>	Number of set commands on this chunk	1.3.x
<code>delete_hits</code>	Number of delete hits to this chunk	1.3.x
<code>incr_hits</code>	Number of increment hits to this chunk	1.3.x
<code>decr_hits</code>	Number of decrement hits to this chunk	1.3.x
<code>cas_hits</code>	Number of CAS hits to this chunk	1.3.x
<code>cas_badval</code>	Number of CAS hits on this chunk where the existing value did not match	1.3.x
<code>mem_requested</code>	The true amount of memory of memory requested within this chunk	1.4.1

The following additional statistics cover the information for the entire server, rather than on a chunk by chunk basis:

Statistic	Description	Version
<code>active_slabs</code>	Total number of slab classes allocated.	
<code>total_malloced</code>	Total amount of memory allocated to slab pages.	

The key values in the slab statistics are the `chunk_size`, and the corresponding `total_chunks` and `used_chunks` parameters. These given an indication of the size usage of the chunks within the system. Remember that one key/value pair is placed into a chunk of a suitable size.

From these stats, you can get an idea of your size and chunk allocation and distribution. If you store many items with a number of largely different sizes, consider adjusting the chunk size growth factor to increase in larger steps to prevent chunk and memory wastage. A good indication of a bad growth factor is a high number of different slab classes, but with relatively few chunks actually in use within each slab. Increasing the growth factor creates fewer slab classes and therefore makes better use of the allocated pages.

17.2.4.3 memcached Item Statistics

To get the `items` statistics, use the `stats items` command, or the API equivalent.

The `items` statistics give information about the individual items allocated within a given slab class.

```
STAT items:2:number 1
STAT items:2:age 452
STAT items:2:evicted 0
STAT items:2:evicted_nonzero 0
STAT items:2:evicted_time 2
STAT items:2:outofmemory 0
STAT items:2:tailrepairs 0
...
STAT items:27:number 1
STAT items:27:age 452
STAT items:27:evicted 0
STAT items:27:evicted_nonzero 0
STAT items:27:evicted_time 2
STAT items:27:outofmemory 0
STAT items:27:tailrepairs 0
```

The prefix number against each statistics relates to the corresponding chunk size, as returned by the `stats slabs` statistics. The result is a display of the number of items stored within each chunk within each slab size, and specific statistics about their age, eviction counts, and out of memory counts. A summary of the statistics is given in the following table.

Statistic	Description	
<code>number</code>	The number of items currently stored in this slab class.	
<code>age</code>	The age of the oldest item within the slab class, in seconds.	
<code>evicted</code>	The number of items evicted to make way for new entries.	
<code>evicted_time</code>	The time of the last evicted entry	
<code>evicted_nonzero</code>	The time of the last evicted non-zero entry	1.4.0
<code>outofmemory</code>	The number of items for this slab class that have triggered an out of memory error (only value when the <code>-M</code> command line option is in effect).	
<code>tailrepairs</code>	Number of times the entries for a particular ID need repairing	

Item level statistics can be used to determine how many items are stored within a given slab and their freshness and recycle rate. You can use this to help identify whether there are certain slab classes that are triggering a much larger number of evictions than others.

17.2.4.4 memcached Size Statistics

To get size statistics, use the `stats sizes` command, or the API equivalent.

The size statistics provide information about the sizes and number of items of each size within the cache. The information is returned as two columns, the first column is the size of the item (rounded up to the nearest 32 byte boundary), and the second column is the count of the number of items of that size within the cache:

```
96 35
128 38
160 807
192 804
224 410
256 222
288 83
320 39
352 53
384 33
416 64
448 51
```

```
480 30
512 54
544 39
576 10065
```

Caution

Running this statistic locks up your cache as each item is read from the cache and its size calculated. On a large cache, this may take some time and prevent any set or get operations until the process completes.

The item size statistics are useful only to determine the sizes of the objects you are storing. Since the actual memory allocation is relevant only in terms of the chunk size and page size, the information is only useful during a careful debugging or diagnostic session.

17.2.4.5 `memcached` Detail Statistics

For `memcached` 1.3.x and higher, you can enable and obtain detailed statistics about the `get`, `set`, and `del` operations on the individual keys stored in the cache, and determine whether the attempts hit (found) a particular key. These operations are only recorded while the detailed stats analysis is turned on.

To enable detailed statistics, you must send the `stats detail on` command to the `memcached` server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail on
OK
```

Individual statistics are recorded for every `get`, `set` and `del` operation on a key, including keys that are not currently stored in the server. For example, if an attempt is made to obtain the value of key `abckey` and it does not exist, the `get` operation on the specified key are recorded while detailed statistics are in effect, even if the key is not currently stored. The `hits`, that is, the number of `get` or `del` operations for a key that exists in the server are also counted.

To turn detailed statistics off, send the `stats detail off` command to the `memcached` server:

```
$ telnet localhost 11211
Trying 127.0.0.1...
Connected to tiger.
Escape character is '^]'.
stats detail off
OK
```

To obtain the detailed statistics recorded during the process, send the `stats detail dump` command to the `memcached` server:

```
stats detail dump
PREFIX hykkey get 0 hit 0 set 1 del 0
PREFIX xyzkey get 0 hit 0 set 1 del 0
PREFIX yukkey get 1 hit 0 set 0 del 0
PREFIX abckey get 3 hit 3 set 1 del 0
END
```

You can use the detailed statistics information to determine whether your `memcached` clients are using a large number of keys that do not exist in the server by comparing the `hit` and `get` or `del` counts. Because the information is recorded by key, you can also determine whether the failures or operations are clustered around specific keys.

17.2.4.6 Using memcached-tool

The `memcached-tool`, located within the `scripts` directory within the `memcached` source directory. The tool provides convenient access to some reports and statistics from any `memcached` instance.

The basic format of the command is:

```
shell> ./memcached-tool hostname:port [command]
```

The default output produces a list of the slab allocations and usage. For example:

```
shell> memcached-tool localhost:11211 display
# Item_Size Max_age Pages Count Full? Evicted Evict_Time OOM
1 80B 93s 1 20 no 0 0 0

33 117.5K 1336s 1 3 no 0 0 0
```

This output is the same if you specify the `command` as `display`:

```
shell> memcached-tool localhost:11211 display
# Item_Size Max_age Pages Count Full? Evicted Evict_Time OOM
1 80B 93s 1 20 no 0 0 0
2 104B 93s 1 16 no 0 0 0
...
```

The output shows a summarized version of the output from the `slabs` statistics. The columns provided in the output are shown below:

- `#`: The slab number
- `Item_Size`: The size of the slab
- `Max_age`: The age of the oldest item in the slab
- `Pages`: The number of pages allocated to the slab

- **Count**: The number of items in this slab
- **Full?**: Whether the slab is fully populated
- **Evicted**: The number of objects evicted from this slab
- **Evict_Time**: The time (in seconds) since the last eviction
- **OOM**: The number of items that have triggered an out of memory error

You can also obtain a dump of the general statistics for the server using the `stats` command:

```
shell> memcached-tool localhost:11211 stats
#localhost:11211  Field      Value
      accepting_conns      1
      bytes                 162

17.2.5 memcached FAQ

17.2.5.1 Can memcached be run on a Windows environment?	2401
17.2.5.2 What is the maximum size of an object you can store in memcached? Is that configurable?	2401
17.2.5.3 Is it true memcached will be much more effective with db-read-intensive applications than with db-write-intensive applications?	2401
17.2.5.4 Is there any overhead in not using persistent connections? If persistent is always recommended, what are the downsides (for example, locking up)?	2401
17.2.5.5 How is an event such as a crash of one of the memcached servers handled by the memcached client?	2401
17.2.5.6 What is a recommended hardware configuration for a memcached server?	2402
17.2.5.7 Is memcached more effective for video and audio as opposed to textual read/writes?	2402
17.2.5.8 Can memcached work with ASPX?	2402
17.2.5.9 How expensive is it to establish a memcache connection? Should those connections be pooled?	2402

17.2.5.10	How is the data handled when the <code>memcached</code> server is down?	2402
17.2.5.11	How are auto-increment columns in the MySQL database coordinated across multiple instances of <code>memcached</code> ?	2402
17.2.5.12	Is compression available?	2402
17.2.5.13	Can we implement different types of <code>memcached</code> as different nodes in the same server, so can there be deterministic and non-deterministic in the same server?	2402
17.2.5.14	What are best practices for testing an implementation, to ensure that it improves performance, and to measure the impact of <code>memcached</code> configuration changes? And would you recommend keeping the configuration very simple to start?	2403

17.2.5.10 Can `memcached` be run on a Windows environment?

No. Currently `memcached` is available only on the Unix/Linux platform. There is an unofficial port available, see <http://www.codeplex.com/memcachedproviders>.

17.2.5.11 What is the maximum size of an object you can store in `memcached`? Is that configurable?

The default maximum object size is 1MB. In `memcached` 1.4.2 and later, you can change the maximum size of an object using the `-I` command line option.

For versions before this, to increase this size, you have to re-compile `memcached`. You can modify the value of the `POWER_BLOCK` within the `slabs.c` file within the source.

In `memcached` 1.4.2 and higher, you can configure the maximum supported object size by using the `-I` command-line option. For example, to increase the maximum object size to 5MB:

```
$ memcached -I 5m
```

If an object is larger than the maximum object size, you must manually split it. `memcached` is very simple: you give it a key and some data, it tries to cache it in RAM. If you try to store more than the default maximum size, the value is just truncated for speed reasons.

17.2.5.12 Is true `memcached` will be much more effective with db-read-intensive applications than with db-write-intensive applications?

Yes. `memcached` plays no role in database writes, it is a method of caching data already read from the database in RAM.

17.2.5.13 Is there any overhead in not using persistent connections? If persistent is always recommended, what are the downsides (for example, locking up)?

If you don't use persistent connections when communicating with `memcached`, there will be a small increase in the latency of opening the connection each time. The effect is comparable to use nonpersistent connections with MySQL.

In general, the chance of locking or other issues with persistent connections is minimal, because there is very little locking within `memcached`. If there is a problem, eventually your request will time out and return no result, so your application will need to load from MySQL again.

17.2.5.14 How is an event such as a crash of one of the `memcached` servers handled by the `memcached` client?

There is no automatic handling of this. If your client fails to get a response from a server, code a fallback mechanism to load the data from the MySQL database.

The client APIs all provide the ability to add and remove `memcached` instances on the fly. If within your application you notice that `memcached` server is no longer responding, you can remove the server from the list of servers, and keys will automatically be redistributed to another `memcached` server in the list. If retaining the cache content on all your servers is important, make sure you use an API that supports a consistent hashing algorithm. For more information, see [Section 17.2.2.5, "memcached Hashing/Distribution Types"](#).

17.2.5.0 What is a recommended hardware configuration for a memcached server?

memcached has a very low processing overhead. All that is required is spare physical RAM capacity. A memcached server does not require a dedicated machine. If you have web, application, or database servers that have spare RAM capacity, then use them with memcached.

To build and deploy a dedicated memcached server, use a relatively low-power CPU, lots of RAM, and one or more Gigabit Ethernet interfaces.

17.2.5.1 Is memcached more effective for video and audio as opposed to textual read/writes?

memcached works equally well for all kinds of data. To memcached, any value you store is just a stream of data. Remember, though, that the maximum size of an object you can store in memcached is 1MB, but can be configured to be larger by using the `-I` option in memcached 1.4.2 and later, or by modifying the source in versions before 1.4.2. If you plan on using memcached with audio and video content, you will probably want to increase the maximum object size. Also remember that memcached is a solution for caching information for reading. It shouldn't be used for writes, except when updating the information in the cache.

17.2.5.2 Can memcached work with ASPX?

There are ports and interfaces for many languages and environments. ASPX relies on an underlying language such as C# or VisualBasic, and if you are using ASP.NET then there is a C# memcached library. For more information, see <https://sourceforge.net/projects/memcacheddotnet/>.

17.2.5.3 How expensive is it to establish a memcache connection? Should those connections be pooled?

Opening the connection is relatively inexpensive, because there is no security, authentication or other handshake taking place before you can start sending requests and getting results. Most APIs support a persistent connection to a memcached instance to reduce the latency. Connection pooling would depend on the API you are using, but if you are communicating directly over TCP/IP, then connection pooling would provide some small performance benefit.

17.2.5.4 How is the data handled when the memcached server is down?

The behavior is entirely application dependent. Most applications fall back to loading the data from the database (just as if they were updating the memcached information). If you are using multiple memcached servers, you might also remove a downed server from the list to prevent it from affecting performance. Otherwise, the client will still attempt to communicate with the memcached server that corresponds to the key you are trying to load.

17.2.5.5 How are auto-increment columns in the MySQL database coordinated across multiple instances of memcached?

They aren't. There is no relationship between MySQL and memcached unless your application (or, if you are using the MySQL UDFs for memcached, your database definition) creates one.

If you are storing information based on an auto-increment key into multiple instances of memcached, the information is only stored on one of the memcached instances anyway. The client uses the key value to determine which memcached instance to store the information. It doesn't store the same information across all the instances, as that would be a waste of cache memory.

17.2.5.6 Is compression available?

Yes. Most of the client APIs support some sort of compression, and some even allow you to specify the threshold at which a value is deemed appropriate for compression during storage.

17.2.5.7 Can we implement different types of memcached as different nodes in the same server, so can there be deterministic and non-deterministic in the same server?

Yes. You can run multiple instances of [memcached](#) on a single server, and in your client configuration you choose the list of servers you want to use.

17.2.5. What are best practices for testing an implementation, to ensure that it improves performance, and to measure the impact of [memcached](#) configuration changes? And would you recommend keeping the configuration very simple to start?

The best way to test the performance is to start up a [memcached](#) instance. First, modify your application so that it stores the data just before the data is about to be used or displayed into [memcached](#). Since the APIs handle the serialization of the data, it should just be a one-line modification to your code. Then, modify the start of the process that would normally load that information from MySQL with the code that requests the data from [memcached](#). If the data cannot be loaded from [memcached](#), default to the MySQL process.

All of the changes required will probably amount to just a few lines of code. To get the best benefit, make sure you cache entire objects (for example, all the components of a web page, blog post, discussion thread, and so on), rather than using [memcached](#) as a simple cache of individual rows of MySQL tables.

Keeping the configuration simple at the start, or even over the long term, is easy with [memcached](#). Once you have the basic structure up and running, often the only ongoing change is to add more servers into the list of servers used by your applications. You don't need to manage the [memcached](#) servers, and there is no complex configuration; just add more servers to the list and let the client API and the [memcached](#) servers make the decisions.

Replication enables data from one MySQL database server (the master) to be copied to one or more MySQL database servers (the slaves). Replication is asynchronous by default; slaves do not need to be connected permanently to receive updates from the master. Depending on the configuration, you can replicate all databases, selected databases, or even selected tables within a database.

Advantages of replication in MySQL include:

- Scale-out solutions - spreading the load among multiple slaves to improve performance. In this environment, all writes and updates must take place on the master server. Reads, however, may take place on one or more slaves. This model can improve the performance of writes (since the master is dedicated to updates), while dramatically increasing read speed across an increasing number of slaves.
- Data security - because data is replicated to the slave, and the slave can pause the replication process, it is possible to run backup services on the slave without corrupting the corresponding master data.
- Analytics - live data can be created on the master, while the analysis of the information can take place on the slave without affecting the performance of the master.

- Long-distance data distribution - you can use replication to create a local copy of data for a remote site to use, without permanent access to the master.

For information on how to use replication in such scenarios, see [Section 18.3, “Replication Solutions”](#).

MySQL 8.0 supports different methods of replication. The traditional method is based on replicating events from the master's binary log, and requires the log files and positions in them to be synchronized between master and slave. The newer method based on *global transaction identifiers* (GTIDs) is transactional and therefore does not require working with log files or positions within these files, which greatly simplifies many common replication tasks. Replication using GTIDs guarantees consistency between master and slave as long as all transactions committed on the master have also been applied on the slave. For more information about GTIDs and GTID-based replication in MySQL, see [Section 18.1.3, “Replication with Global Transaction Identifiers”](#). For information on using binary log file position based replication, see [Section 18.1, “Configuring Replication”](#).

Replication in MySQL supports different types of synchronization. The original type of synchronization is one-way, asynchronous replication, in which one server acts as the master, while one or more other servers act as slaves. In MySQL 8.0, semisynchronous replication is supported in addition to the built-in asynchronous replication. With semisynchronous replication, a commit performed on the master blocks before returning to the session that performed the transaction until at least one slave acknowledges that it has received and logged the events for the transaction; see [Section 18.3.10, “Semisynchronous Replication”](#). MySQL 8.0 also supports delayed replication such that a slave server deliberately lags behind the master by at least a specified amount of time; see [Section 18.3.11, “Delayed Replication”](#). For scenarios where *synchronous* replication is required, use MySQL Cluster (see [MySQL NDB Cluster 7.5 and NDB Cluster 7.6](#)).

There are a number of solutions available for setting up replication between servers, and the best method to use depends on the presence of data and the engine types you are using. For more information on the available options, see [Section 18.1.2, “Setting Up Binary Log File Position Based Replication”](#).

There are two core types of replication format, Statement Based Replication (SBR), which replicates entire SQL statements, and Row Based Replication (RBR), which replicates only the changed rows. You can also use a third variety, Mixed Based Replication (MBR). For more information on the different replication formats, see [Section 18.2.1, “Replication Formats”](#).

Replication is controlled through a number of different options and variables. For more information, see [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).

You can use replication to solve a number of different problems, including performance, supporting the backup of different databases, and as part of a larger solution to alleviate system failures. For information on how to address these issues, see [Section 18.3, “Replication Solutions”](#).

For notes and tips on how different data types and statements are treated during replication, including details of replication features, version compatibility, upgrades, and potential problems and their resolution, see [Section 18.4, “Replication Notes and Tips”](#). For answers to some questions often asked by those who are new to MySQL Replication, see [Section A.13, “MySQL 8.0 FAQ: Replication”](#).

For detailed information on the implementation of replication, how replication works, the process and contents of the binary log, background threads and the rules used to decide how statements are recorded and replicated, see [Section 18.2, “Replication Implementation”](#).

18.1 Configuring Replication

This section describes how to configure the different types of replication available in MySQL and includes the setup and configuration required for a replication environment, including step-by-step instructions for creating a new replication environment. The major components of this section are:

- For a guide to setting up two or more servers for replication using binary log file positions, [Section 18.1.2, “Setting Up Binary Log File Position Based Replication”](#), deals with the configuration of the servers and provides methods for copying data between the master and slaves.

- For a guide to setting up two or more servers for replication using GTID transactions, [Section 18.1.3, “Replication with Global Transaction Identifiers”](#), deals with the configuration of the servers.
- Events in the binary log are recorded using a number of formats. These are referred to as statement-based replication (SBR) or row-based replication (RBR). A third type, mixed-format replication (MIXED), uses SBR or RBR replication automatically to take advantage of the benefits of both SBR and RBR formats when appropriate. The different formats are discussed in [Section 18.2.1, “Replication Formats”](#).
- Detailed information on the different configuration options and variables that apply to replication is provided in [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).
- Once started, the replication process should require little administration or monitoring. However, for advice on common tasks that you may want to execute, see [Section 18.1.7, “Common Replication Administration Tasks”](#).

18.1.1 Binary Log File Position Based Replication Configuration Overview

This section describes replication between MySQL servers based on the binary log file position method, where the MySQL instance operating as the master (the source of the database changes) writes updates and changes as “events” to the binary log. The information in the binary log is stored in different logging formats according to the database changes being recorded. Slaves are configured to read the binary log from the master and to execute the events in the binary log on the slave’s local database.

Each slave receives a copy of the entire contents of the binary log. It is the responsibility of the slave to decide which statements in the binary log should be executed. Unless you specify otherwise, all events in the master binary log are executed on the slave. If required, you can configure the slave to process only events that apply to particular databases or tables.

Important

You cannot configure the master to log only certain events.

Each slave keeps a record of the binary log coordinates: the file name and position within the file that it has read and processed from the master. This means that multiple slaves can be connected to the master and executing different parts of the same binary log. Because the slaves control this process, individual slaves can be connected and disconnected from the server without affecting the master’s operation. Also, because each slave records the current position within the binary log, it is possible for slaves to be disconnected, reconnect and then resume processing.

The master and each slave must be configured with a unique ID (using the `server-id` option). In addition, each slave must be configured with information about the master host name, log file name, and position within that file. These details can be controlled from within a MySQL session using the `CHANGE MASTER TO` statement on the slave. The details are stored within the slave’s master info repository, which can be either a file or a table (see [Section 18.2.4, “Replication Relay and Status Logs”](#)).

18.1.2 Setting Up Binary Log File Position Based Replication

This section describes how to set up a MySQL server to use binary log file position based replication. There are a number of different methods for setting up replication, and the exact method to use depends on how you are setting up replication, and whether you already have data within your master database.

There are some generic tasks that are common to all setups:

- On the master, you must enable binary logging and configure a unique server ID. This might require a server restart. See [Section 18.1.2.1, “Setting the Replication Master Configuration”](#).

- On each slave that you want to connect to the master, you must configure a unique server ID. This might require a server restart. See [Section 18.1.2.2, “Setting the Replication Slave Configuration”](#).
- Optionally, create a separate user for your slaves to use during authentication with the master when reading the binary log for replication. See [Section 18.1.2.3, “Creating a User for Replication”](#).
- Before creating a data snapshot or starting the replication process, on the master you should record the current position in the binary log. You need this information when configuring the slave so that the slave knows where within the binary log to start executing events. See [Section 18.1.2.4, “Obtaining the Replication Master Binary Log Coordinates”](#).
- If you already have data on the master and want to use it to synchronize the slave, you need to create a data snapshot to copy the data to the slave. The storage engine you are using has an impact on how you create the snapshot. When you are using [MyISAM](#), you must stop processing statements on the master to obtain a read-lock, then obtain its current binary log coordinates and dump its data, before permitting the master to continue executing statements. If you do not stop the execution of statements, the data dump and the master status information will not match, resulting in inconsistent or corrupted databases on the slaves. For more information on replicating a [MyISAM](#) master, see [Section 18.1.2.4, “Obtaining the Replication Master Binary Log Coordinates”](#). If you are using [InnoDB](#), you do not need a read-lock and a transaction that is long enough to transfer the data snapshot is sufficient. For more information, see [Section 15.18, “InnoDB and MySQL Replication”](#).
- Configure the slave with settings for connecting to the master, such as the host name, login credentials, and binary log file name and position. See [Section 18.1.2.7, “Setting the Master Configuration on the Slave”](#).

Note

Certain steps within the setup process require the [SUPER](#) privilege. If you do not have this privilege, it might not be possible to enable replication.

After configuring the basic options, select your scenario:

- To set up replication for a fresh installation of a master and slaves that contain no data, see [Setting Up Replication with New Master and Slaves](#).
- To set up replication of a new master using the data from an existing MySQL server, see [Setting Up Replication with Existing Data](#).
- To add replication slaves to an existing replication environment, see [Section 18.1.2.8, “Adding Slaves to a Replication Environment”](#).

Before administering MySQL replication servers, read this entire chapter and try all statements mentioned in [Section 13.4.1, “SQL Statements for Controlling Master Servers”](#), and [Section 13.4.2, “SQL Statements for Controlling Slave Servers”](#). Also familiarize yourself with the replication startup options described in [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).

18.1.2.1 Setting the Replication Master Configuration

To configure a master to use binary log file position based replication, you must enable binary logging and establish a unique server ID. If this has not already been done, a server restart is required.

Binary logging *must* be enabled on the master because the binary log is the basis for replicating changes from the master to its slaves. If binary logging is not enabled on the master using the `log-bin` option, replication is not possible.

Each server within a replication group must be configured with a unique server ID. This ID is used to identify individual servers within the group, and must be a positive integer between 1 and $(2^{32})-1$. How you organize and select the numbers is your choice.

To configure the binary log and server ID options, shut down the MySQL server and edit the `my.cnf` or `my.ini` file. Within the `[mysqld]` section of the configuration file, add the `log-bin` and `server-id`

options. If these options already exist, but are commented out, uncomment the options and alter them according to your needs. For example, to enable binary logging using a log file name prefix of `mysql-bin`, and configure a server ID of 1, use these lines:

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

After making the changes, restart the server.

Note

The following options have an impact on this procedure:

- if you omit `server-id` (or set it explicitly to its default value of 0), the master refuses any connections from slaves.
- For the greatest possible durability and consistency in a replication setup using `InnoDB` with transactions, you should use `innodb_flush_log_at_trx_commit=1` and `sync_binlog=1` in the master `my.cnf` file.
- Ensure that the `skip-networking` option is not enabled on your replication master. If networking has been disabled, the slave can not communicate with the master and replication fails.

18.1.2.2 Setting the Replication Slave Configuration

Each replication slave *must* have a unique server ID. If this has not already been done, this part of slave setup requires a server restart.

If the slave server ID is not already set, or the current value conflicts with the value that you have chosen for the master server, shut down the slave server and edit the `[mysqld]` section of the configuration file to specify a unique server ID. For example:

```
[mysqld]
server-id=2
```

After making the changes, restart the server.

If you are setting up multiple slaves, each one must have a unique `server-id` value that differs from that of the master and from any of the other slaves.

Note

If you omit `server-id` (or set it explicitly to its default value of 0), the slave refuses to connect to a master.

You do not have to enable binary logging on the slave for replication to be set up. However, if you enable binary logging on the slave, you can use the slave's binary log for data backups and crash recovery, and also use the slave as part of a more complex replication topology. For example, where this slave then acts as a master to other slaves.

18.1.2.3 Creating a User for Replication

Each slave connects to the master using a MySQL user name and password, so there must be a user account on the master that the slave can use to connect. Any account can be used for this operation, providing it has been granted the `REPLICATION SLAVE` privilege. You can choose to create a different account for each slave, or connect to the master using the same account for each slave.

Although you do not have to create an account specifically for replication, you should be aware that the replication user name and password are stored in plain text in the master info repository file or table

(see [Section 18.2.4.2, “Slave Status Logs”](#)). Therefore, you may want to create a separate account that has privileges only for the replication process, to minimize the possibility of compromise to other accounts.

To create a new account, use `CREATE USER`. To grant this account the privileges required for replication, use the `GRANT` statement. If you create an account solely for the purposes of replication, that account needs only the `REPLICATION SLAVE` privilege. For example, to set up a new user, `repl`, that can connect for replication from any host within the `mydomain.com` domain, issue these statements on the master:

```
mysql> CREATE USER 'repl'@'%.mydomain.com' IDENTIFIED BY 'slavepass';
mysql> GRANT REPLICATION SLAVE ON *.* TO 'repl'@'%.mydomain.com';
```

See [Section 13.7.1, “Account Management Statements”](#), for more information on statements for manipulation of user accounts.

18.1.2.4 Obtaining the Replication Master Binary Log Coordinates

To configure the slave to start the replication process at the correct point, you need to note the master's current coordinates within its binary log.

Warning

This procedure uses `FLUSH TABLES WITH READ LOCK`, which blocks `COMMIT` operations for `InnoDB` tables.

To obtain the master binary log coordinates, follow these steps:

1. Start a session on the master by connecting to it with the command-line client, and flush all tables and block write statements by executing the `FLUSH TABLES WITH READ LOCK` statement:

```
mysql> FLUSH TABLES WITH READ LOCK;
```

Warning

Leave the client from which you issued the `FLUSH TABLES` statement running so that the read lock remains in effect. If you exit the client, the lock is released.

2. In a different session on the master, use the `SHOW MASTER STATUS` statement to determine the current binary log file name and position:

```
mysql > SHOW MASTER STATUS;
+-----+-----+-----+-----+
| File           | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+-----+-----+-----+-----+
| mysql-bin.000003 | 73      | test        | manual,mysql     |
+-----+-----+-----+-----+
```

The `File` column shows the name of the log file and the `Position` column shows the position within the file. In this example, the binary log file is `mysql-bin.000003` and the position is 73. Record these values. You need them later when you are setting up the slave. They represent the replication coordinates at which the slave should begin processing new updates from the master.

If the master has been running previously without binary logging enabled, the log file name and position values displayed by `SHOW MASTER STATUS` or `mysqldump --master-data` will be empty. In that case, the values that you need to use later when specifying the slave's log file and position are the empty string (' ') and 4.

You now have the information you need to enable the slave to start reading from the binary log in the correct place to start replication.

The next step depends on whether you have existing data on the master. Choose one of the following options:

- If you have existing data that needs to be synchronized with the slave before you start replication, leave the client running so that the lock remains in place. This prevents any further changes being made, so that the data copied to the slave is in synchrony with the master. Proceed to [Section 18.1.2.5, “Choosing a Method for Data Snapshots”](#).
- If you are setting up a new master and slave replication group, you can exit the first session to release the read lock. See [Setting Up Replication with New Master and Slaves](#) for how to proceed.

18.1.2.5 Choosing a Method for Data Snapshots

If the master database contains existing data it is necessary to copy this data to each slave. There are different ways to dump the data from the master database. The following sections describe possible options.

To select the appropriate method of dumping the database, choose between these options:

- Use the `mysqldump` tool to create a dump of all the databases you want to replicate. This is the recommended method, especially when using `InnoDB`.
- If your database is stored in binary portable files, you can copy the raw data files to a slave. This can be more efficient than using `mysqldump` and importing the file on each slave, because it skips the overhead of updating indexes as the `INSERT` statements are replayed. With storage engines such as `InnoDB` this is not recommended.

Creating a Data Snapshot Using `mysqldump`

To create a snapshot of the data in an existing master database, use the `mysqldump` tool. Once the data dump has been completed, import this data into the slave before starting the replication process.

The following example dumps all databases to a file named `dbdump.db`, and includes the `--master-data` option which automatically appends the `CHANGE MASTER TO` statement required on the slave to start the replication process:

```
shell> mysqldump --all-databases --master-data > dbdump.db
```

Note

If you do not use `--master-data`, then it is necessary to lock all tables in a separate session manually. See [Section 18.1.2.4, “Obtaining the Replication Master Binary Log Coordinates”](#).

It is possible to exclude certain databases from the dump using the `mysqldump` tool. If you want to choose which databases to include in the dump, do not use `--all-databases`. Choose one of these options:

- Exclude all the tables in the database using `--ignore-table` option.
- Name only those databases which you want dumped using the `--databases` option.

For more information, see [Section 4.5.4, “mysqldump — A Database Backup Program”](#).

To import the data, either copy the dump file to the slave, or access the file from the master when connecting remotely to the slave.

Creating a Data Snapshot Using Raw Data Files

This section describes how to create a data snapshot using the raw files which make up the database. Employing this method with a table using a storage engine that has complex caching or logging algorithms requires extra steps to produce a perfect “point in time” snapshot: the initial copy command

could leave out cache information and logging updates, even if you have acquired a global read lock. How the storage engine responds to this depends on its crash recovery abilities.

If you use `InnoDB` tables, you can use the `mysqlbackup` command from the MySQL Enterprise Backup component to produce a consistent snapshot. This command records the log name and offset corresponding to the snapshot to be used on the slave. MySQL Enterprise Backup is a commercial product that is included as part of a MySQL Enterprise subscription. See [Section 29.2, “MySQL Enterprise Backup Overview”](#) for detailed information.

This method also does not work reliably if the master and slave have different values for `ft_stopword_file`, `ft_min_word_len`, or `ft_max_word_len` and you are copying tables having full-text indexes.

Assuming the above exceptions do not apply to your database, use the `cold backup` technique to obtain a reliable binary snapshot of `InnoDB` tables: do a `slow shutdown` of the MySQL Server, then copy the data files manually.

To create a raw data snapshot of `MyISAM` tables when your MySQL data files exist on a single file system, you can use standard file copy tools such as `cp` or `copy`, a remote copy tool such as `sftp` or `rsync`, an archiving tool such as `zip` or `tar`, or a file system snapshot tool such as `dump`. If you are replicating only certain databases, copy only those files that relate to those tables. For `InnoDB`, all tables in all databases are stored in the `system tablespace` files, unless you have the `innodb_file_per_table` option enabled.

The following files are not required for replication:

- Files relating to the `mysql` database.
- The master info repository file, if used (see [Section 18.2.4, “Replication Relay and Status Logs”](#)).
- The master's binary log files.
- Any relay log files.

Depending on whether you are using `InnoDB` tables or not, choose one of the following:

If you are using `InnoDB` tables, and also to get the most consistent results with a raw data snapshot, shut down the master server during the process, as follows:

1. Acquire a read lock and get the master's status. See [Section 18.1.2.4, “Obtaining the Replication Master Binary Log Coordinates”](#).
2. In a separate session, shut down the master server:

```
shell> mysqladmin shutdown
```

3. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

4. Restart the master server.

If you are not using `InnoDB` tables, you can get a snapshot of the system from a master without shutting down the server as described in the following steps:

1. Acquire a read lock and get the master's status. See [Section 18.1.2.4, “Obtaining the Replication Master Binary Log Coordinates”](#).
2. Make a copy of the MySQL data files. The following examples show common ways to do this. You need to choose only one of them:

```
shell> tar cf /tmp/db.tar ./data
shell> zip -r /tmp/db.zip ./data
shell> rsync --recursive ./data /tmp/dbdata
```

3. In the client where you acquired the read lock, release the lock:

```
mysql> UNLOCK TABLES;
```

Once you have created the archive or copy of the database, copy the files to each slave before starting the slave replication process.

18.1.2.6 Setting Up Replication Slaves

The following sections describe how to set up slaves. Before you proceed, ensure that you have:

- Configured the MySQL master with the necessary configuration properties. See [Section 18.1.2.1, “Setting the Replication Master Configuration”](#).
- Obtained the master status information. See [Section 18.1.2.4, “Obtaining the Replication Master Binary Log Coordinates”](#).
- On the master, released the read lock:

```
mysql> UNLOCK TABLES;
```

- On the slave, edited the MySQL configuration. See [Section 18.1.2.2, “Setting the Replication Slave Configuration”](#).

The next steps depend on whether you have existing data to import to the slave or not. See [Section 18.1.2.5, “Choosing a Method for Data Snapshots”](#) for more information. Choose one of the following:

- If you do not have a snapshot of a database to import, see [Setting Up Replication with New Master and Slaves](#).
- If you have a snapshot of a database to import, see [Setting Up Replication with Existing Data](#).

Setting Up Replication with New Master and Slaves

When there is no snapshot of a previous database to import, configure the slave to start the replication from the new master.

To set up replication between a master and a new slave:

1. Start up the MySQL slave.
2. Execute a `CHANGE MASTER TO` statement to set the master replication server configuration. See [Section 18.1.2.7, “Setting the Master Configuration on the Slave”](#).

Perform these slave setup steps on each slave.

This method can also be used if you are setting up new servers but have an existing dump of the databases from a different server that you want to load into your replication configuration. By loading the data into a new master, the data is automatically replicated to the slaves.

If you are setting up a new replication environment using the data from a different existing database server to create a new master, run the dump file generated from that server on the new master. The database updates are automatically propagated to the slaves:

```
shell> mysql -h master < fulldb.dump
```

Setting Up Replication with Existing Data

When setting up replication with existing data, transfer the snapshot from the master to the slave before starting replication. The process for importing data to the slave depends on how you created the snapshot of data on the master.

Choose one of the following:

If you used `mysqldump`:

1. Start the slave, using the `--skip-slave-start` option so that replication does not start.
2. Import the dump file:

```
shell> mysql < fulldb.dump
```

If you created a snapshot using the raw data files:

1. Extract the data files into your slave data directory. For example:

```
shell> tar xvf dbdump.tar
```

You may need to set permissions and ownership on the files so that the slave server can access and modify them.

2. Start the slave, using the `--skip-slave-start` option so that replication does not start.
3. Configure the slave with the replication coordinates from the master. This tells the slave the binary log file and position within the file where replication needs to start. Also, configure the slave with the login credentials and host name of the master. For more information on the `CHANGE MASTER TO` statement required, see [Section 18.1.2.7, “Setting the Master Configuration on the Slave”](#).
4. Start the slave threads:

```
mysql> START SLAVE;
```

After you have performed this procedure, the slave connects to the master and replicates any updates that have occurred on the master since the snapshot was taken.

If you have forgotten to set the `server-id` option for the master, slaves cannot connect to it.

If you have forgotten to set the `server-id` option for the slave, you get the following error in the slave's error log:

```
Warning: You should set server-id to a non-0 value if master_host
is set; we will force server id to 2, but this MySQL server will
not act as a slave.
```

You also find error messages in the slave's error log if it is not able to replicate for any other reason.

The slave uses information stored in its master info repository to keep track of how much of the master's binary log it has processed. The repository can be in the form of files or a table, as determined by the value set for `--master-info-repository`. When a slave runs with `--master-info-repository=FILE`, you can find in its data directory two files, named `master.info` and `relay-log.info`. If `--master-info-repository=TABLE` instead, this information is saved in the table `master_slave_info` in the `mysql` database. In either case, do *not* remove or edit the files or table unless you know exactly what you are doing and fully understand the implications. Even in that case, it is preferred that you use the `CHANGE MASTER TO` statement to change replication parameters. The slave can use the values specified in the statement to update the status files automatically. See [Section 18.2.4, “Replication Relay and Status Logs”](#), for more information.

**Note**

The contents of the master info repository override some of the server options specified on the command line or in `my.cnf`. See [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#), for more details.

A single snapshot of the master suffices for multiple slaves. To set up additional slaves, use the same master snapshot and follow the slave portion of the procedure just described.

18.1.2.7 Setting the Master Configuration on the Slave

To set up the slave to communicate with the master for replication, configure the slave with the necessary connection information. To do this, execute the following statement on the slave, replacing the option values with the actual values relevant to your system:

```
mysql> CHANGE MASTER TO
->     MASTER_HOST='master_host_name',
->     MASTER_USER='replication_user_name',
->     MASTER_PASSWORD='replication_password',
->     MASTER_LOG_FILE='recorded_log_file_name',
->     MASTER_LOG_POS=recorded_log_position;
```

**Note**

Replication cannot use Unix socket files. You must be able to connect to the master MySQL server using TCP/IP.

The `CHANGE MASTER TO` statement has other options as well. For example, it is possible to set up secure replication using SSL. For a full list of options, and information about the maximum permissible length for the string-valued options, see [Section 13.4.2.1, “CHANGE MASTER TO Syntax”](#).

18.1.2.8 Adding Slaves to a Replication Environment

You can add another slave to an existing replication configuration without stopping the master. Instead, set up the new slave by making a copy of an existing slave, except that you configure the new slave with a different `server-id` value.

To duplicate an existing slave:

1. Shut down the existing slave:

```
shell> mysqladmin shutdown
```

2. Copy the data directory from the existing slave to the new slave. You can do this by creating an archive using `tar` or `WinZip`, or by performing a direct copy using a tool such as `cp` or `rsync`. Ensure that you also copy the log files and relay log files.

A common problem that is encountered when adding new replication slaves is that the new slave fails with a series of warning and error messages like these:

```
071118 16:44:10 [Warning] Neither --relay-log nor --relay-log-index were used; so
replication may break when this MySQL server acts as a slave and has his hostname
changed!! Please use '--relay-log=new_slave_hostname-relay-bin' to avoid this problem.
071118 16:44:10 [ERROR] Failed to open the relay log './old_slave_hostname-relay-bin.003525'
(relay_log_pos 22940879)
071118 16:44:10 [ERROR] Could not find target log during relay log initialization
071118 16:44:10 [ERROR] Failed to initialize the master info structure
```

This situation can occur if the `--relay-log` option is not specified, as the relay log files contain the host name as part of their file names. This is also true of the relay log index file if the `--relay-log-index` option is not used. See [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#), for more information about these options.

To avoid this problem, use the same value for `--relay-log` on the new slave that was used on the existing slave. If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin`. If this is not possible, copy the existing slave's relay log index file to the new slave and set the `--relay-log-index` option on the new slave to match what was used on the existing slave. If this option was not set explicitly on the existing slave, use `existing_slave_hostname-relay-bin.index`. Alternatively, if you have already tried to start the new slave after following the remaining steps in this section and have encountered errors like those described previously, then perform the following steps:

- a. If you have not already done so, issue a `STOP SLAVE` on the new slave.

If you have already started the existing slave again, issue a `STOP SLAVE` on the existing slave as well.
 - b. Copy the contents of the existing slave's relay log index file into the new slave's relay log index file, making sure to overwrite any content already in the file.
 - c. Proceed with the remaining steps in this section.
3. Copy the master info and relay log info repositories (see [Section 18.2.4, "Replication Relay and Status Logs"](#)) from the existing slave to the new slave. These hold the current log coordinates for the master's binary log and the slave's relay log.
 4. Start the existing slave.
 5. On the new slave, edit the configuration and give the new slave a unique `server-id` not used by the master or any of the existing slaves.
 6. Start the new slave. The slave uses the information in its master info repository to start the replication process.

18.1.3 Replication with Global Transaction Identifiers

This section explains transaction-based replication using *global transaction identifiers* (GTIDs). When using GTIDs, each transaction can be identified and tracked as it is committed on the originating server and applied by any slaves; this means that it is not necessary when using GTIDs to refer to log files or positions within those files when starting a new slave or failing over to a new master, which greatly simplifies these tasks. Because GTID-based replication is completely transaction-based, it is simple to determine whether masters and slaves are consistent; as long as all transactions committed on a master are also committed on a slave, consistency between the two is guaranteed. You can use either statement-based or row-based replication with GTIDs (see [Section 18.2.1, "Replication Formats"](#)); however, for best results, we recommend that you use the row-based format.

This section discusses the following topics:

- How GTIDs are defined and created, and how they are represented in the MySQL Server (see [Section 18.1.3.1, "GTID Concepts"](#)).
- A general procedure for setting up and starting GTID-based replication (see [Section 18.1.3.2, "Setting Up Replication Using GTIDs"](#)).
- Suggested methods for provisioning new replication servers when using GTIDs (see [Section 18.1.3.3, "Using GTIDs for Failover and Scaleout"](#)).
- Restrictions and limitations that you should be aware of when using GTID-based replication (see [Section 18.1.3.4, "Restrictions on Replication with GTIDs"](#)).

For information about MySQL Server options and variables relating to GTID-based replication, see [Section 18.1.6.5, "Global Transaction ID Options and Variables"](#). See also [Section 12.17, "Functions Used with Global Transaction IDs"](#), which describes SQL functions supported by MySQL 8.0 for use with GTIDs.

18.1.3.1 GTID Concepts

A global transaction identifier (GTID) is a unique identifier created and associated with each transaction committed on the server of origin (master). This identifier is unique not only to the server on which it originated, but is unique across all servers in a given replication setup. There is a 1-to-1 mapping between all transactions and all GTIDs.

The following paragraphs provide a basic description of GTIDs. More advanced concepts are covered later in the following sections:

- [GTID Sets](#)
- [mysql.gtid_executed Table](#)
- [mysql.gtid_executed Table Compression](#)

A GTID is represented as a pair of coordinates, separated by a colon character (:), as shown here:

```
GTID = source_id:transaction_id
```

The *source_id* identifies the originating server. Normally, the server's *server_uuid* is used for this purpose. The *transaction_id* is a sequence number determined by the order in which the transaction was committed on this server; for example, the first transaction to be committed has `1` as its *transaction_id*, and the tenth transaction to be committed on the same originating server is assigned a *transaction_id* of `10`. It is not possible for a transaction to have `0` as a sequence number in a GTID. For example, the twenty-third transaction to be committed originally on the server with the UUID `3E11FA47-71CA-11E1-9E33-C80AA9429562` has this GTID:

```
3E11FA47-71CA-11E1-9E33-C80AA9429562:23
```

This format is used to represent GTIDs in the output of statements such as `SHOW SLAVE STATUS` as well as in the binary log. They can also be seen when viewing the log file with `mysqlbinlog --base64-output=DECODE-ROWS` or in the output from `SHOW BINLOG EVENTS`.

As written in the output of statements such as `SHOW MASTER STATUS` or `SHOW SLAVE STATUS`, a sequence of GTIDs originating from the same server may be collapsed into a single expression, as shown here.

```
3E11FA47-71CA-11E1-9E33-C80AA9429562:1-5
```

The example just shown represents the first through fifth transactions originating on the MySQL Server whose *server_uuid* is `3E11FA47-71CA-11E1-9E33-C80AA9429562`.

This format is also used to supply the argument required by the `START SLAVE` options `SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS`.

GTID Sets

A GTID set is a set of global transaction identifiers which is represented as shown here:

```
gtid_set:
  uuid_set [, uuid_set] ...
  | ''

uuid_set:
  uuid:interval[:interval]...

uuid:
  hhhhhhhh-hhhh-hhhh-hhhh-hhhhhhhhhhhh

h:
```

```
[0-9|A-F]
interval:
  n[-n]
  (n >= 1)
```

GTID sets are used in the MySQL Server in several ways. For example, the values stored by the `gtid_executed` and `gtid_purged` system variables are represented as GTID sets. In addition, the functions `GTID_SUBSET()` and `GTID_SUBTRACT()` require GTID sets as input. When GTID sets are returned from server variables, UUIDs are in alphabetical order and numeric intervals are merged and in ascending order.

GTIDs are always preserved between master and slave. This means that you can always determine the source for any transaction applied on any slave by examining its binary log. In addition, once a transaction with a given GTID is committed on a given server, any subsequent transaction having the same GTID is ignored by that server. Thus, a transaction committed on the master can be applied no more than once on the slave, which helps to guarantee consistency.

When GTIDs are in use, the slave has no need for any nonlocal data, such as the name of a file on the master and a position within that file. All necessary information for synchronizing with the master is obtained directly from the replication data stream. GTIDs replace the file-offset pairs previously required to determine points for starting, stopping, or resuming the flow of data between master and slave. therefore, do not include `MASTER_LOG_FILE` or `MASTER_LOG_POS` options in the `CHANGE MASTER TO` statement used to direct a slave to replicate from a given master; instead it is necessary only to enable the `MASTER_AUTO_POSITION` option. For the exact steps needed to configure and start masters and slaves using GTID-based replication, see [Section 18.1.3.2, “Setting Up Replication Using GTIDs”](#).

The generation and life cycle of a GTID consist of the following steps:

1. A transaction is executed and committed on the master.

This transaction is assigned a GTID using the master's UUID and the smallest nonzero transaction sequence number not yet used on this server; the GTID is written to the master's binary log (immediately preceding the transaction itself in the log).

2. After the binary log data is transmitted to the slave and stored in the slave's relay log (using established mechanisms for this process—see [Section 18.2, “Replication Implementation”](#), for details), the slave reads the GTID and sets the value of its `gtid_next` system variable as this GTID. This tells the slave that the next transaction must be logged using this GTID.

It is important to note that the slave sets `gtid_next` in a session context.

3. The slave verifies that this GTID has not already been used to log a transaction in its own binary log. If this GTID has not been used, the slave then writes the GTID, applies the transaction, and writes the transaction to its binary log. By reading and checking the transaction's GTID first, before processing the transaction itself, the slave guarantees not only that no previous transaction having this GTID has been applied on the slave, but also that no other session has already read this GTID but has not yet committed the associated transaction. In other words, multiple clients are not permitted to apply the same transaction concurrently.
4. Because `gtid_next` is not empty, the slave does not attempt to generate a GTID for this transaction but instead writes the GTID stored in this variable—that is, the GTID obtained from the master—immediately preceding the transaction in its binary log.

mysql.gtid_executed Table

GTIDs are stored in a table named `gtid_executed`, in the `mysql` database. A row in this table contains, for each GTID or set of GTIDs that it represents, the UUID of the originating server, and the starting and ending transaction IDs of the set; for a row referencing only a single GTID, these last two values are the same.

The `mysql.gtid_executed` table is created (if it does not already exist) when the MySQL Server is installed or upgraded, using a `CREATE TABLE` statement similar to that shown here:

```
CREATE TABLE gtid_executed (
  source_uuid CHAR(36) NOT NULL,
  interval_start BIGINT(20) NOT NULL,
  interval_end BIGINT(20) NOT NULL,
  PRIMARY KEY (source_uuid, interval_start)
)
```

Warning

As with other MySQL system tables, do not attempt to create or modify this table yourself.

GTIDs are stored in the `mysql.gtid_executed` table only when `gtid_mode` is `ON` or `ON_PERMISSIVE`. GTIDs are stored in this table without regard to whether binary logging is enabled. However, the manner in which they are stored differs depending on whether `log_bin` is `ON` or `OFF`:

- If binary logging is disabled (`log_bin` is `OFF`), the server stores the GTID belonging to each transaction together with the transaction in the table.

In addition, when binary logging is disabled, this table is compressed periodically at a user-configurable rate; see [mysql.gtid_executed Table Compression](#), for more information.

- If binary logging is enabled (`log_bin` is `ON`), then in addition to storing the GTIDs in `mysql.gtid_executed`, whenever the binary log is rotated or the server is shut down, the server writes GTIDs for all transactions that were written into the previous binary log into the new binary log.

In the event of the server stopping unexpectedly, the set of GTIDs from the previous binary log is not saved in the `mysql.gtid_executed` table. In this case, these GTIDs are added to the table and to the set of GTIDs in the `gtid_executed` system variable during recovery.

The `mysql.gtid_executed` table is reset by `RESET MASTER`.

mysql.gtid_executed Table Compression

Over the course of time, the `mysql.gtid_executed` table can become filled with many rows referring to individual GTIDs that originate on the same server, and whose transaction IDs make up a sequence, similar to what is shown here:

```
mysql> SELECT * FROM mysql.gtid_executed;
+-----+-----+-----+
| source_uuid | interval_start | interval_end |
+-----+-----+-----+
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 37 | 37 |
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 38 | 38 |
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 39 | 39 |
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 40 | 40 |
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 41 | 41 |
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 42 | 42 |
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 43 | 43 |
| ... | ... | ... |
```

Considerable space can be saved if this table is compressed periodically by replacing each such set of rows with a single row that spans the entire interval of transaction identifiers, like this:

```
+-----+-----+-----+
| source_uuid | interval_start | interval_end |
+-----+-----+-----+
| 3E11FA47-71CA-11E1-9E33-C80AA9429562 | 37 | 43 |
| ... | ... | ... |
```

When GTIDs are enabled, the server performs this type of compression on the `mysql.gtid_executed` table periodically. You can control the number of transactions that are allowed to elapse before the table is compressed, and thus the compression rate, by setting the `executed_gtids_compression_period` system variable. This variable's default value is 1000; this means that, by default, compression of the table is performed after each 1000 transactions. Setting `executed_gtid_compression_period` to 0 prevents the compression from being performed at all; however, you should be prepared for a potentially large increase in the amount of disk space that may be required by the `gtid_executed` table if you do this.

Note

When binary logging is enabled, the value of `executed_gtids_compression_period` is *not* used and the `mysql.gtid_executed` table is compressed on each binary log rotation.

Compression of the `mysql.gtid_executed` table is performed by a dedicated foreground thread that is created whenever GTIDs are enabled on the server. This thread is not listed in the output of `SHOW PROCESSLIST`, but it can be viewed as a row in the `threads` table, as shown here:

```
mysql> SELECT * FROM performance_schema.threads WHERE NAME LIKE '%gtid%\G
***** 1. row *****
      THREAD_ID: 26
        NAME: thread/sql/compress_gtid_table
         TYPE: FOREGROUND
PROCESSLIST_ID: 1
PROCESSLIST_USER: NULL
PROCESSLIST_HOST: NULL
PROCESSLIST_DB: NULL
PROCESSLIST_COMMAND: Daemon
PROCESSLIST_TIME: 1509
PROCESSLIST_STATE: Suspending
PROCESSLIST_INFO: NULL
PARENT_THREAD_ID: 1
          ROLE: NULL
INSTRUMENTED: YES
      HISTORY: YES
CONNECTION_TYPE: NULL
      THREAD_OS_ID: 18677
```

This thread has the name `thread/sql/compress_gtid_table`, and normally sleeps until `executed_gtids_compression_period` transactions have been executed, then wakes up to perform compression of the `mysql.gtid_executed` table as described previously. It then sleeps until another `executed_gtids_compression_period` transactions have taken place, then wakes up to perform the compression again, repeating this loop indefinitely. Setting this value to 0 when binary logging is disabled means that the thread always sleeps and never wakes up.

18.1.3.2 Setting Up Replication Using GTIDs

This section describes a process for configuring and starting GTID-based replication in MySQL 8.0. This is a “cold start” procedure that assumes either that you are starting the replication master for the first time, or that it is possible to stop it; for information about provisioning replication slaves using GTIDs from a running master, see [Section 18.1.3.3, “Using GTIDs for Failover and Scaleout”](#). For information about changing GTID mode on servers online, see [Section 18.1.5, “Changing Replication Modes on Online Servers”](#).

The key steps in this startup process for the simplest possible GTID replication topology—consisting of one master and one slave—are as follows:

1. If replication is already running, synchronize both servers by making them read-only.
2. Stop both servers.
3. Restart both servers with GTIDs enabled and the correct options configured.

The `mysqld` options necessary to start the servers as described are discussed in the example that follows later in this section.

Note

`server_uuid` must exist for GTIDs to function correctly.

- Instruct the slave to use the master as the replication data source and to use auto-positioning, and then start the slave.

The SQL statements needed to accomplish this step are described in the example that follows later in this section.

- Enable read mode again on both servers, so that they can accept updates.

In the following example, two servers are already running as master and slave, using MySQL's binary log position-based replication protocol. If you are starting with new servers, see [Section 18.1.2.3, “Creating a User for Replication”](#) for information about adding a specific user for replication connections and [Section 18.1.2.1, “Setting the Replication Master Configuration”](#) for information about setting the `server_id` variable. The following examples show how to store `mysqld` startup options in server's option file, see [Section 4.2.6, “Using Option Files”](#) for more information. Alternatively you can use startup options when running `mysqld`.

Most of the steps that follow require the use of the MySQL `root` account or another MySQL user account that has the `SUPER` privilege. `mysqladmin shutdown` requires either the `SUPER` privilege or the `SHUTDOWN` privilege.

Step 1: Synchronize the servers. This step is only required when working with servers which are already replicating without using GTIDs. For new servers proceed to Step 3. Make the servers read-only by setting the `read_only` system variable to `ON` on each server by issuing the following:

```
mysql> SET @@global.read_only = ON;
```

Then, allow the slave to catch up with the master. *It is extremely important that you make sure the slave has processed all updates before continuing.*

Step 2: Stop both servers. Stop each server using `mysqladmin` as shown here, where `username` is the user name for a MySQL user having sufficient privileges to shut down the server:

```
shell> mysqladmin -username -p shutdown
```

Then supply this user's password at the prompt.

Step 3: Start both servers with GTIDs enabled. To enable GTID-based replication, each server must be started with GTID mode enabled by setting the `gtid_mode` variable to `ON`, and with the `enforce_gtid_consistency` variable enabled to ensure that only statements which are safe for GTID-based replication are logged. In addition, you should start slaves with the `--skip-slave-start` option before configuring the slave settings. For more information on GTID related options and variables, see [Section 18.1.6.5, “Global Transaction ID Options and Variables”](#).

It is not mandatory to have binary logging enabled in order to use GTIDs when using the [mysql.gtid_executed Table](#). This means that you can have slave servers using GTIDs but without binary logging. Masters *must* always have binary logging enabled in order to be able to replicate. For example, to start a slave with GTIDs enabled but without binary logging, configure these variables in the server's option file:

```
gtid_mode=ON
enforce-gtid-consistency=true
```

Step 4: Configure the slave to use GTID-based auto-positioning. Tell the slave to use the master with GTID based transactions as the replication data source, and to use GTID-based auto-positioning rather than file-based positioning. Issue a `CHANGE MASTER TO` statement on the slave, including the `MASTER_AUTO_POSITION` option in the statement to tell the slave that the master's transactions are identified by GTIDs.

You may also need to supply appropriate values for the master's host name and port number as well as the user name and password for a replication user account which can be used by the slave to connect to the master; if these have already been set prior to Step 1 and no further changes need to be made, the corresponding options can safely be omitted from the statement shown here.

```
mysql> CHANGE MASTER TO
>     MASTER_HOST = host,
>     MASTER_PORT = port,
>     MASTER_USER = user,
>     MASTER_PASSWORD = password,
>     MASTER_AUTO_POSITION = 1;
```

Neither the `MASTER_LOG_FILE` option nor the `MASTER_LOG_POS` option may be used with `MASTER_AUTO_POSITION` set equal to 1. Attempting to do so causes the `CHANGE MASTER TO` statement to fail with an error.

Assuming that the `CHANGE MASTER TO` statement has succeeded, you can then start the slave by issuing:

```
mysql> START SLAVE;
```

Step 5: Disable read-only mode. This step is only necessary if you configured a server to be read-only in Step 1. To allow the server to begin accepting updates again, issue the following statement:

```
mysql> SET @@global.read_only = OFF;
```

GTID-based replication should now be running, and you can begin (or resume) activity on the master as before. [Section 18.1.3.3, "Using GTIDs for Failover and Scaleout"](#), discusses creation of new slaves when using GTIDs.

18.1.3.3 Using GTIDs for Failover and Scaleout

There are a number of techniques when using MySQL Replication with Global Transaction Identifiers (GTIDs) for provisioning a new slave which can then be used for scaleout, being promoted to master as necessary for failover. This section describes the following techniques:

- [Simple replication](#)
- [Copying data and transactions to the slave](#)
- [Injecting empty transactions](#)
- [Excluding transactions with `gtid_purged`](#)
- [Restoring GTID mode slaves](#)

Global transaction identifiers were added to MySQL Replication for the purpose of simplifying in general management of the replication data flow and of failover activities in particular. Each identifier uniquely identifies a set of binary log events that together make up a transaction. GTIDs play a key role in applying changes to the database: the server automatically skips any transaction having an identifier which the server recognizes as one that it has processed before. This behavior is critical for automatic replication positioning and correct failover.

The mapping between identifiers and sets of events comprising a given transaction is captured in the binary log. This poses some challenges when provisioning a new server with data from another existing server. To reproduce the identifier set on the new server, it is necessary to copy the identifiers from

the old server to the new one, and to preserve the relationship between the identifiers and the actual events. This is necessary for restoring a slave that is immediately available as a candidate to become a new master on failover or switchover.

Simple replication. The easiest way to reproduce all identifiers and transactions on a new server is to make the new server into the slave of a master that has the entire execution history, and enable global transaction identifiers on both servers. See [Section 18.1.3.2, “Setting Up Replication Using GTIDs”](#), for more information.

Once replication is started, the new server copies the entire binary log from the master and thus obtains all information about all GTIDs.

This method is simple and effective, but requires the slave to read the binary log from the master; it can sometimes take a comparatively long time for the new slave to catch up with the master, so this method is not suitable for fast failover or restoring from backup. This section explains how to avoid fetching all of the execution history from the master by copying binary log files to the new server.

Copying data and transactions to the slave. Executing the entire transaction history can be time-consuming when the source server has processed a large number of transactions previously, and this can represent a major bottleneck when setting up a new replication slave. To eliminate this requirement, a snapshot of the data set, the binary logs and the global transaction information the source server contains can be imported to the new slave. The source server can be either the master or the slave, you must ensure that the source has processed all required transactions before copying the data.

There are several variants of this method, the difference being in the manner in which data dumps and transactions from binary logs are transferred to the slave, as outlined here:

Data Set	Transaction History
<ul style="list-style-type: none"> Use the <code>mysql</code> client to import a dump file created with <code>mysqldump</code>. On the source server use the <code>--master-data</code> option to include binary logging information and <code>--set-gtid-purged</code> to <code>AUTO</code> (the default) or <code>ON</code>, to include information about executed transactions in the dump. Stop the source server, copy the contents of the source's data directory to the new slave's data directory, then restart the slave. The slave must be configured for GTID-based replication, in other words <code>gtid_mode=ON</code>. 	<ul style="list-style-type: none"> Import the binary log from the source server to the new slave using <code>mysqlbinlog</code>, with the <code>--read-from-remote-server</code> and <code>--read-from-remote-master</code> options. Copy the source's binary log files to the slave. You can make copies from the slave using <code>mysqlbinlog --read-from-remote-server --raw</code>. These can be read in to the slave in either of the following ways: <ul style="list-style-type: none"> Update the slave's <code>binlog.index</code> file to point to the copied log files. Then execute a <code>CHANGE MASTER TO</code> statement in the <code>mysql</code> client to point to the first log file, and <code>START SLAVE</code> to read them. Use <code>mysqlbinlog > file</code> (without the <code>--raw</code> option) to export the binary log files to SQL files that can be processed by the <code>mysql</code> client.

See also [Section 4.6.8.3, “Using mysqlbinlog to Back Up Binary Log Files”](#).

This method has the advantage that a new server is available almost immediately; only those transactions that were committed while the snapshot or dump file was being replayed still need to be obtained from the existing master. This means that the slave's availability is not instantaneous—but only a relatively short amount of time should be required for the slave to catch up with these few remaining transactions.

Copying over binary logs to the target server in advance is usually faster than reading the entire transaction execution history from the master in real time. However, it may not always be feasible to

move these files to the target when required, due to size or other considerations. The two remaining methods for provisioning a new slave discussed in this section use other means to transfer information about transactions to the new slave.

Injecting empty transactions. The master's global `gtid_executed` variable contains the set of all transactions executed on the master. Rather than copy the binary logs when taking a snapshot to provision a new server, you can instead note the content of `gtid_executed` on the server from which the snapshot was taken. Before adding the new server to the replication chain, simply commit an empty transaction on the new server for each transaction identifier contained in the master's `gtid_executed`, like this:

```
SET GTID_NEXT= 'aaa-bbb-ccc-ddd:N' ;

BEGIN;
COMMIT;

SET GTID_NEXT= 'AUTOMATIC' ;
```

Once all transaction identifiers have been reinstated in this way using empty transactions, you must flush and purge the slave's binary logs, as shown here, where `N` is the nonzero suffix of the current binary log file name:

```
FLUSH LOGS;
PURGE BINARY LOGS TO 'master-bin.00000N' ;
```

You should do this to prevent this server from flooding the replication stream with false transactions in the event that it is later promoted to master. (The `FLUSH LOGS` statement forces the creation of a new binary log file; `PURGE BINARY LOGS` purges the empty transactions, but retains their identifiers.)

This method creates a server that is essentially a snapshot, but in time is able to become a master as its binary log history converges with that of the replication stream (that is, as it catches up with the master or masters). This outcome is similar in effect to that obtained using the remaining provisioning method, which we discuss in the next few paragraphs.

Excluding transactions with `gtid_purged`. The master's global `gtid_purged` variable contains the set of all transactions that have been purged from the master's binary log. As with the method discussed previously (see [Injecting empty transactions](#)), you can record the value of `gtid_executed` on the server from which the snapshot was taken (in place of copying the binary logs to the new server). Unlike the previous method, there is no need to commit empty transactions (or to issue `PURGE BINARY LOGS`); instead, you can set `gtid_purged` on the slave directly, based on the value of `gtid_executed` on the server from which the backup or snapshot was taken.

As with the method using empty transactions, this method creates a server that is functionally a snapshot, but in time is able to become a master as its binary log history converges with that of the replication master or group.

Restoring GTID mode slaves. When restoring a slave in a GTID based replication setup that has encountered an error, injecting an empty transaction may not solve the problem because an event does not have a GTID.

Use `mysqlbinlog` to find the next transaction, which is probably the first transaction in the next log file after the event. Copy everything up to the `COMMIT` for that transaction, being sure to include the `SET @@SESSION.GTID_NEXT`. Even if you are not using row-based replication, you can still run binary log row events in the command line client.

Stop the slave and run the transaction you copied. The `mysqlbinlog` output sets the delimiter to `/*! */;`, so set it back:

```
mysql> DELIMITER ;
```

Restart replication from the correct position automatically:

```
mysql> SET GTID_NEXT=automatic;
mysql> RESET SLAVE;
mysql> START SLAVE;
```

18.1.3.4 Restrictions on Replication with GTIDs

Because GTID-based replication is dependent on transactions, some features otherwise available in MySQL are not supported when using it. This section provides information about restrictions on and limitations of replication with GTIDs.

Updates involving nontransactional storage engines. When using GTIDs, updates to tables using nontransactional storage engines such as [MyISAM](#) cannot be made in the same statement or transaction as updates to tables using transactional storage engines such as [InnoDB](#).

This restriction is due to the fact that updates to tables that use a nontransactional storage engine mixed with updates to tables that use a transactional storage engine within the same transaction can result in multiple GTIDs being assigned to the same transaction.

Such problems can also occur when the master and the slave use different storage engines for their respective versions of the same table, where one storage engine is transactional and the other is not.

In any of the cases just mentioned, the one-to-one correspondence between transactions and GTIDs is broken, with the result that GTID-based replication cannot function correctly.

CREATE TABLE ... SELECT statements. `CREATE TABLE ... SELECT` is not safe for statement-based replication. When using row-based replication, this statement is actually logged as two separate events—one for the creation of the table, and another for the insertion of rows from the source table into the new table just created. When this statement is executed within a transaction, it is possible in some cases for these two events to receive the same transaction identifier, which means that the transaction containing the inserts is skipped by the slave. Therefore, `CREATE TABLE ... SELECT` is not supported when using GTID-based replication.

Temporary tables. `CREATE TEMPORARY TABLE` and `DROP TEMPORARY TABLE` statements are not supported inside transactions when using GTIDs (that is, when the server was started with the `--enforce-gtid-consistency` option). It is possible to use these statements with GTIDs enabled, but only outside of any transaction, and only with `autocommit=1`.

Preventing execution of unsupported statements. To prevent execution of statements that would cause GTID-based replication to fail, all servers must be started with the `--enforce-gtid-consistency` option when enabling GTIDs. This causes statements of any of the types discussed previously in this section to fail with an error.

For information about other required startup options when enabling GTIDs, see [Section 18.1.3.2, “Setting Up Replication Using GTIDs”](#).

`sql_slave_skip_counter` is not supported when using GTIDs. If you need to skip transactions, use the value of the master's `gtid_executed` variable instead; see [Injecting empty transactions](#), for more information.

GTID mode and mysqldump. It is possible to import a dump made using `mysqldump` into a MySQL Server running with GTID mode enabled, provided that there are no GTIDs in the target server's binary log.

GTID mode and mysql_upgrade. It is not recommended to use `mysql_upgrade` with the `--write-binlog` option on a MySQL Server running with `--gtid-mode=ON` because `mysql_upgrade` can make changes to system tables that use the [MyISAM](#) storage engine, which is non-transactional.

18.1.4 MySQL Multi-Source Replication

This section describes MySQL Multi-Source Replication, which enables you to replicate from multiple immediate masters in parallel. This section describes multi-source replication, and how to configure, monitor and troubleshoot it.

18.1.4.1 MySQL Multi-Source Replication Overview

MySQL Multi-Source Replication enables a replication slave to receive transactions from multiple sources simultaneously. Multi-source replication can be used to back up multiple servers to a single server, to merge table shards, and consolidate data from multiple servers to a single server. Multi-source replication does not implement any conflict detection or resolution when applying the transactions, and those tasks are left to the application if required. In a multi-source replication topology, a slave creates a replication channel for each master that it should receive transactions from. See [Section 18.2.3, “Replication Channels”](#). The following sections describe how to set up multi-source replication.

18.1.4.2 Multi-Source Replication Tutorials

This section provides tutorials on how to configure masters and slaves for multi-source replication, and how to start, stop and reset multi-source slaves.

Configuring Multi-Source Replication

This section explains how to configure a multi-source replication topology, and provides details about configuring masters and slaves. Such a topology requires at least two masters and one slave configured.

Masters in a multi-source replication topology can be configured to use either global transaction identifier (GTID) based replication, or binary log position-based replication. See [Section 18.1.3.2, “Setting Up Replication Using GTIDs”](#) for how to configure a master using GTID based replication. See [Section 18.1.2.1, “Setting the Replication Master Configuration”](#) for how to configure a master using file position based replication.

Slaves in a multi-source replication topology require `TABLE` based repositories. Multi-source replication is not compatible with `FILE` based repositories. The type of repository being used by `mysqld` can be configured either at startup, or dynamically.

To configure the type of repository used by a replication slave at startup, start `mysqld` with the following options:

```
--master-info-repository=TABLE --relay-log-info-repository=TABLE
```

To modify an existing replication slave that is using a `FILE` repository to use `TABLE` repositories, convert the existing replication repositories dynamically by running the following commands:

```
STOP SLAVE;
SET GLOBAL master_info_repository = 'TABLE';
SET GLOBAL relay_log_info_repository = 'TABLE';
```

Adding a GTID Based Master to a Multi-Source Replication Slave

This section assumes you have enabled GTID based transactions on the master using `gtid_mode=ON`, enabled a replication user, and ensured that the slave is using `TABLE` based replication repositories. Use the `CHANGE MASTER TO` statement to add a new master to a channel by using a `FOR CHANNEL channel` clause. For more information on replication channels, see [Section 18.2.3, “Replication Channels”](#)

For example, to add a new master with the host name `master1` using port `3451` to a channel called `master-1`:

```
CHANGE MASTER TO MASTER_HOST='master1', MASTER_USER='rpl', MASTER_PORT=3451, MASTER_PASSWORD='', \
MASTER_AUTO_POSITION = 1 FOR CHANNEL 'master-1';
```

Multi-source replication is compatible with auto-positioning. See [Section 13.4.2.1, “CHANGE MASTER TO Syntax”](#) for more information.

Repeat this process for each extra master that you want to add to a channel, changing the host name, port and channel as appropriate.

Adding a Binary Log Based Master to a Multi-Source Replication Slave

This section assumes you have enabled binary logging on the master using `--log-bin`, enabled a replication user, noted the current binary log position, and ensured that the slave is using `TABLE` based replication repositories. You need to know the current `MASTER_LOG_FILE` and `MASTER_LOG_POSITION`. Use the `CHANGE MASTER TO` statement to add a new master to a channel by specifying a `FOR CHANNEL channel` clause. For example, to add a new master with the host name `master1` using port `3451` to a channel called `master-1`:

```
CHANGE MASTER TO MASTER_HOST='master1', MASTER_USER='rpl', MASTER_PORT=3451, MASTER_PASSWORD='' \
MASTER_LOG_FILE='master1-bin.000006', MASTER_LOG_POS=628 FOR CHANNEL 'master-1';
```

Repeat this process for each extra master that you want to add to a channel, changing the host name, port and channel as appropriate.

Starting Multi-Source Replication Slaves

Once you have added all of the channels you want to use as replication masters, use a `START SLAVE thread_types` statement to start replication. When you have enabled multiple channels on a slave, you can choose to either start all channels, or select a specific channel to start.

- To start all currently configured replication channels:

```
START SLAVE thread_types;
```

- To start only a named channel, use a `FOR CHANNEL channel` clause:

```
START SLAVE thread_types FOR CHANNEL channel;
```

Use the `thread_types` option to choose specific threads you want the above statements to start on the slave. See [Section 13.4.2.6, “START SLAVE Syntax”](#) for more information.

Stopping Multi-Source Replication Slaves

The `STOP SLAVE` statement can be used to stop a multi-source replication slave. By default, if you use the `STOP SLAVE` statement on a multi-source replication slave all channels are stopped. Optionally, use the `FOR CHANNEL channel` clause to stop only a specific channel.

- To stop all currently configured replication channels:

```
STOP SLAVE thread_types;
```

- To stop only a named channel, use a `FOR CHANNEL channel` clause:

```
STOP SLAVE thread_types FOR CHANNEL channel;
```

Use the `thread_types` option to choose specific threads you want the above statements to stop on the slave. See [Section 13.4.2.7, “STOP SLAVE Syntax”](#) for more information.

Resetting Multi-Source Replication Slaves

The `RESET SLAVE` statement can be used to reset a multi-source replication slave. By default, if you use the `RESET SLAVE` statement on a multi-source replication slave all channels are reset. Optionally, use the `FOR CHANNEL channel` clause to reset only a specific channel.

- To reset all currently configured replication channels:

```
RESET SLAVE;
```

- To reset only a named channel, use a `FOR CHANNEL channel` clause:

```
RESET SLAVE FOR CHANNEL channel;
```

See [Section 13.4.2.4, “RESET SLAVE Syntax”](#) for more information.

18.1.4.3 Multi-Source Replication Monitoring

To monitor the status of replication channels the following options exist:

- Using the replication Performance Schema tables. The first column of these tables is `Channel_Name`. This enables you to write complex queries based on `Channel_Name` as a key. See [Section 25.11.11, “Performance Schema Replication Tables”](#).
- Using `SHOW SLAVE STATUS FOR CHANNEL channel_name`. By default, if the `FOR CHANNEL channel_name` clause is not used, this command shows the slave status for all channels with one row per channel. The identifier `channel_name` is added as a column in the result set. If a `FOR CHANNEL channel_name` clause is provided, the results show the status of only the named replication channel.

Note

The `SHOW VARIABLES` statement does not work with multiple replication channels. The information that was available through these variables has been migrated to the replication performance tables. Using a `SHOW VARIABLES` statement in a topology with multiple channels shows the status of only the default channel.

Monitoring Channels Using Performance Schema Tables

This section explains how to use the replication Performance Schema tables to monitor channels. You can choose to monitor all channels, or a subset of the existing channels.

To monitor the connection status of all channels:

```
mysql> SELECT * FROM replication_connection_status\G;
***** 1. row *****
CHANNEL_NAME: master1
GROUP_NAME:
SOURCE_UUID: 046e41f8-a223-11e4-a975-0811960cc264

LAST_ERROR_NUMBER: 0
LAST_ERROR_MESSAGE:
LAST_ERROR_TIMESTAMP: 0000-00-00 00:00:00
```

```
2 rows in set (0.00 sec)
```

In the above output there are two channels enabled, and as shown by the `CHANNEL_NAME` field they are called `master1` and `master2`.

The addition of the `CHANNEL_NAME` field enables you to query the Performance Schema tables for a specific channel. To monitor the connection status of a named channel, use a `WHERE channel_name=channel` clause:

```
mysql> SELECT * FROM replication_connection_status WHERE channel_name='master1'\G
***** 1. row *****
CHANNEL_NAME: master1
GROUP_NAME:
SOURCE_UUID: 046e41f8-a223-11e4-a975-0811960cc264
THREAD_ID: 24
SERVICE_STATE: ON
COUNT_RECEIVED_HEARTBEATS: 0
LAST_HEARTBEAT_TIMESTAMP: 0000-00-00 00:00:00
RECEIVED_TRANSACTION_SET: 046e41f8-a223-11e4-a975-0811960cc264:4-37
LAST_ERROR_NUMBER: 0
LAST_ERROR_MESSAGE:
LAST_ERROR_TIMESTAMP: 0000-00-00 00:00:00
1 row in set (0.00 sec)
```

Similarly, the `WHERE channel_name=channel` clause can be used to monitor the other replication Performance Schema tables for a specific channel. For more information, see [Section 25.11.11, “Performance Schema Replication Tables”](#).

18.1.4.4 Multi-Source Replication Error Messages

Error codes and messages provide information about errors encountered in a multi-source replication topology. These error codes and messages are only emitted when multi-source replication is enabled, and provide information related to the channel which generated the error. For example:

```
Slave is already running and Slave is already stopped have been replaced
with Replication thread(s) for channel channel_name are already running
and Replication threads(s) for channel channel_name are already stopped
respectively.
```

The server log messages have also been changed to indicate which channel the log messages relate to. This makes debugging and tracing easier.

18.1.5 Changing Replication Modes on Online Servers

This section describes how to change the mode of replication being used without having to take the server offline.

18.1.5.1 Replication Mode Concepts

To be able to safely configure the replication mode of an online server it is important to understand some key concepts of replication. This section explains these concepts and is essential reading before attempting to modify the replication mode of an online server.

The modes of replication available in MySQL rely on different techniques for identifying transactions which are logged. The types of transactions used by replication are as follows:

- GTID transactions are identified by a global transaction identifier (GTID) in the form `UUID:NUMBER`. Every GTID transaction in a log is always preceded by a `Gtid_log_event`. GTID transactions can be addressed using either the GTID or using the file name and position.
- Anonymous transactions do not have a GTID assigned, and MySQL ensures that every anonymous transaction in a log is preceded by an `Anonymous_gtid_log_event`. In previous versions,

anonymous transactions were not preceded by any particular event. Anonymous transactions can only be addressed using file name and position.

When using GTIDs you can take advantage of auto-positioning and automatic fail-over, as well as use `WAIT_FOR_EXECUTED_GTID_SET()`, `session_track_gtids`, and monitor replicated transactions using Performance Schema tables. With GTIDs enabled you cannot use `sql_slave_skip_counter`, instead use empty transactions.

Transactions in a relay log that was received from a master running a previous version of MySQL may not be preceded by any particular event at all, but after being replayed and logged in the slave's binary log, they are preceded with an `Anonymous_gtid_log_event`.

The ability to configure the replication mode online means that the `gtid_mode` and `enforce_gtid_consistency` variables are now both dynamic and can be set by `SUPER` from a top-level statement. In MySQL 5.6 and below, both of these variables could only be configured using the appropriate option at server start, meaning that changes to the replication mode required a server restart. In all versions `gtid_mode` could be set to `ON` or `OFF`, which corresponded to whether GTIDs were used to identify transactions or not. When `gtid_mode=ON` it is not possible to replicate anonymous transactions, and when `gtid_mode=OFF` only anonymous transactions can be replicated. When `gtid_mode=OFF_PERMISSIVE` then *new* transactions are anonymous while permitting replicated transactions to be either GTID or anonymous transactions. When `gtid_mode=ON_PERMISSIVE` then *new* transactions use GTIDs while permitting replicated transactions to be either GTID or anonymous transactions. This means it is possible to have a replication topology that has servers using both anonymous and GTID transactions. For example a master with `gtid_mode=ON` could be replicating to a slave with `gtid_mode=ON_PERMISSIVE`. The valid values for `gtid_mode` are as follows and in this order:

- `OFF`
- `OFF_PERMISSIVE`
- `ON_PERMISSIVE`
- `ON`

It is important to note that the state of `gtid_mode` can only be changed by one step at a time based on the above order. For example, if `gtid_mode` is currently set to `OFF_PERMISSIVE`, it is possible to change to `OFF` or `ON_PERMISSIVE` but not to `ON`. This is to ensure that the process of changing from anonymous transactions to GTID transactions online is correctly handled by the server. When you switch between `gtid_mode=ON` and `gtid_mode=OFF`, the GTID state (in other words the value of `gtid_executed`) is persistent. This ensures that the GTID set that has been applied by the server is always retained, regardless of changes between types of `gtid_mode`.

The fields related to GTIDs display the correct information regardless of the currently selected `gtid_mode`. This means that fields which display GTID sets, such as `gtid_executed`, `gtid_purged`, `RECEIVED_TRANSACTION_SET` in the `replication_connection_status` Performance Schema table, and the GTID related results of `SHOW SLAVE STATUS`, now return the empty string when there are no GTIDs present. Fields that display a single GTID, such as `CURRENT_TRANSACTION` in the `replication_applier_status_by_worker` Performance Schema table, now display `ANONYMOUS` when GTID transactions are not being used.

Replication from a master using `gtid_mode=ON` provides the ability to use auto-positioning, configured using the `CHANGE MASTER TO MASTER_AUTO_POSITION = 1;` statement. The replication topology being used impacts on whether it is possible to enable auto-positioning or not, as this feature relies on GTIDs and is not compatible with anonymous transactions. An error is generated if auto-positioning is enabled and an anonymous transaction is encountered. It is strongly recommended to ensure there are no anonymous transactions remaining in the topology before enabling auto-positioning, see [Section 18.1.5.2, "Enabling GTID Transactions Online"](#). The valid combinations of `gtid_mode` and auto-positioning on master and slave are shown in the following table, where the master's `gtid_mode` is shown on the horizontal and the slave's `gtid_mode` is on the vertical:

Table 18.1 Valid Combinations of Master and Slave `gtid_mode`

Master/Slave <code>gtid_mode</code>	OFF	OFF_PERMISSIVE	ON_PERMISSIVE	ON
OFF	Y	Y	N	N
OFF_PERMISSIVE	Y	Y	Y	Y*
ON_PERMISSIVE	Y	Y	Y	Y*
ON	N	N	Y	Y*

In the above table, the entries are:

- **Y**: the `gtid_mode` of master and slave is compatible
- **N**: the `gtid_mode` of master and slave is not compatible
- *****: auto-positioning can be used

The currently selected `gtid_mode` also impacts on the `gtid_next` variable. The following table shows the behavior of the server for the different values of `gtid_mode` and `gtid_next`.

Table 18.2 Valid Combinations of `gtid_mode` and `gtid_next`

<code>gtid_next</code>	AUTOMATIC binary log on	AUTOMATIC binary log off	ANONYMOUS	UUID:NUMBER
OFF	ANONYMOUS	ANONYMOUS	ANONYMOUS	Error
OFF_PERMISSIVE	ANONYMOUS	ANONYMOUS	ANONYMOUS	UUID:NUMBER
ON_PERMISSIVE	New GTID	ANONYMOUS	ANONYMOUS	UUID:NUMBER
ON	New GTID	ANONYMOUS	Error	UUID:NUMBER

In the above table, the entries are:

- **ANONYMOUS**: generate an anonymous transaction.
- **Error**: generate an error and fail to execute `SET GTID_NEXT`.
- **UUID:NUMBER**: generate a GTID with the specified `UUID:NUMBER`.
- **New GTID**: generate a GTID with an automatically generated number.

When the binary log is off and `gtid_next` is set to `AUTOMATIC`, then no GTID is generated. This is consistent with the behavior of previous versions.

18.1.5.2 Enabling GTID Transactions Online

This section describes how to enable GTID transactions, and optionally auto-positioning, on servers that are already online and using anonymous transactions. This procedure does not require taking the server offline and is suited to use in production. However, if you have the possibility to take the servers offline when enabling GTID transactions that process is easier.

Before you start, ensure that the servers meet the following pre-conditions:

- All servers in your topology must use MySQL 5.7.6 or later. You cannot enable GTID transactions online on any single server unless all servers which are in the topology are using this version.
- All servers have `gtid_mode` set to the default value `OFF`.

The following procedure can be paused at any time and later resumed where it was, or reversed by jumping to the corresponding step of [Section 18.1.5.3, “Disabling GTID Transactions Online”](#), the

online procedure to disable GTIDs. This makes the procedure fault-tolerant because any unrelated issues that may appear in the middle of the procedure can be handled as usual, and then the procedure continued where it was left off.

Note

It is crucial that you complete every step before continuing to the next step.

To enable GTID transactions:

1. On each server, execute:

```
SET @@GLOBAL.ENFORCE_GTID_CONSISTENCY = WARN;
```

Let the server run for a while with your normal workload and monitor the logs. If this step causes any warnings in the log, adjust your application so that it only uses GTID-compatible features and does not generate any warnings.

Important

This is the first important step. You must ensure that no warnings are being generated in the error logs before going to the next step.

2. On each server, execute:

```
SET @@GLOBAL.ENFORCE_GTID_CONSISTENCY = ON;
```

3. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = OFF_PERMISSIVE;
```

It does not matter which server executes this statement first, but it is important that all servers complete this step before any server begins the next step.

4. On each server, execute:

```
SET @@GLOBAL.GTID_MODE = ON_PERMISSIVE;
```

It does not matter which server executes this statement first.

5. On each server, wait until the status variable `ONGOING_ANONYMOUS_TRANSACTION_COUNT` is zero. This can be checked using:

```
SHOW STATUS LIKE 'ONGOING_ANONYMOUS_TRANSACTION_COUNT';
```

Note

On a replication slave, it is theoretically possible that this shows zero and then non-zero again. This is not a problem, it suffices that it shows zero once.

6. Wait for all transactions generated up to step 5 to replicate to all servers. You can do this without stopping updates: the only important thing is that all anonymous transactions get replicated.

See [Section 18.1.5.4, “Verifying Replication of Anonymous Transactions”](#) for one method of checking that all anonymous transactions have replicated to all servers.

7. If you use binary logs for anything other than replication, for example point in time backup and restore, wait until you do not need the old binary logs having transactions without GTIDs.

For instance, after step 6 has completed, you can execute `FLUSH LOGS` on the server where you are taking backups. Then either explicitly take a backup or wait for the next iteration of any periodic backup routine you may have set up.

Ideally, wait for the server to purge all binary logs that existed when step 6 was completed. Also wait for any backup taken before step 6 to expire.

Important

This is the second important point. It is vital to understand that binary logs containing anonymous transactions, without GTIDs cannot be used after the next step. After this step, you must be sure that transactions without GTIDs do not exist anywhere in the topology.

- On each server, execute:

```
SET @@GLOBAL.GTID_MODE = ON;
```

- On each server, add `gtid-mode=ON` to `my.cnf`.

You are now guaranteed that all transactions have a GTID (except transactions generated in step 5 or earlier, which have already been processed). To start using the GTID protocol so that you can later perform automatic fail-over, execute the following on each slave. Optionally, if you use multi-source replication, do this for each channel and include the `FOR CHANNEL channel` clause:

```
STOP SLAVE [FOR CHANNEL 'channel'];
CHANGE MASTER TO MASTER_AUTO_POSITION = 1 [FOR CHANNEL 'channel'];
START SLAVE [FOR CHANNEL 'channel'];
```

18.1.5.3 Disabling GTID Transactions Online

This section describes how to disable GTID transactions on servers that are already online. This procedure does not require taking the server offline and is suited to use in production. However, if you have the possibility to take the servers offline when disabling GTIDs mode that process is easier.

The process is similar to enabling GTID transactions while the server is online, but reversing the steps. The only thing that differs is the point at which you wait for logged transactions to replicate.

Before you start, ensure that the servers meet the following pre-conditions:

- All servers in your topology must use MySQL 5.7.6 or later. You cannot disable GTID transactions online on any single server unless *all* servers which are in the topology are using this version.
- All servers have `gtid_mode` set to `ON`.

- Execute the following on each slave, and if you using multi-source replication, do it for each channel and include the `FOR CHANNEL channel` clause:

```
STOP SLAVE [FOR CHANNEL 'channel'];
CHANGE MASTER TO MASTER_AUTO_POSITION = 0, MASTER_LOG_FILE = file, \
MASTER_LOG_POS = position [FOR CHANNEL 'channel'];
START SLAVE [FOR CHANNEL 'channel'];
```

- On each server, execute:

```
SET @@GLOBAL.GTID_MODE = ON_PERMISSIVE;
```

- On each server, execute:

```
SET @@GLOBAL.GTID_MODE = OFF_PERMISSIVE;
```

- On each server, wait until the variable `@@GLOBAL.GTID_OWNED` is equal to the empty string. This can be checked using:

```
SELECT @@GLOBAL.GTID_OWNED;
```

On a replication slave, it is theoretically possible that this is empty and then nonempty again. This is not a problem, it suffices that it is empty once.

- Wait for all transactions that currently exist in any binary log to replicate to all slaves. See [Section 18.1.5.4, “Verifying Replication of Anonymous Transactions”](#) for one method of checking that all anonymous transactions have replicated to all servers.
- If you use binary logs for anything else than replication, for example to do point in time backup or restore: wait until you do not need the old binary logs having GTID transactions.

For instance, after step 5 has completed, you can execute `FLUSH LOGS` on the server where you are taking the backup. Then either explicitly take a backup or wait for the next iteration of any periodic backup routine you may have set up.

Ideally, wait for the server to purge all binary logs that existed when step 5 was completed. Also wait for any backup taken before step 5 to expire.

Important

This is the one important point during this procedure. It is important to understand that logs containing GTID transactions cannot be used after the next step. Before proceeding you must be sure that GTID transactions do not exist anywhere in the topology.

- On each server, execute:

```
SET @@GLOBAL.GTID_MODE = OFF;
```

- On each server, set `gtid-mode=OFF` in `my.cnf`.

If you want to set `enforce_gtid_consistency=OFF`, you can do so now. After setting it, you should add `enforce_gtid_consistency=OFF` to your configuration file.

If you want to downgrade to an earlier version of MySQL, you can do so now, using the normal downgrade procedure.

18.1.5.4 Verifying Replication of Anonymous Transactions

This section explains how to monitor a replication topology and verify that all anonymous transactions have been replicated. This is helpful when changing the replication mode online as you can verify that it is safe to change to GTID transactions.

There are several possible ways to wait for transactions to replicate:

The simplest method, which works regardless of your topology but relies on timing is as follows: if you are sure that the slave never lags more than N seconds, just wait for a bit more than N seconds. Or wait for a day, or whatever time period you consider safe for your deployment.

A safer method in the sense that it does not depend on timing: if you only have a master with one or more slaves, do the following:

- On the master, execute:

```
SHOW MASTER STATUS;
```

Note down the values in the `File` and `Position` column.

- On every slave, use the file and position information from the master to execute:

```
SELECT MASTER_POS_WAIT(file, position);
```

If you have a master and multiple levels of slaves, or in other words you have slaves of slaves, repeat step 2 on each level, starting from the master, then all the direct slaves, then all the slaves of slaves, and so on.

If you use a circular replication topology where multiple servers may have write clients, perform step 2 for each master-slave connection, until you have completed the full circle. Repeat the whole process so that you do the full circle *twice*.

For example, suppose you have three servers A, B, and C, replicating in a circle so that A -> B -> C -> A. The procedure is then:

- Do step 1 on A and step 2 on B.
- Do step 1 on B and step 2 on C.
- Do step 1 on C and step 2 on A.
- Do step 1 on A and step 2 on B.
- Do step 1 on B and step 2 on C.
- Do step 1 on C and step 2 on A.

18.1.6 Replication and Binary Logging Options and Variables

The following sections contain information about `mysqld` options and server variables that are used in replication and for controlling the binary log. Options and variables for use on replication masters and replication slaves are covered separately, as are options and variables relating to binary logging and global transaction identifiers (GTIDs). A set of quick-reference tables providing basic information about these options and variables is also included.

Of particular importance is the `--server-id` option.

Command-Line Format	<code>--server-id=#</code>	
System Variable	Name	<code>server_id</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	0
	Min Value	0
	Max Value	4294967295

This option is common to both master and slave replication servers, and is used in replication to enable master and slave servers to identify themselves uniquely. For additional information, see [Section 18.1.6.2, “Replication Master Options and Variables”](#), and [Section 18.1.6.3, “Replication Slave Options and Variables”](#).

On the master and each slave, you *must* use the `--server-id` option to establish a unique replication ID in the range from 1 to $2^{32} - 1$. “Unique”, means that each ID must be different from every other ID in use by any other replication master or slave. For example, `server-id=3`.

The `--server-id` must be used if binary logging is enabled, and a value of 0 is not changed by the server. If you specify `--server-id` without an argument, the effect is the same as using 0. In either case, if the `server_id` is 0, binary logging takes place, but slaves cannot connect to the master, nor can any other servers connect to it as slaves. (Bug #11763963, Bug #56718)

For more information, see [Section 18.1.2.2, “Setting the Replication Slave Configuration”](#).

`server_uuid`

In MySQL 8.0, the server generates a true UUID in addition to the `--server-id` supplied by the user. This is available as the global, read-only variable `server_uuid`.

Note

The presence of the `server_uuid` system variable in MySQL 8.0 does not change the requirement for setting a unique `--server-id` for each MySQL server as part of preparing and running MySQL replication, as described earlier in this section.

System Variable	Name	<code>server_uuid</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	string

When starting, the MySQL server automatically obtains a UUID as follows:

1. Attempt to read and use the UUID written in the file `data_dir/auto.cnf` (where `data_dir` is the server's data directory).
2. If `data_dir/auto.cnf` is not found, generate a new UUID and save it to this file, creating the file if necessary.

The `auto.cnf` file has a format similar to that used for `my.cnf` or `my.ini` files. In MySQL 8.0, `auto.cnf` has only a single `[auto]` section containing a single `server_uuid` setting and value; the file's contents appear similar to what is shown here:

```
[auto]
server_uuid=8a94f357-aab4-11df-86ab-c80aa9429562
```

Important

The `auto.cnf` file is automatically generated; do not attempt to write or modify this file.

When using MySQL replication, masters and slaves know each other's UUIDs. The value of a slave's UUID can be seen in the output of `SHOW SLAVE HOSTS`. Once `START SLAVE` has been executed, the value of the master's UUID is available on the slave in the output of `SHOW SLAVE STATUS`.

Note

Issuing a `STOP SLAVE` or `RESET SLAVE` statement does *not* reset the master's UUID as used on the slave.

A server's `server_uuid` is also used in GTIDs for transactions originating on that server. For more information, see [Section 18.1.3, “Replication with Global Transaction Identifiers”](#).

When starting, the slave I/O thread generates an error and aborts if its master's UUID is equal to its own unless the `--replicate-same-server-id` option has been set. In addition, the slave I/O thread generates a warning if either of the following is true:

- No master having the expected `server_uuid` exists.
- The master's `server_uuid` has changed, although no `CHANGE MASTER TO` statement has ever been executed.

18.1.6.1 Replication and Binary Logging Option and Variable Reference

The following tables list basic information about the MySQL command-line options and system variables applicable to replication and the binary log.

Table 18.3 Summary of Replication options and variables in MySQL 8.0

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
Notes		
abort-slave-event-count		
Yes	No	No
Yes		No

DESCRIPTION: In replication, if set to 1, do not skip events having our server id <code>replicate-wild-do-table</code>		
Yes	No	No
Yes		No
DESCRIPTION: Tells the slave thread to restrict replication to the tables that match the specified wildcard pattern <code>replicate-wild-ignore-table</code>		
Yes	No	No
Yes		No
DESCRIPTION: Tells the slave thread not to replicate to the tables that match the given wildcard pattern <code>report-host</code>		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Host name or IP of the slave to be reported to the master during slave registration <code>report-password</code>		
Yes	Yes	No

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
Notes		
Yes	Global	No
DESCRIPTION: An arbitrary password that the slave server should report to the master. Not the same as the password for the MySQL replication user account.		
report-port		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Port for connecting to slave reported to the master during slave registration		
report-user		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: An arbitrary user name that a slave server should report to the master. Not the same as the name used with the MySQL replication user account.		
Rpl_semi_sync_master_clients		
No	No	Yes
No	Global	No
DESCRIPTION: Number of semisynchronous slaves		
rpl_semi_sync_master_enabled		
No	Yes	No
No	Global	Yes
DESCRIPTION: Whether semisynchronous replication is enabled on the master		
Rpl_semi_sync_master_net_avg_wait_time		
No	No	Yes
No	Global	No
DESCRIPTION: The average time the master waited for a slave reply		
Rpl_semi_sync_master_net_wait_time		
No	No	Yes
No	Global	No
DESCRIPTION: The total time the master waited for slave replies		
Rpl_semi_sync_master_net_waits		
No	No	Yes
No	Global	No
DESCRIPTION: The total number of times the master waited for slave replies		
Rpl_semi_sync_master_no_times		
No	No	Yes
No	Global	No
DESCRIPTION: Number of times the master turned off semisynchronous replication		
Rpl_semi_sync_master_no_tx		
No	No	Yes
No	Global	No

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
Notes		
DESCRIPTION: Number of commits not acknowledged successfully Rpl_semi_sync_master_status		
No	No	Yes
No	Global	No
DESCRIPTION: Whether semisynchronous replication is operational on the master Rpl_semi_sync_master_timefunc_failures		
No	No	Yes
No	Global	No
DESCRIPTION: Number of times the master failed when calling time functions rpl_semi_sync_master_timeout		
No	Yes	No
No	Global	Yes
DESCRIPTION: Number of milliseconds to wait for slave acknowledgment rpl_semi_sync_master_trace_level		
No	Yes	No
No	Global	Yes
DESCRIPTION: The semisynchronous replication debug trace level on the master Rpl_semi_sync_master_tx_avg_wait_time		
No	No	Yes
No	Global	No
DESCRIPTION: The average time the master waited for each transaction Rpl_semi_sync_master_tx_wait_time		
No	No	Yes
No	Global	No
DESCRIPTION: The total time the master waited for transactions Rpl_semi_sync_master_tx_waits		
No	No	Yes
No	Global	No
DESCRIPTION: The total number of times the master waited for transactions rpl_semi_sync_master_wait_for_slave_count		
No	Yes	No
No	Global	Yes
DESCRIPTION: How many slave acknowledgments the master must receive per transaction before proceeding rpl_semi_sync_master_wait_no_slave		
No	Yes	No
No	Global	Yes
DESCRIPTION: Whether master waits for timeout even with no slaves		

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
Notes		
rpl_semi_sync_master_wait_point		
No	Yes	No
No	Global	Yes
DESCRIPTION: The wait point for slave transaction receipt acknowledgment		
Rpl_semi_sync_master_wait_pos_backtraverse		
No	No	Yes
No	Global	No
DESCRIPTION: The total number of times the master waited for an event with binary coordinates lower than events waited for previously		
Rpl_semi_sync_master_wait_sessions		
No	No	Yes
No	Global	No
DESCRIPTION: Number of sessions currently waiting for slave replies		
Rpl_semi_sync_master_yes_tx		
No	No	Yes
No	Global	No
DESCRIPTION: Number of commits acknowledged successfully		
rpl_semi_sync_slave_enabled		
No	Yes	No
No	Global	Yes
DESCRIPTION: Whether semisynchronous replication is enabled on slave		
Rpl_semi_sync_slave_status		
No	No	Yes
No	Global	No
DESCRIPTION: Whether semisynchronous replication is operational on slave		
rpl_semi_sync_slave_trace_level		
No	Yes	No
No	Global	Yes
DESCRIPTION: The semisynchronous replication debug trace level on the slave		
rpl_stop_slave_timeout		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Set the number of seconds that STOP SLAVE waits before timing out.		
server_uuid		
No	Yes	No
No	Global	No
DESCRIPTION: The server's globally unique ID, automatically (re)generated at server start		
show-slave-auth-info		

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
Notes		
Yes	No	No
Yes		No
DESCRIPTION: Show user name and password in SHOW SLAVE HOSTS on this master simplified_binlog_gtid_recovery		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Controls how binary logs are iterated during GTID recovery skip-slave-start		
Yes	No	No
Yes		No
DESCRIPTION: If set, slave is not autostarted slave-checkpoint-group		
Yes	No	No
Yes		No
DESCRIPTION: Maximum number of transactions processed by a multi-threaded slave before a checkpoint operation is called to update progress status. Not supported by MySQL Cluster. slave-checkpoint-period		
Yes	No	No
Yes		No
DESCRIPTION: Update progress status of multi-threaded slave and flush relay log info to disk after this number of milliseconds. Not supported by MySQL Cluster. slave-load-tmpdir		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: The location where the slave should put its temporary files when replicating a LOAD DATA INFILE statement slave-max-allowed-packet		
Yes	No	No
Yes		No
DESCRIPTION: Maximum size, in bytes, of a packet that can be sent from a replication master to a slave; overrides max_allowed_packet. slave_net_timeout		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Number of seconds to wait for more data from a master/slave connection before aborting the read slave-parallel-type		
Yes	No	No
Yes		No

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
Notes		
DESCRIPTION: Tells the slave to use database partitioning (DATABASE) or timestamp information (LOGICAL_CLOCK) from the master to parallelize transactions. The default is DATABASE.		
slave-parallel-workers		
Yes	No	No
Yes		No
DESCRIPTION: Number of worker threads for executing events in parallel. Set to 0 (the default) to disable slave multi-threading. Not supported by MySQL Cluster.		
slave-pending-jobs-size-max		
Yes	No	No
No		No
DESCRIPTION: Maximum size of slave worker queues holding events not yet applied.		
slave-rows-search-algorithms		
Yes	No	No
Yes		No
DESCRIPTION: Determines search algorithms used for slave update batching. Any 2 or 3 from the list INDEX_SEARCH, TABLE_SCAN, HASH_SCAN; the default is TABLE_SCAN,INDEX_SCAN.		
slave-skip-errors		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Tells the slave thread to continue replication when a query returns an error from the provided list		
slave_checkpoint_group		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Maximum number of transactions processed by a multi-threaded slave before a checkpoint operation is called to update progress status. Not supported by MySQL Cluster.		
slave_checkpoint_period		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Update progress status of multi-threaded slave and flush relay log info to disk after this number of milliseconds. Not supported by MySQL Cluster.		
slave_compressed_protocol		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Use compression on master/slave protocol		
slave_exec_mode		
Yes	Yes	No
Yes	Global	Yes

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
Notes		
DESCRIPTION: Allows for switching the slave thread between IDEMPOTENT mode (key and some other errors suppressed) and STRICT mode; STRICT mode is the default, except for MySQL Cluster, where IDEMPOTENT is always used		
Slave_heartbeat_period		
No	No	Yes
No	Global	No
DESCRIPTION: The slave's replication heartbeat interval, in seconds		
slave_max_allowed_packet		
No	Yes	No
No	Global	Yes
DESCRIPTION: Maximum size, in bytes, of a packet that can be sent from a replication master to a slave; overrides max_allowed_packet.		
Slave_open_temp_tables		
No	No	Yes
No	Global	No
DESCRIPTION: Number of temporary tables that the slave SQL thread currently has open		
slave_parallel_type		
No	Yes	No
No	Global	Yes
DESCRIPTION: Tells the slave to use database partitioning (DATABASE) or information (LOGICAL_CLOCK) from master to parallelize transactions. The default is DATABASE.		
slave_parallel_workers		
Yes	Yes	No
No	Global	Yes
DESCRIPTION: Number of worker threads for executing events in parallel. Set to 0 (the default) to disable slave multi-threading. Not supported by MySQL Cluster.		
slave_pending_jobs_size_max		
No	Yes	No
No	Global	Yes
DESCRIPTION: Maximum size of slave worker queues holding events not yet applied.		
slave_preserve_commit_order		
Yes	Yes	No
No	Global	Yes
DESCRIPTION: Ensures that all commits by slave workers happen in the same order as on the master to maintain consistency when using parallel worker threads.		
Slave_retried_transactions		
No	No	Yes
No	Global	No
DESCRIPTION: The total number of times since startup that the replication slave SQL thread has retried transactions		

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
Notes		
slave_rows_search_algorithms		
No	Yes	No
No	Global	Yes
DESCRIPTION: Determines search algorithms used for slave update batching. Any 2 or 3 from the list INDEX_SEARCH, TABLE_SCAN, HASH_SCAN; the default is TABLE_SCAN,INDEX_SCAN.		
Slave_running		
No	No	Yes
No	Global	No
DESCRIPTION: The state of this server as a replication slave (slave I/O thread status)		
slave_transaction_retries		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Number of times the slave SQL thread will retry a transaction in case it failed with a deadlock or elapsed lock wait timeout, before giving up and stopping		
slave_type_conversions		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Controls type conversion mode on replication slave. Value is a list of zero or more elements from the list: ALL_LOSSY, ALL_NON_LOSSY. Set to an empty string to disallow type conversions between master and slave.		
sql_slave_skip_counter		
No	Yes	No
No	Global	Yes
DESCRIPTION: Number of events from the master that a slave server should skip. Not compatible with GTID replication.		
sync_binlog		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Synchronously flush binary log to disk after every #th event		
sync_master_info		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Synchronize master.info to disk after every #th event.		
sync_relay_log		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Synchronize relay log to disk after every #th event.		
sync_relay_log_info		
Yes	Yes	No

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
Notes		
Yes	Global	Yes
DESCRIPTION: Synchronize relay.info file to disk after every #th event.		

Section 18.1.6.2, “Replication Master Options and Variables”, provides more detailed information about options and variables relating to replication master servers. For more information about options and variables relating to replication slaves, see Section 18.1.6.3, “Replication Slave Options and Variables”.

Table 18.4 Summary of Binary Logging options and variables in MySQL 8.0

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
Notes		
binlog-checksum		
Yes	No	No
Yes		No
DESCRIPTION: Enable/disable binary log checksums		
binlog-do-db		
Yes	No	No
Yes		No
DESCRIPTION: Limits binary logging to specific databases		
binlog_format		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Specifies the format of the binary log		
binlog-ignore-db		
Yes	No	No
Yes		No
DESCRIPTION: Tells the master that updates to the given database should not be logged to the binary log		
binlog-row-event-max-size		
Yes	No	No
Yes		No
DESCRIPTION: Binary log max event size		
binlog-rows-query-log-events		
Yes	No	No
Yes		No
DESCRIPTION: Enables logging of rows query log events when using row-based logging. Disabled by default. Do not enable when producing logs for pre-5.6.2 slaves/readers.		
Binlog_cache_disk_use		
No	No	Yes
No	Global	No

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
Notes		
DESCRIPTION: Number of transactions that used a temporary file instead of the binary log cache binlog_cache_size		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Size of the cache to hold the SQL statements for the binary log during a transaction Binlog_cache_use		
No	No	Yes
No	Global	No
DESCRIPTION: Number of transactions that used the temporary binary log cache binlog_checksum		
No	Yes	No
No	Global	Yes
DESCRIPTION: Enable/disable binary log checksums binlog_direct_non_transactional_updates		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Causes updates using statement format to nontransactional engines to be written directly to binary log. See documentation before using. binlog_error_action		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Controls what happens when the server cannot write to the binary log. binlog_group_commit_sync_delay		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Sets the number of microseconds to wait before synchronizing transactions to disk. binlog_group_commit_sync_no_delay_count		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Sets the maximum number of transactions to wait for before aborting the current delay specified by <code>binlog_group_commit_sync_delay</code> . binlog_max_flush_queue_time		
No	Yes	No
No	Global	Yes
DESCRIPTION: How long to read transactions before flushing to binary log binlog_order_commits		
No	Yes	No
No	Global	Yes
DESCRIPTION: Whether to commit in same order as writes to binary log		

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
Notes		
binlog_row_image		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Use full or minimal images when logging row changes. Allowed values are full, minimal, and noblob.		
binlog_rows_query_log_events		
No	Yes	No
No	Both	Yes
DESCRIPTION: When TRUE, enables logging of rows query log events in row-based logging mode. FALSE by default. Do not enable when producing logs for pre-5.6.2 replication slaves or other readers.		
Binlog_stmt_cache_disk_use		
No	No	Yes
No	Global	No
DESCRIPTION: Number of nontransactional statements that used a temporary file instead of the binary log statement cache		
binlog_stmt_cache_size		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Size of the cache to hold nontransactional statements for the binary log during a transaction		
Binlog_stmt_cache_use		
No	No	Yes
No	Global	No
DESCRIPTION: Number of statements that used the temporary binary log statement cache		
binlogging_impossible_mode		
Yes	Yes	No
Yes	Both	Yes
DESCRIPTION: Deprecated and will be removed in a future version. Use the renamed binlog_error_action instead.		
Com_show_binlog_events		
No	No	Yes
No	Both	No
DESCRIPTION: Count of SHOW BINLOG EVENTS statements		
Com_show_binlogs		
No	No	Yes
No	Both	No
DESCRIPTION: Count of SHOW BINLOGS statements		
log-bin-use-v1-row-events		
Yes	Yes	No

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
Notes		
Yes	Global	No
DESCRIPTION: Use version 1 binary log row events log_bin_basename		
No	Yes	No
No	Global	No
DESCRIPTION: Complete path to binary log, including filename log_bin_use_v1_row_events		
Yes	Yes	No
Yes	Global	No
DESCRIPTION: Shows whether server is using version 1 binary log row events master-verify-checksum		
Yes	No	No
Yes		No
DESCRIPTION: Cause master to examine checksums when reading from the binary log master_verify_checksum		
No	Yes	No
No	Global	Yes
DESCRIPTION: Cause master to read checksums from binary log. max-binlog-dump-events		
Yes	No	No
Yes		No
DESCRIPTION: Option used by mysql-test for debugging and testing of replication max_binlog_cache_size		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Can be used to restrict the total size used to cache a multi-statement transaction max_binlog_size		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Binary log will be rotated automatically when size exceeds this value max_binlog_stmt_cache_size		
Yes	Yes	No
Yes	Global	Yes
DESCRIPTION: Can be used to restrict the total size used to cache all nontransactional statements during a transaction slave-sql-verify-checksum		
Yes	No	No
Yes		No

Option or Variable Name		
Command Line	System Variable	Status Variable
Option File	Scope	Dynamic
Notes		
DESCRIPTION: Cause slave to examine checksums when reading from the relay log		
<code>slave_sql_verify_checksum</code>		
No	Yes	No
No	Global	Yes
DESCRIPTION: Cause slave to examine checksums when reading from relay log.		
<code>sporadic-binlog-dump-fail</code>		
Yes	No	No
Yes		No
DESCRIPTION: Option used by mysql-test for debugging and testing of replication		

Section 18.1.6.4, “Binary Logging Options and Variables”, provides more detailed information about options and variables relating to binary logging. For additional general information about the binary log, see Section 5.4.4, “The Binary Log”.

For information about the `sql_log_bin` and `sql_log_off` variables, see Section 5.1.5, “Server System Variables”.

For a table showing *all* command-line options, system and status variables used with `mysqld`, see Section 5.1.3, “Server Option and Variable Reference”.

18.1.6.2 Replication Master Options and Variables

This section describes the server options and system variables that you can use on replication master servers. You can specify the options either on the [command line](#) or in an [option file](#). You can specify system variable values using [SET](#).

On the master and each slave, you must use the `server-id` option to establish a unique replication ID. For each server, you should pick a unique positive integer in the range from 1 to $2^{32} - 1$, and each ID must be different from every other ID in use by any other replication master or slave. Example: `server-id=3`.

For options used on the master for controlling binary logging, see Section 18.1.6.4, “Binary Logging Options and Variables”.

Startup Options for Replication Masters

The following list describes startup options for controlling replication master servers. Replication-related system variables are discussed later in this section.

- `--show-slave-auth-info`

Command-Line Format	<code>--show-slave-auth-info</code>	
Permitted Values	Type	boolean
	Default	<code>FALSE</code>

Display slave user names and passwords in the output of `SHOW SLAVE HOSTS` on the master server for slaves started with the `--report-user` and `--report-password` options.

System Variables Used on Replication Masters

The following system variables are used to control replication masters:

- `auto_increment_increment`

System Variable	Name	<code>auto_increment_increment</code>
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	1
	Min Value	1
	Max Value	65535

`auto_increment_increment` and `auto_increment_offset` are intended for use with master-to-master replication, and can be used to control the operation of `AUTO_INCREMENT` columns. Both variables have global and session values, and each can assume an integer value between 1 and 65,535 inclusive. Setting the value of either of these two variables to 0 causes its value to be set to 1 instead. Attempting to set the value of either of these two variables to an integer greater than 65,535 or less than 0 causes its value to be set to 65,535 instead. Attempting to set the value of `auto_increment_increment` or `auto_increment_offset` to a noninteger value produces an error, and the actual value of the variable remains unchanged.

Note

`auto_increment_increment` is intended for use with MySQL Cluster, which is not currently supported in MySQL 8.0.

These two variables affect `AUTO_INCREMENT` column behavior as follows:

- `auto_increment_increment` controls the interval between successive column values. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name          | Value |
+-----+-----+
| auto_increment_increment | 1     |
| auto_increment_offset  | 1     |
+-----+-----+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoincl
-> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.04 sec)

mysql> SET @@auto_increment_increment=10;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name          | Value |
+-----+-----+
| auto_increment_increment | 10    |
| auto_increment_offset  | 1     |
+-----+-----+
2 rows in set (0.01 sec)

mysql> INSERT INTO autoincl VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0
```

```
mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1 |
| 11 |
| 21 |
| 31 |
+-----+
4 rows in set (0.00 sec)
```

- `auto_increment_offset` determines the starting point for the `AUTO_INCREMENT` column value. Consider the following, assuming that these statements are executed during the same session as the example given in the description for `auto_increment_increment`:

```
mysql> SET @@auto_increment_offset=5;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 10 |
| auto_increment_offset | 5 |
+-----+-----+
2 rows in set (0.00 sec)

mysql> CREATE TABLE autoinc2
  -> (col INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO autoinc2 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc2;
+-----+
| col |
+-----+
| 5 |
| 15 |
| 25 |
| 35 |
+-----+
4 rows in set (0.02 sec)
```

When the value of `auto_increment_offset` is greater than that of `auto_increment_increment`, the value of `auto_increment_offset` is ignored.

If either of these variables is changed, and then new rows inserted into a table containing an `AUTO_INCREMENT` column, the results may seem counterintuitive because the series of `AUTO_INCREMENT` values is calculated without regard to any values already present in the column, and the next value inserted is the least value in the series that is greater than the maximum existing value in the `AUTO_INCREMENT` column. The series is calculated like this:

$$\text{auto_increment_offset} + N \times \text{auto_increment_increment}$$

where N is a positive integer value in the series [1, 2, 3, ...]. For example:

```
mysql> SHOW VARIABLES LIKE 'auto_inc%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| auto_increment_increment | 10 |
| auto_increment_offset | 5 |
+-----+-----+
```

```

2 rows in set (0.00 sec)

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1 |
| 11 |
| 21 |
| 31 |
+-----+
4 rows in set (0.00 sec)

mysql> INSERT INTO autoinc1 VALUES (NULL), (NULL), (NULL), (NULL);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT col FROM autoinc1;
+-----+
| col |
+-----+
| 1 |
| 11 |
| 21 |
| 31 |
| 35 |
| 45 |
| 55 |
| 65 |
+-----+
8 rows in set (0.00 sec)
    
```

The values shown for `auto_increment_increment` and `auto_increment_offset` generate the series $5 + N \times 10$, that is, [5, 15, 25, 35, 45, ...]. The highest value present in the `col` column prior to the `INSERT` is 31, and the next available value in the `AUTO_INCREMENT` series is 35, so the inserted values for `col` begin at that point and the results are as shown for the `SELECT` query.

It is not possible to restrict the effects of these two variables to a single table; these variables control the behavior of all `AUTO_INCREMENT` columns in *all* tables on the MySQL server. If the global value of either variable is set, its effects persist until the global value is changed or overridden by setting the session value, or until `mysqld` is restarted. If the local value is set, the new value affects `AUTO_INCREMENT` columns for all tables into which new rows are inserted by the current user for the duration of the session, unless the values are changed during that session.

The default value of `auto_increment_increment` is 1. See [Section 18.4.1.1, “Replication and AUTO_INCREMENT”](#).

- `auto_increment_offset`

System Variable	Name	<code>auto_increment_offset</code>
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	1
	Min Value	1
	Max Value	65535

This variable has a default value of 1. For more information, see the description for [auto_increment_increment](#).

Note

[auto_increment_offset](#) is intended for use with MySQL Cluster, which is not currently supported in MySQL 8.0.

18.1.6.3 Replication Slave Options and Variables

This section explains the server options and system variables that apply to slave replication servers and contains the following:

[Startup Options for Replication Slaves](#)

[Options for Logging Slave Status to Tables](#)

[System Variables Used on Replication Slaves](#)

Specify the options either on the [command line](#) or in an [option file](#). Many of the options can be set while the server is running by using the `CHANGE MASTER TO` statement. Specify system variable values using `SET`.

Server ID. On the master and each slave, you must use the `server-id` option to establish a unique replication ID in the range from 1 to $2^{32} - 1$. “Unique” means that each ID must be different from every other ID in use by any other replication master or slave. Example `my.cnf` file:

```
[mysqld]
server-id=3
```

Startup Options for Replication Slaves

This section explains startup options for controlling replication slave servers. Many of these options can be set while the server is running by using the `CHANGE MASTER TO` statement. Others, such as the `--replicate-*` options, can be set only when the slave server starts. Replication-related system variables are discussed later in this section.

- `--log-slave-updates`

Command-Line Format	<code>--log-slave-updates</code>	
System Variable	Name	<code>log_slave_updates</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	boolean
	Default	<code>OFF</code>

Normally, a slave does not write any updates that are received from a master server to its own binary log. This option causes the slave to write the updates performed by its SQL thread to its own binary log. For this option to have any effect, the slave must also be started with the `--log-bin` option to enable binary logging. `--log-slave-updates` is used when you want to chain replication servers. For example, you might want to set up replication servers using this arrangement:

```
A -> B -> C
```

Here, `A` serves as the master for the slave `B`, and `B` serves as the master for the slave `C`. For this to work, `B` must be both a master *and* a slave. You must start both `A` and `B` with `--log-bin` to enable

binary logging, and B with the `--log-slave-updates` option so that updates received from A are logged by B to its binary log.

- `--log-warnings[=level]`

Deprecated	5.7.2	
Command-Line Format	<code>--log-warnings[=#]</code>	
System Variable	Name	<code>log_warnings</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values (32-bit platforms)	Type	integer
	Default	2
	Min Value	0
	Max Value	4294967295
Permitted Values (64-bit platforms)	Type	integer
	Default	2
	Min Value	0
	Max Value	18446744073709551615

Note

The `log_error_verbosity` system variable is preferred over, and should be used instead of, the `--log-warnings` option or `log_warnings` system variable. For more information, see the descriptions of `log_error_verbosity` and `log_warnings`. The `--log-warnings` command-line option and `log_warnings` system variable are deprecated and will be removed in a future MySQL release.

Causes the server to record more messages to the error log about what it is doing. With respect to replication, the server generates warnings that it succeeded in reconnecting after a network or connection failure, and provides information about how each slave thread started. This variable is enabled by default with a value of 2. To disable it, set it to 0. The server logs messages about statements that are unsafe for statement-based logging if the value is greater than 0. Aborted connections and access-denied errors for new connection attempts are logged if the value is greater than 1. See [Section B.5.2.10, “Communication Errors and Aborted Connections”](#).

Note

The effects of this option are not limited to replication. It produces warnings across a spectrum of server activities.

- `--master-info-file=file_name`

Command-Line Format	<code>--master-info-file=file_name</code>	
Permitted Values	Type	file name
	Default	<code>master.info</code>

The name to use for the file in which the slave records information about the master. The default name is `master.info` in the data directory. For information about the format of this file, see [Section 18.2.4.2, “Slave Status Logs”](#).

- `--master-retry-count=count`

Deprecated	5.6.1	
Command-Line Format	<code>--master-retry-count=#</code>	
Permitted Values (32-bit platforms)	Type	integer
	Default	86400
	Min Value	0
	Max Value	4294967295
Permitted Values (64-bit platforms)	Type	integer
	Default	86400
	Min Value	0
	Max Value	18446744073709551615

The number of times that the slave tries to connect to the master before giving up. Reconnects are attempted at intervals set by the `MASTER_CONNECT_RETRY` option of the `CHANGE MASTER TO` statement (default 60). Reconnects are triggered when data reads by the slave time out according to the `--slave-net-timeout` option. The default value is 86400. A value of 0 means “infinite”; the slave attempts to connect forever.

This option is deprecated and will be removed in a future MySQL release. Applications should be updated to use the `MASTER_RETRY_COUNT` option of the `CHANGE MASTER TO` statement instead.

- `--max-relay-log-size=size`

Command-Line Format	<code>--max-relay-log-size=#</code>	
System Variable	Name	<code>max_relay_log_size</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	0
	Min Value	0
	Max Value	1073741824

The size at which the server rotates relay log files automatically. If this value is nonzero, the relay log is rotated automatically when its size exceeds this value. If this value is zero (the default), the size at which relay log rotation occurs is determined by the value of `max_binlog_size`. For more information, see [Section 18.2.4.1, “The Slave Relay Log”](#).

- `--relay-log=file_name`

Command-Line Format	<code>--relay-log=file_name</code>	
System Variable	Name	<code>relay_log</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	file name

The base name for the relay log. For the default replication channel, the default base name for relay logs is `host_name-relay-bin`. For non-default replication channels, the default base name for relay logs is `host_name-channel-relay-bin`, where `channel` is the name of the replication channel recorded in this relay log. The server writes the file in the data directory unless the base name is given with a leading absolute path name to specify a different directory. The server creates relay log files in sequence by adding a numeric suffix to the base name.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default base name is used only if the option is not actually specified*. If you use the `--relay-log` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see [Section 4.2.3, “Specifying Program Options”](#).

If you specify this option, the value specified is also used as the base name for the relay log index file. You can override this behavior by specifying a different relay log index file base name using the `--relay-log-index` option.

When the server reads an entry from the index file, it checks whether the entry contains a relative path. If it does, the relative part of the path is replaced with the absolute path set using the `--relay-log` option. An absolute path remains unchanged; in such a case, the index must be edited manually to enable the new path or paths to be used. Previously, manual intervention was required whenever relocating the binary log or relay log files. (Bug #11745230, Bug #12133)

You may find the `--relay-log` option useful in performing the following tasks:

- Creating relay logs whose names are independent of host names.
- If you need to put the relay logs in some area other than the data directory because your relay logs tend to be very large and you do not want to decrease `max_relay_log_size`.
- To increase speed by using load-balancing between disks.

You can obtain the relay log file name (and path) from the `relay_log_basename` system variable.

- `--relay-log-index=file_name`

Command-Line Format	<code>--relay-log-index=file_name</code>	
System Variable	Name	<code>relay_log_index</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	file name

The name to use for the relay log index file. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the server. For the default replication channel,

the default name is `host_name-relay-bin.index`. For non-default replication channels, the default name is `host_name-channel-relay-bin.index`, where `channel` is the name of the replication channel recorded in this relay log index.

Due to the manner in which MySQL parses server options, if you specify this option, you must supply a value; *the default base name is used only if the option is not actually specified*. If you use the `--relay-log-index` option without specifying a value, unexpected behavior is likely to result; this behavior depends on the other options used, the order in which they are specified, and whether they are specified on the command line or in an option file. For more information about how MySQL handles server options, see [Section 4.2.3, “Specifying Program Options”](#).

If you specify this option, the value specified is also used as the base name for the relay logs. You can override this behavior by specifying a different relay log file base name using the `--relay-log` option.

- `--relay-log-info-file=file_name`

Command-Line Format	<code>--relay-log-info-file=file_name</code>	
Permitted Values	Type	file name
	Default	<code>relay-log.info</code>

The name to use for the file in which the slave records information about the relay logs. The default name is `relay-log.info` in the data directory. For information about the format of this file, see [Section 18.2.4.2, “Slave Status Logs”](#).

- `--relay-log-purge={0|1}`

Command-Line Format	<code>--relay-log-purge</code>	
System Variable	Name	<code>relay_log_purge</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	<code>TRUE</code>

Disable or enable automatic purging of relay logs as soon as they are no longer needed. The default value is 1 (enabled). This is a global variable that can be changed dynamically with `SET GLOBAL relay_log_purge = N`. Disabling purging of relay logs when using the `--relay-log-recovery` option risks data consistency and is therefore not crash-safe.

- `--relay-log-recovery={0|1}`

Command-Line Format	<code>--relay-log-recovery</code>	
Permitted Values	Type	boolean
	Default	<code>FALSE</code>

Enables automatic relay log recovery immediately following server startup. The recovery process creates a new relay log file, initializes the SQL thread position to this new relay log, and initializes the I/O thread to the SQL thread position. Reading of the relay log from the master then continues. This should be used following a crash on the replication slave to ensure that no possibly corrupted relay logs are processed. The default value is 0 (disabled).

To provide a crash-safe slave, this option must be enabled (set to 1), `--relay-log-info-repository` must be set to `TABLE`, and `relay-log-purge` must be enabled. Enabling the `--relay-log-recovery` option when `relay-log-purge` is disabled risks reading the relay log from

files that were not purged, leading to data inconsistency, and is therefore not crash-safe. See [Crash-safe replication](#), for more information.

When using a multi-threaded slave (in other words `slave_parallel_workers` is greater than 0), inconsistencies such as gaps can occur in the sequence of transactions that have been executed from the relay log. Enabling the `--relay-log-recovery` option when there are inconsistencies causes an error and the option has no effect. The solution in this situation is to issue `START SLAVE UNTIL SQL_AFTER_MTS_GAPS`, which brings the server to a more consistent state, then issue `RESET SLAVE` to remove the relay logs. See [Section 18.4.1.34, “Replication and Transaction Inconsistencies”](#) for more information.

- `--relay-log-space-limit=size`

Command-Line Format	<code>--relay-log-space-limit=#</code>	
System Variable	Name	<code>relay_log_space_limit</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values (32-bit platforms)	Type	integer
	Default	0
	Min Value	0
	Max Value	4294967295
Permitted Values (64-bit platforms)	Type	integer
	Default	0
	Min Value	0
	Max Value	18446744073709551615

This option places an upper limit on the total size in bytes of all relay logs on the slave. A value of 0 means “no limit”. This is useful for a slave server host that has limited disk space. When the limit is reached, the I/O thread stops reading binary log events from the master server until the SQL thread has caught up and deleted some unused relay logs. Note that this limit is not absolute: There are cases where the SQL thread needs more events before it can delete relay logs. In that case, the I/O thread exceeds the limit until it becomes possible for the SQL thread to delete some relay logs because not doing so would cause a deadlock. You should not set `--relay-log-space-limit` to less than twice the value of `--max-relay-log-size` (or `--max-binlog-size` if `--max-relay-log-size` is 0). In that case, there is a chance that the I/O thread waits for free space because `--relay-log-space-limit` is exceeded, but the SQL thread has no relay log to purge and is unable to satisfy the I/O thread. This forces the I/O thread to ignore `--relay-log-space-limit` temporarily.

- `--replicate-do-db=db_name`

Command-Line Format	<code>--replicate-do-db=name</code>	
Permitted Values	Type	string

Creates a replication filter that selects using the name of a database. Such filters can also be created using `CHANGE REPLICATION FILTER REPLICATE_DO_DB`. Supports replication channel specific filters, enabling multi-source replication slaves to use specific filters for different sources. To configure a replication channel specific filter on a channel named `channel_1` use `--replicate-do-db=db_name` on the channel.

`do-db:channel_1:db_name`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See [Section 18.2.5.4, “Replication Channel Based Filters”](#) for more information. The precise effect of this filter depends on whether statement-based or row-based replication is in use.

Statement-based replication. Tell the slave SQL thread to restrict replication to statements where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* replicate cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` while a different database (or no database) is selected.

Warning

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, if you supply a comma separated list then the list is treated as the name of a single database.

An example of what does not work as you might expect when using statement-based replication: If the slave is started with `--replicate-do-db=sales` and you issue the following statements on the master, the `UPDATE` statement is *not* replicated:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “check just the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

Row-based replication. Tells the slave SQL thread to restrict replication to database `db_name`. Only tables belonging to `db_name` are changed; the current database has no effect on this. Suppose that the slave is started with `--replicate-do-db=sales` and row-based replication is in effect, and then the following statements are run on the master:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The `february` table in the `sales` database on the slave is changed in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, issuing the following statements on the master has no effect on the slave when using row-based replication and `--replicate-do-db=sales`:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the statement `USE prices` were changed to `USE sales`, the `UPDATE` statement's effects would still not be replicated.

Another important difference in how `--replicate-do-db` is handled in statement-based replication as opposed to row-based replication occurs with regard to statements that refer to multiple databases. Suppose that the slave is started with `--replicate-do-db=db1`, and the following statements are executed on the master:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based replication, then both tables are updated on the slave. However, when using row-based replication, only `table1` is affected on the slave; since `table2` is in a

different database, `table2` on the slave is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement would have no effect on the slave when using statement-based replication. However, if you are using row-based replication, the `UPDATE` would change `table1` on the slave, but not `table2`—in other words, only tables in the database named by `--replicate-do-db` are changed, and the choice of default database has no effect on this behavior.

If you need cross-database updates to work, use `--replicate-wild-do-table=db_name.%` instead. See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

Note

This option affects replication in the same manner that `--binlog-do-db` affects binary logging, and the effects of the replication format on how `--replicate-do-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-do-db`.

This option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements.

- `--replicate-ignore-db=db_name`

Command-Line Format	<code>--replicate-ignore-db=name</code>	
Permitted Values	Type	string

Creates a replication filter using the name of a database. Such filters can also be created using `CHANGE REPLICATION FILTER REPLICATE_IGNORE_DB`. Supports replication channel specific filters, enabling multi-source replication slaves to use specific filters for different sources. To configure a replication channel specific filter on a channel named `channel_1` use `--replicate-ignore-db:channel_1:db_name`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See [Section 18.2.5.4, “Replication Channel Based Filters”](#) for more information.

As with `--replicate-do-db`, the precise effect of this filtering depends on whether statement-based or row-based replication is in use, and are described in the next several paragraphs.

Statement-based replication. Tells the slave SQL thread not to replicate any statement where the default database (that is, the one selected by `USE`) is `db_name`.

Row-based replication. Tells the slave SQL thread not to update any tables in the database `db_name`. The default database has no effect.

When using statement-based replication, the following example does not work as you might expect. Suppose that the slave is started with `--replicate-ignore-db=sales` and you issue the following statements on the master:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement *is* replicated in such a case because `--replicate-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based replication, the `UPDATE` statement's effects are *not* propagated to the slave, and the slave's copy of the `sales.january` table is unchanged; in this instance, `--replicate-ignore-db=sales` causes *all* changes made to tables in the master's copy of the `sales` database to be ignored by the slave.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, if you supply a comma separated list then the list will be treated as the name of a single database.

You should not use this option if you are using cross-database updates and you do not want these updates to be replicated. See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

If you need cross-database updates to work, use `--replicate-wild-ignore-table=db_name.%` instead. See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

Note

This option affects replication in the same manner that `--binlog-ignore-db` affects binary logging, and the effects of the replication format on how `--replicate-ignore-db` affects replication behavior are the same as those of the logging format on the behavior of `--binlog-ignore-db`.

This option has no effect on `BEGIN`, `COMMIT`, or `ROLLBACK` statements.

- `--replicate-do-table=db_name.tbl_name`

Command-Line Format	<code>--replicate-do-table=name</code>	
Permitted Values	Type	string

Creates a replication filter by telling the slave SQL thread to restrict replication to a given table. To specify more than one table, use this option multiple times, once for each table. This works for both cross-database updates and default database updates, in contrast to `--replicate-do-db`. See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#). You can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_DO_TABLE` statement.

Supports replication channel specific filters, enabling multi-source replication slaves to use specific filters for different sources. To configure a replication channel specific filter on a channel named `channel_1` use `--replicate-do-table:channel_1:db_name.tbl_name`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See [Section 18.2.5.4, “Replication Channel Based Filters”](#) for more information.

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*db` options.

- `--replicate-ignore-table=db_name.tbl_name`

Command-Line Format	<code>--replicate-ignore-table=name</code>	
Permitted Values	Type	string

Creates a replication filter by telling the slave SQL thread not to replicate any statement that updates the specified table, even if any other tables might be updated by the same statement. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates, in contrast to `--replicate-ignore-db`. See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#). You can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_IGNORE_TABLE` statement.

Supports replication channel specific filters, enabling multi-source replication slaves to use specific filters for different sources. To configure a replication channel specific filter on a channel named `channel_1` use `--replicate-ignore-table:channel_1:db_name.tbl_name`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See [Section 18.2.5.4, “Replication Channel Based Filters”](#) for more information.

This option affects only statements that apply to tables. It does not affect statements that apply only to other database objects, such as stored routines. To filter statements operating on stored routines, use one or more of the `--replicate-*-db` options.

- `--replicate-rewrite-db=from_name->to_name`

Command-Line Format	<code>--replicate-rewrite-db=<i>old_name</i>-><i>new_name</i></code>	
Permitted Values	Type	string

Tells the slave to create a replication filter that translates the default database (that is, the one selected by `USE`) to `to_name` if it was `from_name` on the master. Only statements involving tables are affected (not statements such as `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), and only if `from_name` is the default database on the master. To specify multiple rewrites, use this option multiple times. The server uses the first one with a `from_name` value that matches. The database name translation is done *before* the `--replicate-*` rules are tested. You can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB` statement.

Supports replication channel specific filters, enabling multi-source replication slaves to use specific filters for different sources. To configure a replication channel specific filter on a channel named `channel_1` use `--replicate-rewrite-db:channel_1:(db_name1->db_name2)`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See [Section 18.2.5.4, “Replication Channel Based Filters”](#) for more information.

Statements in which table names are qualified with database names when using this option do not work with table-level replication filtering options such as `--replicate-do-table`. Suppose we have a database named `a` on the master, one named `b` on the slave, each containing a table `t`, and have started the master with `--replicate-rewrite-db='a->b'`. At a later point in time, we execute `DELETE FROM a.t`. In this case, no relevant filtering rule works, for the reasons shown here:

1. `--replicate-do-table=a.t` does not work because the slave has table `t` in database `b`.
2. `--replicate-do-table=b.t` does not match the original statement and so is ignored.
3. `--replicate-do-table=*.t` is handled identically to `--replicate-do-table=a.t`, and thus does not work, either.

Similarly, the `--replication-rewrite-db` option does not work with cross-database updates.

If you use this option on the command line and the `>` character is special to your command interpreter, quote the option value. For example:

```
shell> mysqld --replicate-rewrite-db="olddb->newdb"
```

- `--replicate-same-server-id`

Command-Line Format	<code>--replicate-same-server-id</code>	
Permitted Values	Type	boolean
	Default	<code>FALSE</code>

To be used on slave servers. Usually you should use the default setting of 0, to prevent infinite loops caused by circular replication. If set to 1, the slave does not skip events having its own server ID. Normally, this is useful only in rare configurations. Cannot be set to 1 if `--log-slave-updates` is used. By default, the slave I/O thread does not write binary log events to the relay log if they have the slave's server ID (this optimization helps save disk usage). If you want to use `--replicate-same-`

`server-id`, be sure to start the slave with this option before you make the slave read its own events that you want the slave SQL thread to execute.

- `--replicate-wild-do-table=db_name.tbl_name`

Command-Line Format	<code>--replicate-wild-do-table=name</code>	
Permitted Values	Type	string

Creates a replication filter by telling the slave thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns. Patterns can contain the `%` and `_` wildcard characters, which have the same meaning as for the `LIKE` pattern-matching operator. To specify more than one table, use this option multiple times, once for each table. This works for cross-database updates. See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#). You can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_WILD_DO_TABLE` statement.

Supports replication channel specific filters, enabling multi-source replication slaves to use specific filters for different sources. To configure a replication channel specific filter on a channel named `channel_1` use `--replicate-wild-do-table:channel_1:db_name.tbl_name`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See [Section 18.2.5.4, “Replication Channel Based Filters”](#) for more information.

This option applies to tables, views, and triggers. It does not apply to stored procedures and functions, or events. To filter statements operating on the latter objects, use one or more of the `--replicate-*-db` options.

Example: `--replicate-wild-do-table=foo%.bar%` replicates only updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

If the table name pattern is `%`, it matches any table name and the option also applies to database-level statements (`CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`). For example, if you use `--replicate-wild-do-table=foo%.`, database-level statements are replicated if the database name matches the pattern `foo%`.

To include literal wildcard characters in the database or table name patterns, escape them with a backslash. For example, to replicate all tables of a database that is named `my_own%db`, but not replicate tables from the `my1ownAABCdb` database, you should escape the `_` and `%` characters like this: `--replicate-wild-do-table=my_own\%db`. If you use the option on the command line, you might need to double the backslashes or quote the option value, depending on your command interpreter. For example, with the `bash` shell, you would need to type `--replicate-wild-do-table=my_own\\%db`.

- `--replicate-wild-ignore-table=db_name.tbl_name`

Command-Line Format	<code>--replicate-wild-ignore-table=name</code>	
Permitted Values	Type	string

Creates a replication filter which keeps the slave thread from replicating a statement in which any table matches the given wildcard pattern. To specify more than one table to ignore, use this option multiple times, once for each table. This works for cross-database updates. See [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#). You can also create such a filter by issuing a `CHANGE REPLICATION FILTER REPLICATE_WILD_IGNORE_TABLE` statement.

Supports replication channel specific filters, enabling multi-source replication slaves to use specific filters for different sources. To configure a replication channel specific filter on a channel named `channel_1` use `--replicate-wild-ignore:channel_1:db_name.tbl_name`. In this case, the first colon is interpreted as a separator and subsequent colons are literal colons. See [Section 18.2.5.4, “Replication Channel Based Filters”](#) for more information.

Example: `--replicate-wild-ignore-table=foo%.bar%` does not replicate updates that use a table where the database name starts with `foo` and the table name starts with `bar`.

For information about how matching works, see the description of the `--replicate-wild-do-table` option. The rules for including literal wildcard characters in the option value are the same as for `--replicate-wild-ignore-table` as well.

- `--report-host=host_name`

Command-Line Format	<code>--report-host=host_name</code>	
System Variable	Name	<code>report_host</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	string

The host name or IP address of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server. Leave the value unset if you do not want the slave to register itself with the master.

Note

It is not sufficient for the master to simply read the IP address of the slave from the TCP/IP socket after the slave connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the slave from the master or other hosts.

- `--report-password=password`

Command-Line Format	<code>--report-password=name</code>	
System Variable	Name	<code>report_password</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	string

The account password of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the master was started with `--show-slave-auth-info`.

Although the name of this option might imply otherwise, `--report-password` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the password for the MySQL replication user account.

- `--report-port=slave_port_num`

Command-Line Format	<code>--report-port=#</code>	
System Variable	Name	<code>report_port</code>
	Variable Scope	Global
	Dynamic Variable	No

Permitted Values	Type	integer
	Default	[<code>slave_port</code>]
	Min Value	0
	Max Value	65535

The TCP/IP port number for connecting to the slave, to be reported to the master during slave registration. Set this only if the slave is listening on a nondefault port or if you have a special tunnel from the master or other clients to the slave. If you are not sure, do not use this option.

The default value for this option is the port number actually used by the slave (Bug #13333431). This is also the default value displayed by `SHOW SLAVE HOSTS`.

- `--report-user=user_name`

Command-Line Format	<code>--report-user=name</code>	
System Variable	Name	<code>report_user</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	string

The account user name of the slave to be reported to the master during slave registration. This value appears in the output of `SHOW SLAVE HOSTS` on the master server if the master was started with `--show-slave-auth-info`.

Although the name of this option might imply otherwise, `--report-user` is not connected to the MySQL user privilege system and so is not necessarily (or even likely to be) the same as the name of the MySQL replication user account.

- `--slave-checkpoint-group=#`

Command-Line Format	<code>--slave-checkpoint-group=#</code>	
Permitted Values	Type	integer
	Default	512
	Min Value	32
	Max Value	524280
	Block Size	8

Sets the maximum number of transactions that can be processed by a multi-threaded slave before a checkpoint operation is called to update its status as shown by `SHOW SLAVE STATUS`. Setting this option has no effect on slaves for which multi-threading is not enabled.

This option works in combination with the `--slave-checkpoint-period` option in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

a value that is not such a multiple, but the server rounds it down to the next lower multiple of 8 before storing the value. (*Exception:* No such rounding is performed by the debug server.) Regardless of how the server was built, the default value is 512, and the maximum allowed value is 524280.

- `--slave-checkpoint-period=#`

Command-Line Format	<code>--slave-checkpoint-period=#</code>	
Permitted Values	Type	integer
	Default	300
	Min Value	1
	Max Value	4G

Sets the maximum time (in milliseconds) that is allowed to pass before a checkpoint operation is called to update the status of a multi-threaded slave as shown by `SHOW SLAVE STATUS`. Setting this option has no effect on slaves for which multi-threading is not enabled.

This option works in combination with the `--slave-checkpoint-group` option in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this option is 1, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 0. Regardless of how the server was built, the default value is 300, and the maximum possible value is 4294967296 (4GB).

- `--slave-parallel-workers`

Command-Line Format	<code>--slave-parallel-workers=#</code>	
Permitted Values	Type	integer
	Default	0
	Min Value	0
	Max Value	1024

Sets the number of slave applier threads for executing replication transactions in parallel. Setting this variable to a number greater than 0 creates a multi-threaded slave with this number of applier threads. When set to 0 (the default) parallel execution is disabled and the slave uses a single applier thread.

A multi-threaded slave provides parallel execution by using a coordinator thread and the number of applier threads configured by this option. The way which transactions are distributed among applier threads is configured by `--slave-parallel-type`. For more information about multi-threaded slaves see `slave-parallel-workers`.

- `--slave-pending-jobs-size-max=#`

Command-Line Format	<code>--slave-pending-jobs-size-max=#</code>	
Permitted Values	Type	integer
	Default	16M
	Min Value	1024
	Max Value	

	Max Value	18EB
	Block Size	1024

For multi-threaded slaves, this option sets the maximum amount of memory (in bytes) available to slave worker queues holding events not yet applied. Setting this option has no effect on slaves for which multi-threading is not enabled.

The minimum possible value for this option is 1024; the default is 16MB. The maximum possible value is 18446744073709551615 (16 exabytes). Values that are not exact multiples of 1024 are rounded down to the next-highest multiple of 1024 prior to being stored.

Important

The value for this option must not be less than the master's value for `max_allowed_packet`; otherwise a slave worker queue may become full while there remain events coming from the master to be processed.

- `--skip-slave-start`

Command-Line Format	<code>--skip-slave-start</code>	
Permitted Values	Type	boolean
	Default	FALSE

Tells the slave server not to start the slave threads when the server starts. To start the threads later, use a `START SLAVE` statement.

- `--slave_compressed_protocol={0|1}`

Command-Line Format	<code>--slave-compressed-protocol</code>	
System Variable	Name	<code>slave_compressed_protocol</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	OFF

If this option is set to 1, use compression for the slave/master protocol if both the slave and the master support it. The default is 0 (no compression).

- `--slave-load-tmpdir=dir_name`

Command-Line Format	<code>--slave-load-tmpdir=dir_name</code>	
System Variable	Name	<code>slave_load_tmpdir</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	directory name
	Default	/tmp

The name of the directory where the slave creates temporary files. This option is by default equal to the value of the `tmpdir` system variable. When the slave SQL thread replicates a `LOAD DATA INFILE` statement, it extracts the file to be loaded from the relay log into temporary files, and then loads these into the table. If the file loaded on the master is huge, the temporary files on the slave are huge, too. Therefore, it might be advisable to use this option to tell the slave to put temporary files in a directory located in some file system that has a lot of available space. In that case, the relay logs are huge as well, so you might also want to use the `--relay-log` option to place the relay logs in that file system.

The directory specified by this option should be located in a disk-based file system (not a memory-based file system) because the temporary files used to replicate `LOAD DATA INFILE` must survive machine restarts. The directory also should not be one that is cleared by the operating system during the system startup process.

- `slave-max-allowed-packet=bytes`

Command-Line Format	<code>--slave-max-allowed-packet=#</code>	
Permitted Values	Type	integer
	Default	1073741824
	Min Value	1024
	Max Value	1073741824

This option sets the maximum packet size in bytes for the slave SQL and I/O threads, so that large updates using row-based replication do not cause replication to fail because an update exceeded `max_allowed_packet`. (Bug #12400221, Bug #60926)

The corresponding server variable `slave_max_allowed_packet` always has a value that is a positive integer multiple of 1024; if you set it to some value that is not such a multiple, the value is automatically rounded down to the next highest multiple of 1024. (For example, if you start the server with `--slave-max-allowed-packet=10000`, the value used is 9216; setting 0 as the value causes 1024 to be used.) A truncation warning is issued in such cases.

The maximum (and default) value is 1073741824 (1 GB); the minimum is 1024.

- `--slave-net-timeout=seconds`

Command-Line Format	<code>--slave-net-timeout=#</code>	
System Variable	Name	<code>slave_net_timeout</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	60
	Min Value	1

The number of seconds to wait for more data from the master before the slave considers the connection broken, aborts the read, and tries to reconnect. The first retry occurs immediately after the timeout. The interval between retries is controlled by the `MASTER_CONNECT_RETRY` option for the `CHANGE MASTER TO` statement, and the number of reconnection attempts is limited by the `--master-retry-count` option. The default value is 60 seconds (one minute).

- `--slave-parallel-type=type`

Command-Line Format	<code>--slave-parallel-type=type</code>	
Permitted Values	Type	enumeration
	Default	DATABASE
	Valid Values	DATABASE
LOGICAL_CLOCK		

When using a multi-threaded slave (`slave_parallel_workers` is greater than 0), this option specifies the policy used to decide which transactions are allowed to execute in parallel on the slave. The possible values are:

- **DATABASE**: Transactions that update different databases are applied in parallel. This value is only appropriate if data is partitioned into multiple databases which are being updated independently and concurrently on the master. Only recommended if there are no cross-database constraints, as such constraints may be violated on the slave.
- **LOGICAL_CLOCK**: Transactions that are part of the same binary log group commit on a master are applied in parallel on a slave. There are no cross-database constraints, and data does not need to be partitioned into multiple databases.

Regardless of the value of this variable, there is no special configuration required on the master. When `slave_preserve_commit_order=1`, you can only use **LOGICAL_CLOCK**. If your replication topology uses multiple levels of slaves, **LOGICAL_CLOCK** may achieve less parallelization for each level the slave is away from the master.

- `slave-rows-search-algorithms=list`

Command-Line Format	<code>--slave-rows-search-algorithms=list</code>	
Permitted Values	Type	set
	Default	TABLE_SCAN, INDEX_SCAN
	Valid Values	TABLE_SCAN, INDEX_SCAN
		INDEX_SCAN, HASH_SCAN
		TABLE_SCAN, HASH_SCAN
TABLE_SCAN, INDEX_SCAN, HASH_SCAN (equivalent to INDEX_SCAN, HASH_SCAN)		
Permitted Values (>= 8.0.2)	Type	set
	Default	INDEX_SCAN, HASH_SCAN
	Valid Values	TABLE_SCAN, INDEX_SCAN
		INDEX_SCAN, HASH_SCAN
		TABLE_SCAN, HASH_SCAN
TABLE_SCAN, INDEX_SCAN, HASH_SCAN (equivalent to INDEX_SCAN, HASH_SCAN)		

When preparing batches of rows for row-based logging and replication, this option controls how the rows are searched for matches—that is, whether or not hashing is used for searches using a primary or unique key, some other key, or no key at all. Specify a comma-separated list of any 2 (or all 3) values from the list **INDEX_SCAN**, **TABLE_SCAN**, **HASH_SCAN**. The list need not be quoted, but must contain no spaces, whether or not quotes are used. Possible combinations (lists) and their effects are shown in the following table:

Index used / option value	<code>INDEX_SCAN, HASH_SCAN</code> or <code>INDEX_SCAN, TABLE_SCAN, HASH_SCAN</code>	<code>INDEX_SCAN, TABLE_SCAN</code>	<code>TABLE_SCAN, HASH_SCAN</code>
Primary key or unique key	Index scan	Index scan	Hash scan over index
(Other) Key	Hash scan over index	Index scan	Hash scan over index
No index	Hash scan	Table scan	Hash scan

The order in which the algorithms are specified in the list does not make any difference in the order in which they are displayed by a `SELECT` or `SHOW VARIABLES` statement (which is the same as that used in the table just shown previously).

- The default value is `INDEX_SCAN, HASH_SCAN`. With this setting, hashing is used for any searches that do not use a primary or unique key. Specifying `INDEX_SCAN, TABLE_SCAN, HASH_SCAN` has the same effect as specifying `INDEX_SCAN, HASH_SCAN`.
- To force hashing for *all* searches, set this option to `TABLE_SCAN, HASH_SCAN`.
- To remove hashing, set this option to `TABLE_SCAN, INDEX_SCAN`. With this setting, all searches that can use indexes do use them, and searches without any indexes use table scans.

It is possible to specify single values for this option, but this is not optimal, because setting a single value limits searches to using only that algorithm. In particular, setting `INDEX_SCAN` alone is not recommended, as in that case searches are unable to find rows at all if no index is present.

Note

There is only a performance advantage for `INDEX_SCAN` and `HASH_SCAN` if the row events are big enough. The size of row events is configured using `--binlog-row-event-max-size`. For example, suppose a `DELETE` statement which deletes 25,000 rows generates large `Delete_row_event` events. In this case if `slave_rows_search_algorithms` is set to `INDEX_SCAN` or `HASH_SCAN` there is a performance improvement. However, if there are 25,000 `DELETE` statements and each is represented by a separate event then setting `slave_rows_search_algorithms` to `INDEX_SCAN` or `HASH_SCAN` provides no performance improvement while executing these separate events.

- `--slave-skip-errors=[err_code1,err_code2,...|all|ddl_exist_errors]`

Command-Line Format	<code>--slave-skip-errors=name</code>	
System Variable	Name	<code>slave_skip_errors</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	string
	Default	<code>OFF</code>
	Valid Values	<code>OFF</code>
		<code>[list of error codes]</code>
		<code>all</code>
<code>ddl_exist_errors</code>		

Normally, replication stops when an error occurs on the slave, which gives you the opportunity to resolve the inconsistency in the data manually. This option causes the slave SQL thread to continue replication when a statement returns any of the errors listed in the option value.

Do not use this option unless you fully understand why you are getting errors. If there are no bugs in your replication setup and client programs, and no bugs in MySQL itself, an error that stops replication should never occur. Indiscriminate use of this option results in slaves becoming hopelessly out of synchrony with the master, with you having no idea why this has occurred.

For error codes, you should use the numbers provided by the error message in your slave error log and in the output of `SHOW SLAVE STATUS`. [Appendix B, Errors, Error Codes, and Common Problems](#), lists server error codes.

You can also (but should not) use the very nonrecommended value of `all` to cause the slave to ignore all error messages and keeps going regardless of what happens. Needless to say, if you use `all`, there are no guarantees regarding the integrity of your data. Please do not complain (or file bug reports) in this case if the slave's data is not anywhere close to what it is on the master. *You have been warned.*

MySQL 8.0 supports an additional shorthand value `ddl_exist_errors`, which is equivalent to the error code list `1007,1008,1050,1051,1054,1060,1061,1068,1094,1146`.

Examples:

```
--slave-skip-errors=1062,1053
--slave-skip-errors=all
--slave-skip-errors=ddl_exist_errors
```

- `--slave-sql-verify-checksum={0|1}`

Command-Line Format	<code>--slave-sql-verify-checksum=value</code>	
Permitted Values	Type	boolean
	Default	0
	Valid Values	0 1

When this option is enabled, the slave examines checksums read from the relay log, in the event of a mismatch, the slave stops with an error. Disabled by default.

The following options are used internally by the MySQL test suite for replication testing and debugging. They are not intended for use in a production setting.

- `--abort-slave-event-count`

Command-Line Format	<code>--abort-slave-event-count=#</code>	
Permitted Values	Type	integer
	Default	0
	Min Value	0

When this option is set to some positive integer `value` other than 0 (the default) it affects replication behavior as follows: After the slave SQL thread has started, `value` log events are permitted to be executed; after that, the slave SQL thread does not receive any more events, just as if the network connection from the master were cut. The slave thread continues to run, and the output from `SHOW SLAVE STATUS` displays `Yes` in both the `Slave_IO_Running` and the `Slave_SQL_Running` columns, but no further events are read from the relay log.

- `--disconnect-slave-event-count`

Command-Line Format	<code>--disconnect-slave-event-count=#</code>	
Permitted Values	Type	integer
	Default	0

Options for Logging Slave Status to Tables

MySQL 8.0 supports logging of replication slave status information to tables or files. Writing of the master info log and the relay log info log can be configured separately using the two server options listed here:

- `--master-info-repository={FILE|TABLE}`

Command-Line Format	<code>--master-info-repository=FILE TABLE</code>	
Permitted Values (<= 8.0.1)	Type	string
	Default	FILE
	Valid Values	FILE
TABLE		
Permitted Values (>= 8.0.2)	Type	string
	Default	TABLE
	Valid Values	FILE
TABLE		

This option causes the server to write its master info log to a file or a table.

The default value for this option is `TABLE`. With this setting, the log is written to the `slave_master_info` table in the `mysql` database.

If you use `FILE`, the name of the file defaults to `master.info`. You can change the name of the file using the `--master-info-file` server option.

- `--relay-log-info-repository={FILE|TABLE}`

Command-Line Format	<code>--relay-log-info-repository=FILE TABLE</code>	
Permitted Values (<= 8.0.1)	Type	string
	Default	FILE
	Valid Values	FILE
TABLE		
Permitted Values (>= 8.0.2)	Type	string
	Default	TABLE
	Valid Values	FILE
TABLE		

This option causes the server to write its relay log info to a file or a table.

The default value for this option is `TABLE`. With this setting, the log is written to the `slave_relay_log_info` table in the `mysql` database.

For replication to be crash-safe, this option must be set to `TABLE`; in addition, the `--relay-log-recovery` option must be enabled. See [Crash-safe replication](#), for more information.

The info log tables and their contents are considered local to a given MySQL Server. They are not replicated, and changes to them are not written to the binary log.

For more information, see [Section 18.2.4, “Replication Relay and Status Logs”](#).

System Variables Used on Replication Slaves

The following list describes system variables for controlling replication slave servers. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used with replication slaves are listed earlier in this section.

- `slave_allow_batching`

Command-Line Format	<code>--slave-allow-batching</code>	
System Variable	Name	<code>slave_allow_batching</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	<code>off</code>

Whether or not batched updates are enabled on replication slaves.

Setting this variable has an effect only when using replication with the `NDB` storage engine; in MySQL Server 8.0, it is present but does nothing. For more information, see [Starting NDB Cluster Replication \(Single Replication Channel\)](#).

- `init_slave`

Command-Line Format	<code>--init-slave=name</code>	
System Variable	Name	<code>init_slave</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	string

This variable is similar to `init_connect`, but is a string to be executed by a slave server each time the SQL thread starts. The format of the string is the same as for the `init_connect` variable. The setting of this variable takes effect for subsequent `START SLAVE` statements.

Note

The SQL thread sends an acknowledgment to the client before it executes `init_slave`. Therefore, it is not guaranteed that `init_slave` has been executed when `START SLAVE` returns. See [Section 13.4.2.6, “START SLAVE Syntax”](#), for more information.

- `log_slow_slave_statements`

System Variable	Name	<code>log_slow_slave_statements</code>
------------------------	-------------	--

	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	OFF

When the slow query log is enabled, this variable enables logging for queries that have taken more than `long_query_time` seconds to execute on the slave. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` statements.

- `master_info_repository`

Command-Line Format	<code>--master-info-repository=FILE TABLE</code>	
System Variable	Name	<code>master_info_repository</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values (<= 8.0.1)	Type	string
	Default	FILE
	Valid Values	FILE TABLE
Permitted Values (>= 8.0.2)	Type	string
	Default	TABLE
	Valid Values	FILE TABLE

The setting of this variable determines whether the slave logs master status and connection information to a `FILE` (`master.info`), or to a `TABLE` (`mysql.slave_master_info`). You can only change the value of this variable when no replication threads are executing.

The setting of this variable also has a direct influence on the effect had by the setting of the `sync_master_info` system variable; see that variable's description for further information.

This variable must be set to `TABLE` before configuring multiple replication channels. If you are using multiple replication channels then you cannot set this variable back to `FILE`.

- `relay_log`

Command-Line Format	<code>--relay-log=file_name</code>	
System Variable	Name	<code>relay_log</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	file name

The base name of the relay log file, with no paths and no file extension. By default `relay-log`. The file name of individual files for the default replication channel is `relay-log.XXXXXXX`, and for additional replication channels is `relay-log-channel.XXXXXXX`.

- `relay_log_basename`

System Variable	Name	<code>relay_log_basename</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	file name
	Default	<code>datadir + '/' + hostname + '-relay-bin'</code>

Holds the name and complete path to the relay log file.

- `relay_log_index`

Command-Line Format	<code>--relay-log-index</code>	
System Variable	Name	<code>relay_log_index</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	file name
	Default	<code>*host_name*-relay-bin.index</code>

The name of the relay log index file for the default replication channel. The default name is `host_name-relay-bin.index` in the data directory, where `host_name` is the name of the slave server.

- `relay_log_info_file`

Command-Line Format	<code>--relay-log-info-file=file_name</code>	
System Variable	Name	<code>relay_log_info_file</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	file name
	Default	<code>relay-log.info</code>

The name of the file in which the slave records information about the relay logs, when `relay_log_info_repository=FILE`. If `relay_log_info_repository=TABLE`, it is the file name that would be used in case the repository was changed to `FILE`). The default name is `relay-log.info` in the data directory.

- `relay_log_info_repository`

System Variable	Name	<code>relay_log_info_repository</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values (<= 8.0.1)	Type	string
	Default	<code>FILE</code>

	Valid Values	FILE TABLE
Permitted Values (>= 8.0.2)	Type	string
	Default	TABLE
	Valid Values	FILE TABLE

This variable determines whether the slave's position in the relay logs is written to a **FILE** (`relay-log.info`) or to a **TABLE** (`mysql.slave_relay_log_info`). You can only change the value of this variable when no replication threads are executing.

The setting of this variable also has a direct influence on the effect had by the setting of the `sync_relay_log_info` system variable; see that variable's description for further information.

This variable must be set to **TABLE** before configuring multiple replication channels. If you are using multiple replication channels then you cannot set this variable back to **FILE**.

- `relay_log_recovery`

Command-Line Format	<code>--relay-log-recovery</code>	
System Variable	Name	<code>relay_log_recovery</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	boolean
	Default	<code>FALSE</code>

Enables automatic relay log recovery immediately following server startup. The recovery process creates a new relay log file, initializes the SQL thread position to this new relay log, and initializes the I/O thread to the SQL thread position. Reading of the relay log from the master then continues. In MySQL 5.7, this global variable is read-only; its value can be changed by starting the slave with the `--relay-log-recovery` option, which should be used following a crash on the replication slave to ensure that no possibly corrupted relay logs are processed, and must be used in order to guarantee a crash-safe slave. The default value is 0 (disabled).

This variable also interacts with `relay-log-purge`, which controls purging of logs when they are no longer needed. Enabling the `--relay-log-recovery` option when `relay-log-purge` is disabled risks reading the relay log from files that were not purged, leading to data inconsistency, and is therefore not crash-safe.

When `relay_log_recovery` is enabled and the slave has stopped due to errors encountered while running in multi-threaded mode, you can use `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` to ensure that all gaps are processed before switching back to single-threaded mode or executing a `CHANGE MASTER TO` statement.

- `rpl_stop_slave_timeout`

Command-Line Format	<code>--rpl-stop-slave-timeout=seconds</code>	
System Variable	Name	<code>rpl_stop_slave_timeout</code>
	Variable Scope	Global
	Dynamic Variable	Yes

Permitted Values	Type	integer
	Default	31536000
	Min Value	2
	Max Value	31536000

You can control the length of time (in seconds) that `STOP SLAVE` waits before timing out by setting this variable. This can be used to avoid deadlocks between `STOP SLAVE` and other slave SQL statements using different client connections to the slave. The maximum and default value of `rpl_stop_slave_timeout` is 31536000 seconds (1 year). The minimum is 2 seconds. Changes to this variable take effect for subsequent `STOP SLAVE` statements. This variable affects only the client that issues a `STOP SLAVE` statement. When the timeout is reached, the issuing client stops waiting for the slave threads to stop, but the slave threads continue to try to stop.

- `slave_checkpoint_group`

Command-Line Format	<code>--slave-checkpoint-group=#</code>	
System Variable	Name	<code>slave_checkpoint_group=#</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	512
	Min Value	32
	Max Value	524280
	Block Size	8

Sets the maximum number of transactions that can be processed by a multi-threaded slave before a checkpoint operation is called to update its status as shown by `SHOW SLAVE STATUS`. Setting this variable has no effect on slaves for which multi-threading is not enabled. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` commands.

This variable works in combination with the `slave_checkpoint_period` system variable in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this variable is 32, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 1. The effective value is always a multiple of 8; you can set it to a value that is not such a multiple, but the server rounds it down to the next lower multiple of 8 before storing the value. (*Exception*: No such rounding is performed by the debug server.) Regardless of how the server was built, the default value is 512, and the maximum allowed value is 524280.

- `slave_checkpoint_period`

Command-Line Format	<code>--slave-checkpoint-period=#</code>	
System Variable	Name	<code>slave_checkpoint_period=#</code>
	Variable Scope	Global
	Scope	

	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	300
	Min Value	1
	Max Value	4G

Sets the maximum time (in milliseconds) that is allowed to pass before a checkpoint operation is called to update the status of a multi-threaded slave as shown by `SHOW SLAVE STATUS`. Setting this variable has no effect on slaves for which multi-threading is not enabled. Setting this variable takes effect for all replication channels immediately, including running channels.

This variable works in combination with the `slave_checkpoint_group` system variable in such a way that, when either limit is exceeded, the checkpoint is executed and the counters tracking both the number of transactions and the time elapsed since the last checkpoint are reset.

The minimum allowed value for this variable is 1, unless the server was built using `-DWITH_DEBUG`, in which case the minimum value is 0. Regardless of how the server was built, the default value is 300, and the maximum possible value is 4294967296 (4GB).

- `slave_compressed_protocol`

Command-Line Format	<code>--slave-compressed-protocol</code>	
System Variable	Name	<code>slave_compressed_protocol</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	OFF

Whether to use compression of the slave/master protocol if both the slave and the master support it. Changes to this variable take effect on subsequent connection attempts; this includes after issuing a `START SLAVE` statement, as well as reconnections made by a running I/O thread (for example after issuing a `CHANGE MASTER TO MASTER_RETRY_COUNT` statement).

- `slave_exec_mode`

Command-Line Format	<code>--slave-exec-mode=mode</code>	
System Variable	Name	<code>slave_exec_mode</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	enumeration
	Default	STRICT (ALL)
	Default	IDEMPOTENT (NDB)
	Valid Values	IDEMPOTENT STRICT

Controls how a slave thread resolves conflicts and errors during replication. `IDEMPOTENT` mode causes suppression of duplicate-key and no-key-found errors; `STRICT` means no such suppression takes place.

`IDEMPOTENT` mode is intended for use in multi-master replication, circular replication, and some other special replication scenarios. *This mode should be used only when you are absolutely sure that duplicate-key errors and key-not-found errors can safely be ignored.* It is meant to be used in fail-over scenarios where multi-master replication or circular replication is employed, and is not recommended for use in other cases.

Setting this variable takes immediate effect for all replication channels, including running channels.

- `slave_load_tmpdir`

Command-Line Format	<code>--slave-load-tmpdir=dir_name</code>	
System Variable	Name	<code>slave_load_tmpdir</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	directory name
	Default	<code>/tmp</code>

The name of the directory where the slave creates temporary files for replicating `LOAD DATA INFILE` statements. Setting this variable takes effect for all replication channels immediately, including running channels.

- `slave_max_allowed_packet`

System Variable	Name	<code>slave_max_allowed_packet</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	<code>1073741824</code>
	Min Value	<code>1024</code>
	Max Value	<code>1073741824</code>

This variable sets the maximum packet size for the slave SQL and I/O threads, so that large updates using row-based replication do not cause replication to fail because an update exceeded `max_allowed_packet`. Setting this variable takes effect for all replication channels immediately, including running channels.

This global variable always has a value that is a positive integer multiple of 1024; if you set it to some value that is not, the value is rounded down to the next highest multiple of 1024 for it is stored or used; setting `slave_max_allowed_packet` to 0 causes 1024 to be used. (A truncation warning is issued in all such cases.) The default and maximum value is 1073741824 (1 GB); the minimum is 1024.

`slave_max_allowed_packet` can also be set at startup, using the `--slave-max-allowed-packet` option.

- `slave_net_timeout`

Command-Line Format	<code>--slave-net-timeout=#</code>	
System Variable	Name	<code>slave_net_timeout</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	60
	Min Value	1

The number of seconds to wait for more data from a master/slave connection before aborting the read. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` commands.

- `slave_parallel_type=type`

Command-Line Format	<code>--slave-parallel-type=type</code>	
Permitted Values	Type	enumeration
	Default	<code>DATABASE</code>
	Valid Values	<code>DATABASE</code> <code>LOGICAL_CLOCK</code>

When using a multi-threaded slave (`slave_parallel_workers` is greater than 0), this variable specifies the policy used to decide which transactions are allowed to execute in parallel on the slave. See `--slave-parallel-type` for more information.

- `slave_parallel_workers`

Command-Line Format	<code>--slave-parallel-workers=#</code>	
System Variable	Name	<code>slave_parallel_workers</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	0
	Min Value	0
	Max Value	1024

Sets the number of slave applier threads for executing replication transactions in parallel. Setting this variable to a number greater than 0 creates a multi-threaded slave with this number of applier threads. When set to 0 (the default) parallel execution is disabled and the slave uses a single applier thread. Setting `slave_parallel_workers` has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` statements. Retrying of transactions is supported when multi-threading is enabled on a slave.

A multi-threaded slave provides parallel execution by using a coordinator thread and the number of applier threads configured by this variable. The way which transactions are distributed among applier threads is configured by `slave_parallel_type`. The transactions that the slave applies in parallel may commit out of order, unless `slave_preserve_commit_order=1`. Therefore, checking for the most recently executed transaction does not guarantee that all previous transactions from the master have been executed on the slave. This has implications for logging and recovery when using a multi-threaded slave. For example, on a multi-threaded slave the `START SLAVE UNTIL` statement only supports using `SQL_AFTER_MTS_GAPS`.

- `slave_pending_jobs_size_max`

System Variable	Name	<code>slave_pending_jobs_size_max</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	16M
	Min Value	1024
	Max Value	18EB
	Block Size	1024

For multi-threaded slaves, this variable sets the maximum amount of memory (in bytes) available to slave worker queues holding events not yet applied. Setting this variable has no effect on slaves for which multi-threading is not enabled. Setting this variable has no immediate effect. The state of the variable applies on all subsequent `START SLAVE` commands.

The minimum possible value for this variable is 1024; the default is 16MB. The maximum possible value is 18446744073709551615 (16 exabytes). Values that are not exact multiples of 1024 are rounded down to the next-highest multiple of 1024 prior to being stored.

Important

The value of this variable must not be less than the master's value for `max_allowed_packet`; otherwise a slave worker queue may become full while there remain events coming from the master to be processed.

- `slave_preserve_commit_order`

Command-Line Format	<code>--slave-preserve-commit-order=value</code>	
System Variable	Name	<code>slave_preserve_commit_order</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	0
	Valid Values	0
		1

For multi-threaded slaves, enabling this variable ensures that transactions are externalized on the slave in the same order as they appear in the slave's relay log. Setting this variable has no effect on slaves for which multi-threading is not enabled. All replication threads (for all replication channels if you are using multiple replication channels) must be stopped before changing this variable. `--log-bin` and `--log-slave-updates` must be enabled on the slave. In addition `--slave-parallel-type` must be set to `LOGICAL_CLOCK`.

Once a multi-threaded slave has been started, transactions can begin to execute in parallel. With `slave_preserve_commit_order` enabled, the executing thread waits until all previous transactions are committed before committing. While the slave thread is waiting for other workers to commit their transactions it reports its status as `Waiting for preceding transaction to commit`. Enabling this mode on a multi-threaded slave ensures that it never enters a state that the master was not in. This makes it well suited to using replication for read scale-out. See [Section 18.3.5, "Using Replication for Scale-Out"](#).

When using a multi-threaded slave, if `slave_preserve_commit_order` is not enabled, there is a chance of gaps in the sequence of transactions that have been executed from the slave's relay log. When this option is enabled, there is not this chance of gaps, but `Exec_master_log_pos` may be behind the position up to which has been executed. See [Section 18.4.1.34, "Replication and Transaction Inconsistencies"](#) for more information.

- `slave_rows_search_algorithms`

System Variable	Name	<code>slave_rows_search_algorithms=list</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	set
	Default	<code>TABLE_SCAN, INDEX_SCAN</code>
	Valid Values	<code>TABLE_SCAN, INDEX_SCAN</code>
		<code>INDEX_SCAN, HASH_SCAN</code>
		<code>TABLE_SCAN, HASH_SCAN</code>
		<code>TABLE_SCAN, INDEX_SCAN, HASH_SCAN</code> (equivalent to <code>INDEX_SCAN, HASH_SCAN</code>)
Permitted Values (>= 8.0.2)	Type	set
	Default	<code>INDEX_SCAN, HASH_SCAN</code>
	Valid Values	<code>TABLE_SCAN, INDEX_SCAN</code>
		<code>INDEX_SCAN, HASH_SCAN</code>
		<code>TABLE_SCAN, HASH_SCAN</code>
		<code>TABLE_SCAN, INDEX_SCAN, HASH_SCAN</code> (equivalent to <code>INDEX_SCAN, HASH_SCAN</code>)

When preparing batches of rows for row-based logging and replication, this variable controls how the rows are searched for matches—that is, whether or not hashing is used for searches using a primary or unique key, some other key, or using no key at all. Setting this variable takes effect for all replication channels immediately, including running channels.

Specify a comma-separated list of any 2 (or all 3) values from the list `INDEX_SCAN`, `TABLE_SCAN`, `HASH_SCAN`. The value is expected as a string, so the value must be quoted. In addition, the value must not contain any spaces. Possible combinations (lists) and their effects are shown in the following table:

Index used / option value	<code>INDEX_SCAN, HASH_SCAN</code> or <code>INDEX_SCAN, TABLE_SCAN, HASH_SCAN</code>	<code>INDEX_SCAN, TABLE_SCAN</code>	<code>TABLE_SCAN, HASH_SCAN</code>
<i>Primary key or unique key</i>	Index scan	Index scan	Hash scan over index
<i>(Other) Key</i>	Hash scan over index	Index scan	Hash scan over index
<i>No index</i>	Hash scan	Table scan	Hash scan

The order in which the algorithms are specified in the list does not make any difference in the order in which they are displayed by a `SELECT` or `SHOW VARIABLES` statement (which is the same as that used in the table just shown previously).

- The default value is `INDEX_SCAN, HASH_SCAN`. With this setting, hashing is used for any searches that do not use a primary or unique key. Specifying `INDEX_SCAN, TABLE_SCAN, HASH_SCAN` has the same effect as specifying `INDEX_SCAN, HASH_SCAN`.
- To force hashing for *all* searches, set this option to `TABLE_SCAN, HASH_SCAN`.
- To remove hashing, set this option to `TABLE_SCAN, INDEX_SCAN`. With this setting, all searches that can use indexes do use them, and searches without any indexes use table scans.

It is possible to specify single values for this option, but this is not optimal, because setting a single value limits searches to using only that algorithm. In particular, setting `INDEX_SCAN` alone is not recommended, as in that case searches are unable to find rows at all if no index is present.

Note

There is only a performance advantage for `INDEX_SCAN` and `HASH_SCAN` if the row events are big enough. The size of row events is configured using `--binlog-row-event-max-size`. For example, suppose a `DELETE` statement which deletes 25,000 rows generates large `Delete_row_event` events. In this case if `slave_rows_search_algorithms` is set to `INDEX_SCAN` or `HASH_SCAN` there is a performance improvement. However, if there are 25,000 `DELETE` statements and each is represented by a separate event then setting `slave_rows_search_algorithms` to `INDEX_SCAN` or `HASH_SCAN` provides no performance improvement while executing these separate events.

- `slave_skip_errors`

Command-Line Format	<code>--slave-skip-errors=name</code>	
System Variable	Name	<code>slave_skip_errors</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	string
	Default	<code>OFF</code>
	Valid Values	<code>OFF</code>
		<code>[list of error codes]</code>
		<code>all</code>
	<code>ddl_exist_errors</code>	

Normally, replication stops when an error occurs on the slave, which gives you the opportunity to resolve the inconsistency in the data manually. This variable causes the slave SQL thread to continue replication when a statement returns any of the errors listed in the variable value. The setting of this variable takes effect immediately, even for running replication threads.

- `slave_sql_verify_checksum`

System Variable	Name	<code>slave_sql_verify_checksum</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	1
	Valid Values	0
		1

Cause the slave SQL thread to verify data using the checksums read from the relay log. In the event of a mismatch, the slave stops with an error. Setting this variable takes effect for all replication channels immediately, including running channels.

Note

The slave I/O thread always reads checksums if possible when accepting events from over the network.

- `slave_transaction_retries`

Command-Line Format	<code>--slave-transaction-retries=#</code>	
System Variable	Name	<code>slave_transaction_retries</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values (32-bit platforms)	Type	integer
	Default	10
	Min Value	0
	Max Value	4294967295
Permitted Values (64-bit platforms)	Type	integer
	Default	10
	Min Value	0
	Max Value	18446744073709551615

If a replication slave SQL thread fails to execute a transaction because of an InnoDB deadlock or because the transaction's execution time exceeded InnoDB's `innodb_lock_wait_timeout`, it automatically retries `slave_transaction_retries` times before stopping with an error. The

default value is 10. Setting this variable takes effect for all replication channels immediately, including running channels.

Retrying of transactions is supported when multi-threading is enabled on a slave. In previous versions, `slave_transaction_retries` was treated as equal to 0 when using multi-threaded slaves.

- `slave_type_conversions`

Command-Line Format	<code>--slave-type-conversions=set</code>	
System Variable	Name	<code>slave_type_conversions</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	set
	Default	
	Valid Values	<code>ALL_LOSSY</code>
		<code>ALL_NON_LOSSY</code>
<code>ALL_SIGNED</code>		
	<code>ALL_UNSIGNED</code>	

Controls the type conversion mode in effect on the slave when using row-based replication. Its value is a comma-delimited set of zero or more elements from the list: `ALL_LOSSY`, `ALL_NON_LOSSY`, `ALL_SIGNED`, `ALL_UNSIGNED`. Set this variable to an empty string to disallow type conversions between the master and the slave. Setting this variable takes effect for all replication channels immediately, including running channels.

For additional information on type conversion modes applicable to attribute promotion and demotion in row-based replication, see [Row-based replication: attribute promotion and demotion](#).

- `sql_slave_skip_counter`

System Variable	Name	<code>sql_slave_skip_counter</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer

The number of events from the master that a slave server should skip. Setting the option has no immediate effect. The variable applies to the next `START SLAVE` statement; the next `START SLAVE` statement also changes the value back to 0. When this variable is set to a non-zero value and there are multiple replication channels configured, the `START SLAVE` statement can only be used with the `FOR CHANNEL channel` clause.

This option is incompatible with GTID-based replication, and must not be set to a nonzero value when `--gtid-mode=ON`. If you need to skip transactions when employing GTIDs, use `gtid_executed` from the master instead. See [Injecting empty transactions](#), for information about how to do this.

Important

If skipping the number of events specified by setting this variable would cause the slave to begin in the middle of an event group, the slave continues

to skip until it finds the beginning of the next event group and begins from that point. For more information, see [Section 13.4.2.5, “SET GLOBAL sql_slave_skip_counter Syntax”](#).

- `sync_master_info`

Command-Line Format	<code>--sync-master-info=#</code>	
System Variable	Name	<code>sync_master_info</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values (32-bit platforms)	Type	integer
	Default	10000
	Min Value	0
	Max Value	4294967295
Permitted Values (64-bit platforms)	Type	integer
	Default	10000
	Min Value	0
	Max Value	18446744073709551615

The effects of this variable on a replication slave depend on whether the slave's `master_info_repository` is set to `FILE` or `TABLE`, as explained in the following paragraphs.

master_info_repository = FILE. If the value of `sync_master_info` is greater than 0, the slave synchronizes its `master.info` file to disk (using `fdatsync()`) after every `sync_master_info` events. If it is 0, the MySQL server performs no synchronization of the `master.info` file to disk; instead, the server relies on the operating system to flush its contents periodically as with any other file.

master_info_repository = TABLE. If the value of `sync_master_info` is greater than 0, the slave updates its master info repository table after every `sync_master_info` events. If it is 0, the table is never updated.

The default value for `sync_master_info` is 10000. Setting this variable takes effect for all replication channels immediately, including running channels.

- `sync_relay_log`

Command-Line Format	<code>--sync-relay-log=#</code>	
System Variable	Name	<code>sync_relay_log</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values (32-bit platforms)	Type	integer
	Default	10000

	Min Value	0
	Max Value	4294967295
Permitted Values (64-bit platforms)	Type	integer
	Default	10000
	Min Value	0
	Max Value	18446744073709551615

If the value of this variable is greater than 0, the MySQL server synchronizes its relay log to disk (using `fdatasync()`) after every `sync_relay_log` events are written to the relay log. Setting this variable takes effect for all replication channels immediately, including running channels.

Setting `sync_relay_log` to 0 causes no synchronization to be done to disk; in this case, the server relies on the operating system to flush the relay log's contents from time to time as for any other file.

A value of 1 is the safest choice because in the event of a crash you lose at most one event from the relay log. However, it is also the slowest choice (unless the disk has a battery-backed cache, which makes synchronization very fast).

- `sync_relay_log_info`

Command-Line Format	<code>--sync-relay-log-info=#</code>	
System Variable	Name	<code>sync_relay_log_info</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values (32-bit platforms)	Type	integer
	Default	10000
	Min Value	0
	Max Value	4294967295
Permitted Values (64-bit platforms)	Type	integer
	Default	10000
	Min Value	0
	Max Value	18446744073709551615

The effects of this variable on the slave depend on the server's `relay_log_info_repository` setting (`FILE` or `TABLE`), and if this is `TABLE`, additionally on whether the storage engine used by the relay log info table is transactional (such as `InnoDB`) or not (`MyISAM`). The effects of these factors on the behavior of the server for `sync_relay_log_info` values of zero and greater than zero are shown in the following table:

<code>sync_relay_log_info</code>	<code>relay_log_info_repository</code>		
	FILE	TABLE	
		Transactional	Nontransactional
$N > 0$	The slave synchronizes its <code>relay-log.info</code> file to disk (using <code>fdatasync()</code>) after every N transactions.	The table is updated after each transaction. (N is effectively ignored.)	The table is updated after every N events.
0	The MySQL server performs no synchronization of the <code>relay-log.info</code> file to disk; instead, the server relies on the operating system to flush its contents periodically as with any other file.		The table is never updated.

The default value for `sync_relay_log_info` is 10000. Setting this variable takes effect for all replication channels immediately, including running channels.

18.1.6.4 Binary Logging Options and Variables

Startup Options Used with Binary Logging

System Variables Used with Binary Logging

You can use the `mysqld` options and system variables that are described in this section to affect the operation of the binary log as well as to control which statements are written to the binary log. For additional information about the binary log, see [Section 5.4.4, “The Binary Log”](#). For additional information about using MySQL server options and system variables, see [Section 5.1.4, “Server Command Options”](#), and [Section 5.1.5, “Server System Variables”](#).

Startup Options Used with Binary Logging

The following list describes startup options for enabling and configuring the binary log. System variables used with binary logging are discussed later in this section.

- `--binlog-row-event-max-size=N`

Command-Line Format	<code>--binlog-row-event-max-size=#</code>	
Permitted Values (32-bit platforms)	Type	integer
	Default	8192
	Min Value	256
	Max Value	4294967295
Permitted Values (64-bit platforms)	Type	integer
	Default	8192
	Min Value	256
	Max Value	18446744073709551615

Specify the maximum size of a row-based binary log event, in bytes. Rows are grouped into events smaller than this size if possible. The value should be a multiple of 256. The default is 8192. See [Section 18.2.1, “Replication Formats”](#).

- `--log-bin[=base_name]`

Command-Line Format	<code>--log-bin</code>	
System Variable	Name	<code>log_bin</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	file name

Enable binary logging. The server logs all statements that change data to the binary log, which is used for backup and replication. See [Section 5.4.4, “The Binary Log”](#).

The option value, if given, is the base name for the log sequence. The server creates binary log files in sequence by adding a numeric suffix to the base name. It is recommended that you specify a base name (see [Section B.5.7, “Known Issues in MySQL”](#), for the reason). Otherwise, MySQL uses `host_name-bin` as the base name.

When the server reads an entry from the index file, it checks whether the entry contains a relative path, and if it does, the relative part of the path is replaced with the absolute path set using the `--log-bin` option. An absolute path remains unchanged; in such a case, the index must be edited manually to enable the new path or paths to be used. (In older versions of MySQL, manual intervention was required whenever relocating the binary log or relay log files.) (Bug #11745230, Bug #12133)

Setting this option causes the `log_bin` system variable to be set to `ON` (or `1`), and not to the base name. The binary log file name (with path) is available as the `log_bin_basename` system variable.

If you specify this option without also specifying a `--server-id`, the server is not allowed to start. (Bug #11763963, Bug #56739)

- `--log-bin-index[=file_name]`

Command-Line Format	<code>--log-bin-index=<i>file_name</i></code>	
Permitted Values	Type	file name

The index file for binary log file names. See [Section 5.4.4, “The Binary Log”](#). If you omit the file name, and if you did not specify one with `--log-bin`, MySQL uses `host_name-bin.index` as the file name.

- `--log-bin-trust-function-creators[={0|1}]`

Command-Line Format	<code>--log-bin-trust-function-creators</code>	
System Variable	Name	<code>log_bin_trust_function_creators</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	<code>FALSE</code>

This option sets the corresponding `log_bin_trust_function_creators` system variable. If no argument is given, the option sets the variable to 1. `log_bin_trust_function_creators` affects how MySQL enforces restrictions on stored function and trigger creation. See [Section 23.7, “Binary Logging of Stored Programs”](#).

- `--log-bin-use-v1-row-events[={0|1}]`

Command-Line Format	<code>--log-bin-use-v1-row-events[={0 1}]</code>	
System Variable	Name	<code>log_bin_use_v1_row_events</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	boolean
	Default	0

MySQL 8.0 uses Version 2 binary log row events, which cannot be read by MySQL Server releases prior to MySQL 5.6.6. Setting this option to 1 causes `mysqld` to write the binary log using Version 1 logging events, which is the only version of binary log events used in previous releases, and thus produce binary logs that can be read by older slaves. Setting `--log-bin-use-v1-row-events` to 0 (the default) causes `mysqld` to use Version 2 binary log events.

The value used for this option can be obtained from the read-only `log_bin_use_v1_row_events` system variable.

Statement selection options. The options in the following list affect which statements are written to the binary log, and thus sent by a replication master server to its slaves. There are also options for slave servers that control which statements received from the master should be executed or ignored. For details, see [Section 18.1.6.3, “Replication Slave Options and Variables”](#).

- `--binlog-do-db=db_name`

Command-Line Format	<code>--binlog-do-db=name</code>	
Permitted Values	Type	string

This option affects binary logging in a manner similar to the way that `--replicate-do-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-do-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-do-db` always apply in determining whether or not the statement is logged.

Statement-based logging. Only those statements are written to the binary log where the default database (that is, the one selected by `USE`) is `db_name`. To specify more than one database, use this option multiple times, once for each database; however, doing so does *not* cause cross-database statements such as `UPDATE some_db.some_table SET foo='bar'` to be logged while a different database (or no database) is selected.

**Warning**

To specify multiple databases you *must* use multiple instances of this option. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

An example of what does not work as you might expect when using statement-based logging: If the server is started with `--binlog-do-db=sales` and you issue the following statements, the `UPDATE` statement is *not* logged:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The main reason for this “just check the default database” behavior is that it is difficult from the statement alone to know whether it should be replicated (for example, if you are using multiple-table `DELETE` statements or multiple-table `UPDATE` statements that act across multiple databases). It is also faster to check only the default database rather than all databases if there is no need.

Another case which may not be self-evident occurs when a given database is replicated even though it was not specified when setting the option. If the server is started with `--binlog-do-db=sales`, the following `UPDATE` statement is logged even though `prices` was not included when setting `--binlog-do-db`:

```
USE sales;
UPDATE prices.discounts SET percentage = percentage + 10;
```

Because `sales` is the default database when the `UPDATE` statement is issued, the `UPDATE` is logged.

Row-based logging. Logging is restricted to database `db_name`. Only changes to tables belonging to `db_name` are logged; the default database has no effect on this. Suppose that the server is started with `--binlog-do-db=sales` and row-based logging is in effect, and then the following statements are executed:

```
USE prices;
UPDATE sales.february SET amount=amount+100;
```

The changes to the `february` table in the `sales` database are logged in accordance with the `UPDATE` statement; this occurs whether or not the `USE` statement was issued. However, when using the row-based logging format and `--binlog-do-db=sales`, changes made by the following `UPDATE` are not logged:

```
USE prices;
UPDATE prices.march SET amount=amount-25;
```

Even if the `USE prices` statement were changed to `USE sales`, the `UPDATE` statement's effects would still not be written to the binary log.

Another important difference in `--binlog-do-db` handling for statement-based logging as opposed to the row-based logging occurs with regard to statements that refer to multiple databases. Suppose that the server is started with `--binlog-do-db=db1`, and the following statements are executed:

```
USE db1;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

If you are using statement-based logging, the updates to both tables are written to the binary log. However, when using the row-based format, only the changes to `table1` are logged; `table2` is in a

different database, so it is not changed by the `UPDATE`. Now suppose that, instead of the `USE db1` statement, a `USE db4` statement had been used:

```
USE db4;
UPDATE db1.table1 SET col1 = 10, db2.table2 SET col2 = 20;
```

In this case, the `UPDATE` statement is not written to the binary log when using statement-based logging. However, when using row-based logging, the change to `table1` is logged, but not that to `table2`—in other words, only changes to tables in the database named by `--binlog-do-db` are logged, and the choice of default database has no effect on this behavior.

- `--binlog-ignore-db=db_name`

Command-Line Format	<code>--binlog-ignore-db=name</code>	
Permitted Values	Type	string

This option affects binary logging in a manner similar to the way that `--replicate-ignore-db` affects replication.

The effects of this option depend on whether the statement-based or row-based logging format is in use, in the same way that the effects of `--replicate-ignore-db` depend on whether statement-based or row-based replication is in use. You should keep in mind that the format used to log a given statement may not necessarily be the same as that indicated by the value of `binlog_format`. For example, DDL statements such as `CREATE TABLE` and `ALTER TABLE` are always logged as statements, without regard to the logging format in effect, so the following statement-based rules for `--binlog-ignore-db` always apply in determining whether or not the statement is logged.

Statement-based logging. Tells the server to not log any statement where the default database (that is, the one selected by `USE`) is `db_name`.

When there is no default database, no `--binlog-ignore-db` options are applied, and such statements are always logged. (Bug #11829838, Bug #60188)

Row-based format. Tells the server not to log updates to any tables in the database `db_name`. The current database has no effect.

When using statement-based logging, the following example does not work as you might expect. Suppose that the server is started with `--binlog-ignore-db=sales` and you issue the following statements:

```
USE prices;
UPDATE sales.january SET amount=amount+1000;
```

The `UPDATE` statement *is* logged in such a case because `--binlog-ignore-db` applies only to the default database (determined by the `USE` statement). Because the `sales` database was specified explicitly in the statement, the statement has not been filtered. However, when using row-based logging, the `UPDATE` statement's effects are *not* written to the binary log, which means that no changes to the `sales.january` table are logged; in this instance, `--binlog-ignore-db=sales` causes *all* changes made to tables in the master's copy of the `sales` database to be ignored for purposes of binary logging.

To specify more than one database to ignore, use this option multiple times, once for each database. Because database names can contain commas, the list will be treated as the name of a single database if you supply a comma-separated list.

You should not use this option if you are using cross-database updates and you do not want these updates to be logged.

Checksum options. MySQL 8.0 supports reading and writing of binary log checksums. These are enabled using the two options listed here:

- `--binlog-checksum={NONE|CRC32}`

Command-Line Format	<code>--binlog-checksum=type</code>	
Permitted Values	Type	string
	Default	CRC32
	Valid Values	NONE CRC32

Enabling this option causes the master to write checksums for events written to the binary log. Set to `NONE` to disable, or the name of the algorithm to be used for generating checksums; currently, only CRC32 checksums are supported, and CRC32 is the default.

- `--master-verify-checksum={0|1}`

Command-Line Format	<code>--master-verify-checksum=name</code>	
Permitted Values	Type	boolean
	Default	OFF

Enabling this option causes the master to verify events from the binary log using checksums, and to stop with an error in the event of a mismatch. Disabled by default.

To control reading of checksums by the slave (from the relay) log, use the `--slave-sql-verify-checksum` option.

Testing and debugging options. The following binary log options are used in replication testing and debugging. They are not intended for use in normal operations.

- `--max-binlog-dump-events=N`

Command-Line Format	<code>--max-binlog-dump-events=#</code>	
Permitted Values	Type	integer
	Default	0

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--sporadic-binlog-dump-fail`

Command-Line Format	<code>--sporadic-binlog-dump-fail</code>	
Permitted Values	Type	boolean
	Default	FALSE

This option is used internally by the MySQL test suite for replication testing and debugging.

- `--binlog-rows-query-log-events`

Command-Line Format	<code>--binlog-rows-query-log-events</code>	
Permitted Values	Type	boolean
	Default	FALSE

System Variables Used with Binary Logging

The following list describes system variables for controlling binary logging. They can be set at server startup and some of them can be changed at runtime using `SET`. Server options used to control binary logging are listed earlier in this section. For information about the `sql_log_bin` and `sql_log_off` variables, see [Section 5.1.5, “Server System Variables”](#).

- `binlog_cache_size`

Command-Line Format	<code>--binlog-cache-size=#</code>	
System Variable	Name	<code>binlog_cache_size</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values (32-bit platforms)	Type	integer
	Default	<code>32768</code>
	Min Value	<code>4096</code>
	Max Value	<code>4294967295</code>
Permitted Values (64-bit platforms)	Type	integer
	Default	<code>32768</code>
	Min Value	<code>4096</code>
	Max Value	<code>18446744073709551615</code>

The size of the cache to hold changes to the binary log during a transaction. A binary log cache is allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (`--log-bin` option). If you often use large transactions, you can increase this cache size to get better performance. The `Binlog_cache_use` and `Binlog_cache_disk_use` status variables can be useful for tuning the size of this variable. See [Section 5.4.4, “The Binary Log”](#).

`binlog_cache_size` sets the size for the transaction cache only; the size of the statement cache is governed by the `binlog_stmt_cache_size` system variable.

- `binlog_checksum`

System Variable	Name	<code>binlog_checksum</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	string
	Default	<code>CRC32</code>
	Valid Values	<code>NONE</code>
		<code>CRC32</code>

When `binlog_checksum` is disabled (value `NONE`), the server verifies that it is writing only complete events to the binary log by writing and checking the event length (rather than a checksum) for each event.

Changing the value of this variable causes the binary log to be rotated; checksums are always written to an entire binary log file, and never to only part of one.

Setting this variable on the master to a value unrecognized by the slave causes the slave to set its own `binlog_checksum` value to `NONE`, and to stop replication with an error. (Bug #13553750, Bug #61096) If backward compatibility with older slaves is a concern, you may want to set the value explicitly to `NONE`.

- `binlog_direct_non_transactional_updates`

Command-Line Format	<code>--binlog-direct-non-transactional-updates[=value]</code>	
System Variable	Name	<code>binlog_direct_non_transactional_updates</code>
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	<code>OFF</code>

Due to concurrency issues, a slave can become inconsistent when a transaction contains updates to both transactional and nontransactional tables. MySQL tries to preserve causality among these statements by writing nontransactional statements to the transaction cache, which is flushed upon commit. However, problems arise when modifications done to nontransactional tables on behalf of a transaction become immediately visible to other connections because these changes may not be written immediately into the binary log.

The `binlog_direct_non_transactional_updates` variable offers one possible workaround to this issue. By default, this variable is disabled. Enabling `binlog_direct_non_transactional_updates` causes updates to nontransactional tables to be written directly to the binary log, rather than to the transaction cache.

`binlog_direct_non_transactional_updates` works only for statements that are replicated using the statement-based binary logging format; that is, it works only when the value of `binlog_format` is `STATEMENT`, or when `binlog_format` is `MIXED` and a given statement is being replicated using the statement-based format. This variable has no effect when the binary log format is `ROW`, or when `binlog_format` is set to `MIXED` and a given statement is replicated using the row-based format.

Important

Before enabling this variable, you must make certain that there are no dependencies between transactional and nontransactional tables; an example of such a dependency would be the statement `INSERT INTO myisam_table SELECT * FROM innodb_table`. Otherwise, such statements are likely to cause the slave to diverge from the master.

In MySQL 8.0, this variable has no effect when the binary log format is `ROW` or `MIXED`. (Bug #51291)

- `binlog_error_action`

Command-Line Format	<code>--binlog-error-action[=value]</code>	
System Variable	Name	<code>binlog_error_action</code>

	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values	Type	enumeration
	Default	IGNORE_ERROR
	Valid Values	IGNORE_ERROR ABORT_SERVER
Permitted Values	Type	enumeration
	Default	ABORT_SERVER
	Valid Values	IGNORE_ERROR ABORT_SERVER

Controls what happens when the server encounters an error such as not being able to write to, flush or synchronize the binary log, which can cause the master's log to become inconsistent and replication slaves to lose synchronization.

This variable defaults to `ABORT_SERVER`, which makes the server halt logging and shut down whenever it encounters such an error with the binary log. Upon server restart, all of the previously prepared and binary logged transactions are committed, while any transactions which were prepared but not binary logged due to the error are aborted.

When `binlog_error_action` is set to `IGNORE_ERROR`, if the server encounters such an error it continues the ongoing transaction, logs the error then halts logging, and continues performing updates. To resume binary logging `log_bin` must be enabled again. This provides backward compatibility with older versions of MySQL.

In previous releases this variable was named `binlogging_impossible_mode`.

- `binlog_format`

Command-Line Format	<code>--binlog-format=format</code>	
System Variable	Name	<code>binlog_format</code>
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values	Type	enumeration
	Default	ROW
	Valid Values	ROW
		STATEMENT MIXED

This variable sets the binary logging format, and can be any one of `STATEMENT`, `ROW`, or `MIXED`. See [Section 18.2.1, “Replication Formats”](#). `binlog_format` is set by the `--binlog-format` option at startup, or by the `binlog_format` variable at runtime.

Note

While you can change the logging format at runtime, it is *not* recommended that you change it while replication is ongoing. This is due in part to the fact

that slaves do not honor the master's `binlog_format` setting; a given MySQL Server can change only its own logging format.

The default is `ROW`.

You must have the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege to set either the global or session `binlog_format` value.

The rules governing when changes to this variable take effect and how long the effect lasts are the same as for other MySQL server system variables. For more information, see [Section 13.7.4.1, “SET Syntax for Variable Assignment”](#).

When `MIXED` is specified, statement-based replication is used, except for cases where only row-based replication is guaranteed to lead to proper results. For example, this happens when statements contain user-defined functions (UDF) or the `UUID()` function. An exception to this rule is that `MIXED` always uses statement-based replication for stored functions and triggers.

There are exceptions when you cannot switch the replication format at runtime:

- From within a stored function or a trigger.
- If the session is currently in row-based replication mode and has open temporary tables.
- From within a transaction.

Trying to switch the format in those cases results in an error.

The binary log format affects the behavior of the following server options:

- `--replicate-do-db`
- `--replicate-ignore-db`
- `--binlog-do-db`
- `--binlog-ignore-db`

These effects are discussed in detail in the descriptions of the individual options.

- `binlog_group_commit_sync_delay`

Command-Line Format	<code>--binlog-group-commit-sync-delay=#</code>	
System Variable	Name	<code>binlog_group_commit_sync_delay</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	0
	Min Value	0
	Max Value	1000000

Controls how many microseconds the binary log commit waits before synchronizing the binary log file to disk. By default `binlog_group_commit_sync_delay` is set to 0, meaning that there is no delay. Setting `binlog_group_commit_sync_delay` to a microsecond delay enables more transactions to be synchronized together to disk at once, reducing the overall time to commit a group

of transactions because the larger groups require fewer time units per group. With the correct tuning, this can increase slave performance without compromising the master's throughput.

- [binlog_group_commit_sync_no_delay_count](#)

Command-Line Format	<code>--binlog-group-commit-sync-no-delay-count=#</code>	
System Variable	Name	binlog_group_commit_sync_no_delay_count
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	0
	Min Value	0
	Max Value	1000000

The maximum number of transactions to wait for before aborting the current delay as specified by [binlog-group-commit-sync-delay](#). If [binlog-group-commit-sync-delay](#) is set to 0, then this option has no effect.

- [binlogging_impossible_mode](#)

Deprecated	5.7.6	
Command-Line Format	<code>--binlogging-impossible-mode[=value]</code>	
System Variable	Name	binlogging_impossible_mode
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values	Type	enumeration
	Default	IGNORE_ERROR
	Valid Values	IGNORE_ERROR ABORT_SERVER

This option is deprecated and will be removed in a future MySQL release. Use the renamed [binlog_error_action](#) to control what happens when the server cannot write to the binary log.

- [binlog_max_flush_queue_time](#)

Deprecated	5.7.9	
System Variable	Name	binlog_max_flush_queue_time
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	0

	Min Value	0
	Max Value	100000

Formerly, this controlled the time in microseconds to continue reading transactions from the flush queue before proceeding with group commit. In MySQL 8.0, this variable no longer has any effect.

`binlog_max_flush_queue_time` is deprecated as of MySQL 5.7.9, and is marked for eventual removal in a future MySQL release.

- `binlog_order_commits`

System Variable	Name	<code>binlog_order_commits</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	ON

When this variable is enabled on a master (the default), transactions are externalized in the same order as they are written to the binary log. If disabled, transactions may be committed in parallel. In some cases, disabling this variable might produce a performance increment.

- `binlog_row_image`

Command-Line Format	<code>--binlog-row-image=image_type</code>	
System Variable	Name	<code>binlog_row_image=image_type</code>
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values	Type	enumeration
	Default	<code>full</code>
	Valid Values	<code>full</code> (Log all columns)
		<code>minimal</code> (Log only changed columns, and columns needed to identify rows)
	<code>noblob</code> (Log all columns, except for unneeded BLOB and TEXT columns)	

For MySQL row-based replication, this variable determines how row images are written to the binary log. Runtime changes to this variable require the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege, even for the session value.

In MySQL row-based replication, each row change event contains two images, a “before” image whose columns are matched against when searching for the row to be updated, and an “after” image containing the changes. Normally, MySQL logs full rows (that is, all columns) for both the before and after images. However, it is not strictly necessary to include every column in both images, and we can often save disk, memory, and network usage by logging only those columns which are actually required.

**Note**

When deleting a row, only the before image is logged, since there are no changed values to propagate following the deletion. When inserting a row, only the after image is logged, since there is no existing row to be matched. Only when updating a row are both the before and after images required, and both written to the binary log.

For the before image, it is necessary only that the minimum set of columns required to uniquely identify rows is logged. If the table containing the row has a primary key, then only the primary key column or columns are written to the binary log. Otherwise, if the table has a unique key all of whose columns are `NOT NULL`, then only the columns in the unique key need be logged. (If the table has neither a primary key nor a unique key without any `NULL` columns, then all columns must be used in the before image, and logged.) In the after image, it is necessary to log only the columns which have actually changed.

You can cause the server to log full or minimal rows using the `binlog_row_image` system variable. This variable actually takes one of three possible values, as shown in the following list:

- `full`: Log all columns in both the before image and the after image.
- `minimal`: Log only those columns in the before image that are required to identify the row to be changed; log only those columns in the after image that are actually changed.
- `noblob`: Log all columns (same as `full`), except for `BLOB` and `TEXT` columns that are not required to identify rows, or that have not changed.

The default value is `full`.

When using `minimal` or `noblob`, deletes and updates are guaranteed to work correctly for a given table if and only if the following conditions are true for both the source and destination tables:

- All columns must be present and in the same order; each column must use the same data type as its counterpart in the other table.
- The tables must have identical primary key definitions.

(In other words, the tables must be identical with the possible exception of indexes that are not part of the tables' primary keys.)

If these conditions are not met, it is possible that the primary key column values in the destination table may prove insufficient to provide a unique match for a delete or update. In this event, no warning or error is issued; the master and slave silently diverge, thus breaking consistency.

Setting this variable has no effect when the binary logging format is `STATEMENT`. When `binlog_format` is `MIXED`, the setting for `binlog_row_image` is applied to changes that are logged using row-based format, but this setting no effect on changes logged as statements.

Setting `binlog_row_image` on either the global or session level does not cause an implicit commit; this means that this variable can be changed while a transaction is in progress without affecting the transaction.

- `binlog_row_metadata`

Introduced	8.0.1	
Command-Line Format	<code>--binlog-row-metadata=metadata_type</code>	
System Variable	Name	<code>binlog_row_metadata=metadata_type</code>

	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	enumeration
	Default	<code>MINIMAL</code>
	Valid Values	<code>FULL</code> (All metadata is included.) <code>MINIMAL</code> (Limit included metadata.)

Configures the amount of table metadata added to the binary log when using row-based logging. When set to `MINIMAL`, the default, only metadata related to `SIGNED` flags, column character set and geometry types are logged. When set to `FULL` complete metadata for tables is logged, such as column name, `ENUM` or `SET` string values, `PRIMARY KEY` information, and so on.

The extended metadata serves the following purposes:

- Slaves use the metadata to transfer data when its table structure is different from the master's.
- External software can use the metadata to decode row events and store the data into external databases, such as a data warehouse.
- `binlog_rows_query_log_events`

System Variable	Name	<code>binlog_rows_query_log_events</code>
	Variable Scope	Global, Session
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	<code>FALSE</code>

The `binlog_rows_query_log_events` system variable affects row-based logging only. When enabled, it causes the MySQL Server to write informational log events such as row query log events into its binary log. This information can be used for debugging and related purposes; such as obtaining the original query issued on the master when it cannot be reconstructed from the row updates. Runtime changes to this variable require the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege, even for the session value.

These events are normally ignored by MySQL programs reading the binary log and so cause no issues when replicating or restoring from backup. To view them, increase the verbosity level by using `mysqlbinlog`'s `--verbose` option twice, either as `-vv` or `--verbose --verbose`.

- `binlog_stmt_cache_size`

Command-Line Format	<code>--binlog-stmt-cache-size=#</code>	
System Variable	Name	<code>binlog_stmt_cache_size</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values (32-bit platforms)	Type	integer
	Default	<code>32768</code>

	Min Value	4096
	Max Value	4294967295
Permitted Values (64-bit platforms)	Type	integer
	Default	32768
	Min Value	4096
	Max Value	18446744073709551615

This variable determines the size of the cache for the binary log to hold nontransactional statements issued during a transaction. Separate binary log transaction and statement caches are allocated for each client if the server supports any transactional storage engines and if the server has the binary log enabled (`--log-bin` option). If you often use large nontransactional statements during transactions, you can increase this cache size to get better performance. The `Binlog_stmt_cache_use` and `Binlog_stmt_cache_disk_use` status variables can be useful for tuning the size of this variable. See [Section 5.4.4, “The Binary Log”](#).

The `binlog_cache_size` system variable sets the size for the transaction cache.

- `binlog_transaction_dependency_tracking`

Introduced	8.0.1	
Command-Line Format	<code>--binlog-transaction-dependency-tracking=value</code>	
System Variable	Name	<code>binlog_transaction_dependency_tracking</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	enumeration
	Default	<code>COMMIT_ORDER</code>
	Valid Values	<code>COMMIT_ORDER</code>
		<code>WRITESET</code>
	<code>WRITESET_SESSION</code>	

The source of dependency information on the master used to determine which transactions can be executed in parallel by the slave's multi-threaded applier. This variable can take one of the three values described in the following list:

- `COMMIT_ORDER`: Dependency information is generated from the master's commit timestamps. This is the default. This mode is also used for any transactions without write sets, even if this variable's is `WRITESET` or `WRITESET_SESSION`; this is also the case for transactions updating tables without primary keys and transactions updating tables having foreign key constraints.
- `WRITESET`: Dependency information is generated from the master's write set, and any transactions which write different tuples can be parallelized.
- `WRITESET_SESSION`: Dependency information is generated from the master's write set, but no two updates from the same session can be reordered.

`WRITESET` and `WRITESET_SESSION` modes do not deliver any transaction dependencies that are newer than those that would have been returned in `COMMIT_ORDER` mode.

The value of this variable cannot be set to anything other than `COMMIT_ORDER` if `transaction_write_set_extraction` is `OFF`. You should also note that the value of `transaction_write_set_extraction` cannot be changed if the current value of `binlog_transaction_dependency_tracking` is `WRITESET` or `WRITESET_SESSION`.

The number of row hashes to be kept and checked for the latest transaction to have changed a given row is determined by the value of `binlog_transaction_dependency_history_size`.

- `binlog_transaction_dependency_history_size`

Introduced	8.0.1	
Command-Line Format	<code>--binlog-transaction-dependency-size=#</code>	
System Variable	Name	<code>binlog_transaction_dependency_history_size</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	25000
	Min Value	1
	Max Value	1000000

Sets an upper limit on the number of row hashes which are kept in memory and used for looking up the transaction that last modified a given row. Once this number of hashes has been reached, the history is purged.

- `log_bin`

System Variable	Name	<code>log_bin</code>
	Variable Scope	Global
	Dynamic Variable	No

Whether the binary log is enabled. If the `--log-bin` option is used, then the value of this variable is `ON`; otherwise it is `OFF`. This variable reports only on the status of binary logging (enabled or disabled); it does not actually report the value to which `--log-bin` is set.

See [Section 5.4.4, “The Binary Log”](#).

- `log_bin_basename`

System Variable	Name	<code>log_bin_basename</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	file name
	Default	<code>datadir + '/' + hostname + '-bin'</code>

Holds the name and complete path to the binary log file. Unlike the `log_bin` system variable, `log_bin_basename` reflects the name set with the `--log-bin` server option.

- `log_bin_index`

System Variable	Name	<code>log_bin_index</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	file name

The index file for binary log file names.

- `log_bin_use_v1_row_events`

Command-Line Format	<code>--log-bin-use-v1-row-events[={0 1}]</code>	
System Variable	Name	<code>log_bin_use_v1_row_events</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	boolean
	Default	0

Shows whether Version 2 binary logging is in use. A value of 1 shows that the server is writing the binary log using Version 1 logging events (the only version of binary log events used in previous releases), and thus producing a binary log that can be read by older slaves. 0 indicates that Version 2 binary log events are in use.

This variable is read-only. To switch between Version 1 and Version 2 binary event binary logging, it is necessary to restart `mysqld` with the `--log-bin-use-v1-row-events` option.

- `log_slave_updates`

Command-Line Format	<code>--log-slave-updates</code>	
System Variable	Name	<code>log_slave_updates</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	boolean
	Default	<code>FALSE</code>

Whether updates received by a slave server from a master server should be logged to the slave's own binary log. Binary logging must be enabled on the slave for this variable to have any effect. See [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).

- `log_statements_unsafe_for_binlog`

System Variable	Name	<code>log_statements_unsafe_for_binlog</code>
	Variable Scope	Global

	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	ON

If error 1592 is encountered, controls whether the generated warnings are added to the error log or not.

- [master_verify_checksum](#)

System Variable	Name	master_verify_checksum
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	OFF

Enabling this variable causes the master to examine checksums when reading from the binary log. [master_verify_checksum](#) is disabled by default; in this case, the master uses the event length from the binary log to verify events, so that only complete events are read from the binary log.

- [max_binlog_cache_size](#)

Command-Line Format	<code>--max-binlog-cache-size=#</code>	
System Variable	Name	max_binlog_cache_size
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	18446744073709551615
	Min Value	4096
	Max Value	18446744073709551615

If a transaction requires more than this many bytes of memory, the server generates a `Multi-statement transaction required more than 'max_binlog_cache_size' bytes of storage` error. The minimum value is 4096. The maximum possible value is 16EB (exabytes). The maximum recommended value is 4GB; this is due to the fact that MySQL currently cannot work with binary log positions greater than 4GB.

[max_binlog_cache_size](#) sets the size for the transaction cache only; the upper limit for the statement cache is governed by the [max_binlog_stmt_cache_size](#) system variable.

In MySQL 8.0, the visibility to sessions of [max_binlog_cache_size](#) matches that of the [binlog_cache_size](#) system variable; in other words, changing its value effects only new sessions that are started after the value is changed.

- [max_binlog_size](#)

System Variable	Name	<code>max_binlog_size</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	1073741824
	Min Value	4096
	Max Value	1073741824

If a write to the binary log causes the current log file size to exceed the value of this variable, the server rotates the binary logs (closes the current file and opens the next one). The minimum value is 4096 bytes. The maximum and default value is 1GB.

A transaction is written in one chunk to the binary log, so it is never split between several binary logs. Therefore, if you have big transactions, you might see binary log files larger than `max_binlog_size`.

If `max_relay_log_size` is 0, the value of `max_binlog_size` applies to relay logs as well.

- `max_binlog_stmt_cache_size`

Command-Line Format	<code>--max-binlog-stmt-cache-size=#</code>	
System Variable	Name	<code>max_binlog_stmt_cache_size</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	18446744073709547520
	Min Value	4096
	Max Value	18446744073709547520

If nontransactional statements within a transaction require more than this many bytes of memory, the server generates an error. The minimum value is 4096. The maximum and default values are 4GB on 32-bit platforms and 16EB (exabytes) on 64-bit platforms.

`max_binlog_stmt_cache_size` sets the size for the statement cache only; the upper limit for the transaction cache is governed exclusively by the `max_binlog_cache_size` system variable.

- `original_commit_timestamp`

Introduced	8.0.1	
Status Variable	Name	<code>original_commit_timestamp</code>
	Variable Scope	Session
	Dynamic Variable	Yes

Permitted Values	Type	numeric
-------------------------	-------------	---------

For internal use by replication. When re-executing a transaction on a slave, this is set to the time when the transaction was committed on the original master, measured in microseconds since the epoch. This allows the original commit timestamp to be propagated throughout a replication topology.

- `sync_binlog`

Command-Line Format	<code>--sync-binlog=#</code>	
System Variable	Name	<code>sync_binlog</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	1
	Min Value	0
	Max Value	4294967295
Permitted Values (32-bit platforms)	Type	integer
	Default	0
	Min Value	0
	Max Value	4294967295
Permitted Values (64-bit platforms)	Type	integer
	Default	0
	Min Value	0
	Max Value	4294967295

Controls the number of binary log commit groups to collect before synchronizing the binary log to disk. When `sync_binlog=0`, the binary log is never synchronized to disk, and when `sync_binlog` is set to a value greater than 0 this number of binary log commit groups is periodically synchronized to disk. When `sync_binlog=1`, all transactions are synchronized to the binary log before they are committed. Therefore, even in the event of an unexpected restart, any transactions that are missing from the binary log are only in prepared state. This causes the server's automatic recovery routine to roll back those transactions. This guarantees that no transaction is lost from the binary log, and is the safest option. However this can have a negative impact on performance because of an increased number of disk writes. Using a higher value improves performance, but with the increased risk of data loss.

When `sync_binlog=0` or `sync_binlog` is greater than 1, transactions are committed without having been synchronized to disk. Therefore, in the event of a power failure or operating system crash, it is possible that the server has committed some transactions that have not been synchronized to the binary log. Therefore it is impossible for the recovery routine to recover these transactions and they will be lost from the binary log.

The default value of `sync_binlog` is 1, which is the safest choice, but as noted above can impact performance.

Prior to MySQL 5.7.7, the default value was 0, which configures no synchronizing to disk—in this case, the server relies on the operating system to flush the binary log's contents from time to time as for any other file.

18.1.6.5 Global Transaction ID Options and Variables

[Startup Options Used with GTID Replication](#)

[System Variables Used with GTID Replication](#)

The MySQL Server options and system variables described in this section are used to monitor and control Global Transaction Identifiers (GTIDs).

For additional information, see [Section 18.1.3, “Replication with Global Transaction Identifiers”](#).

Startup Options Used with GTID Replication

The following server startup options are used with GTID-based replication:

- `--enforce-gtid-consistency`

Command-Line Format	<code>--enforce-gtid-consistency[=<i>value</i>]</code>	
System Variable	Name	<code>enforce_gtid_consistency</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	enumeration
	Default	<code>OFF</code>
	Valid Values	<code>OFF</code>
		<code>ON</code>
	<code>WARN</code>	

When enabled, the server enforces GTID consistency by allowing execution of only statements that can be safely logged using a GTID. You *must* set this option to `ON` before enabling GTID based replication.

The values that `--enforce-gtid-consistency` can be configured to are:

- `OFF`: all transactions are allowed to violate GTID consistency.
- `ON`: no transaction is allowed to violate GTID consistency.
- `WARN`: all transactions are allowed to violate GTID consistency, but a warning is generated in this case.

Setting `--enforce-gtid-consistency` without a value is an alias for `--enforce-gtid-consistency=ON`. This impacts on the behavior of the variable, see [enforce_gtid_consistency](#).

Only statements that can be logged using GTID safe statements can be logged when `enforce-gtid-consistency` is set to `ON`, so the operations listed here cannot be used with this option:

- `CREATE TABLE ... SELECT` statements
- `CREATE TEMPORARY TABLE` or `DROP TEMPORARY TABLE` statements inside transactions

- Transactions or statements that update both transactional and nontransactional tables. There is an exception that nontransactional DML is allowed in the same transaction or in the same statement as transactional DML, if all *nontransactional* tables are temporary.

For more information, see [Section 18.1.3.4, “Restrictions on Replication with GTIDs”](#).

- `--executed-gtids-compression-period`

Deprecated	5.7.6	
Command-Line Format	<code>--executed-gtids-compression-period=#</code>	
Permitted Values	Type	integer
	Default	1000
	Min Value	0
	Max Value	4294967295

This option is deprecated and will be removed in a future MySQL release. Use the renamed `gtid_executed_compression_period` to control how the `gtid_executed` table is compressed.

- `--gtid-mode`

Command-Line Format	<code>--gtid-mode=MODE</code>	
System Variable	Name	<code>gtid_mode</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	enumeration
	Default	OFF
	Valid Values	OFF
		OFF_PERMISSIVE
		ON_PERMISSIVE
ON		

This option specifies whether global transaction identifiers (GTIDs) are used to identify transactions. Setting this option to `--gtid-mode=ON` requires that `enforce-gtid-consistency` be set to `ON`. The `gtid_mode` variable is dynamic and enables GTID based replication to be configured online. Before using this feature, see [Section 18.1.5, “Changing Replication Modes on Online Servers”](#).

- `--gtid-executed-compression-period`

Command-Line Format	<code>--gtid-executed-compression-period=#</code>	
Permitted Values	Type	integer
	Default	1000
	Min Value	0
	Max Value	4294967295

Compress the `mysql.gtid_executed` table each time this many transactions have taken place. A setting of 0 means that this table is not compressed. No compression of the table occurs when binary logging is enabled, therefore the option has no effect unless `log_bin` is `OFF`.

See [mysql.gtid_executed Table Compression](#), for more information.

System Variables Used with GTID Replication

The following system variables are used with GTID-based replication:

- `binlog_gtid_simple_recovery`

Command-Line Format	<code>--binlog-gtid-simple-recovery</code>	
System Variable	Name	<code>binlog_gtid_simple_recovery</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	boolean
	Default	<code>FALSE</code>
Permitted Values	Type	boolean
	Default	<code>TRUE</code>

This variable controls how binary log files are iterated during the search for GTIDs when MySQL starts or restarts.

When `binlog_gtid_simple_recovery=FALSE`, the method of iterating the binary log files is:

- To initialize `gtid_executed`, binary log files are iterated from the newest file, stopping at the first binary log that has any `Previous_gtids_log_event`. All GTIDs from `Previous_gtids_log_event` and `Gtid_log_events` are read from this binary log file. This GTID set is stored internally and called `gtids_in_binlog`. The value of `gtid_executed` is computed as the union of this set and the GTIDs stored in the `mysql.gtid_executed` table.

This process could take a long time if you had a large number of binary log files without GTID events, for example created when `gtid_mode=OFF`.

- To initialize `gtid_purged`, binary log files are iterated from the oldest to the newest, stopping at the first binary log that contains either a `Previous_gtids_log_event` that is non-empty (that has at least one GTID) or that has at least one `Gtid_log_event`. From this binary log it reads `Previous_gtids_log_event`. This GTID set is subtracted from `gtids_in_binlog` and the result stored in the internal variable `gtids_in_binlog_not_purged`. The value of `gtid_purged` is initialized to the value of `gtid_executed`, minus `gtids_in_binlog_not_purged`.

When `binlog_gtid_simple_recovery=TRUE`, which is the default, the server iterates only the oldest and the newest binary log files and the values of `gtid_purged` and `gtid_executed` are computed based only on `Previous_gtids_log_event` or `Gtid_log_event` found in these files. This ensures only two binary log files are iterated during server restart or when binary logs are being purged.

Note

If this option is enabled, `gtid_executed` and `gtid_purged` may be initialized incorrectly in the following situations:

- The newest binary log was generated by MySQL 5.7.5 or older, and `gtid_mode` was `ON` for some binary logs but `OFF` for the newest binary log.
- A `SET GTID_PURGED` statement was issued on a MySQL version prior to 5.7.7, and the binary log that was active at the time of the `SET GTID_PURGED` has not yet been purged.

If an incorrect GTID set is computed in either situation, it will remain incorrect even if the server is later restarted, regardless of the value of this option.

- `enforce_gtid_consistency`

Command-Line Format	<code>--enforce-gtid-consistency[=value]</code>	
System Variable	Name	<code>enforce_gtid_consistency</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	enumeration
	Default	<code>OFF</code>
	Valid Values	<code>OFF</code>
		<code>ON</code>
	<code>WARN</code>	

Depending on the value of this variable, the server enforces GTID consistency by allowing execution of only statements that can be safely logged using a GTID. You *must* set this variable to `ON` before enabling GTID based replication.

The values that `enforce_gtid_consistency` can be configured to are:

- `OFF`: all transactions are allowed to violate GTID consistency.
- `ON`: no transaction is allowed to violate GTID consistency.
- `WARN`: all transactions are allowed to violate GTID consistency, but a warning is generated in this case.

For more information on statements that can be logged using GTID based replication, see `--enforce-gtid-consistency`.

Prior to MySQL 5.7.6, the boolean `enforce-gtid-consistency` defaulted to `OFF`. To maintain compatibility with previous versions, in MySQL 5.7.6 the enumeration defaults to `OFF`, and setting `--enforce-gtid-consistency` without a value is interpreted as setting the value to `ON`. The variable also has multiple textual aliases for the values: `0=OFF=FALSE`, `1=ON=TRUE`, `2=WARN`. This differs from other enumeration types but maintains compatibility with the boolean type used in previous versions. These changes impact on what is returned by the variable. Using `SELECT @@ENFORCE_GTID_CONSISTENCY`, `SHOW VARIABLES LIKE 'ENFORCE_GTID_CONSISTENCY'`, and `SELECT * FROM INFORMATION_SCHEMA.VARIABLES WHERE 'VARIABLE_NAME' = 'ENFORCE_GTID_CONSISTENCY'`, all return the textual form, not the numeric form. This is an incompatible change, since `@@ENFORCE_GTID_CONSISTENCY` returns the numeric form for booleans but returns the textual form for `SHOW` and the Information Schema.

- `executed_gtids_compression_period`

Deprecated	5.7.6
-------------------	-------

System Variable	Name	<code>executed_gtids_compression_period</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	1000
	Min Value	0
	Max Value	4294967295

This option is deprecated and will be removed in a future MySQL release. Use the renamed `gtid_executed_compression_period` to control how the `gtid_executed` table is compressed.

- `gtid_executed`

System Variable	Name	<code>gtid_executed</code>
	Variable Scope	Global, Session
	Dynamic Variable	No
System Variable	Name	<code>gtid_executed</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	string

When used with global scope, this variable contains a representation of the set of all transactions executed on the server and GTIDs that have been set by a `SET gtid_purged` statement. This is the same as the value of the `Executed_Gtid_Set` column in the output of `SHOW MASTER STATUS` and `SHOW SLAVE STATUS`. The value of this variable is a GTID set, see [GTID Sets](#) for more information.

When the server starts, `@@global.gtid_executed` is initialized. See [binlog_gtid_simple_recovery](#) for more information on how binary logs are iterated to populate `gtid_executed`. GTIDs are then added to the set as transactions are executed, or if any `SET gtid_purged` statement is executed.

The set of transactions that can be found in the binary logs at any given time is equal to `GTID_SUBTRACT(@@global.gtid_executed, @@global.gtid_purged)`; that is, to all transactions in the binary log that have not yet been purged.

Issuing `RESET MASTER` causes the global value (but not the session value) of this variable to be reset to an empty string. GTIDs are not otherwise removed from this set other than when the set is cleared due to `RESET MASTER`.

Prior to MySQL 5.7.7, this variable could also be used with session scope, where it contained a representation of the set of transactions that are written to the cache in the current session. The session scope was deprecated in MySQL 5.7.7.

System Variable	Name	<code>gtid_executed_compression_period</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	1000
	Min Value	0
	Max Value	4294967295

Compress the `mysql.gtid_executed` table each time this many transactions have been processed. A setting of 0 means that this table is not compressed. Since no compression of the table occurs when using the binary log, setting the value of the variable has no effect unless binary logging is disabled.

See [mysql.gtid_executed Table Compression](#), for more information.

- `gtid_mode`

System Variable	Name	<code>gtid_mode</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	enumeration
	Default	OFF
	Valid Values	OFF
		OFF_PERMISSIVE
		ON_PERMISSIVE
ON		

Controls whether GTID based logging is enabled and what type of transactions the logs can contain. Prior to MySQL 5.7.6 this variable was read-only and was set using the `--gtid-mode` option only. MySQL 5.7.6 enables this variable to be set dynamically. You must have the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege to set this variable. `enforce_gtid_consistency` must be true before you can set `gtid_mode=ON`. Before modifying this variable, see [Section 18.1.5, “Changing Replication Modes on Online Servers”](#).

Logged transactions can be either anonymous or use GTIDs. Anonymous transactions rely on binary log file and position to identify specific transactions. GTID transactions have a unique identifier that is used to refer to transactions. The different modes are:

- `OFF`: Both new and replicated transactions must be anonymous.
- `OFF_PERMISSIVE`: New transactions are anonymous. Replicated transactions can be either anonymous or GTID transactions.
- `ON_PERMISSIVE`: New transactions are GTID transactions. Replicated transactions can be either anonymous or GTID transactions.
- `ON`: Both new and replicated transactions must be GTID transactions.

Changes from one value to another can only be one step at a time. For example, if `gtid_mode` is currently set to `OFF_PERMISSIVE`, it is possible to change to `OFF` or `ON_PERMISSIVE` but not to `ON`.

The values of `gtid_purged` and `gtid_executed` are persistent regardless of the value of `gtid_mode`. Therefore even after changing the value of `gtid_mode`, these variables contain the correct values.

- `gtid_next`

System Variable	Name	<code>gtid_next</code>
	Variable Scope	Session
	Dynamic Variable	Yes
Permitted Values	Type	enumeration
	Default	<code>AUTOMATIC</code>
	Valid Values	<code>AUTOMATIC</code>
		<code>ANONYMOUS</code>
	<code>UUID:NUMBER</code>	

This variable is used to specify whether and how the next GTID is obtained. `gtid_next` can take any of the following values:

- `AUTOMATIC`: Use the next automatically-generated global transaction ID.
- `ANONYMOUS`: Transactions do not have global identifiers, and are identified by file and position only.
- A global transaction ID in `UUID:NUMBER` format.

Exactly which of the above options are valid depends on the setting of `gtid_mode`, see [Section 18.1.5.1, “Replication Mode Concepts”](#) for more information. Setting this variable has no effect if `gtid_mode` is `OFF`.

After this variable has been set to `UUID:NUMBER`, and a transaction has been committed or rolled back, an explicit `SET GTID_NEXT` statement must again be issued before any other statement.

`DROP TABLE` or `DROP TEMPORARY TABLE` fails with an explicit error when used on a combination of nontemporary tables with temporary tables, or of temporary tables using transactional storage engines with temporary tables using nontransactional storage engines.

- `gtid_owned`

System Variable	Name	<code>gtid_owned</code>
	Variable Scope	Global, Session
	Dynamic Variable	No
Permitted Values	Type	string

This read-only variable holds a list whose contents depend on its scope. When used with session scope, the list holds all GTIDs that are owned by this client; when used with global scope, it holds a list of all GTIDs along with their owners.

System Variable	Name	gtid_purged
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	string

The set of all transactions that have been purged from the binary log. This is a subset of the set of transactions in [gtid_executed](#). The value of this variable is a GTID set, see [GTID Sets](#) for more information.

When the server starts, the global value of [gtid_purged](#) is initialized to a set of GTIDs. See [binlog_gtid_simple_recovery](#) for more information on how binary logs are iterated to populate [gtid_purged](#). Issuing `RESET MASTER` causes the value of this variable to be reset to an empty string.

There are two ways to set [gtid_purged](#). When [gtid_set](#) is a superset of [gtid_purged](#), and goes not intersect with `gtid_subtract(gtid_executed - gtid_purged)` use:

```
SET @@GLOBAL.GTID_PURGED = 'gtid_set'
```

The result is that `GTID_PURGED` is set equal to [gtid_set](#), and `GTID_EXECUTED` becomes the union of [gtid_set](#) and the previous value of `GTID_EXECUTED`.

When [gtid_set](#) does not intersect with [gtid_executed](#) use:

```
SET @@GLOBAL.GTID_PURGED = '+gtid_set'
```

The result is that [gtid_set](#) is added to both [gtid_executed](#) and [gtid_purged](#).

If all existing binary logs were generated using MySQL 5.7.6 or later, after issuing a `SET gtid_purged` statement, `binlog_gtid_simple_recovery=TRUE` (the default setting in MySQL 5.7.7 and later) can safely be used. If binary logs from MySQL 5.7.7 or earlier exist, there is a chance that [gtid_purged](#) may be computed incorrectly. See [binlog_gtid_simple_recovery](#) for more information. If you are using MySQL 5.7.7 or earlier, after issuing a `SET gtid_purged` statement note down the current binary log file name, which can be checked using `SHOW MASTER STATUS`. If the server is restarted before this file has been purged, then you should use `binlog_gtid_simple_recovery=FALSE` to avoid [gtid_purged](#) or [gtid_executed](#) being computed incorrectly.

- [simplified_binlog_gtid_recovery](#)

Deprecated	5.7.6	
Command-Line Format	<code>--simplified-binlog-gtid-recovery</code>	
System Variable	Name	simplified_binlog_gtid_recovery
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	boolean
	Default	<code>FALSE</code>

This option is deprecated and will be removed in a future MySQL release. Use the renamed [binlog_gtid_simple_recovery](#) to control how MySQL iterates through binary log files after a crash.

18.1.7 Common Replication Administration Tasks

Once replication has been started it executes without requiring much regular administration. This section describes how to check the status of replication and how to pause a slave.

18.1.7.1 Checking Replication Status

The most common task when managing a replication process is to ensure that replication is taking place and that there have been no errors between the slave and the master. The primary statement for this is `SHOW SLAVE STATUS`, which you must execute on each slave:

```
mysql> SHOW SLAVE STATUS\G
***** 1. row *****
      Slave_IO_State: Waiting for master to send event
      Master_Host: master1
      Master_User: root
      Master_Port: 3306
      Connect_Retry: 60
      Master_Log_File: mysql-bin.000004
      Read_Master_Log_Pos: 931
      Relay_Log_File: slave1-relay-bin.000056
      Relay_Log_Pos: 950
      Relay_Master_Log_File: mysql-bin.000004
      Slave_IO_Running: Yes
      Slave_SQL_Running: Yes
      Replicate_Do_DB:
      Replicate_Ignore_DB:
      Replicate_Do_Table:
      Replicate_Ignore_Table:
      Replicate_Wild_Do_Table:
      Replicate_Wild_Ignore_Table:
      Last_Errno: 0
      Last_Error:
      Skip_Counter: 0
      Exec_Master_Log_Pos: 931
      Relay_Log_Space: 1365
      Until_Condition: None
      Until_Log_File:
      Until_Log_Pos: 0
      Master_SSL_Allowed: No
      Master_SSL_CA_File:
      Master_SSL_CA_Path:
      Master_SSL_Cert:
      Master_SSL_Cipher:
      Master_SSL_Key:
      Seconds_Behind_Master: 0
      Master_SSL_Verify_Server_Cert: No
      Last_IO_Errno: 0
      Last_IO_Error:
      Last_SQL_Errno: 0
      Last_SQL_Error:
      Replicate_Ignore_Server_Ids: 0
```

The key fields from the status report to examine are:

- **Slave_IO_State**: The current status of the slave. See [Section 8.14.5, “Replication Slave I/O Thread States”](#), and [Section 8.14.6, “Replication Slave SQL Thread States”](#), for more information.
- **Slave_IO_Running**: Whether the I/O thread for reading the master's binary log is running. Normally, you want this to be `Yes` unless you have not yet started replication or have explicitly stopped it with `STOP SLAVE`.

- `Slave_SQL_Running`: Whether the SQL thread for executing events in the relay log is running. As with the I/O thread, this should normally be `Yes`.
- `Last_IO_Error`, `Last_SQL_Error`: The last errors registered by the I/O and SQL threads when processing the relay log. Ideally these should be blank, indicating no errors.
- `Seconds_Behind_Master`: The number of seconds that the slave SQL thread is behind processing the master binary log. A high number (or an increasing one) can indicate that the slave is unable to handle events from the master in a timely fashion.

A value of 0 for `Seconds_Behind_Master` can usually be interpreted as meaning that the slave has caught up with the master, but there are some cases where this is not strictly true. For example, this can occur if the network connection between master and slave is broken but the slave I/O thread has not yet noticed this—that is, `slave_net_timeout` has not yet elapsed.

It is also possible that transient values for `Seconds_Behind_Master` may not reflect the situation accurately. When the slave SQL thread has caught up on I/O, `Seconds_Behind_Master` displays 0; but when the slave I/O thread is still queuing up a new event, `Seconds_Behind_Master` may show a large value until the SQL thread finishes executing the new event. This is especially likely when the events have old timestamps; in such cases, if you execute `SHOW SLAVE STATUS` several times in a relatively short period, you may see this value change back and forth repeatedly between 0 and a relatively large value.

Several pairs of fields provide information about the progress of the slave in reading events from the master binary log and processing them in the relay log:

- (`Master_Log_file`, `Read_Master_Log_Pos`): Coordinates in the master binary log indicating how far the slave I/O thread has read events from that log.
- (`Relay_Master_Log_File`, `Exec_Master_Log_Pos`): Coordinates in the master binary log indicating how far the slave SQL thread has executed events received from that log.
- (`Relay_Log_File`, `Relay_Log_Pos`): Coordinates in the slave relay log indicating how far the slave SQL thread has executed the relay log. These correspond to the preceding coordinates, but are expressed in slave relay log coordinates rather than master binary log coordinates.

On the master, you can check the status of connected slaves using `SHOW PROCESSLIST` to examine the list of running processes. Slave connections have `Binlog Dump` in the `Command` field:

```
mysql> SHOW PROCESSLIST \G;
***** 4. row *****
  Id: 10
  User: root
  Host: slave1:58371
  db: NULL
Command: Binlog Dump
  Time: 777
  State: Has sent all binlog to slave; waiting for binlog to be updated
  Info: NULL
```

Because it is the slave that drives the replication process, very little information is available in this report.

For slaves that were started with the `--report-host` option and are connected to the master, the `SHOW SLAVE HOSTS` statement on the master shows basic information about the slaves. The output includes the ID of the slave server, the value of the `--report-host` option, the connecting port, and master ID:

```
mysql> SHOW SLAVE HOSTS;
+-----+-----+-----+-----+-----+
| Server_id | Host   | Port | Rpl_recovery_rank | Master_id |
+-----+-----+-----+-----+-----+
```

```
|      10 | slave1 | 3306 |      0 |      1 |
+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

18.1.7.2 Pausing Replication on the Slave

You can stop and start replication on the slave using the `STOP SLAVE` and `START SLAVE` statements.

To stop processing of the binary log from the master, use `STOP SLAVE`:

```
mysql> STOP SLAVE;
```

When replication is stopped, the slave I/O thread stops reading events from the master binary log and writing them to the relay log, and the SQL thread stops reading events from the relay log and executing them. You can pause the I/O or SQL thread individually by specifying the thread type:

```
mysql> STOP SLAVE IO_THREAD;
mysql> STOP SLAVE SQL_THREAD;
```

To start execution again, use the `START SLAVE` statement:

```
mysql> START SLAVE;
```

To start a particular thread, specify the thread type:

```
mysql> START SLAVE IO_THREAD;
mysql> START SLAVE SQL_THREAD;
```

For a slave that performs updates only by processing events from the master, stopping only the SQL thread can be useful if you want to perform a backup or other task. The I/O thread will continue to read events from the master but they are not executed. This makes it easier for the slave to catch up when you restart the SQL thread.

Stopping only the I/O thread enables the events in the relay log to be executed by the SQL thread up to the point where the relay log ends. This can be useful when you want to pause execution to catch up with events already received from the master, when you want to perform administration on the slave but also ensure that it has processed all updates to a specific point. This method can also be used to pause event receipt on the slave while you conduct administration on the master. Stopping the I/O thread but permitting the SQL thread to run helps ensure that there is not a massive backlog of events to be executed when replication is started again.

18.2 Replication Implementation

Replication is based on the master server keeping track of all changes to its databases (updates, deletes, and so on) in its binary log. The binary log serves as a written record of all events that modify database structure or content (data) from the moment the server was started. Typically, `SELECT` statements are not recorded because they modify neither database structure nor content.

Each slave that connects to the master requests a copy of the binary log. That is, it pulls the data from the master, rather than the master pushing the data to the slave. The slave also executes the events from the binary log that it receives. This has the effect of repeating the original changes just as they were made on the master. Tables are created or their structure modified, and data is inserted, deleted, and updated according to the changes that were originally made on the master.

Because each slave is independent, the replaying of the changes from the master's binary log occurs independently on each slave that is connected to the master. In addition, because each slave receives a copy of the binary log only by requesting it from the master, the slave is able to read and update the copy of the database at its own pace and can start and stop the replication process at will without affecting the ability to update to the latest database status on either the master or slave side.

For more information on the specifics of the replication implementation, see [Section 18.2.2, “Replication Implementation Details”](#).

Masters and slaves report their status in respect of the replication process regularly so that you can monitor them. See [Section 8.14, “Examining Thread Information”](#), for descriptions of all replicated-related states.

The master binary log is written to a local relay log on the slave before it is processed. The slave also records information about the current position with the master's binary log and the local relay log. See [Section 18.2.4, “Replication Relay and Status Logs”](#).

Database changes are filtered on the slave according to a set of rules that are applied according to the various configuration options and variables that control event evaluation. For details on how these rules are applied, see [Section 18.2.5, “How Servers Evaluate Replication Filtering Rules”](#).

18.2.1 Replication Formats

Replication works because events written to the binary log are read from the master and then processed on the slave. The events are recorded within the binary log in different formats according to the type of event. The different replication formats used correspond to the binary logging format used when the events were recorded in the master's binary log. The correlation between binary logging formats and the terms used during replication are:

- When using statement-based binary logging, the master writes SQL statements to the binary log. Replication of the master to the slave works by executing the SQL statements on the slave. This is called *statement-based replication* (often abbreviated as *SBR*), which corresponds to the standard MySQL statement-based binary logging format. Replication capabilities in MySQL version 5.1.4 and earlier used this format exclusively.
- When using row-based logging, the master writes *events* to the binary log that indicate how individual table rows are changed. Replication of the master to the slave works by copying the events representing the changes to the table rows to the slave. This is called *row-based replication* (often abbreviated as *RBR*).

Row-based logging is the default method.

- You can also configure MySQL to use a mix of both statement-based and row-based logging, depending on which is most appropriate for the change to be logged. This is called *mixed-format logging*. When using mixed-format logging, a statement-based log is used by default. Depending on certain statements, and also the storage engine being used, the log is automatically switched to row-based in particular cases. Replication using the mixed format is often referred to as *mixed-based replication* or *mixed-format replication*. For more information, see [Section 5.4.4.3, “Mixed Binary Logging Format”](#).

When using `MIXED` format, the binary logging format is determined in part by the storage engine being used and the statement being executed. For more information on mixed-format logging and the rules governing the support of different logging formats, see [Section 5.4.4.3, “Mixed Binary Logging Format”](#).

The logging format in a running MySQL server is controlled by setting the `binlog_format` server system variable. This variable can be set with session or global scope. The rules governing when and how the new setting takes effect are the same as for other MySQL server system variables—setting the variable for the current session lasts only until the end of that session, and the change is not visible to other sessions; setting the variable globally requires a restart of the server to take effect. For more information, see [Section 13.7.4.1, “SET Syntax for Variable Assignment”](#).

There are conditions under which you cannot change the binary logging format at runtime or doing so causes replication to fail. See [Section 5.4.4.2, “Setting The Binary Log Format”](#).

You must have the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege to set either the global or session `binlog_format` value.

The statement-based and row-based replication formats have different issues and limitations. For a comparison of their relative advantages and disadvantages, see [Section 18.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

With statement-based replication, you may encounter issues with replicating stored routines or triggers. You can avoid these issues by using row-based replication instead. For more information, see [Section 23.7, “Binary Logging of Stored Programs”](#).

18.2.1.1 Advantages and Disadvantages of Statement-Based and Row-Based Replication

Each binary logging format has advantages and disadvantages. For most users, the mixed replication format should provide the best combination of data integrity and performance. If, however, you want to take advantage of the features specific to the statement-based or row-based replication format when performing certain tasks, you can use the information in this section, which provides a summary of their relative advantages and disadvantages, to determine which is best for your needs.

- [Advantages of statement-based replication](#)
- [Disadvantages of statement-based replication](#)
- [Advantages of row-based replication](#)
- [Disadvantages of row-based replication](#)

Advantages of statement-based replication

- Proven technology.
- Less data written to log files. When updates or deletes affect many rows, this results in *much* less storage space required for log files. This also means that taking and restoring from backups can be accomplished more quickly.
- Log files contain all statements that made any changes, so they can be used to audit the database.

Disadvantages of statement-based replication

- **Statements that are unsafe for SBR.**
Not all statements which modify data (such as `INSERT DELETE`, `UPDATE`, and `REPLACE` statements) can be replicated using statement-based replication. Any nondeterministic behavior is difficult to replicate when using statement-based replication. Examples of such Data Modification Language (DML) statements include the following:
 - A statement that depends on a UDF or stored program that is nondeterministic, since the value returned by such a UDF or stored program or depends on factors other than the parameters supplied to it. (Row-based replication, however, simply replicates the value returned by the UDF or stored program, so its effect on table rows and data is the same on both the master and slave.) See [Section 18.4.1.12, “Replication of Invoked Features”](#), for more information.
 - `DELETE` and `UPDATE` statements that use a `LIMIT` clause without an `ORDER BY` are nondeterministic. See [Section 18.4.1.17, “Replication and LIMIT”](#).
 - Locking read statements (`SELECT ... FOR UPDATE` and `SELECT ... FOR SHARE`) that use `NOWAIT` or `SKIP LOCKED` options. See [Locking Read Concurrency with NOWAIT and SKIP LOCKED](#).
 - Deterministic UDFs must be applied on the slaves.
 - Statements using any of the following functions cannot be replicated properly using statement-based replication:
 - `LOAD_FILE()`
 - `UUID()`, `UUID_SHORT()`

- `USER()`
- `FOUND_ROWS()`
- `SYSDATE()` (unless both the master and the slave are started with the `--sysdate-is-now` option)
- `GET_LOCK()`
- `IS_FREE_LOCK()`
- `IS_USED_LOCK()`
- `MASTER_POS_WAIT()`
- `RAND()`
- `RELEASE_LOCK()`
- `SLEEP()`
- `VERSION()`

However, all other functions are replicated correctly using statement-based replication, including `NOW()` and so forth.

For more information, see [Section 18.4.1.16, “Replication and System Functions”](#).

Statements that cannot be replicated correctly using statement-based replication are logged with a warning like the one shown here:

```
[Warning] Statement is not safe to log in statement format.
```

A similar warning is also issued to the client in such cases. The client can display it using `SHOW WARNINGS`.

- `INSERT ... SELECT` requires a greater number of row-level locks than with row-based replication.
- `UPDATE` statements that require a table scan (because no index is used in the `WHERE` clause) must lock a greater number of rows than with row-based replication.
- For `InnoDB`: An `INSERT` statement that uses `AUTO_INCREMENT` blocks other nonconflicting `INSERT` statements.
- For complex statements, the statement must be evaluated and executed on the slave before the rows are updated or inserted. With row-based replication, the slave only has to modify the affected rows, not execute the full statement.
- If there is an error in evaluation on the slave, particularly when executing complex statements, statement-based replication may slowly increase the margin of error across the affected rows over time. See [Section 18.4.1.28, “Slave Errors During Replication”](#).
- Stored functions execute with the same `NOW()` value as the calling statement. However, this is not true of stored procedures.
- Deterministic UDFs must be applied on the slaves.
- Table definitions must be (nearly) identical on master and slave. See [Section 18.4.1.10, “Replication with Differing Table Definitions on Master and Slave”](#), for more information.

Advantages of row-based replication

- All changes can be replicated. This is the safest form of replication.

Note

Statements that update the information in the `mysql` database—such as `GRANT`, `REVOKE` and the manipulation of triggers, stored routines (including stored procedures), and views—are all replicated to slaves using statement-based replication.

For statements such as `CREATE TABLE ... SELECT`, a `CREATE` statement is generated from the table definition and replicated using statement-based format, while the row insertions are replicated using row-based format.

- Fewer row locks are required on the master, which thus achieves higher concurrency, for the following types of statements:
 - `INSERT ... SELECT`
 - `INSERT` statements with `AUTO_INCREMENT`
 - `UPDATE` or `DELETE` statements with `WHERE` clauses that do not use keys or do not change most of the examined rows.
- Fewer row locks are required on the slave for any `INSERT`, `UPDATE`, or `DELETE` statement.

Disadvantages of row-based replication

- RBR can generate more data that must be logged. To replicate a DML statement (such as an `UPDATE` or `DELETE` statement), statement-based replication writes only the statement to the binary log. By contrast, row-based replication writes each changed row to the binary log. If the statement changes many rows, row-based replication may write significantly more data to the binary log; this is true even for statements that are rolled back. This also means that making and restoring a backup can require more time. In addition, the binary log is locked for a longer time to write the data, which may cause concurrency problems. Use `binlog_row_image=minimal` to reduce the disadvantage considerably.
- Deterministic UDFs that generate large `BLOB` values take longer to replicate with row-based replication than with statement-based replication. This is because the `BLOB` column value is logged, rather than the statement generating the data.
- You cannot see on the slave what statements were received from the master and executed. However, you can see what data was changed using `mysqlbinlog` with the options `--base64-output=DECODE-ROWS` and `--verbose`.

Alternatively, use the `binlog_rows_query_log_events` variable, which if enabled adds a `Rows_query` event with the statement to `mysqlbinlog` output when the `-vv` option is used.
- For tables using the `MyISAM` storage engine, a stronger lock is required on the slave for `INSERT` statements when applying them as row-based events to the binary log than when applying them as statements. This means that concurrent inserts on `MyISAM` tables are not supported when using row-based replication.

18.2.1.2 Usage of Row-Based Logging and Replication

MySQL uses statement-based logging (SBL), row-based logging (RBL) or mixed-format logging. The type of binary log used impacts the size and efficiency of logging. Therefore the choice between row-based replication (RBR) or statement-based replication (SBR) depends on your application and environment. This section describes known issues when using a row-based format log, and describes some best practices using it in replication.

For additional information, see [Section 18.2.1, “Replication Formats”](#), and [Section 18.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

- **Row-based logging of temporary tables.** As noted in [Section 18.4.1.24, “Replication and Temporary Tables”](#), temporary tables are not replicated when using row-based format. When using mixed format logging, “safe” statements involving temporary tables are logged using statement-based format. For more information, see [Section 18.2.1.1, “Advantages and Disadvantages of Statement-Based and Row-Based Replication”](#).

Temporary tables are not replicated when using row-based format because there is no need. In addition, because temporary tables can be read only from the thread which created them, there is seldom if ever any benefit obtained from replicating them, even when using statement-based format.

In MySQL 8.0, you can switch from statement-based to row-based binary logging mode even when temporary tables have been created. However, while using the row-based format, the MySQL server cannot determine the logging mode that was in effect when a given temporary table was created. For this reason, the server in such cases logs a `DROP TEMPORARY TABLE IF EXISTS` statement for each temporary table that still exists for a given client session when that session ends. While this means that it is possible that an unnecessary `DROP TEMPORARY TABLE` statement might be logged in some cases, the statement is harmless, and does not cause an error even if the table does not exist, due to the presence of the `IF EXISTS` option.

Nontransactional DML statements involving temporary tables are allowed when using `binlog_format=ROW`, as long as any nontransactional tables affected by the statements are temporary tables (Bug #14272672).

- **RBL and synchronization of nontransactional tables.** When many rows are affected, the set of changes is split into several events; when the statement commits, all of these events are written to the binary log. When executing on the slave, a table lock is taken on all tables involved, and then the rows are applied in batch mode. Depending on the engine used for the slave's copy of the table, this may or may not be effective.
- **Latency and binary log size.** RBL writes changes for each row to the binary log and so its size can increase quite rapidly. This can significantly increase the time required to make changes on the slave that match those on the master. You should be aware of the potential for this delay in your applications.
- **Reading the binary log.** `mysqlbinlog` displays row-based events in the binary log using the `BINLOG` statement (see [Section 13.7.6.1, “BINLOG Syntax”](#)). This statement displays an event as a base 64-encoded string, the meaning of which is not evident. When invoked with the `--base64-output=DECODE-ROWS` and `--verbose` options, `mysqlbinlog` formats the contents of the binary log to be human readable. When binary log events were written in row-based format and you want to read or recover from a replication or database failure you can use this command to read contents of the binary log. For more information, see [Section 4.6.8.2, “mysqlbinlog Row Event Display”](#).
- **Binary log execution errors and `slave_exec_mode`.** If `slave_exec_mode` is `IDEMPOTENT`, a failure to apply changes from RBL because the original row cannot be found does not trigger an error or cause replication to fail. This means that it is possible that updates are not applied on the slave, so that the master and slave are no longer synchronized. Latency issues and use of nontransactional tables with RBR when `slave_exec_mode` is `IDEMPOTENT` can cause the master and slave to diverge even further. For more information about `slave_exec_mode`, see [Section 5.1.5, “Server System Variables”](#).

Note

`slave_exec_mode=IDEMPOTENT` is generally useful only for circular replication or multi-master replication with MySQL Cluster, for which `IDEMPOTENT` is the default value.

For other scenarios, setting `slave_exec_mode` to `STRICT` is normally sufficient; this is the default value for storage engines other than `NDB`.

The `NDBCLUSTER` storage engine is currently not supported in MySQL 8.0. See [MySQL NDB Cluster 7.5 and NDB Cluster 7.6](#).

- **Filtering based on server ID not supported.** In MySQL 8.0, you can filter based on server ID by using the `IGNORE_SERVER_IDS` option for the `CHANGE MASTER TO` statement. This option works with statement-based and row-based logging formats. Another method to filter out changes on some slaves is to use a `WHERE` clause that includes the relation `@@server_id <> id_value` clause with `UPDATE` and `DELETE` statements. For example, `WHERE @@server_id <> 1`. However, this does not work correctly with row-based logging. To use the `server_id` system variable for statement filtering, use statement-based logging.
- **Database-level replication options.** The effects of the `--replicate-do-db`, `--replicate-ignore-db`, and `--replicate-rewrite-db` options differ considerably depending on whether row-based or statement-based logging is used. Therefore, it is recommended to avoid database-level options and instead use table-level options such as `--replicate-do-table` and `--replicate-ignore-table`. For more information about these options and the impact replication format has on how they operate, see [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).
- **RBL, nontransactional tables, and stopped slaves.** When using row-based logging, if the slave server is stopped while a slave thread is updating a nontransactional table, the slave database can reach an inconsistent state. For this reason, it is recommended that you use a transactional storage engine such as `InnoDB` for all tables replicated using the row-based format. Use of `STOP SLAVE` or `STOP SLAVE SQL_THREAD` prior to shutting down the slave MySQL server helps prevent issues from occurring, and is always recommended regardless of the logging format or storage engine you use.

18.2.1.3 Determination of Safe and Unsafe Statements in Binary Logging

The “safeness” of a statement in MySQL Replication, refers to whether the statement and its effects can be replicated correctly using statement-based format. If this is true of the statement, we refer to the statement as *safe*; otherwise, we refer to it as *unsafe*.

In general, a statement is safe if it deterministic, and unsafe if it is not. However, certain nondeterministic functions are *not* considered unsafe (see [Nondeterministic functions not considered unsafe](#), later in this section). In addition, statements using results from floating-point math functions—which are hardware-dependent—are always considered unsafe (see [Section 18.4.1.13, “Replication and Floating-Point Values”](#)).

Handling of safe and unsafe statements. A statement is treated differently depending on whether the statement is considered safe, and with respect to the binary logging format (that is, the current value of `binlog_format`).

- When using row-based logging, no distinction is made in the treatment of safe and unsafe statements.
- When using mixed-format logging, statements flagged as unsafe are logged using the row-based format; statements regarded as safe are logged using the statement-based format.
- When using statement-based logging, statements flagged as being unsafe generate a warning to this effect. Safe statements are logged normally.

Each statement flagged as unsafe generates a warning. Formerly, if a large number of such statements were executed on the master, this could lead to excessively large error log files. To prevent this, MySQL 5.7 provides a warning suppression mechanism, which behaves as follows: Whenever the 50 most recent `ER_BINLOG_UNSAFE_STATEMENT` warnings have been generated more than 50 times in any 50-second period, warning suppression is enabled. When activated, this causes such warnings not to be written to the error log; instead, for each 50 warnings of this type, a note `The last warning was repeated N times in last S seconds` is written to the error log. This continues as long as the 50 most recent such warnings were issued in 50 seconds or less; once the rate has decreased below this threshold, the warnings are once again logged normally. Warning suppression has no effect

on how the safety of statements for statement-based logging is determined, nor on how warnings are sent to the client. MySQL clients still receive one warning for each such statement.

For more information, see [Section 18.2.1, “Replication Formats”](#).

Statements considered unsafe.

Statements with the following characteristics are considered unsafe:

- **Statements containing system functions that may return a different value on slave.** These functions include `FOUND_ROWS()`, `GET_LOCK()`, `IS_FREE_LOCK()`, `IS_USED_LOCK()`, `LOAD_FILE()`, `MASTER_POS_WAIT()`, `PASSWORD()`, `RAND()`, `RELEASE_LOCK()`, `ROW_COUNT()`, `SESSION_USER()`, `SLEEP()`, `SYSDATE()`, `SYSTEM_USER()`, `USER()`, `UUID()`, and `UUID_SHORT()`.

Nondeterministic functions not considered unsafe. Although these functions are not deterministic, they are treated as safe for purposes of logging and replication: `CONNECTION_ID()`, `CURDATE()`, `CURRENT_DATE()`, `CURRENT_TIME()`, `CURRENT_TIMESTAMP()`, `CURTIME()`, `LAST_INSERT_ID()`, `LOCALTIME()`, `LOCALTIMESTAMP()`, `NOW()`, `UNIX_TIMESTAMP()`, `UTC_DATE()`, `UTC_TIME()`, and `UTC_TIMESTAMP()`.

For more information, see [Section 18.4.1.16, “Replication and System Functions”](#).

- **References to system variables.** Most system variables are not replicated correctly using the statement-based format. See [Section 18.4.1.38, “Replication and Variables”](#). For exceptions, see [Section 5.4.4.3, “Mixed Binary Logging Format”](#).
- **UDFs.** Since we have no control over what a UDF does, we must assume that it is executing unsafe statements.
- **Fulltext plugin.** This plugin may behave differently on different MySQL servers; therefore, statements depending on it could have different results. For this reason, all statements relying on the fulltext plugin are treated as unsafe in MySQL.
- **Trigger or stored program updates a table having an AUTO_INCREMENT column.** This is unsafe because the order in which the rows are updated may differ on the master and the slave.

In addition, an `INSERT` into a table that has a composite primary key containing an `AUTO_INCREMENT` column that is not the first column of this composite key is unsafe.

For more information, see [Section 18.4.1.1, “Replication and AUTO_INCREMENT”](#).

- **INSERT ... ON DUPLICATE KEY UPDATE statements on tables with multiple primary or unique keys.** When executed against a table that contains more than one primary or unique key, this statement is considered unsafe, being sensitive to the order in which the storage engine checks the keys, which is not deterministic, and on which the choice of rows updated by the MySQL Server depends.

An `INSERT ... ON DUPLICATE KEY UPDATE` statement against a table having more than one unique or primary key is marked as unsafe for statement-based replication. (Bug #11765650, Bug #58637)

- **Updates using LIMIT.** The order in which rows are retrieved is not specified, and is therefore considered unsafe. See [Section 18.4.1.17, “Replication and LIMIT”](#).
- **Accesses or references log tables.** The contents of the system log table may differ between master and slave.
- **Nontransactional operations after transactional operations.** Within a transaction, allowing any nontransactional reads or writes to execute after any transactional reads or writes is considered unsafe.

For more information, see [Section 18.4.1.33, “Replication and Transactions”](#).

- **Accesses or references self-logging tables.** All reads and writes to self-logging tables are considered unsafe. Within a transaction, any statement following a read or write to self-logging tables is also considered unsafe.
- **LOAD DATA INFILE statements.** `LOAD DATA INFILE` is treated as unsafe and when `binlog_format=mixed` the statement is logged in row-based format. When `binlog_format=statement` `LOAD DATA INFILE` does not generate a warning, unlike other unsafe statements.

For additional information, see [Section 18.4.1, “Replication Features and Issues”](#).

18.2.2 Replication Implementation Details

MySQL replication capabilities are implemented using three threads, one on the master server and two on the slave:

- **Binlog dump thread.** The master creates a thread to send the binary log contents to a slave when the slave connects. This thread can be identified in the output of `SHOW PROCESSLIST` on the master as the `Binlog Dump` thread.

The binary log dump thread acquires a lock on the master's binary log for reading each event that is to be sent to the slave. As soon as the event has been read, the lock is released, even before the event is sent to the slave.

- **Slave I/O thread.** When a `START SLAVE` statement is issued on a slave server, the slave creates an I/O thread, which connects to the master and asks it to send the updates recorded in its binary logs.

The slave I/O thread reads the updates that the master's `Binlog Dump` thread sends (see previous item) and copies them to local files that comprise the slave's relay log.

The state of this thread is shown as `Slave_IO_running` in the output of `SHOW SLAVE STATUS` or as `Slave_running` in the output of `SHOW STATUS`.

- **Slave SQL thread.** The slave creates an SQL thread to read the relay log that is written by the slave I/O thread and execute the events contained therein.

In the preceding description, there are three threads per master/slave connection. A master that has multiple slaves creates one binary log dump thread for each currently connected slave, and each slave has its own I/O and SQL threads.

A slave uses two threads to separate reading updates from the master and executing them into independent tasks. Thus, the task of reading statements is not slowed down if statement execution is slow. For example, if the slave server has not been running for a while, its I/O thread can quickly fetch all the binary log contents from the master when the slave starts, even if the SQL thread lags far behind. If the slave stops before the SQL thread has executed all the fetched statements, the I/O thread has at least fetched everything so that a safe copy of the statements is stored locally in the slave's relay logs, ready for execution the next time that the slave starts.

The `SHOW PROCESSLIST` statement provides information that tells you what is happening on the master and on the slave regarding replication. For information on master states, see [Section 8.14.4, “Replication Master Thread States”](#). For slave states, see [Section 8.14.5, “Replication Slave I/O Thread States”](#), and [Section 8.14.6, “Replication Slave SQL Thread States”](#).

The following example illustrates how the three threads show up in the output from `SHOW PROCESSLIST`.

On the master server, the output from `SHOW PROCESSLIST` looks like this:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
```

```

    Id: 2
    User: root
    Host: localhost:32931
    db: NULL
Command: Binlog Dump
    Time: 94
    State: Has sent all binlog to slave; waiting for binlog to
           be updated
    Info: NULL

```

Here, thread 2 is a [Binlog Dump](#) replication thread that services a connected slave. The [State](#) information indicates that all outstanding updates have been sent to the slave and that the master is waiting for more updates to occur. If you see no [Binlog Dump](#) threads on a master server, this means that replication is not running; that is, no slaves are currently connected.

On a slave server, the output from [SHOW PROCESSLIST](#) looks like this:

```

mysql> SHOW PROCESSLIST\G
***** 1. row *****
    Id: 10
    User: system user
    Host:
    db: NULL
Command: Connect
    Time: 11
    State: Waiting for master to send event
    Info: NULL
***** 2. row *****
    Id: 11
    User: system user
    Host:
    db: NULL
Command: Connect
    Time: 11
    State: Has read all relay log; waiting for the slave I/O
           thread to update it
    Info: NULL

```

The [State](#) information indicates that thread 10 is the I/O thread that is communicating with the master server, and thread 11 is the SQL thread that is processing the updates stored in the relay logs. At the time that [SHOW PROCESSLIST](#) was run, both threads were idle, waiting for further updates.

The value in the [Time](#) column can show how late the slave is compared to the master. See [Section A.13, “MySQL 8.0 FAQ: Replication”](#). If sufficient time elapses on the master side without activity on the [Binlog Dump](#) thread, the master determines that the slave is no longer connected. As for any other client connection, the timeouts for this depend on the values of [net_write_timeout](#) and [net_retry_count](#); for more information about these, see [Section 5.1.5, “Server System Variables”](#).

The [SHOW SLAVE STATUS](#) statement provides additional information about replication processing on a slave server. See [Section 18.1.7.1, “Checking Replication Status”](#).

18.2.3 Replication Channels

Replication channels represent the path of transactions flowing from a master to a slave. This section describes how channels can be used in a replication topology, and the impact they have on single-source replication.

To provide compatibility with previous versions, the MySQL server automatically creates on startup a default channel whose name is the empty string (""). This channel is always present; it cannot be created or destroyed by the user. If no other channels (having nonempty names) have been created, replication statements act on the default channel only, so that all replication statements from older slaves function as expected (see [Section 18.2.3.2, “Compatibility with Previous Replication Statements”](#)). Statements applying to replication channels as described in this section can be used only when there is at least one named channel.

A replication channel encompasses the path of transactions transmitted from a master to a slave. In multi-source replication a slave opens multiple channels, one per master, and each channel has its own relay log and applier (SQL) threads. Once transactions are received by a replication channel's receiver (I/O) thread, they are added to the channel's relay log file and passed through to an applier thread. This enables channels to function independently.

A replication channel is also associated with a host name and port. You can assign multiple channels to the same combination of host name and port; in MySQL 8.0, the maximum number of channels that can be added to one slave in a multi-source replication topology is 256. Each replication channel must have a unique (nonempty) name (see [Section 18.2.3.4, “Replication Channel Naming Conventions”](#)). Channels can be configured independently.

18.2.3.1 Commands for Operations on a Single Channel

To enable existing MySQL replication statements to act on individual replication channels use the `FOR CHANNEL channel_name` clause with the following replication statements:

- `CHANGE MASTER TO`
- `START SLAVE`
- `STOP SLAVE`
- `SHOW RELAYLOG EVENTS`
- `FLUSH RELAY LOGS`
- `SHOW SLAVE STATUS`
- `RESET SLAVE`

Similarly, an additional `channel_name` parameter is introduced for the following functions:

- `MASTER_POS_WAIT()`
- `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()`

The following statements are disallowed for the `group_replication_recovery` channel.

- `START SLAVE`
- `STOP SLAVE`

18.2.3.2 Compatibility with Previous Replication Statements

When a replication slave has multiple channels and a `FOR CHANNEL channel_name` option is not specified, a valid statement generally acts on all available channels.

For example, the following statements behave as expected:

- `START SLAVE` starts replication threads for all channels, except the `group_replication_recovery` channel.
- `STOP SLAVE` stops replication threads for all the channels, except the `group_replication_recovery` channel.
- `SHOW SLAVE STATUS` reports the status for all channels.
- `FLUSH RELAY LOGS` flushes the relay logs for all channels.
- `RESET SLAVE` resets all channels.

Warning

Use `RESET SLAVE` with caution as this statement deletes all existing channels, purges their relay log files, and recreates only the default channel.

Some replication statements cannot operate on all channels. In this case, error 1964 `Multiple channels exist on the slave. Please provide channel name as an argument.` is generated. The following statements and functions generate this error when used in a multi-source replication topology and a `FOR CHANNEL channel_name` option is not used to specify which channel to act on:

- `SHOW RELAYLOG EVENTS`
- `CHANGE MASTER TO`
- `MASTER_POS_WAIT()`
- `WAIT_UNTIL_SQL_THREAD_AFTER_GTIDS()`
- `WAIT_FOR_EXECUTED_GTID_SET()`

Note that a default channel always exists in a single source replication topology, where statements and functions behave as in previous versions of MySQL.

18.2.3.3 Startup Options and Replication Channels

This section describes startup options which are impacted by the addition of replication channels.

The following startup options *must* be configured correctly to use multi-source replication.

- `--relay-log-info-repository`

This must be set to `TABLE`. If this option is set to `FILE`, attempting to add more sources to a slave fails with `ER_SLAVE_NEW_CHANNEL_WRONG_REPOSITORY`.

- `--master-info-repository`

This must be set to `TABLE`. If this option is set to `FILE`, attempting to add more sources to a slave fails with `ER_SLAVE_NEW_CHANNEL_WRONG_REPOSITORY`.

The following startup options now affect *all* channels in a replication topology.

- `--log-slave-updates`

All transactions received by the slave (even from multiple sources) are written in the binary log.

- `--relay-log-purge`

When set, each channel purges its own relay log automatically.

- `--slave_transaction_retries`

Applier threads of all channels retry transactions.

- `--skip-slave-start`

No replication threads start on any channels.

- `--slave-skip-errors`

Execution continues and errors are skipped for all channels.

The values set for the following startup options apply on each channel; since these are `mysqld` startup options, they are applied on every channel.

- `--max-relay-log-size=size`

Maximum size of the individual relay log file for each channel; after reaching this limit, the file is rotated.

- `--relay-log-space-limit=size`

Upper limit for the total size of all relay logs combined, for each individual channel. For N channels, the combined size of these logs is limited to `relay_log_space_limit * N`.

- `--slave-parallel-workers=value`

Number of slave parallel workers per channel.

- `--slave-checkpoint-group`

Waiting time by an I/O thread for each source.

- `--relay-log-index=filename`

Base name for each channel's relay log index file. See [Section 18.2.3.4, "Replication Channel Naming Conventions"](#).

- `--relay-log=filename`

Denotes the base name of each channel's relay log file. See [Section 18.2.3.4, "Replication Channel Naming Conventions"](#).

- `--slave_net_timeout=N`

This value is set per channel, so that each channel waits for N seconds to check for a broken connection.

- `--slave-skip-counter=N`

This value is set per channel, so that each channel skips N events from its master.

18.2.3.4 Replication Channel Naming Conventions

This section describes how naming conventions are impacted by replication channels.

Each replication channel has a unique name which is a string with a maximum length of 64 characters and is case insensitive. Because channel names are used in slave tables, the character set used for these is always UTF-8. Although you are generally free to use any name for channels, the following names are reserved:

- `group_replication_applier`
- `group_replication_recovery`

The name you choose for a replication channel also influences the file names used by a multi-source replication slave. The relay log files and index files for each channel are named `base_name-relay-bin-channel_name.0000x`, where `base_name` is generally a host name (if not specified using `--log-bin`) and `channel_name` is the name of the channel logged to this file.

18.2.4 Replication Relay and Status Logs

During replication, a slave server creates several logs that hold the binary log events relayed from the master to the slave, and to record information about the current status and location within the relay log. There are three types of logs used in the process, listed here:

- The *relay log* consists of the events read from the binary log of the master and written by the slave I/O thread. Events in the relay log are executed on the slave as part of the SQL thread.
- The *master info log* contains status and current configuration information for the slave's connection to the master. This log holds information on the master host name, login credentials, and coordinates indicating how far the slave has read from the master's binary log.

This log can be written to the `mysql.slave_master_info` table instead of a file, by starting the slave with `--master-info-repository=TABLE`.

- The *relay log info log* holds status information about the execution point within the slave's relay log.

This log can be written to the `mysql.slave_relay_log_info` table instead of a file by starting the slave with `--relay-log-info-repository=TABLE`.

Crash-safe replication. In order for replication to be crash-safe when using tables for logging status and relay information, these tables must use a transactional storage engine, such as `InnoDB`. In MySQL 8.0 these tables are created using `InnoDB`.

Therefore, in order to guarantee crash safety on the slave, you must run the slave with `--relay-log-recovery` enabled, in addition to setting `--relay-log-info-repository` to `TABLE`.

In MySQL 8.0, a warning is given when `mysqld` is unable to initialize the replication logging tables, but the slave is allowed to continue starting. This situation is most likely to occur when upgrading from a version of MySQL that does not support slave logging tables to one in which they are supported.

In MySQL 8.0, execution of any statement requiring a write lock on either or both of the `slave_master_info` and `slave_relay_log_info` tables is disallowed while replication is ongoing, while statements that perform only reads are permitted at any time.

Important

Do not attempt to update or insert rows in the `slave_master_info` or `slave_relay_log_info` table manually. Doing so can cause undefined behavior, and is not supported.

18.2.4.1 The Slave Relay Log

The relay log, like the binary log, consists of a set of numbered files containing events that describe database changes, and an index file that contains the names of all used relay log files.

The term “relay log file” generally denotes an individual numbered file containing database events. The term “relay log” collectively denotes the set of numbered relay log files plus the index file.

Relay log files have the same format as binary log files and can be read using `mysqlbinlog` (see [Section 4.6.8, “mysqlbinlog — Utility for Processing Binary Log Files”](#)).

By default, relay log file names have the form `host_name-relay-bin.nnnnnn` in the data directory, where `host_name` is the name of the slave server host and `nnnnnn` is a sequence number. Successive relay log files are created using successive sequence numbers, beginning with `000001`. The slave uses an index file to track the relay log files currently in use. The default relay log index file name is `host_name-relay-bin.index` in the data directory.

The default relay log file and relay log index file names can be overridden with, respectively, the `--relay-log` and `--relay-log-index` server options (see [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#)).

If a slave uses the default host-based relay log file names, changing a slave's host name after replication has been set up can cause replication to fail with the errors `Failed to open the relay log` and `Could not find target log during relay log initialization`. This is a known issue (see [Bug #2122](#)). If you anticipate that a slave's host name might change in the future (for example, if networking is set up on the slave such that its host name can be modified using DHCP), you can avoid this issue entirely by using the `--relay-log` and `--relay-log-index` options to specify relay log file names explicitly when you initially set up the slave. This will make the names independent of server host name changes.

If you encounter the issue after replication has already begun, one way to work around it is to stop the slave server, prepend the contents of the old relay log index file to the new one, and then restart the slave. On a Unix system, this can be done as shown here:

```
shell> cat new_relay_log_name.index >> old_relay_log_name.index
shell> mv old_relay_log_name.index new_relay_log_name.index
```

A slave server creates a new relay log file under the following conditions:

- Each time the I/O thread starts.
- When the logs are flushed; for example, with `FLUSH LOGS` or `mysqladmin flush-logs`.
- When the size of the current relay log file becomes “too large,” determined as follows:
 - If the value of `max_relay_log_size` is greater than 0, that is the maximum relay log file size.
 - If the value of `max_relay_log_size` is 0, `max_binlog_size` determines the maximum relay log file size.

The SQL thread automatically deletes each relay log file as soon as it has executed all events in the file and no longer needs it. There is no explicit mechanism for deleting relay logs because the SQL thread takes care of doing so. However, `FLUSH LOGS` rotates relay logs, which influences when the SQL thread deletes them.

18.2.4.2 Slave Status Logs

A replication slave server creates two logs. By default, these logs are files named `master.info` and `relay-log.info` and created in the data directory. The names and locations of these files can be changed by using the `--master-info-file` and `--relay-log-info-file` options, respectively. In MySQL 8.0, either or both of these logs can also be written to tables in the `mysql` database by starting the server with the appropriate option: use `--master-info-repository` to have the master info log written to the `mysql.slave_master_info` table, and use `--relay-log-info-repository` to have the relay log info log written to the `mysql.slave_relay_log_info` table. See [Section 18.1.6, “Replication and Binary Logging Options and Variables”](#).

The two status logs contain information like that shown in the output of the `SHOW SLAVE STATUS` statement, which is discussed in [Section 13.4.2, “SQL Statements for Controlling Slave Servers”](#). Because the status logs are stored on disk, they survive a slave server's shutdown. The next time the slave starts up, it reads the two logs to determine how far it has proceeded in reading binary logs from the master and in processing its own relay logs.

The master info log file or table should be protected because it contains the password for connecting to the master. See [Section 6.1.2.3, “Passwords and Logging”](#).

The slave I/O thread updates the master info log. The following table shows the correspondence between the lines in the `master.info` file, the columns in the `mysql.slave_master_info` table, and the columns displayed by `SHOW SLAVE STATUS`.

Line in <code>master.info</code> File	<code>slave_master_info</code> Table Column	<code>SHOW SLAVE STATUS</code> Column	Description
1	<code>Number_of_lines</code>	[None]	Number of lines in the file, or columns in the table
2	<code>Master_log_name</code>	<code>Master_Log_File</code>	The name of the master binary log currently

Line in master.info File	slave_master_info Table Column	SHOW SLAVE STATUS Column	Description
			being read from the master
3	Master_log_pos	Read_Master_Log_Pos	The current position within the master binary log that have been read from the master
4	Host	Master_Host	The host name of the master
5	User_name	Master_User	The user name used to connect to the master
6	User_password	Password (not shown by SHOW SLAVE STATUS)	The password used to connect to the master
7	Port	Master_Port	The network port used to connect to the master
8	Connect_retry	Connect_Retry	The period (in seconds) that the slave will wait before trying to reconnect to the master
9	Enabled_ssl	Master_SSL_Allowed	Indicates whether the server supports SSL connections
10	Ssl_ca	Master_SSL_CA_File	The file used for the Certificate Authority (CA) certificate
11	Ssl_capath	Master_SSL_CA_Path	The path to the Certificate Authority (CA) certificates
12	Ssl_cert	Master_SSL_Cert	The name of the SSL certificate file
13	Ssl_cipher	Master_SSL_Cipher	The list of possible ciphers used in the handshake for the SSL connection

Line in master.info File	slave_master_info Table Column	SHOW SLAVE STATUS Column	Description
14	Ssl_key	Master_SSL_Key	The name of the SSL key file
15	Ssl_verify_server_cert	Master_SSL_Verify_Server_Cert	Whether to verify the server certificate
16	Heartbeat	[None]	Interval between replication heartbeats, in seconds
17	Bind	Master_Bind	Which of the slave's network interfaces should be used for connecting to the master
18	Ignored_server_ids	Replicate_Ignore_Server_Ids	The list of server IDs to be ignored. Note that for Ignored_server_ids the list of server IDs is preceded by the total number of server IDs to ignore.
19	Uuid	Master_UUID	The master's unique ID
20	Retry_count	Master_Retry_Count	Maximum number of reconnection attempts permitted
21	Ssl_crl	[None]	Path to an ssl certificate revocation list file
22	Ssl_crl_path	[None]	Path to a directory containing ssl certificate revocation list files
23	Enabled_auto_position	Auto_position	If autopositioning is in use or not
24	Channel_name	Channel_name	The name of the replication channel

The slave SQL thread updates the relay log info log. In MySQL 8.0, the `relay-log.info` file includes a line count and a replication delay value. The following table shows the correspondence between the lines in the `relay-log.info` file, the columns in the `mysql.slave_relay_log_info` table, and the columns displayed by `SHOW SLAVE STATUS`.

Line in <code>relay-log.info</code>	<code>slave_relay_log_info</code> Table Column	<code>SHOW SLAVE STATUS</code> Column	Description
1	<code>Number_of_lines</code>	[None]	Number of lines in the file or columns in the table
2	<code>Relay_log_name</code>	<code>Relay_Log_File</code>	The name of the current relay log file
3	<code>Relay_log_pos</code>	<code>Relay_Log_Pos</code>	The current position within the relay log file; events up to this position have been executed on the slave database
4	<code>Master_log_name</code>	<code>Relay_Master_Log_File</code>	The name of the master binary log file from which the events in the relay log file were read
5	<code>Master_log_pos</code>	<code>Exec_Master_Log_Pos</code>	The equivalent position within the master's binary log file of events that have already been executed
6	<code>Sql_delay</code>	<code>SQL_Delay</code>	The number of seconds that the slave must lag the master
7	<code>Number_of_workers</code>	[None]	The number of slave worker threads for executing replication events (transactions) in parallel
8	<code>Id</code>	[None]	ID used for internal purposes; currently this is always 1
9	<code>Channel_name</code>	<code>Channel_name</code>	The name of the replication channel

In older versions of MySQL (prior to MySQL 5.6), the `relay-log.info` file does not include a line count or a delay value (and the `slave_relay_log_info` table is not available).

Line	Status Column	Description
1	<code>Relay_Log_File</code>	The name of the current relay log file
2	<code>Relay_Log_Pos</code>	The current position within the relay log file; events up to this position have been executed on the slave database
3	<code>Relay_Master_Log_File</code>	The name of the master binary log file from which the events in the relay log file were read
4	<code>Exec_Master_Log_Pos</code>	The equivalent position within the master's binary log file of events that have already been executed

Note

If you downgrade a slave server to a version older than MySQL 5.6, the older server does not read the `relay-log.info` file correctly. To address this, modify the file in a text editor by deleting the initial line containing the number of lines.

The contents of the `relay-log.info` file and the states shown by the `SHOW SLAVE STATUS` statement might not match if the `relay-log.info` file has not been flushed to disk. Ideally, you should only view `relay-log.info` on a slave that is offline (that is, `mysqld` is not running). For a running system, you can use `SHOW SLAVE STATUS`, or query the `slave_master_info` and `slave_relay_log_info` tables if you are writing the status logs to tables.

When you back up the slave's data, you should back up these two status logs, along with the relay log files. The status logs are needed to resume replication after you restore the data from the slave. If you lose the relay logs but still have the relay log info log, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use `CHANGE MASTER TO` with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options to tell the slave to re-read the binary logs from that point. Of course, this requires that the binary logs still exist on the master.

18.2.5 How Servers Evaluate Replication Filtering Rules

If a master server does not write a statement to its binary log, the statement is not replicated. If the server does log the statement, the statement is sent to all slaves and each slave determines whether to execute it or ignore it.

On the master, you can control which databases to log changes for by using the `--binlog-do-db` and `--binlog-ignore-db` options to control binary logging. For a description of the rules that servers use in evaluating these options, see [Section 18.2.5.1, "Evaluation of Database-Level Replication and Binary Logging Options"](#). You should not use these options to control which databases and tables are replicated. Instead, use filtering on the slave to control the events that are executed on the slave.

On the slave side, decisions about whether to execute or ignore statements received from the master are made according to the `--replicate-*` options that the slave was started with. (See [Section 18.1.6, "Replication and Binary Logging Options and Variables"](#).) The filters governed by these options can also be set dynamically using the `CHANGE REPLICATION FILTER` statement. The rules governing such filters are the same whether they are created on startup using `--replicate-*` options or while the slave server is running by `CHANGE REPLICATION FILTER`.

In the simplest case, when there are no `--replicate-*` options, the slave executes all statements that it receives from the master. Otherwise, the result depends on the particular options given.

Database-level options (`--replicate-do-db`, `--replicate-ignore-db`) are checked first; see [Section 18.2.5.1, "Evaluation of Database-Level Replication and Binary Logging Options"](#), for a description of this process. If no database-level options are used, option checking proceeds to any table-level options that may be in use (see [Section 18.2.5.2, "Evaluation of Table-Level Replication"](#)).

Options”, for a discussion of these). If one or more database-level options are used but none are matched, the statement is not replicated.

For statements affecting databases only (that is, `CREATE DATABASE`, `DROP DATABASE`, and `ALTER DATABASE`), database-level options always take precedence over any `--replicate-wild-do-table` options. In other words, for such statements, `--replicate-wild-do-table` options are checked if and only if there are no database-level options that apply. This is a change in behavior from previous versions of MySQL, where the statement `CREATE DATABASE dbx` was not replicated if the slave had been started with `--replicate-do-db=dbx --replicate-wild-do-table=db%.t1`. (Bug #46110)

To make it easier to determine what effect an option set will have, it is recommended that you avoid mixing “do” and “ignore” options, or wildcard and nonwildcard options.

If any `--replicate-rewrite-db` options were specified, they are applied before the `--replicate-*` filtering rules are tested.

Note

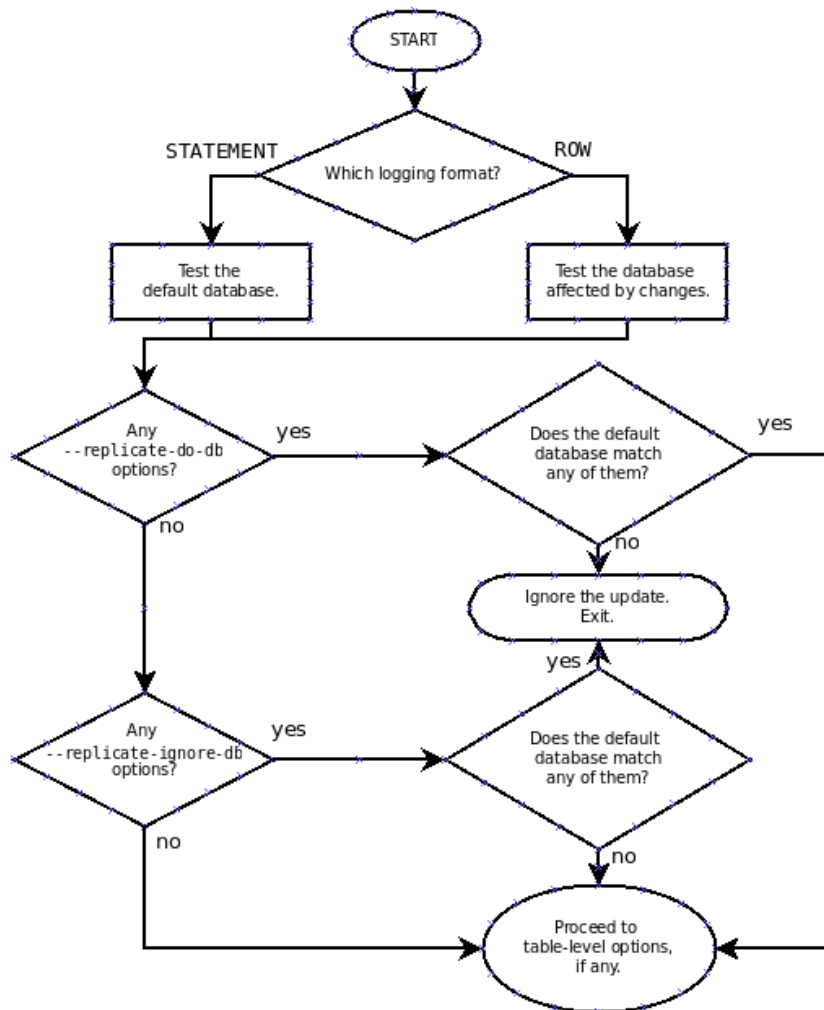

In MySQL 8.0, all replication filtering options follow the same rules for case sensitivity that apply to names of databases and tables elsewhere in the MySQL server, including the effects of the `lower_case_table_names` system variable.

This is a change from previous versions of MySQL. (Bug #51639)

18.2.5.1 Evaluation of Database-Level Replication and Binary Logging Options

When evaluating replication options, the slave begins by checking to see whether there are any `--replicate-do-db` or `--replicate-ignore-db` options that apply. When using `--binlog-do-db` or `--binlog-ignore-db`, the process is similar, but the options are checked on the master.

With statement-based replication, the default database is checked for a match. With row-based replication, the database where data is to be changed is the database that is checked. Regardless of the binary logging format, checking of database-level options proceeds as shown in the following diagram.

The steps involved are listed here:

1. Are there any `--replicate-do-db` options?
 - **Yes.** Do any of them match the database?
 - **Yes.** Execute the statement and exit.
 - **No.** Ignore the statement and exit.
 - **No.** Continue to step 2.
2. Are there any `--replicate-ignore-db` options?
 - **Yes.** Do any of them match the database?
 - **Yes.** Ignore the statement and exit.
 - **No.** Continue to step 3.
 - **No.** Continue to step 3.
3. Proceed to checking the table-level replication options, if there are any. For a description of how these options are checked, see [Section 18.2.5.2, "Evaluation of Table-Level Replication Options"](#).

Important

A statement that is still permitted at this stage is not yet actually executed. The statement is not executed until all table-level options (if any) have also been checked, and the outcome of that process permits execution of the statement.

For binary logging, the steps involved are listed here:

1. Are there any `--binlog-do-db` or `--binlog-ignore-db` options?
 - **Yes.** Continue to step 2.
 - **No.** Log the statement and exit.
2. Is there a default database (has any database been selected by `USE`)?
 - **Yes.** Continue to step 3.
 - **No.** Ignore the statement and exit.
3. There is a default database. Are there any `--binlog-do-db` options?
 - **Yes.** Do any of them match the database?
 - **Yes.** Log the statement and exit.
 - **No.** Ignore the statement and exit.
 - **No.** Continue to step 4.
4. Do any of the `--binlog-ignore-db` options match the database?
 - **Yes.** Ignore the statement and exit.
 - **No.** Log the statement and exit.

Important

For statement-based logging, an exception is made in the rules just given for the `CREATE DATABASE`, `ALTER DATABASE`, and `DROP DATABASE` statements. In those cases, the database being *created*, *altered*, or *dropped* replaces the default database when determining whether to log or ignore updates.

`--binlog-do-db` can sometimes mean “ignore other databases”. For example, when using statement-based logging, a server running with only `--binlog-do-db=sales` does not write to the binary log statements for which the default database differs from `sales`. When using row-based logging with the same option, the server logs only those updates that change data in `sales`.

18.2.5.2 Evaluation of Table-Level Replication Options

The slave checks for and evaluates table options only if either of the following two conditions is true:

- No matching database options were found.
- One or more database options were found, and were evaluated to arrive at an “execute” condition according to the rules described in the previous section (see [Section 18.2.5.1, “Evaluation of Database-Level Replication and Binary Logging Options”](#)).

First, as a preliminary condition, the slave checks whether statement-based replication is enabled. If so, and the statement occurs within a stored function, the slave executes the statement and exits.

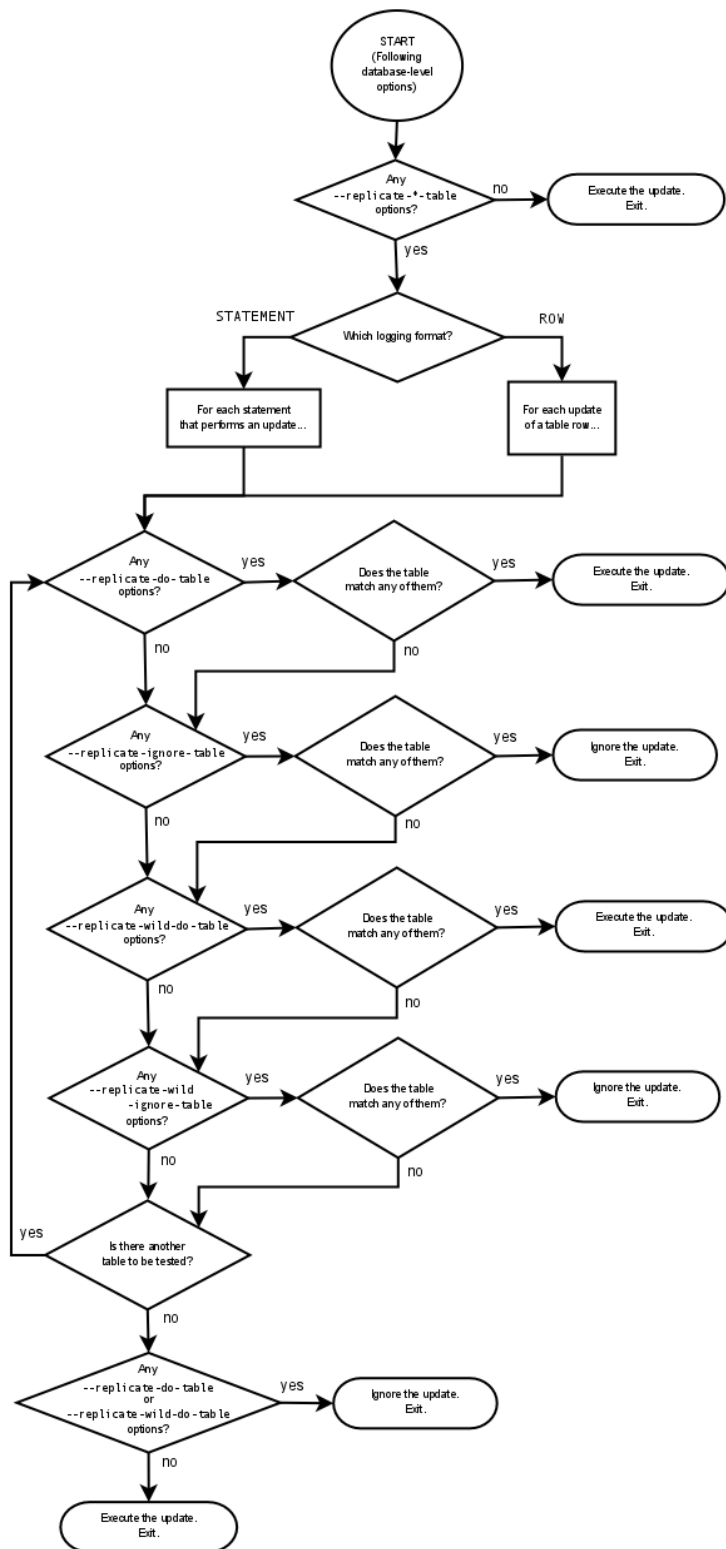

If row-based replication is enabled, the slave does not know whether a statement occurred within a stored function on the master, so this condition does not apply.

Note

For statement-based replication, replication events represent statements (all changes making up a given event are associated with a single SQL statement); for row-based replication, each event represents a change in a single table row (thus a single statement such as `UPDATE mytable SET mycol = 1` may yield many row-based events). When viewed in terms of events, the process of checking table options is the same for both row-based and statement-based replication.

Having reached this point, if there are no table options, the slave simply executes all events. If there are any `--replicate-do-table` or `--replicate-wild-do-table` options, the event must match one of these if it is to be executed; otherwise, it is ignored. If there are any `--replicate-ignore-table` or `--replicate-wild-ignore-table` options, all events are executed except those that match any of these options. This process is illustrated in the following diagram.

The following steps describe this evaluation in more detail:

1. Are there any table options?
 - **Yes.** Continue to step 2.
 - **No.** Execute the event and exit.
2. Are there any `--replicate-do-table` options?

- **Yes.** Does the table match any of them?
 - **Yes.** Execute the event and exit.
 - **No.** Continue to step 3.
 - **No.** Continue to step 3.
3. Are there any `--replicate-ignore-table` options?
- **Yes.** Does the table match any of them?
 - **Yes.** Ignore the event and exit.
 - **No.** Continue to step 4.
 - **No.** Continue to step 4.
4. Are there any `--replicate-wild-do-table` options?
- **Yes.** Does the table match any of them?
 - **Yes.** Execute the event and exit.
 - **No.** Continue to step 5.
 - **No.** Continue to step 5.
5. Are there any `--replicate-wild-ignore-table` options?
- **Yes.** Does the table match any of them?
 - **Yes.** Ignore the event and exit.
 - **No.** Continue to step 6.
 - **No.** Continue to step 6.
6. Are there any `--replicate-do-table` or `--replicate-wild-do-table` options?
- **Yes.** Ignore the event and exit.
 - **No.** Execute the event and exit.

18.2.5.3 Replication Rule Application

This section provides additional explanation and examples of usage for different combinations of replication filtering options.

Some typical combinations of replication filter rule types are given in the following table:

Condition (Types of Options)	Outcome
No <code>--replicate-*</code> options at all:	The slave executes all events that it receives from the master.
<code>--replicate-*-db</code> options, but no table options:	The slave accepts or ignores events using the database options. It executes all events permitted by those options because there are no table restrictions.
<code>--replicate-*-table</code> options, but no database options:	All events are accepted at the database-checking stage because there are no database conditions. The slave executes or ignores events based solely on the table options.

Condition (Types of Options)	Outcome
A combination of database and table options:	The slave accepts or ignores events using the database options. Then it evaluates all events permitted by those options according to the table options. This can sometimes lead to results that seem counterintuitive, and that may be different depending on whether you are using statement-based or row-based replication; see the text for an example.

A more complex example follows, in which we examine the outcomes for both statement-based and row-based settings.

Suppose that we have two tables `mytbl1` in database `db1` and `mytbl2` in database `db2` on the master, and the slave is running with the following options (and no other replication filtering options):

```
replicate-ignore-db = db1
replicate-do-table  = db2.tbl2
```

Now we execute the following statements on the master:

```
USE db1;
INSERT INTO db2.tbl2 VALUES (1);
```

The results on the slave vary considerably depending on the binary log format, and may not match initial expectations in either case.

Statement-based replication. The `USE` statement causes `db1` to be the default database. Thus the `--replicate-ignore-db` option matches, and the `INSERT` statement is ignored. The table options are not checked.

Row-based replication. The default database has no effect on how the slave reads database options when using row-based replication. Thus, the `USE` statement makes no difference in how the `--replicate-ignore-db` option is handled: the database specified by this option does not match the database where the `INSERT` statement changes data, so the slave proceeds to check the table options. The table specified by `--replicate-do-table` matches the table to be updated, and the row is inserted.

18.2.5.4 Replication Channel Based Filters

This section explains how to work with replication filters when multiple replication channels exist, for example in a multi-source replication topology. In previous MySQL versions replication filters were global - filters were applied to all replication channels. In MySQL 8.0 replication filters can be global or channel specific, enabling you to configure multi-source replication slaves with replication filters on specific replication channels. For more background information, see [Section 18.1.4, “MySQL Multi-Source Replication”](#) and [Section 18.2.3, “Replication Channels”](#).

Important

Group Replication channels cannot be configured with channel specific replication filters.

Overview of Replication Filters and Channels

When multiple replication channels exist, for example in a multi-source replication topology, replication filters are applied as follows:

- Any global replication filter specified is added to the global replication filters of the filter type (`do_db`, `do_ignore_table`, and so on).
- Any channel specific replication filter adds the filter to the specified channel’s replication filters for the specified filter type.

- Each slave replication channel copies global replication filters to its channel specific replication filters if no channel specific replication filter of this type is configured.
- Each channel uses its channel specific replication filters to filter the replication stream.

The syntax to create channel specific replication filters extends the existing SQL statements and command options. When a replication channel is not specified the global replication filter is configured to ensure backwards compatibility. The `CHANGE REPLICATION FILTER` statement supports the `FOR CHANNEL` clause to configure channel specific filters online. The `--replicate-*` command options to configure filters can specify a replication channel using the form `--replicate-filter_type:channel_name=filter_details`. For example, suppose channels `channel_1` and `channel_2` exist before the server starts, starting the slave with the command line options `--replicate-do-db=db1 --replicate-do-db=channel_1:db2 --replicate-do-db=db3 --replicate-ignore-db=db4 --replicate-ignore-db=channel_2:db5` would result in:

- *Global replication filters:* `do_db=db1,db3, ignore_db=db4`
- *Channel specific filters on channel_1:* `do_db=db2 ignore_db=db4`
- *Channel specific filters on channel_2:* `do_db=db1,db3 ignore_db=db5`

To monitor the replication filters in such a setup use the `replication_applier_global_filters` and `replication_applier_filters` tables.

Configuring Channel Specific Replication Filters at Startup

The replication filter related command options can take an optional `channel_name` followed by a colon, followed by the filter specification. The first colon is interpreted as a separator, subsequent colons are interpreted as literal colons. The following command options support channel specific replication filters using this format:

- `--replicate-do-db=channel_name:database_id`
- `--replicate-ignore-db=channel_name:database_id`
- `--replicate-do-table=channel_name:table_id`
- `--replicate-ignore-table=channel_name:table_id`
- `--replicate-rewrite-db=channel_name:db1-db2`
- `--replicate-wild-do-table=channel_name:table regexid`
- `--replicate-wild-ignore-table=channel_name:table regexid`

If you use a colon but do not specify a `channel_name` for the filter option, for example `--replicate-do-db=:database_id`, the option configures the replication filter for the default replication channel. The default replication channel is the replication channel which always exists once replication has been started, and differs from multi-source replication channels which you create manually. When neither the colon nor a `channel_name` is specified the option configures the global replication filters, for example `--replicate-do-db=database_id` configures the global `--replicate-do-db` filter.

If you configure multiple `rewrite-db=from_name->to_name` options with the same `from_name` database, all filters are added together (put into the `rewrite_do` list) and the first one takes effect.

Changing Channel Specific Replication Filters Online

In addition to the `--replicate-*` options, replication filters can be configured using the `CHANGE REPLICATION FILTER` statement. This removes the need to restart the server, but the slave applier

thread must be stopped while making the change. To make this statement apply the filter to a specific channel, use the `FOR CHANNEL channel` clause. For example:

```
CHANGE REPLICATION FILTER REPLICATE_DO_DB=(db1) FOR CHANNEL channel_1;
```

When a `FOR CHANNEL` clause is provided, the statement acts on the specified channel's replication filters. If multiple types of filters (`do_db`, `do_ignore_table`, `wild_do_table`, and so on) are specified, only the specified filter types are replaced by the statement. In a replication topology with multiple channels, for example on a multi-source replication slave, when no `FOR CHANNEL` clause is provided, the statement acts on the global replication filters and all channels' replication filters, using a similar logic as the `FOR CHANNEL` case. For more information see [Section 13.4.2.2, "CHANGE REPLICATION FILTER Syntax"](#).

Removing Channel Specific Replication Filters

When channel specific replication filters have been configured, you can remove the filter by issuing an empty filter type statement. For example to remove all `REPLICATE_REWRITE_DB` filters from a replication channel named `channel_1` issue:

```
CHANGE REPLICATION FILTER REPLICATE_REWRITE_DB=() FOR CHANNEL channel_1;
```

Any `REPLICATE_REWRITE_DB` filters previously configured, using either command options or `CHANGE REPLICATION FILTER`, are removed.

18.3 Replication Solutions

Replication can be used in many different environments for a range of purposes. This section provides general notes and advice on using replication for specific solution types.

For information on using replication in a backup environment, including notes on the setup, backup procedure, and files to back up, see [Section 18.3.1, "Using Replication for Backups"](#).

For advice and tips on using different storage engines on the master and slaves, see [Section 18.3.4, "Using Replication with Different Master and Slave Storage Engines"](#).

Using replication as a scale-out solution requires some changes in the logic and operation of applications that use the solution. See [Section 18.3.5, "Using Replication for Scale-Out"](#).

For performance or data distribution reasons, you may want to replicate different databases to different replication slaves. See [Section 18.3.6, "Replicating Different Databases to Different Slaves"](#)

As the number of replication slaves increases, the load on the master can increase and lead to reduced performance (because of the need to replicate the binary log to each slave). For tips on improving your replication performance, including using a single secondary server as a replication master, see [Section 18.3.7, "Improving Replication Performance"](#).

For guidance on switching masters, or converting slaves into masters as part of an emergency failover solution, see [Section 18.3.8, "Switching Masters During Failover"](#).

To secure your replication communication, you can encrypt the communication channel. For step-by-step instructions, see [Section 18.3.9, "Setting Up Replication to Use Secure Connections"](#).

18.3.1 Using Replication for Backups

To use replication as a backup solution, replicate data from the master to a slave, and then back up the data slave. The slave can be paused and shut down without affecting the running operation of the master, so you can produce an effective snapshot of "live" data that would otherwise require the master to be shut down.

How you back up a database depends on its size and whether you are backing up only the data, or the data and the replication slave state so that you can rebuild the slave in the event of failure. There are therefore two choices:

- If you are using replication as a solution to enable you to back up the data on the master, and the size of your database is not too large, the `mysqldump` tool may be suitable. See [Section 18.3.1.1, “Backing Up a Slave Using mysqldump”](#).
- For larger databases, where `mysqldump` would be impractical or inefficient, you can back up the raw data files instead. Using the raw data files option also means that you can back up the binary and relay logs that will enable you to recreate the slave in the event of a slave failure. For more information, see [Section 18.3.1.2, “Backing Up Raw Data from a Slave”](#).

Another backup strategy, which can be used for either master or slave servers, is to put the server in a read-only state. The backup is performed against the read-only server, which then is changed back to its usual read/write operational status. See [Section 18.3.1.3, “Backing Up a Master or Slave by Making It Read Only”](#).

18.3.1.1 Backing Up a Slave Using mysqldump

Using `mysqldump` to create a copy of a database enables you to capture all of the data in the database in a format that enables the information to be imported into another instance of MySQL Server (see [Section 4.5.4, “mysqldump — A Database Backup Program”](#)). Because the format of the information is SQL statements, the file can easily be distributed and applied to running servers in the event that you need access to the data in an emergency. However, if the size of your data set is very large, `mysqldump` may be impractical.

When using `mysqldump`, you should stop replication on the slave before starting the dump process to ensure that the dump contains a consistent set of data:

1. Stop the slave from processing requests. You can stop replication completely on the slave using `mysqladmin`:

```
shell> mysqladmin stop-slave
```

Alternatively, you can stop only the slave SQL thread to pause event execution:

```
shell> mysql -e 'STOP SLAVE SQL_THREAD;'
```

This enables the slave to continue to receive data change events from the master's binary log and store them in the relay logs using the I/O thread, but prevents the slave from executing these events and changing its data. Within busy replication environments, permitting the I/O thread to run during backup may speed up the catch-up process when you restart the slave SQL thread.

2. Run `mysqldump` to dump your databases. You may either dump all databases or select databases to be dumped. For example, to dump all databases:

```
shell> mysqldump --all-databases > fulldb.dump
```

3. Once the dump has completed, start slave operations again:

```
shell> mysqladmin start-slave
```

In the preceding example, you may want to add login credentials (user name, password) to the commands, and bundle the process up into a script that you can run automatically each day.

If you use this approach, make sure you monitor the slave replication process to ensure that the time taken to run the backup does not affect the slave's ability to keep up with events from the master. See [Section 18.1.7.1, “Checking Replication Status”](#). If the slave is unable to keep up, you may want to add another slave and distribute the backup process. For an example of how to configure this scenario, see [Section 18.3.6, “Replicating Different Databases to Different Slaves”](#).

18.3.1.2 Backing Up Raw Data from a Slave

To guarantee the integrity of the files that are copied, backing up the raw data files on your MySQL replication slave should take place while your slave server is shut down. If the MySQL server is still

running, background tasks may still be updating the database files, particularly those involving storage engines with background processes such as [InnoDB](#). With [InnoDB](#), these problems should be resolved during crash recovery, but since the slave server can be shut down during the backup process without affecting the execution of the master it makes sense to take advantage of this capability.

To shut down the server and back up the files:

1. Shut down the slave MySQL server:

```
shell> mysqladmin shutdown
```

2. Copy the data files. You can use any suitable copying or archive utility, including [cp](#), [tar](#) or [WinZip](#). For example, assuming that the data directory is located under the current directory, you can archive the entire directory as follows:

```
shell> tar cf /tmp/dbbackup.tar ./data
```

3. Start the MySQL server again. Under Unix:

```
shell> mysqld_safe &
```

Under Windows:

```
C:\> "C:\Program Files\MySQL\MySQL Server 8.0\bin\mysqld"
```

Normally you should back up the entire data directory for the slave MySQL server. If you want to be able to restore the data and operate as a slave (for example, in the event of failure of the slave), then in addition to the slave's data, you should also back up the slave status files, the master info and relay log info repositories, and the relay log files. These files are needed to resume replication after you restore the slave's data.

If you lose the relay logs but still have the [relay-log.info](#) file, you can check it to determine how far the SQL thread has executed in the master binary logs. Then you can use [CHANGE MASTER TO](#) with the [MASTER_LOG_FILE](#) and [MASTER_LOG_POS](#) options to tell the slave to re-read the binary logs from that point. This requires that the binary logs still exist on the master server.

If your slave is replicating [LOAD DATA INFILE](#) statements, you should also back up any [SQL_LOAD-*](#) files that exist in the directory that the slave uses for this purpose. The slave needs these files to resume replication of any interrupted [LOAD DATA INFILE](#) operations. The location of this directory is the value of the [--slave-load-tmpdir](#) option. If the server was not started with that option, the directory location is the value of the [tmpdir](#) system variable.

18.3.1.3 Backing Up a Master or Slave by Making It Read Only

It is possible to back up either master or slave servers in a replication setup by acquiring a global read lock and manipulating the [read_only](#) system variable to change the read-only state of the server to be backed up:

1. Make the server read-only, so that it processes only retrievals and blocks updates.
2. Perform the backup.
3. Change the server back to its normal read/write state.

Note

The instructions in this section place the server to be backed up in a state that is safe for backup methods that get the data from the server, such as [mysqldump](#) (see [Section 4.5.4, "mysqldump — A Database Backup Program"](#)). You should not attempt to use these instructions to make a binary backup by copying files directly because the server may still have modified data cached in memory and not flushed to disk.

The following instructions describe how to do this for a master server and for a slave server. For both scenarios discussed here, suppose that you have the following replication setup:

- A master server M1
- A slave server S1 that has M1 as its master
- A client C1 connected to M1
- A client C2 connected to S1

In either scenario, the statements to acquire the global read lock and manipulate the `read_only` variable are performed on the server to be backed up and do not propagate to any slaves of that server.

Scenario 1: Backup with a Read-Only Master

Put the master M1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While M1 is in a read-only state, the following properties are true:

- Requests for updates sent by C1 to M1 will block because the server is in read-only mode.
- Requests for query results sent by C1 to M1 will succeed.
- Making a backup on M1 is safe.
- Making a backup on S1 is not safe. This server is still running, and might be processing the binary log or update requests coming from client C2

While M1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on M1 completes, restore M1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

Although performing the backup on M1 is safe (as far as the backup is concerned), it is not optimal for performance because clients of M1 are blocked from executing updates.

This strategy applies to backing up a master server in a replication setup, but can also be used for a single server in a nonreplication setting.

Scenario 2: Backup with a Read-Only Slave

Put the slave S1 in a read-only state by executing these statements on it:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

While S1 is in a read-only state, the following properties are true:

- The master M1 will continue to operate, so making a backup on the master is not safe.
- The slave S1 is stopped, so making a backup on the slave S1 is safe.

These properties provide the basis for a popular backup scenario: Having one slave busy performing a backup for a while is not a problem because it does not affect the entire network, and the system is still

running during the backup. In particular, clients can still perform updates on the master server, which remains unaffected by backup activity on the slave.

While S1 is read only, perform the backup. For example, you can use `mysqldump`.

After the backup operation on S1 completes, restore S1 to its normal operational state by executing these statements:

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

After the slave is restored to normal operation, it again synchronizes to the master by catching up with any outstanding updates from the binary log of the master.

18.3.2 Handling an Unexpected Halt of a Replication Slave

In order for replication to be resilient to unexpected halts of the server (sometimes described as crash-safe) it must be possible for the slave to recover its state before halting. This section describes the impact of an unexpected halt of a slave during replication and how to configure a slave for the best chance of recovery to continue replication.

After an unexpected halt of a slave, upon restart the I/O thread must recover the information about which transactions have been received, and the SQL thread must recover which transactions have been executed already. For information on the slave logs required for recovery, see [Section 18.2.4, “Replication Relay and Status Logs”](#). The information required for recovery was traditionally stored in files, which had the risk of losing synchrony with the master depending at which stage of processing a transaction the slave halted at, or even corruption of the files themselves. In MySQL 8.0 you can instead use tables to store this information. These tables are created using `InnoDB`, and by using this transactional storage engine the information is always recoverable upon restart. To configure MySQL 8.0 to store the replication information in tables, set `relay_log_info_repository` and `master_info_repository` to `TABLE`. The server then stores information required for the recovery of the I/O thread in the `mysql.slave_master_info` table and information required for the recovery of the SQL thread in the `mysql.slave_relay_log_info` table. With this configuration, DML transactions and also atomic DDLs update the `mysql.slave_relay_log_info` atomically with the replicated data. In all other cases, the `mysql.slave_relay_log_info` table may be missing updates associated with replicated data if the server halts unexpectedly. Restoring updates in this case is a manual process.

Exactly how a replication slave recovers from an unexpected halt is influenced by the chosen method of replication, whether the slave is single-threaded or multi-threaded, the setting of variables such as `relay_log_recovery`, and whether features such as `MASTER_AUTO_POSITION` are being used.

The following table shows the impact of these different factors on how a single-threaded slave recovers from an unexpected halt.

Table 18.5 Factors Influencing Single-threaded Replication Slave Recovery

<code>MASTER_AUTO_POSITION</code>	<code>relay_log_recovery</code>	<code>relay_log_info_repository</code>	Crash type	Recovery guaranteed	Relay log impact
OFF	Any	1	Any	Yes	Lost
OFF	Any	1	Server	Yes	Lost
OFF	Any	1	OS	No	Lost
OFF	Any	0	Server	Yes	Remains
OFF	Any	0	OS	No	Remains
ON	ON	Any	Any	Yes	Lost
ON	OFF	0	Server	Yes	Remains

GTID	MASTER_AUTO_POSITION	relay_log_recovery	relay_log_info_repository	Crash type	Recovery guaranteed	Relay log impact
ON	OFF	0	Any	OS	No	Remains

As the table shows, when using a single-threaded slave the following configurations are most resilient to unexpected halts:

- When using GTIDs and MASTER_AUTO_POSITION, set relay_log_recovery=1. With this configuration the setting of relay_log_info_repository and other variables does not impact on recovery.
- When using file position based replication, set relay_log_recovery=1 and relay_log_info_repository=TABLE.

Note

During recovery the relay log is lost.

The following table shows the impact of these different factors on how a multi-threaded slave recovers from an unexpected halt.

Table 18.6 Factors Influencing Multi-threaded Replication Slave Recovery

GTID	sync_relay_log	MASTER_AUTO_POSITION	relay_log_recovery	relay_log_info_repository	Crash type	Recovery guaranteed	Relay log impact
OFF	1	Any	1	TABLE	Any	Yes	Lost
OFF	>1	Any	1	TABLE	Server	Yes	Lost
OFF	>1	Any	1	Any	OS	No	Lost
OFF	1	Any	0	TABLE	Server	Yes	Remains
OFF	1	Any	0	TABLE	OS	No	Remains
ON	Any	ON	Any	Any	Any	Yes	Lost
ON	1	OFF	0	TABLE	Server	Yes	Remains
ON	1	OFF	0	Any	OS	No	Remains

As the table shows, when using a multi-threaded slave the following configurations are most resilient to unexpected halts:

- When using GTIDs and MASTER_AUTO_POSITION, set relay_log_recovery=1. With this configuration the setting of relay_log_info_repository and other variables does not impact on recovery.
- When using file position based replication, set relay_log_recovery=1, sync_relay_log=1, and relay_log_info_repository=TABLE.

Note

During recovery the relay log is lost.

It is important to note the impact of sync_relay_log=1, which requires a write of to the relay log per transaction. Although this setting is the most resilient to an unexpected halt, with at most one unwritten transaction being lost, it also has the potential to greatly increase the load on storage. Without sync_relay_log=1, the effect of an unexpected halt depends on how the relay log is handled by the operating system. Also note that when relay_log_recovery=0, the next time the slave is started after an unexpected halt the relay log is processed as part of recovery. After this process completes, the relay log is deleted.

An unexpected halt of a multi-threaded replication slave using the recommended file position based replication configuration above may result in a relay log with transaction inconsistencies (gaps in the sequence of transactions) caused by the unexpected halt. See [Section 18.4.1.34, “Replication and Transaction Inconsistencies”](#). In MySQL 5.7.13 and later, if the relay log recovery process encounters such transaction inconsistencies they are filled and the recovery process continues automatically. In MySQL versions prior to MySQL 5.7.13, this process is not automatic and requires starting the server with `relay_log_recovery=0`, starting the slave with `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` to fix any transaction inconsistencies and then restarting the slave with `relay_log_recovery=1`.

When you are using multi-source replication and `relay_log_recovery=1`, after restarting due to an unexpected halt all replication channels go through the relay log recovery process. Any inconsistencies found in the relay log due to an unexpected halt of a multi-threaded slave are filled.

18.3.3 Monitoring Row-based Replication

The current progress of the replication applier (SQL) thread when using row-based replication is monitored through Performance Schema instrument stages, enabling you to track the processing of operations and check the amount of work completed and work estimated. When these Performance Schema instrument stages are enabled the `events_stages_current` table shows stages for applier threads and their progress. For background information, see [Section 25.11.5, “Performance Schema Stage Event Tables”](#).

To track progress of all three row-based replication event types (write, update, delete):

- Enable the three Performance Schema stages by issuing:

```
mysql> UPDATE performance_schema.setup_instruments SET ENABLED = 'YES'
-> WHERE NAME LIKE 'stage/sql/Applying batch of row changes%';
```

- Wait for some events to be processed by the replication applier thread and then check progress by looking into the `events_stages_current` table. For example to get progress for `update` events issue:

```
mysql> SELECT WORK_COMPLETED, WORK_ESTIMATED FROM performance_schema.events_stages_current
-> WHERE EVENT_NAME LIKE 'stage/sql/Applying batch of row changes (update)';
```

- If `binlog_rows_query_log_events` is enabled, information about queries is stored in the binary log and is exposed in the `processlist_info` field. To see the original query that triggered this event:

```
mysql> SELECT db, processlist_state, processlist_info FROM performance_schema.threads
-> WHERE processlist_state LIKE 'stage/sql/Applying batch of row changes%' AND thread_id = N;
```

18.3.4 Using Replication with Different Master and Slave Storage Engines

It does not matter for the replication process whether the source table on the master and the replicated table on the slave use different engine types. In fact, the `default_storage_engine` system variable is not replicated.

This provides a number of benefits in the replication process in that you can take advantage of different engine types for different replication scenarios. For example, in a typical scale-out scenario (see [Section 18.3.5, “Using Replication for Scale-Out”](#)), you want to use `InnoDB` tables on the master to take advantage of the transactional functionality, but use `MyISAM` on the slaves where transaction support is not required because the data is only read. When using replication in a data-logging environment you may want to use the `Archive` storage engine on the slave.

Configuring different engines on the master and slave depends on how you set up the initial replication process:

- If you used `mysqldump` to create the database snapshot on your master, you could edit the dump file text to change the engine type used on each table.

Another alternative for `mysqldump` is to disable engine types that you do not want to use on the slave before using the dump to build the data on the slave. For example, you can add the `--skip-federated` option on your slave to disable the `FEDERATED` engine. If a specific engine does not exist for a table to be created, MySQL will use the default engine type, usually `MyISAM`. (This requires that the `NO_ENGINE_SUBSTITUTION` SQL mode is not enabled.) If you want to disable additional engines in this way, you may want to consider building a special binary to be used on the slave that only supports the engines you want.

- If you are using raw data files (a binary backup) to set up the slave, you will be unable to change the initial table format. Instead, use `ALTER TABLE` to change the table types after the slave has been started.
- For new master/slave replication setups where there are currently no tables on the master, avoid specifying the engine type when creating new tables.

If you are already running a replication solution and want to convert your existing tables to another engine type, follow these steps:

1. Stop the slave from running replication updates:

```
mysql> STOP SLAVE;
```

This will enable you to change engine types without interruptions.

2. Execute an `ALTER TABLE ... ENGINE='engine_type'` for each table to be changed.
3. Start the slave replication process again:

```
mysql> START SLAVE;
```

Although the `default_storage_engine` variable is not replicated, be aware that `CREATE TABLE` and `ALTER TABLE` statements that include the engine specification will be correctly replicated to the slave. For example, if you have a CSV table and you execute:

```
mysql> ALTER TABLE csvtable Engine='MyISAM';
```

The above statement will be replicated to the slave and the engine type on the slave will be converted to `MyISAM`, even if you have previously changed the table type on the slave to an engine other than CSV. If you want to retain engine differences on the master and slave, you should be careful to use the `default_storage_engine` variable on the master when creating a new table. For example, instead of:

```
mysql> CREATE TABLE tablea (columna int) Engine=MyISAM;
```

Use this format:

```
mysql> SET default_storage_engine=MyISAM;
mysql> CREATE TABLE tablea (columna int);
```

When replicated, the `default_storage_engine` variable will be ignored, and the `CREATE TABLE` statement will execute on the slave using the slave's default engine.

18.3.5 Using Replication for Scale-Out

You can use replication as a scale-out solution; that is, where you want to split up the load of database queries across multiple database servers, within some reasonable limitations.

Because replication works from the distribution of one master to one or more slaves, using replication for scale-out works best in an environment where you have a high number of reads and low number of writes/updates. Most Web sites fit into this category, where users are browsing the Web site, reading articles, posts, or viewing products. Updates only occur during session management, or when making a purchase or adding a comment/message to a forum.

Replication in this situation enables you to distribute the reads over the replication slaves, while still enabling your web servers to communicate with the replication master when a write is required. You can see a sample replication layout for this scenario in [Figure 18.1, “Using Replication to Improve Performance During Scale-Out”](#).

Figure 18.1 Using Replication to Improve Performance During Scale-Out

If the part of your code that is responsible for database access has been properly abstracted/modularized, converting it to run with a replicated setup should be very smooth and easy. Change the implementation of your database access to send all writes to the master, and to send reads to either the master or a slave. If your code does not have this level of abstraction, setting up a replicated system gives you the opportunity and motivation to clean it up. Start by creating a wrapper library or module that implements the following functions:

- `safe_writer_connect()`
- `safe_reader_connect()`
- `safe_reader_statement()`
- `safe_writer_statement()`

`safe_` in each function name means that the function takes care of handling all error conditions. You can use different names for the functions. The important thing is to have a unified interface for connecting for reads, connecting for writes, doing a read, and doing a write.

Then convert your client code to use the wrapper library. This may be a painful and scary process at first, but it pays off in the long run. All applications that use the approach just described are able to take advantage of a master/slave configuration, even one involving multiple slaves. The code is much easier to maintain, and adding troubleshooting options is trivial. You need modify only one or two functions; for example, to log how long each statement took, or which statement among those issued gave you an error.

If you have written a lot of code, you may want to automate the conversion task by writing a conversion script. Ideally, your code uses consistent programming style conventions. If not, then you are probably better off rewriting it anyway, or at least going through and manually regularizing it to use a consistent style.

18.3.6 Replicating Different Databases to Different Slaves

There may be situations where you have a single master and want to replicate different databases to different slaves. For example, you may want to distribute different sales data to different departments to help spread the load during data analysis. A sample of this layout is shown in [Figure 18.2, “Using Replication to Replicate Databases to Separate Replication Slaves”](#).

Figure 18.2 Using Replication to Replicate Databases to Separate Replication Slaves

You can achieve this separation by configuring the master and slaves as normal, and then limiting the binary log statements that each slave processes by using the `--replicate-wild-do-table` configuration option on each slave.

Important

You should *not* use `--replicate-do-db` for this purpose when using statement-based replication, since statement-based replication causes this option's affects to vary according to the database that is currently selected. This applies to mixed-format replication as well, since this enables some updates to be replicated using the statement-based format.

However, it should be safe to use `--replicate-do-db` for this purpose if you are using row-based replication only, since in this case the currently selected database has no effect on the option's operation.

For example, to support the separation as shown in [Figure 18.2, “Using Replication to Replicate Databases to Separate Replication Slaves”](#), you should configure each replication slave as follows, before executing `START SLAVE`:

- Replication slave 1 should use `--replicate-wild-do-table=databaseA.%`.
- Replication slave 2 should use `--replicate-wild-do-table=databaseB.%`.
- Replication slave 3 should use `--replicate-wild-do-table=databaseC.%`.

Each slave in this configuration receives the entire binary log from the master, but executes only those events from the binary log that apply to the databases and tables included by the `--replicate-wild-do-table` option in effect on that slave.

If you have data that must be synchronized to the slaves before replication starts, you have a number of choices:

- Synchronize all the data to each slave, and delete the databases, tables, or both that you do not want to keep.
- Use `mysqldump` to create a separate dump file for each database and load the appropriate dump file on each slave.
- Use a raw data file dump and include only the specific files and databases that you need for each slave.

**Note**

This does not work with [InnoDB](#) databases unless you use `innodb_file_per_table`.

18.3.7 Improving Replication Performance

As the number of slaves connecting to a master increases, the load, although minimal, also increases, as each slave uses a client connection to the master. Also, as each slave must receive a full copy of the master binary log, the network load on the master may also increase and create a bottleneck.

If you are using a large number of slaves connected to one master, and that master is also busy processing requests (for example, as part of a scale-out solution), then you may want to improve the performance of the replication process.

One way to improve the performance of the replication process is to create a deeper replication structure that enables the master to replicate to only one slave, and for the remaining slaves to connect to this primary slave for their individual replication requirements. A sample of this structure is shown in [Figure 18.3, “Using an Additional Replication Host to Improve Performance”](#).

Figure 18.3 Using an Additional Replication Host to Improve Performance

For this to work, you must configure the MySQL instances as follows:

- Master 1 is the primary master where all changes and updates are written to the database. Binary logging should be enabled on this machine.
- Master 2 is the slave to the Master 1 that provides the replication functionality to the remainder of the slaves in the replication structure. Master 2 is the only machine permitted to connect to Master 1. Master 2 also has binary logging enabled, and the `--log-slave-updates` option so that replication instructions from Master 1 are also written to Master 2's binary log so that they can then be replicated to the true slaves.
- Slave 1, Slave 2, and Slave 3 act as slaves to Master 2, and replicate the information from Master 2, which actually consists of the upgrades logged on Master 1.

The above solution reduces the client load and the network interface load on the primary master, which should improve the overall performance of the primary master when used as a direct database solution.

If your slaves are having trouble keeping up with the replication process on the master, there are a number of options available:

- If possible, put the relay logs and the data files on different physical drives. To do this, use the `--relay-log` option to specify the location of the relay log.
- If the slaves are significantly slower than the master, you may want to divide up the responsibility for replicating different databases to different slaves. See [Section 18.3.6, “Replicating Different Databases to Different Slaves”](#).

- If your master makes use of transactions and you are not concerned about transaction support on your slaves, use `MyISAM` or another nontransactional engine on the slaves. See [Section 18.3.4, “Using Replication with Different Master and Slave Storage Engines”](#).
- If your slaves are not acting as masters, and you have a potential solution in place to ensure that you can bring up a master in the event of failure, then you can switch off `--log-slave-updates`. This prevents “dumb” slaves from also logging events they have executed into their own binary log.

18.3.8 Switching Masters During Failover

When using replication with GTIDs (see [Section 18.1.3, “Replication with Global Transaction Identifiers”](#)), you can provide failover between master and slaves in the event of a failure using `mysqlfailover`, which is provided by the MySQL Utilities; see [mysqlfailover — Automatic replication health monitoring and failover](#), for more information. If you are not using GTIDs and therefore cannot use `mysqlfailover`, you must set up a master and one or more slaves; then, you need to write an application or script that monitors the master to check whether it is up, and instructs the slaves and applications to change to another master in case of failure. This section discusses some of the issues encountered when setting up failover in this way.

You can tell a slave to change to a new master using the `CHANGE MASTER TO` statement. The slave does not check whether the databases on the master are compatible with those on the slave; it simply begins reading and executing events from the specified coordinates in the new master's binary log. In a failover situation, all the servers in the group are typically executing the same events from the same binary log file, so changing the source of the events should not affect the structure or integrity of the database, provided that you exercise care in making the change.

Slaves should be run with the `--log-bin` option, and if not using GTIDs then they should also be run without `--log-slave-updates`. In this way, the slave is ready to become a master without restarting the slave `mysqld`. Assume that you have the structure shown in [Figure 18.4, “Redundancy Using Replication, Initial Structure”](#).

Figure 18.4 Redundancy Using Replication, Initial Structure

In this diagram, the `MySQL Master` holds the master database, the `MySQL Slave` hosts are replication slaves, and the `Web Client` machines are issuing database reads and writes. Web clients that issue only reads (and would normally be connected to the slaves) are not shown, as they do not need to switch to a new server in the event of failure. For a more detailed example of a read/write scale-out replication structure, see [Section 18.3.5, “Using Replication for Scale-Out”](#).

Each `MySQL Slave` (`Slave 1`, `Slave 2`, and `Slave 3`) is a slave running with `--log-bin` and without `--log-slave-updates`. Because updates received by a slave from the master are not

logged in the binary log unless `--log-slave-updates` is specified, the binary log on each slave is empty initially. If for some reason `MySQL Master` becomes unavailable, you can pick one of the slaves to become the new master. For example, if you pick `Slave 1`, all `Web Clients` should be redirected to `Slave 1`, which writes the updates to its binary log. `Slave 2` and `Slave 3` should then replicate from `Slave 1`.

The reason for running the slave without `--log-slave-updates` is to prevent slaves from receiving updates twice in case you cause one of the slaves to become the new master. If `Slave 1` has `--log-slave-updates` enabled, it writes any updates that it receives from `Master` in its own binary log. This means that, when `Slave 2` changes from `Master` to `Slave 1` as its master, it may receive updates from `Slave 1` that it has already received from `Master`.

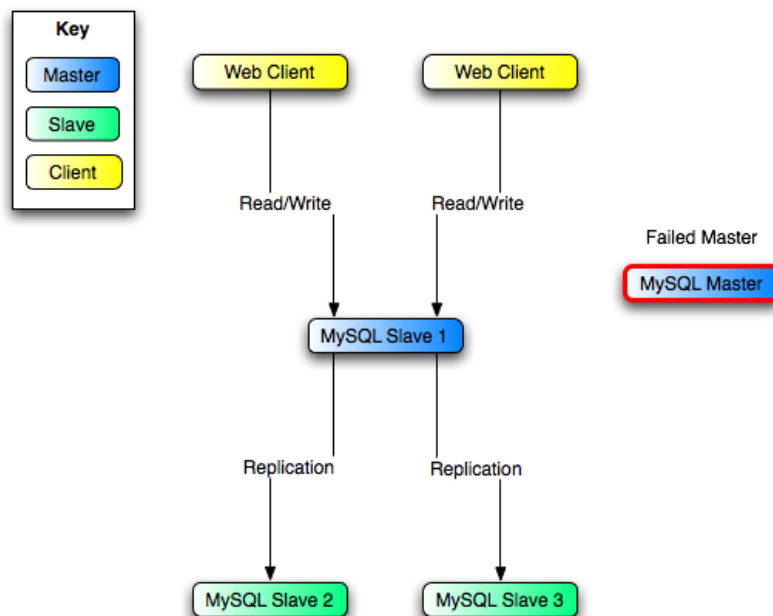

Make sure that all slaves have processed any statements in their relay log. On each slave, issue `STOP SLAVE IO_THREAD`, then check the output of `SHOW PROCESSLIST` until you see `Has read all relay log`. When this is true for all slaves, they can be reconfigured to the new setup. On the slave `Slave 1` being promoted to become the master, issue `STOP SLAVE` and `RESET MASTER`.

On the other slaves `Slave 2` and `Slave 3`, use `STOP SLAVE` and `CHANGE MASTER TO MASTER_HOST='Slave1'` (where `'Slave1'` represents the real host name of `Slave 1`). To use `CHANGE MASTER TO`, add all information about how to connect to `Slave 1` from `Slave 2` or `Slave 3` (`user`, `password`, `port`). When issuing the `CHANGE MASTER TO` statement in this, there is no need to specify the name of the `Slave 1` binary log file or log position to read from, since the first binary log file and position 4, are the defaults. Finally, execute `START SLAVE` on `Slave 2` and `Slave 3`.

Once the new replication setup is in place, you need to tell each `Web Client` to direct its statements to `Slave 1`. From that point on, all updates statements sent by `Web Client` to `Slave 1` are written to the binary log of `Slave 1`, which then contains every update statement sent to `Slave 1` since `Master` died.

The resulting server structure is shown in [Figure 18.5, “Redundancy Using Replication, After Master Failure”](#).

Figure 18.5 Redundancy Using Replication, After Master Failure

When `Master` becomes available again, you should make it a slave of `Slave 1`. To do this, issue on `Master` the same `CHANGE MASTER TO` statement as that issued on `Slave 2` and `Slave 3` previously. `Master` then becomes a slave of `Slave 1` and picks up the `Web Client` writes that it missed while it was offline.

To make `Master` a master again, use the preceding procedure as if `Slave 1` was unavailable and `Master` was to be the new master. During this procedure, do not forget to run `RESET MASTER` on `Master` before making `Slave 1`, `Slave 2`, and `Slave 3` slaves of `Master`. If you fail to do this, the slaves may pick up stale writes from the `Web Client` applications dating from before the point at which `Master` became unavailable.

You should be aware that there is no synchronization between slaves, even when they share the same master, and thus some slaves might be considerably ahead of others. This means that in some cases the procedure outlined in the previous example might not work as expected. In practice, however, relay logs on all slaves should be relatively close together.

One way to keep applications informed about the location of the master is to have a dynamic DNS entry for the master. With `bind` you can use `nsupdate` to update the DNS dynamically.

18.3.9 Setting Up Replication to Use Secure Connections

To use a secure connection for encrypting the transfer of the binary log required during replication, both the master and the slave servers must support encrypted network connections. If either server does not support secure connections (because it has not been compiled or configured for them), replication through an encrypted connection is not possible.

Setting up secure connections for replication is similar to doing so for client/server connections. You must obtain (or create) a suitable security certificate that you can use on the master, and a similar certificate (from the same certificate authority) on each slave. You must also obtain suitable key files.

For more information on setting up a server and client for secure connections, see [Section 6.4.4, “Configuring MySQL to Use Secure Connections”](#).

To enable secure connections on the master, you must create or obtain suitable certificate and key files, and then add the following configuration options to the master's configuration within the `[mysqld]` section of the master's `my.cnf` file, changing the file names as necessary:

```
[mysqld]
ssl-ca=cacert.pem
ssl-cert=server-cert.pem
ssl-key=server-key.pem
```

The paths to the files may be relative or absolute; we recommend that you always use complete paths for this purpose.

The options are as follows:

- `ssl-ca` identifies the Certificate Authority (CA) certificate.
- `ssl-cert` identifies the server public key certificate. This can be sent to the client and authenticated against the CA certificate that it has.
- `ssl-key` identifies the server private key.

On the slave, there are two ways to specify the information required for connecting securely to the master. You can either name the slave certificate and key files in the `[client]` section of the slave's `my.cnf` file, or you can explicitly specify that information using the `CHANGE MASTER TO` statement:

- To name the slave certificate and key files using an option file, add the following lines to the `[client]` section of the slave's `my.cnf` file, changing the file names as necessary:

```
[client]
ssl-ca=cacert.pem
ssl-cert=client-cert.pem
ssl-key=client-key.pem
```

Restart the slave server, using the `--skip-slave-start` option to prevent the slave from connecting to the master. Use `CHANGE MASTER TO` to specify the master configuration, using the `MASTER_SSL` option to connect securely:

```
mysql> CHANGE MASTER TO
-> MASTER_HOST='master_hostname',
-> MASTER_USER='replicate',
-> MASTER_PASSWORD='password',
-> MASTER_SSL=1;
```

- To specify the certificate and key names using the `CHANGE MASTER TO` statement, append the appropriate `MASTER_SSL_XXX` options:

```
mysql> CHANGE MASTER TO
-> MASTER_HOST='master_hostname',
-> MASTER_USER='replicate',
-> MASTER_PASSWORD='password',
-> MASTER_SSL=1,
-> MASTER_SSL_CA = 'ca_file_name',
-> MASTER_SSL_CAPATH = 'ca_directory_name',
-> MASTER_SSL_CERT = 'cert_file_name',
-> MASTER_SSL_KEY = 'key_file_name';
```

After the master information has been updated, start the slave replication process:

```
mysql> START SLAVE;
```

You can use the `SHOW SLAVE STATUS` statement to confirm that a secure connection was established successfully.

For more information on the `CHANGE MASTER TO` statement, see [Section 13.4.2.1, “CHANGE MASTER TO Syntax”](#).

If you want to enforce the use of secure connections during replication, create a user and use the `REQUIRE SSL` option, then grant that user the `REPLICATION SLAVE` privilege. For example:

```
mysql> CREATE USER 'repl'@'%.mydomain.com' IDENTIFIED BY 'slavepass'
-> REQUIRE SSL;
mysql> GRANT REPLICATION SLAVE ON *.*
-> TO 'repl'@'%.mydomain.com';
```

If the account already exists, you can add `REQUIRE SSL` to it with this statement:

```
mysql> ALTER USER 'repl'@'%.mydomain.com' REQUIRE SSL;
```

18.3.10 Semisynchronous Replication

In addition to the built-in asynchronous replication, MySQL 8.0 supports an interface to semisynchronous replication that is implemented by plugins. This section discusses what semisynchronous replication is and how it works. The following sections cover the administrative interface to semisynchronous replication and how to install, configure, and monitor it.

MySQL replication by default is asynchronous. The master writes events to its binary log but does not know whether or when a slave has retrieved and processed them. With asynchronous replication, if the master crashes, transactions that it has committed might not have been transmitted to any slave. Consequently, failover from master to slave in this case may result in failover to a server that is missing transactions relative to the master.

Semisynchronous replication can be used as an alternative to asynchronous replication:

- A slave indicates whether it is semisynchronous-capable when it connects to the master.
- If semisynchronous replication is enabled on the master side and there is at least one semisynchronous slave, a thread that performs a transaction commit on the master blocks and waits until at least one semisynchronous slave acknowledges that it has received all events for the transaction, or until a timeout occurs.
- The slave acknowledges receipt of a transaction's events only after the events have been written to its relay log and flushed to disk.
- If a timeout occurs without any slave having acknowledged the transaction, the master reverts to asynchronous replication. When at least one semisynchronous slave catches up, the master returns to semisynchronous replication.
- Semisynchronous replication must be enabled on both the master and slave sides. If semisynchronous replication is disabled on the master, or enabled on the master but on no slaves, the master uses asynchronous replication.

While the master is blocking (waiting for acknowledgment from a slave), it does not return to the session that performed the transaction. When the block ends, the master returns to the session, which then can proceed to execute other statements. At this point, the transaction has committed on the master side, and receipt of its events has been acknowledged by at least one slave.

The number of slave acknowledgments the master must receive per transaction before proceeding is configurable using the `rpl_semi_sync_master_wait_for_slave_count` system variable. The default value is 1.

Blocking also occurs after rollbacks that are written to the binary log, which occurs when a transaction that modifies nontransactional tables is rolled back. The rolled-back transaction is logged even though it has no effect for transactional tables because the modifications to the nontransactional tables cannot be rolled back and must be sent to slaves.

For statements that do not occur in transactional context (that is, when no transaction has been started with `START TRANSACTION` or `SET autocommit = 0`), autocommit is enabled and each statement commits implicitly. With semisynchronous replication, the master blocks for each such statement, just as it does for explicit transaction commits.

To understand what the “semi” in “semisynchronous replication” means, compare it with asynchronous and fully synchronous replication:

- With asynchronous replication, the master writes events to its binary log and slaves request them when they are ready. There is no guarantee that any event will ever reach any slave.
- With fully synchronous replication, when a master commits a transaction, all slaves also will have committed the transaction before the master returns to the session that performed the transaction. The drawback of this is that there might be a lot of delay to complete a transaction.
- Semisynchronous replication falls between asynchronous and fully synchronous replication. The master waits only until at least one slave has received and logged the events. It does not wait for all slaves to acknowledge receipt, and it requires only receipt, not that the events have been fully executed and committed on the slave side.

Compared to asynchronous replication, semisynchronous replication provides improved data integrity because when a commit returns successfully, it is known that the data exists in at least two places. Until a semisynchronous master receives acknowledgment from the number of slaves configured by `rpl_semi_sync_master_wait_for_slave_count`, the transaction is on hold and not committed.

Semisynchronous replication also places a rate limit on busy sessions by constraining the speed at which binary log events can be sent from master to slave. When one user is too busy, this will slow it down, which is useful in some deployment situations.

Semisynchronous replication does have some performance impact because commits are slower due to the need to wait for slaves. This is the tradeoff for increased data integrity. The amount of slowdown is at least the TCP/IP roundtrip time to send the commit to the slave and wait for the acknowledgment of receipt by the slave. This means that semisynchronous replication works best for close servers communicating over fast networks, and worst for distant servers communicating over slow networks.

The `rpl_semi_sync_master_wait_point` system variable controls the point at which a semisynchronous replication master waits for slave acknowledgment of transaction receipt before returning a status to the client that committed the transaction. These values are permitted:

- `AFTER_SYNC` (the default): The master writes each transaction to its binary log and the slave, and syncs the binary log to disk. The master waits for slave acknowledgment of transaction receipt after the sync. Upon receiving acknowledgment, the master commits the transaction to the storage engine and returns a result to the client, which then can proceed.
- `AFTER_COMMIT`: The master writes each transaction to its binary log and the slave, syncs the binary log, and commits the transaction to the storage engine. The master waits for slave acknowledgment of transaction receipt after the commit. Upon receiving acknowledgment, the master returns a result to the client, which then can proceed.

The replication characteristics of these settings differ as follows:

- With `AFTER_SYNC`, all clients see the committed transaction at the same time: After it has been acknowledged by the slave and committed to the storage engine on the master. Thus, all clients see the same data on the master.

In the event of master failure, all transactions committed on the master have been replicated to the slave (saved to its relay log). A crash of the master and failover to the slave is lossless because the slave is up to date.

- With `AFTER_COMMIT`, the client issuing the transaction gets a return status only after the server commits to the storage engine and receives slave acknowledgment. After the commit and before slave acknowledgment, other clients can see the committed transaction before the committing client.

If something goes wrong such that the slave does not process the transaction, then in the event of a master crash and failover to the slave, it is possible that such clients will see a loss of data relative to what they saw on the master.

18.3.10.1 Semisynchronous Replication Administrative Interface

The administrative interface to semisynchronous replication has several components:

- Two plugins implement semisynchronous capability. There is one plugin for the master side and one for the slave side.
- System variables control plugin behavior. Some examples:

- `rpl_semi_sync_master_enabled`

Controls whether semisynchronous replication is enabled on the master. To enable or disable the plugin, set this variable to 1 or 0, respectively. The default is 0 (off).

- `rpl_semi_sync_master_timeout`

A value in milliseconds that controls how long the master waits on a commit for acknowledgment from a slave before timing out and reverting to asynchronous replication. The default value is 10000 (10 seconds).

- `rpl_semi_sync_slave_enabled`

Similar to `rpl_semi_sync_master_enabled`, but controls the slave plugin.

All `rpl_semi_sync_xxx` system variables are described at [Section 5.1.5, “Server System Variables”](#).

- Status variables enable semisynchronous replication monitoring. Some examples:

- `Rpl_semi_sync_master_clients`

The number of semisynchronous slaves.

- `Rpl_semi_sync_master_status`

Whether semisynchronous replication currently is operational on the master. The value is 1 if the plugin has been enabled and a commit acknowledgment has not occurred. It is 0 if the plugin is not enabled or the master has fallen back to asynchronous replication due to commit acknowledgment timeout.

- `Rpl_semi_sync_master_no_tx`

The number of commits that were not acknowledged successfully by a slave.

- `Rpl_semi_sync_master_yes_tx`

The number of commits that were acknowledged successfully by a slave.

- `Rpl_semi_sync_slave_status`

Whether semisynchronous replication currently is operational on the slave. This is 1 if the plugin has been enabled and the slave I/O thread is running, 0 otherwise.

All `Rpl_semi_sync_xxx` status variables are described at [Section 5.1.7, “Server Status Variables”](#).

The system and status variables are available only if the appropriate master or slave plugin has been installed with `INSTALL PLUGIN`.

18.3.10.2 Semisynchronous Replication Installation and Configuration

Semisynchronous replication is implemented using plugins, so the plugins must be installed into the server to make them available. After a plugin has been installed, you control it by means of the system variables associated with it. These system variables are unavailable until the associated plugin has been installed.

This section describes how to install the semisynchronous replication plugins. For general information about installing plugins, see [Section 5.6.2, “Installing and Uninstalling Plugins”](#).

To use semisynchronous replication, the following requirements must be satisfied:

- MySQL 5.5 or higher must be installed.
- The capability of installing plugins requires a MySQL server that supports dynamic loading. To verify this, check that the value of the `have_dynamic_loading` system variable is `YES`. Binary distributions should support dynamic loading.
- Replication must already be working, see [Section 18.1, “Configuring Replication”](#).
- There must not be multiple replication channels configured. Semisynchronous replication is only compatible with the default replication channel. See [Section 18.2.3, “Replication Channels”](#).

To set up semisynchronous replication, use the following instructions. The `INSTALL PLUGIN`, `SET GLOBAL`, `STOP SLAVE`, and `START SLAVE` statements mentioned here require the `REPLICATION_SLAVE_ADMIN` or `SUPER` privilege.

MySQL distributions include semisynchronous replication plugin files for the master side and the slave side.

To be usable by a master or slave server, the appropriate plugin library file must be located in the MySQL plugin directory (the directory named by the `plugin_dir` system variable). If necessary, set the value of `plugin_dir` at server startup to tell the server the plugin directory location.

The plugin library file base names are `semisync_master` and `semisync_slave`. The file name suffix differs per platform (for example, `.so` for Unix and Unix-like systems, `.dll` for Windows).

The master plugin library file must be present in the plugin directory of the master server. The slave plugin library file must be present in the plugin directory of each slave server.

To load the plugins, use the `INSTALL PLUGIN` statement on the master and on each slave that is to be semisynchronous (adjust the `.so` suffix for your platform as necessary).

On the master:

```
INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
```

On each slave:

```
INSTALL PLUGIN rpl_semi_sync_slave SONAME 'semisync_slave.so';
```

If an attempt to install a plugin results in an error on Linux similar to that shown here, you must install `libimf`:

```
mysql> INSTALL PLUGIN rpl_semi_sync_master SONAME 'semisync_master.so';
ERROR 1126 (HY000): Can't open shared library
'/usr/local/mysql/lib/plugin/semisync_master.so'
(errno: 22 libimf.so: cannot open shared object file:
No such file or directory)
```

You can obtain `libimf` from <http://dev.mysql.com/downloads/os-linux.html>.

To see which plugins are installed, use the `SHOW PLUGINS` statement, or query the `INFORMATION_SCHEMA.PLUGINS` table.

To verify plugin installation, examine the `INFORMATION_SCHEMA.PLUGINS` table or use the `SHOW PLUGINS` statement (see [Section 5.6.3, "Obtaining Server Plugin Information"](#)). For example:

```
mysql> SELECT PLUGIN_NAME, PLUGIN_STATUS
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE '%semi%';
+-----+-----+
| PLUGIN_NAME          | PLUGIN_STATUS |
+-----+-----+
| rpl_semi_sync_master | ACTIVE        |
+-----+-----+
```

If the plugin fails to initialize, check the server error log for diagnostic messages.

After a semisynchronous replication plugin has been installed, it is disabled by default. The plugins must be enabled both on the master side and the slave side to enable semisynchronous replication. If only one side is enabled, replication will be asynchronous.

To control whether an installed plugin is enabled, set the appropriate system variables. You can set these variables at runtime using `SET GLOBAL`, or at server startup on the command line or in an option file.

At runtime, these master-side system variables are available:

```
SET GLOBAL rpl_semi_sync_master_enabled = {0|1};
SET GLOBAL rpl_semi_sync_master_timeout = N;
```

On the slave side, this system variable is available:

```
SET GLOBAL rpl_semi_sync_slave_enabled = {0|1};
```

For `rpl_semi_sync_master_enabled` or `rpl_semi_sync_slave_enabled`, the value should be 1 to enable semisynchronous replication or 0 to disable it. By default, these variables are set to 0.

For `rpl_semi_sync_master_timeout`, the value `N` is given in milliseconds. The default value is 10000 (10 seconds).

If you enable semisynchronous replication on a slave at runtime, you must also start the slave I/O thread (stopping it first if it is already running) to cause the slave to connect to the master and register as a semisynchronous slave:

```
STOP SLAVE IO_THREAD;
START SLAVE IO_THREAD;
```

If the I/O thread is already running and you do not restart it, the slave continues to use asynchronous replication.

At server startup, the variables that control semisynchronous replication can be set as command-line options or in an option file. A setting listed in an option file takes effect each time the server starts. For example, you can set the variables in `my.cnf` files on the master and slave sides as follows.

On the master:

```
[mysqld]
rpl_semi_sync_master_enabled=1
rpl_semi_sync_master_timeout=1000 # 1 second
```

On each slave:

```
[mysqld]
rpl_semi_sync_slave_enabled=1
```

18.3.10.3 Semisynchronous Replication Monitoring

The plugins for the semisynchronous replication capability expose several system and status variables that you can examine to determine its configuration and operational state.

The system variable reflect how semisynchronous replication is configured. To check their values, use `SHOW VARIABLES`:

```
mysql> SHOW VARIABLES LIKE 'rpl_semi_sync%';
```

The status variables enable you to monitor the operation of semisynchronous replication. To check their values, use `SHOW STATUS`:

```
mysql> SHOW STATUS LIKE 'Rpl_semi_sync%';
```

When the master switches between asynchronous or semisynchronous replication due to commit-blocking timeout or a slave catching up, it sets the value of the `Rpl_semi_sync_master_status` status variable appropriately. Automatic fallback from semisynchronous to asynchronous replication on the master means that it is possible for the `rpl_semi_sync_master_enabled` system variable to have a value of 1 on the master side even when semisynchronous replication is in fact not operational at the moment. You can monitor the `Rpl_semi_sync_master_status` status variable to determine whether the master currently is using asynchronous or semisynchronous replication.

To see how many semisynchronous slaves are connected, check `Rpl_semi_sync_master_clients`.

The number of commits that have been acknowledged successfully or unsuccessfully by slaves are indicated by the `Rpl_semi_sync_master_yes_tx` and `Rpl_semi_sync_master_no_tx` variables.

On the slave side, `Rpl_semi_sync_slave_status` indicates whether semisynchronous replication currently is operational.

18.3.11 Delayed Replication

MySQL supports delayed replication such that a slave server deliberately executes transactions later than the master by at least a specified amount of time. This section describes how to configure a replication delay on a slave, and how to monitor replication delay.

Compared to previous versions, MySQL 8.0 uses a different method for delaying replication that depends on two timestamps added in MySQL 8.0.1 - `immediate_commit_timestamp` and `original_commit_timestamp`, which are explained in [Replication Delay Timestamps](#). If all servers in the replication topology are running MySQL version 8.0.1 or later, delayed replication is measured using these timestamps. If either the immediate master or slave is not using these timestamps, the implementation of delayed replication from MySQL 5.7 used, see [Delayed Replication](#). This section describes delayed replication between servers which are all using these timestamps.

The default replication delay is 0 seconds. Use the `CHANGE MASTER TO MASTER_DELAY=N` statement to set the delay to `N` seconds. A transaction received from the master is not executed until at least `N` seconds later than its commit on the immediate master. The delay happens per transaction (not event as in previous MySQL versions) and the actual delay is imposed only on `gtid_log_event` or `anonymous_gtid_log_event`. The other events in the transaction always follow these events without any waiting time imposed on them.

Note

`START SLAVE` and `STOP SLAVE` take effect immediately and ignore any delay. `RESET SLAVE` resets the delay to 0.

The `replication_applier_configuration` Performance Schema table contains the `DESIRED_DELAY` column which shows the delay configured using the `MASTER_DELAY` option. The `replication_applier_status` Performance Schema table contains the `REMAINING_DELAY` column which shows the number of delay seconds remaining.

Delayed replication can be used for several purposes:

- To protect against user mistakes on the master. With a delay you can roll back a delayed slave to the time just before the mistake.
- To test how the system behaves when there is a lag. For example, in an application, a lag might be caused by a heavy load on the slave. However, it can be difficult to generate this load level. Delayed replication can simulate the lag without having to simulate the load. It can also be used to debug conditions related to a lagging slave.
- To inspect what the database looked like in the past, without having to reload a backup. For example, by configuring a slave with a delay of one week, if you then need to see what the database looked like before the last few days' worth of development, the delayed slave can be inspected.

Replication Delay Timestamps

MySQL 8.0 provides a new method for measuring delay (also referred to as replication lag) in replication topologies that depends on the following timestamps associated with the GTID of each transaction (instead of each event) written to the binary log.

- `original_commit_timestamp`: the number of microseconds since epoch when the transaction was written (committed) to the binary log of the original master.
- `immediate_commit_timestamp`: the number of microseconds since epoch when the transaction was written (committed) to the binary log of the immediate master.

The output of `mysqlbinlog` displays these timestamps in two formats, microseconds from epoch and also `TIMESTAMP` format, which is based on the user defined timezone for better readability. For example:

```
#170404 10:48:05 server id 1  end_log_pos 233 CRC32 0x016ce647      GTID      last_committed=0
\ sequence_number=1      original_committed_timestamp=1491299285661130      immediate_commit_timestamp=1491299285661130
# original_commit_timestamp=1491299285661130 (2017-04-04 10:48:05.661130 WEST)
# immediate_commit_timestamp=1491299285661130 (2017-04-04 10:48:05.843771 WEST)
/*!80001 SET @@session.original_commit_timestamp=1491299285661130/*!*/;
      SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa:1'/*!*/;
# at 233
```

As a rule, the `original_commit_timestamp` is always the same on all replicas where the transaction is applied. In master-slave replication, the `original_commit_timestamp` of a transaction in the (original) master's binary log is always the same as its `immediate_commit_timestamp`. In the slave's relay log, the `original_commit_timestamp` and `immediate_commit_timestamp` of the transaction are the same as in the master's binary log; whereas in its own binary log, the transaction's `immediate_commit_timestamp` corresponds to when the slave committed the transaction.

In a Group Replication setup, when the original master is a member of a group, the `original_commit_timestamp` is generated when the transaction is ready to be committed. In other words, when it finished executing on the original master and its write set is ready to be sent to all members of the group for certification. Therefore, the same `original_commit_timestamp` is replicated to all servers (regardless of whether it is a group member or slave replicating from a member) applying the transaction and each stores in its binary log the local commit time using `immediate_commit_timestamp`.

View change events, which are exclusive to Group Replication, are a special case. Transactions containing these events are generated by each server but share the same GTID (so, they are not first executed in a master and then replicated to the group, but all members of the group execute and apply the same transaction). Since there is no original master, these transactions have their `original_commit_timestamp` set to zero.

Monitoring Replication Delay

One of the most common ways to monitor replication delay (lag) in previous MySQL versions was by relying on the `Seconds_Behind_Master` field in the output of `SHOW SLAVE STATUS`. However, this metric is not suitable when using replication topologies more complex than the traditional master-slave setup, such as Group Replication. The addition of `immediate_commit_timestamp` and `original_commit_timestamp` to MySQL 8 provides a much finer degree of information about replication delay. The recommended method to monitor replication delay in a topology that supports these timestamps is using the following Performance Schema tables.

- `replication_connection_status`: current status of the connection to the master, provides information on the last and current transaction the connection thread queued into the relay log.
- `replication_applier_status_by_coordinator`: current status of the coordinator thread that only displays information when using a multi-threaded slave, provides information on the last transaction buffered by the coordinator thread to a worker's queue, as well as the transaction it is currently buffering.
- `replication_applier_status_by_worker`: current status of the thread(s) applying transactions received from the master, provides information about the transactions applied by the applier thread, or by each worker when using a multi-threaded slave.

Using these tables you can monitor information about the last transaction the corresponding thread processed and the transaction that thread is currently processing. This information comprises:

- a transaction's GTID
- a transaction's `original_commit_timestamp` and `immediate_commit_timestamp`, retrieved from the slave's relay log
- the time a thread started processing a transaction
- for the last processed transaction, the time the thread finished processing it

In addition to the Performance Schema tables, the output of `SHOW SLAVE STATUS` has three fields that show:

- `SQL_Delay`: A nonnegative integer indicating the replication delay configured using `CHANGE MASTER TO MASTER_DELAY=N`, measured in seconds.
- `SQL_Remaining_Delay`: When `Slave_SQL_Running_State` is `Waiting until MASTER_DELAY seconds after master executed event`, this field contains an integer indicating the number of seconds left of the delay. At other times, this field is `NULL`.
- `Slave_SQL_Running_State`: A string indicating the state of the SQL thread (analogous to `Slave_IO_State`). The value is identical to the `State` value of the SQL thread as displayed by `SHOW PROCESSLIST`.

When the slave SQL thread is waiting for the delay to elapse before executing an event, `SHOW PROCESSLIST` displays its `State` value as `Waiting until MASTER_DELAY seconds after master executed event`.

18.4 Replication Notes and Tips

18.4.1 Replication Features and Issues

The following sections provide information about what is supported and what is not in MySQL replication, and about specific issues and situations that may occur when replicating certain statements.

Statement-based replication depends on compatibility at the SQL level between the master and slave. In others, successful SBR requires that any SQL features used be supported by both the master and the slave servers. For example, if you use a feature on the master server that is available only in MySQL 8.0 (or later), you cannot replicate to a slave that uses MySQL 5.7 (or earlier).

Such incompatibilities also can occur within a release series when using pre-production releases of MySQL. For example, the `SLEEP()` function is available beginning with MySQL 5.0.12. If you use this function on the master, you cannot replicate to a slave that uses MySQL 5.0.11 or earlier.

For this reason, use Generally Available (GA) releases of MySQL for statement-based replication in a production setting, since we do not introduce new SQL statements or change their behavior within a given release series once that series reaches GA release status.

If you are planning to use statement-based replication between MySQL 8.0 and a previous MySQL release series, it is also a good idea to consult the edition of the *MySQL Reference Manual* corresponding to the earlier release series for information regarding the replication characteristics of that series.

With MySQL's statement-based replication, there may be issues with replicating stored routines or triggers. You can avoid these issues by using MySQL's row-based replication instead. For a detailed list of issues, see [Section 23.7, "Binary Logging of Stored Programs"](#). For more information about

row-based logging and row-based replication, see [Section 5.4.4.1, “Binary Logging Formats”](#), and [Section 18.2.1, “Replication Formats”](#).

For additional information specific to replication and [InnoDB](#), see [Section 15.18, “InnoDB and MySQL Replication”](#). For information relating to replication with MySQL Cluster, see [NDB Cluster Replication](#).

18.4.1.1 Replication and `AUTO_INCREMENT`

Statement-based replication of `AUTO_INCREMENT`, `LAST_INSERT_ID()`, and `TIMESTAMP` values is done correctly, subject to the following exceptions:

- A statement invoking a trigger or function that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. In MySQL 8.0, such statements are marked as unsafe. (Bug #45677)
- An `INSERT` into a table that has a composite primary key that includes an `AUTO_INCREMENT` column that is not the first column of this composite key is not safe for statement-based logging or replication. In MySQL 8.0 and later, such statements are marked as unsafe. (Bug #11754117, Bug #45670)

This issue does not affect tables using the [InnoDB](#) storage engine, since an [InnoDB](#) table with an `AUTO_INCREMENT` column requires at least one key where the auto-increment column is the only or leftmost column.

- Adding an `AUTO_INCREMENT` column to a table with `ALTER TABLE` might not produce the same ordering of the rows on the slave and the master. This occurs because the order in which the rows are numbered depends on the specific storage engine used for the table and the order in which the rows were inserted. If it is important to have the same order on the master and slave, the rows must be ordered before assigning an `AUTO_INCREMENT` number. Assuming that you want to add an `AUTO_INCREMENT` column to a table `t1` that has columns `col1` and `col2`, the following statements produce a new table `t2` identical to `t1` but with an `AUTO_INCREMENT` column:

```
CREATE TABLE t2 LIKE t1;
ALTER TABLE t2 ADD id INT AUTO_INCREMENT PRIMARY KEY;
INSERT INTO t2 SELECT * FROM t1 ORDER BY col1, col2;
```

Important

To guarantee the same ordering on both master and slave, the `ORDER BY` clause must name *all* columns of `t1`.

The instructions just given are subject to the limitations of `CREATE TABLE ... LIKE`: Foreign key definitions are ignored, as are the `DATA DIRECTORY` and `INDEX DIRECTORY` table options. If a table definition includes any of those characteristics, create `t2` using a `CREATE TABLE` statement that is identical to the one used to create `t1`, but with the addition of the `AUTO_INCREMENT` column.

Regardless of the method used to create and populate the copy having the `AUTO_INCREMENT` column, the final step is to drop the original table and then rename the copy:

```
DROP t1;
ALTER TABLE t2 RENAME t1;
```

See also [Section B.5.6.1, “Problems with ALTER TABLE”](#).

18.4.1.2 Replication and `BLACKHOLE` Tables

The `BLACKHOLE` storage engine accepts data but discards it and does not store it. When performing binary logging, all inserts to such tables are always logged, regardless of the logging format in use. Updates and deletes are handled differently depending on whether statement based or row based logging is in use. With the statement based logging format, all statements affecting `BLACKHOLE` tables

are logged, but their effects ignored. When using row-based logging, updates and deletes to such tables are simply skipped—they are not written to the binary log. A warning is logged whenever this occurs.

For this reason we recommend when you replicate to tables using the `BLACKHOLE` storage engine that you have the `binlog_format` server variable set to `STATEMENT`, and not to either `ROW` or `MIXED`.

18.4.1.3 Replication and Character Sets

The following applies to replication between MySQL servers that use different character sets:

- If the master has databases with a character set different from the global `character_set_server` value, you should design your `CREATE TABLE` statements so that they do not implicitly rely on the database default character set. A good workaround is to state the character set and collation explicitly in `CREATE TABLE` statements.

18.4.1.4 Replication and CHECKSUM TABLE

`CHECKSUM TABLE` returns a checksum that is calculated row by row, using a method that depends on the table row storage format, which is not guaranteed to remain the same between MySQL release series. For example, the storage format for temporal types such as `TIME`, `DATETIME`, and `TIMESTAMP` changed in MySQL 5.6 prior to MySQL 5.6.5, so if a 5.5 table is upgraded to MySQL 5.6, the checksum value may change.

18.4.1.5 Replication of CREATE ... IF NOT EXISTS Statements

MySQL applies these rules when various `CREATE ... IF NOT EXISTS` statements are replicated:

- Every `CREATE DATABASE IF NOT EXISTS` statement is replicated, whether or not the database already exists on the master.
- Similarly, every `CREATE TABLE IF NOT EXISTS` statement without a `SELECT` is replicated, whether or not the table already exists on the master. This includes `CREATE TABLE IF NOT EXISTS ... LIKE`. Replication of `CREATE TABLE IF NOT EXISTS ... SELECT` follows somewhat different rules; see [Section 18.4.1.6, “Replication of CREATE TABLE ... SELECT Statements”](#), for more information.
- `CREATE EVENT IF NOT EXISTS` is always replicated in MySQL 8.0, whether or not the event named in the statement already exists on the master.

See also Bug #45574.

18.4.1.6 Replication of CREATE TABLE ... SELECT Statements

This section discusses how MySQL replicates `CREATE TABLE ... SELECT` statements.

MySQL 8.0 does not allow a `CREATE TABLE ... SELECT` statement to make any changes in tables other than the table that is created by the statement. Some older versions of MySQL permitted these statements to do so; this means that, when using statement-based replication between a MySQL 5.6 or later slave and a master running a previous version of MySQL, a `CREATE TABLE ... SELECT` statement causing changes in other tables on the master fails on the slave, causing replication to stop. To prevent this from happening, you should use row-based replication, rewrite the offending statement before running it on the master, or upgrade the master to MySQL 8.0. (If you choose to upgrade the master, keep in mind that such a `CREATE TABLE ... SELECT` statement fails following the upgrade unless it is rewritten to remove any side effects on other tables.) This is not an issue when using row-based replication, because the statement is logged as a `CREATE TABLE` statement with any changes to table data logged as row-insert events, rather than as the entire `CREATE TABLE ... SELECT`.

These behaviors are not dependent on MySQL version:

- `CREATE TABLE ... SELECT` always performs an implicit commit ([Section 13.3.3, “Statements That Cause an Implicit Commit”](#)).
- If destination table does not exist, logging occurs as follows. It does not matter whether `IF NOT EXISTS` is present.
 - `STATEMENT` or `MIXED` format: The statement is logged as written.
 - `ROW` format: The statement is logged as a `CREATE TABLE` statement followed by a series of insert-row events.
- If the statement fails, nothing is logged. This includes the case that the destination table exists and `IF NOT EXISTS` is not given.

When the destination table exists and `IF NOT EXISTS` is given, MySQL 8.0 ignores the statement completely; nothing is inserted or logged. The handling of such statements in this regard has changed considerably in previous MySQL releases; if you are replicating from a MySQL 5.5.6 or older master to a newer slave, see [Replication of CREATE ... IF NOT EXISTS Statements](#), for more information.

18.4.1.7 Replication of CREATE SERVER, ALTER SERVER, and DROP SERVER

In MySQL 8.0, the statements `CREATE SERVER`, `ALTER SERVER`, and `DROP SERVER` are not written to the binary log, regardless of the binary logging format that is in use.

18.4.1.8 Replication of CURRENT_USER()

The following statements support use of the `CURRENT_USER()` function to take the place of the name of (and, possibly, the host for) an affected user or a definer; in such cases, `CURRENT_USER()` is expanded where and as needed:

- `DROP USER`
- `RENAME USER`
- `GRANT`
- `REVOKE`
- `CREATE FUNCTION`
- `CREATE PROCEDURE`
- `CREATE TRIGGER`
- `CREATE EVENT`
- `CREATE VIEW`
- `ALTER EVENT`
- `ALTER VIEW`
- `SET PASSWORD`

When `CURRENT_USER()` or `CURRENT_USER` is used as the definer in any of the statements `CREATE FUNCTION`, `CREATE PROCEDURE`, `CREATE TRIGGER`, `CREATE EVENT`, `CREATE VIEW`, or `ALTER VIEW` when binary logging is enabled, the function reference is expanded before it is written to the binary log, so that the statement refers to the same user on both the master and the slave when the statement is replicated. `CURRENT_USER()` or `CURRENT_USER` is also expanded prior to being written to the binary log when used in `DROP USER`, `RENAME USER`, `GRANT`, `REVOKE`, or `ALTER EVENT`.

18.4.1.9 Replication of DROP ... IF EXISTS Statements

The `DROP DATABASE IF EXISTS`, `DROP TABLE IF EXISTS`, and `DROP VIEW IF EXISTS` statements are always replicated, even if the database, table, or view to be dropped does not exist on the master. This is to ensure that the object to be dropped no longer exists on either the master or the slave, once the slave has caught up with the master.

`DROP ... IF EXISTS` statements for stored programs (stored procedures and functions, triggers, and events) are also replicated, even if the stored program to be dropped does not exist on the master.

18.4.1.10 Replication with Differing Table Definitions on Master and Slave

Source and target tables for replication do not have to be identical. A table on the master can have more or fewer columns than the slave's copy of the table. In addition, corresponding table columns on the master and the slave can use different data types, subject to certain conditions.

Note

Replication between tables which are partitioned differently from one another is not supported. See [Section 18.4.1.19, "Replication and Partitioning"](#).

In all cases where the source and target tables do not have identical definitions, the database and table names must be the same on both the master and the slave. Additional conditions are discussed, with examples, in the following two sections.

Replication with More Columns on Master or Slave

You can replicate a table from the master to the slave such that the master and slave copies of the table have differing numbers of columns, subject to the following conditions:

- Columns common to both versions of the table must be defined in the same order on the master and the slave.

(This is true even if both tables have the same number of columns.)

- Columns common to both versions of the table must be defined before any additional columns.

This means that executing an `ALTER TABLE` statement on the slave where a new column is inserted into the table within the range of columns common to both tables causes replication to fail, as shown in the following example:

Suppose that a table `t`, existing on the master and the slave, is defined by the following `CREATE TABLE` statement:

```
CREATE TABLE t (
  c1 INT,
  c2 INT,
  c3 INT
);
```

Suppose that the `ALTER TABLE` statement shown here is executed on the slave:

```
ALTER TABLE t ADD COLUMN cnew1 INT AFTER c3;
```

The previous `ALTER TABLE` is permitted on the slave because the columns `c1`, `c2`, and `c3` that are common to both versions of table `t` remain grouped together in both versions of the table, before any columns that differ.

However, the following `ALTER TABLE` statement cannot be executed on the slave without causing replication to break:

```
ALTER TABLE t ADD COLUMN cnew2 INT AFTER c2;
```

Replication fails after execution on the slave of the `ALTER TABLE` statement just shown, because the new column `cnew2` comes between columns common to both versions of `t`.

- Each “extra” column in the version of the table having more columns must have a default value.

A column's default value is determined by a number of factors, including its type, whether it is defined with a `DEFAULT` option, whether it is declared as `NULL`, and the server SQL mode in effect at the time of its creation; for more information, see [Section 11.7, “Data Type Default Values”](#)).

In addition, when the slave's copy of the table has more columns than the master's copy, each column common to the tables must use the same data type in both tables.

Examples. The following examples illustrate some valid and invalid table definitions:

More columns on the master. The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

The following table definitions would raise an error because the definitions of the columns common to both versions of the table are in a different order on the slave than they are on the master:

```
master> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT);
```

The following table definitions would also raise an error because the definition of the extra column on the master appears before the definitions of the columns common to both versions of the table:

```
master> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT);
```

More columns on the slave. The following table definitions are valid and replicate correctly:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

The following definitions raise an error because the columns common to both versions of the table are not defined in the same order on both the master and the slave:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c2 INT, c1 INT, c3 INT);
```

The following table definitions also raise an error because the definition for the extra column in the slave's version of the table appears before the definitions for the columns which are common to both versions of the table:

```
master> CREATE TABLE t1 (c1 INT, c2 INT);
slave> CREATE TABLE t1 (c3 INT, c1 INT, c2 INT);
```

The following table definitions fail because the slave's version of the table has additional columns compared to the master's version, and the two versions of the table use different data types for the common column `c2`:

```
master> CREATE TABLE t1 (c1 INT, c2 BIGINT);
```

```
slave> CREATE TABLE t1 (c1 INT, c2 INT, c3 INT);
```

Replication of Columns Having Different Data Types

Corresponding columns on the master's and the slave's copies of the same table ideally should have the same data type. However, this is not always strictly enforced, as long as certain conditions are met.

It is usually possible to replicate from a column of a given data type to another column of the same type and same size or width, where applicable, or larger. For example, you can replicate from a `CHAR(10)` column to another `CHAR(10)`, or from a `CHAR(10)` column to a `CHAR(25)` column without any problems. In certain cases, it is also possible to replicate from a column having one data type (on the master) to a column having a different data type (on the slave); when the data type of the master's version of the column is promoted to a type that is the same size or larger on the slave, this is known as *attribute promotion*.

Attribute promotion can be used with both statement-based and row-based replication, and is not dependent on the storage engine used by either the master or the slave. However, the choice of logging format does have an effect on the type conversions that are permitted; the particulars are discussed later in this section.

Important

Whether you use statement-based or row-based replication, the slave's copy of the table cannot contain more columns than the master's copy if you wish to employ attribute promotion.

Statement-based replication. When using statement-based replication, a simple rule of thumb to follow is, "If the statement run on the master would also execute successfully on the slave, it should also replicate successfully". In other words, if the statement uses a value that is compatible with the type of a given column on the slave, the statement can be replicated. For example, you can insert any value that fits in a `TINYINT` column into a `BIGINT` column as well; it follows that, even if you change the type of a `TINYINT` column in the slave's copy of a table to `BIGINT`, any insert into that column on the master that succeeds should also succeed on the slave, since it is impossible to have a legal `TINYINT` value that is large enough to exceed a `BIGINT` column.

Row-based replication: attribute promotion and demotion. Row-based replication in MySQL 8.0 supports attribute promotion and demotion between smaller data types and larger types. It is also possible to specify whether or not to permit lossy (truncated) or non-lossy conversions of demoted column values, as explained later in this section.

Lossy and non-lossy conversions. In the event that the target type cannot represent the value being inserted, a decision must be made on how to handle the conversion. If we permit the conversion but truncate (or otherwise modify) the source value to achieve a "fit" in the target column, we make what is known as a *lossy conversion*. A conversion which does not require truncation or similar modifications to fit the source column value in the target column is a *non-lossy conversion*.

Type conversion modes (slave_type_conversions variable). The setting of the `slave_type_conversions` global server variable controls the type conversion mode used on the slave. This variable takes a set of values from the following table, which shows the effects of each mode on the slave's type-conversion behavior:

Mode	Effect
<code>ALL_LOSSY</code>	In this mode, type conversions that would mean loss of information are permitted. This does not imply that non-lossy conversions are permitted, merely that only cases requiring either lossy conversions or no conversion at all are permitted; for example, enabling <i>only</i> this

Mode	Effect
	mode permits an <code>INT</code> column to be converted to <code>TINYINT</code> (a lossy conversion), but not a <code>TINYINT</code> column to an <code>INT</code> column (non-lossy). Attempting the latter conversion in this case would cause replication to stop with an error on the slave.
<code>ALL_NON_LOSSY</code>	This mode permits conversions that do not require truncation or other special handling of the source value; that is, it permits conversions where the target type has a wider range than the source type. Setting this mode has no bearing on whether lossy conversions are permitted; this is controlled with the <code>ALL_LOSSY</code> mode. If only <code>ALL_NON_LOSSY</code> is set, but not <code>ALL_LOSSY</code> , then attempting a conversion that would result in the loss of data (such as <code>INT</code> to <code>TINYINT</code> , or <code>CHAR(25)</code> to <code>VARCHAR(20)</code>) causes the slave to stop with an error.
<code>ALL_LOSSY, ALL_NON_LOSSY</code>	When this mode is set, all supported type conversions are permitted, whether or not they are lossy conversions.
<code>ALL_SIGNED</code>	Treat promoted integer types as signed values (the default behavior).
<code>ALL_UNSIGNED</code>	Treat promoted integer types as unsigned values.
<code>ALL_SIGNED, ALL_UNSIGNED</code>	Treat promoted integer types as signed if possible, otherwise as unsigned.
[empty]	When <code>slave_type_conversions</code> is not set, no attribute promotion or demotion is permitted; this means that all columns in the source and target tables must be of the same types. This mode is the default.

When an integer type is promoted, its signedness is not preserved. By default, the slave treats all such values as signed. You can control this behavior using `ALL_SIGNED`, `ALL_UNSIGNED`, or both. `ALL_SIGNED` tells the slave to treat all promoted integer types as signed; `ALL_UNSIGNED` instructs it to treat these as unsigned. Specifying both causes the slave to treat the value as signed if possible, otherwise to treat it as unsigned; the order in which they are listed is not significant. Neither `ALL_SIGNED` nor `ALL_UNSIGNED` has any effect if at least one of `ALL_LOSSY` or `ALL_NONLOSSY` is not also used.

Changing the type conversion mode requires restarting the slave with the new `slave_type_conversions` setting.

Supported conversions. Supported conversions between different but similar data types are shown in the following list:

- Between any of the integer types `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, and `BIGINT`.

This includes conversions between the signed and unsigned versions of these types.

Lossy conversions are made by truncating the source value to the maximum (or minimum) permitted by the target column. For ensuring non-lossy conversions when going from unsigned to signed types, the target column must be large enough to accommodate the range of values in the source column. For example, you can demote `TINYINT UNSIGNED` non-lossily to `SMALLINT`, but not to `TINYINT`.

- Between any of the decimal types `DECIMAL`, `FLOAT`, `DOUBLE`, and `NUMERIC`.

`FLOAT` to `DOUBLE` is a non-lossy conversion; `DOUBLE` to `FLOAT` can only be handled lossily. A conversion from `DECIMAL(M,D)` to `DECIMAL(M',D')` where $D' \geq D$ and $(M' - D') \geq (M - D)$ is non-lossy; for any case where $M' < M$, $D' < D$, or both, only a lossy conversion can be made.

For any of the decimal types, if a value to be stored cannot be fit in the target type, the value is rounded down according to the rounding rules defined for the server elsewhere in the documentation. See [Section 12.22.4, “Rounding Behavior”](#), for information about how this is done for decimal types.

- Between any of the string types `CHAR`, `VARCHAR`, and `TEXT`, including conversions between different widths.

Conversion of a `CHAR`, `VARCHAR`, or `TEXT` to a `CHAR`, `VARCHAR`, or `TEXT` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first N characters of the string on the slave, where N is the width of the target column.

Important

Replication between columns using different character sets is not supported.

- Between any of the binary data types `BINARY`, `VARBINARY`, and `BLOB`, including conversions between different widths.

Conversion of a `BINARY`, `VARBINARY`, or `BLOB` to a `BINARY`, `VARBINARY`, or `BLOB` column the same size or larger is never lossy. Lossy conversion is handled by inserting only the first N bytes of the string on the slave, where N is the width of the target column.

- Between any 2 `BIT` columns of any 2 sizes.

When inserting a value from a `BIT(M)` column into a `BIT(M')` column, where $M' > M$, the most significant bits of the `BIT(M')` columns are cleared (set to zero) and the M bits of the `BIT(M)` value are set as the least significant bits of the `BIT(M')` column.

When inserting a value from a source `BIT(M)` column into a target `BIT(M')` column, where $M' < M$, the maximum possible value for the `BIT(M')` column is assigned; in other words, an “all-set” value is assigned to the target column.

Conversions between types not in the previous list are not permitted.

18.4.1.11 Replication and `DIRECTORY` Table Options

If a `DATA DIRECTORY` or `INDEX DIRECTORY` table option is used in a `CREATE TABLE` statement on the master server, the table option is also used on the slave. This can cause problems if no corresponding directory exists in the slave host file system or if it exists but is not accessible to the slave server. This can be overridden by using the `NO_DIR_IN_CREATE` server SQL mode on the slave, which causes the slave to ignore the `DATA DIRECTORY` and `INDEX DIRECTORY` table options when replicating `CREATE TABLE` statements. The result is that `MyISAM` data and index files are created in the table’s database directory.

For more information, see [Section 5.1.8, “Server SQL Modes”](#).

18.4.1.12 Replication of Invoked Features

Replication of invoked features such as user-defined functions (UDFs) and stored programs (stored procedures and functions, triggers, and events) provides the following characteristics:

- The effects of the feature are always replicated.
- The following statements are replicated using statement-based replication:
 - `CREATE EVENT`
 - `ALTER EVENT`

- `DROP EVENT`
- `CREATE PROCEDURE`
- `DROP PROCEDURE`
- `CREATE FUNCTION`
- `DROP FUNCTION`
- `CREATE TRIGGER`
- `DROP TRIGGER`

However, the *effects* of features created, modified, or dropped using these statements are replicated using row-based replication.

Note

Attempting to replicate invoked features using statement-based replication produces the warning `Statement is not safe to log in statement format`. For example, trying to replicate a UDF with statement-based replication generates this warning because it currently cannot be determined by the MySQL server whether the UDF is deterministic. If you are absolutely certain that the invoked feature's effects are deterministic, you can safely disregard such warnings.

- In the case of `CREATE EVENT` and `ALTER EVENT`:
 - The status of the event is set to `SLAVESIDE_DISABLED` on the slave regardless of the state specified (this does not apply to `DROP EVENT`).
 - The master on which the event was created is identified on the slave by its server ID. The `ORIGINATOR` column in `INFORMATION_SCHEMA.EVENTS` and the `originator` column in `mysql.event` store this information. See [Section 24.8, “The INFORMATION_SCHEMA EVENTS Table”](#), and [Section 13.7.5.18, “SHOW EVENTS Syntax”](#), for more information.
- The feature implementation resides on the slave in a renewable state so that if the master fails, the slave can be used as the master without loss of event processing.

To determine whether there are any scheduled events on a MySQL server that were created on a different server (that was acting as a replication master), query the `INFORMATION_SCHEMA.EVENTS` table in a manner similar to what is shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED' ;
```

Alternatively, you can use the `SHOW EVENTS` statement, like this:

```
SHOW EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED' ;
```

When promoting a replication slave having such events to a replication master, you must enable each event using `ALTER EVENT event_name ENABLE`, where *event_name* is the name of the event.

If more than one master was involved in creating events on this slave, and you wish to identify events that were created only on a given master having the server ID *master_id*, modify the previous query on the `EVENTS` table to include the `ORIGINATOR` column, as shown here:

```
SELECT EVENT_SCHEMA, EVENT_NAME, ORIGINATOR
FROM INFORMATION_SCHEMA.EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED'
AND ORIGINATOR = 'master_id'
```

You can employ `ORIGINATOR` with the `SHOW EVENTS` statement in a similar fashion:

```
SHOW EVENTS
WHERE STATUS = 'SLAVESIDE_DISABLED'
AND ORIGINATOR = 'master_id'
```

Before enabling events that were replicated from the master, you should disable the MySQL Event Scheduler on the slave (using a statement such as `SET GLOBAL event_scheduler = OFF;`), run any necessary `ALTER EVENT` statements, restart the server, then re-enable the Event Scheduler on the slave afterward (using a statement such as `SET GLOBAL event_scheduler = ON;`)-

If you later demote the new master back to being a replication slave, you must disable manually all events enabled by the `ALTER EVENT` statements. You can do this by storing in a separate table the event names from the `SELECT` statement shown previously, or using `ALTER EVENT` statements to rename the events with a common prefix such as `replicated_` to identify them.

If you rename the events, then when demoting this server back to being a replication slave, you can identify the events by querying the `EVENTS` table, as shown here:

```
SELECT CONCAT(EVENT_SCHEMA, '.', EVENT_NAME) AS 'Db.Event'
FROM INFORMATION_SCHEMA.EVENTS
WHERE INSTR(EVENT_NAME, 'replicated_') = 1;
```

18.4.1.13 Replication and Floating-Point Values

With statement-based replication, values are converted from decimal to binary. Because conversions between decimal and binary representations of them may be approximate, comparisons involving floating-point values are inexact. This is true for operations that use floating-point values explicitly, or that use values that are converted to floating-point implicitly. Comparisons of floating-point values might yield different results on master and slave servers due to differences in computer architecture, the compiler used to build MySQL, and so forth. See [Section 12.2, “Type Conversion in Expression Evaluation”](#), and [Section B.5.4.8, “Problems with Floating-Point Values”](#).

18.4.1.14 Replication and Fractional Seconds Support

MySQL 8.0 permits fractional seconds for `TIME`, `DATETIME`, and `TIMESTAMP` values, with up to microseconds (6 digits) precision. See [Section 11.3.6, “Fractional Seconds in Time Values”](#).

There may be problems replicating from a master server that understands fractional seconds to an older slave (MySQL 5.6.3 and earlier) that does not:

- For `CREATE TABLE` statements containing columns that have an `fsp` (fractional seconds precision) value greater than 0, replication will fail due to parser errors.
- Statements that use temporal data types with an `fsp` value of 0 will work for with statement-based logging but not row-based logging. In the latter case, the data types have binary formats and type codes on the master that differ from those on the slave.
- Some expression results will differ on master and slave. Examples: On the master, the `timestamp` system variable returns a value that includes a microseconds fractional part; on the slave, it returns an integer. On the master, functions that return a result that includes the current time (such as `CURTIME()`, `SYSDATE()`, or `UTC_TIMESTAMP()`) interpret an argument as an `fsp` value and the return value includes a fractional seconds part of that many digits. On the slave, these functions permit an argument but ignore it.

18.4.1.15 Replication and FLUSH

Some forms of the `FLUSH` statement are not logged because they could cause problems if replicated to a slave: `FLUSH LOGS`, `FLUSH MASTER`, `FLUSH SLAVE`, and `FLUSH TABLES WITH READ LOCK`. For a syntax example, see [Section 13.7.6.3, “FLUSH Syntax”](#). The `FLUSH TABLES`, `ANALYZE TABLE`, `OPTIMIZE TABLE`, and `REPAIR TABLE` statements are written to the binary log and thus replicated to slaves. This is not normally a problem because these statements do not modify table data.

However, this behavior can cause difficulties under certain circumstances. If you replicate the privilege tables in the `mysql` database and update those tables directly without using `GRANT`, you must issue a `FLUSH PRIVILEGES` on the slaves to put the new privileges into effect. In addition, if you use `FLUSH TABLES` when renaming a `MyISAM` table that is part of a `MERGE` table, you must issue `FLUSH TABLES` manually on the slaves. These statements are written to the binary log unless you specify `NO_WRITE_TO_BINLOG` or its alias `LOCAL`.

18.4.1.16 Replication and System Functions

Certain functions do not replicate well under some conditions:

- The `USER()`, `CURRENT_USER()` (or `CURRENT_USER`), `UID()`, `VERSION()`, and `LOAD_FILE()` functions are replicated without change and thus do not work reliably on the slave unless row-based replication is enabled. (See [Section 18.2.1, “Replication Formats”](#).)

`USER()` and `CURRENT_USER()` are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (See also [Section 18.4.1.8, “Replication of CURRENT_USER\(\)”](#).) This is also true for `VERSION()` and `RAND()`.

- For `NOW()`, the binary log includes the timestamp. This means that the value *as returned by the call to this function on the master* is replicated to the slave. To avoid unexpected results when replicating between MySQL servers in different time zones, set the time zone on both master and slave. See also [Section 18.4.1.32, “Replication and Time Zones”](#)

To explain the potential problems when replicating between servers which are in different time zones, suppose that the master is located in New York, the slave is located in Stockholm, and both servers are using local time. Suppose further that, on the master, you create a table `mytable`, perform an `INSERT` statement on this table, and then select from the table, as shown here:

```
mysql> CREATE TABLE mytable (mycol TEXT);
Query OK, 0 rows affected (0.06 sec)

mysql> INSERT INTO mytable VALUES ( NOW() );
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM mytable;
+-----+
| mycol |
+-----+
| 2009-09-01 12:00:00 |
+-----+
1 row in set (0.00 sec)
```

Local time in Stockholm is 6 hours later than in New York; so, if you issue `SELECT NOW()` on the slave at that exact same instant, the value `2009-09-01 18:00:00` is returned. For this reason, if you select from the slave's copy of `mytable` after the `CREATE TABLE` and `INSERT` statements just shown have been replicated, you might expect `mycol` to contain the value `2009-09-01 18:00:00`. However, this is not the case; when you select from the slave's copy of `mytable`, you obtain exactly the same result as on the master:

```
mysql> SELECT * FROM mytable;
+-----+
| mycol |
+-----+
| 2009-09-01 12:00:00 |
+-----+
```

```
1 row in set (0.00 sec)
```

Unlike `NOW()`, the `SYSDATE()` function is not replication-safe because it is not affected by `SET TIMESTAMP` statements in the binary log and is nondeterministic if statement-based logging is used. This is not a problem if row-based logging is used.

An alternative is to use the `--sysdate-is-now` option to cause `SYSDATE()` to be an alias for `NOW()`. This must be done on the master and the slave to work correctly. In such cases, a warning is still issued by this function, but can safely be ignored as long as `--sysdate-is-now` is used on both the master and the slave.

`SYSDATE()` is automatically replicated using row-based replication when using `MIXED` mode, and generates a warning in `STATEMENT` mode.

See also [Section 18.4.1.32, “Replication and Time Zones”](#).

- *The following restriction applies to statement-based replication only, not to row-based replication.* The `GET_LOCK()`, `RELEASE_LOCK()`, `IS_FREE_LOCK()`, and `IS_USED_LOCK()` functions that handle user-level locks are replicated without the slave knowing the concurrency context on the master. Therefore, these functions should not be used to insert into a master table because the content on the slave would differ. For example, do not issue a statement such as `INSERT INTO mytable VALUES(GET_LOCK(...))`.

These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode.

As a workaround for the preceding limitations when statement-based replication is in effect, you can use the strategy of saving the problematic function result in a user variable and referring to the variable in a later statement. For example, the following single-row `INSERT` is problematic due to the reference to the `UUID()` function:

```
INSERT INTO t VALUES(UUID());
```

To work around the problem, do this instead:

```
SET @my_uuid = UUID();
INSERT INTO t VALUES(@my_uuid);
```

That sequence of statements replicates because the value of `@my_uuid` is stored in the binary log as a user-variable event prior to the `INSERT` statement and is available for use in the `INSERT`.

The same idea applies to multiple-row inserts, but is more cumbersome to use. For a two-row insert, you can do this:

```
SET @my_uuid1 = UUID(); @my_uuid2 = UUID();
INSERT INTO t VALUES(@my_uuid1),(@my_uuid2);
```

However, if the number of rows is large or unknown, the workaround is difficult or impracticable. For example, you cannot convert the following statement to one in which a given individual user variable is associated with each row:

```
INSERT INTO t2 SELECT UUID(), * FROM t1;
```

Within a stored function, `RAND()` replicates correctly as long as it is invoked only once during the execution of the function. (You can consider the function execution timestamp and random number seed as implicit inputs that are identical on the master and slave.)

The `FOUND_ROWS()` and `ROW_COUNT()` functions are not replicated reliably using statement-based replication. A workaround is to store the result of the function call in a user variable, and then use that

in the `INSERT` statement. For example, if you wish to store the result in a table named `mytable`, you might normally do so like this:

```
SELECT SQL_CALC_FOUND_ROWS FROM mytable LIMIT 1;
INSERT INTO mytable VALUES( FOUND_ROWS() );
```

However, if you are replicating `mytable`, you should use `SELECT ... INTO`, and then store the variable in the table, like this:

```
SELECT SQL_CALC_FOUND_ROWS INTO @found_rows FROM mytable LIMIT 1;
INSERT INTO mytable VALUES(@found_rows);
```

In this way, the user variable is replicated as part of the context, and applied on the slave correctly.

These functions are automatically replicated using row-based replication when using `MIXED` mode, and generate a warning in `STATEMENT` mode. (Bug #12092, Bug #30244)

18.4.1.17 Replication and LIMIT

Statement-based replication of `LIMIT` clauses in `DELETE`, `UPDATE`, and `INSERT ... SELECT` statements is unsafe since the order of the rows affected is not defined. (Such statements can be replicated correctly with statement-based replication only if they also contain an `ORDER BY` clause.) When such a statement is encountered:

- When using `STATEMENT` mode, a warning that the statement is not safe for statement-based replication is now issued.

When using `STATEMENT` mode, warnings are issued for DML statements containing `LIMIT` even when they also have an `ORDER BY` clause (and so are made deterministic). This is a known issue. (Bug #42851)

- When using `MIXED` mode, the statement is now automatically replicated using row-based mode.

18.4.1.18 Replication and LOAD DATA INFILE

In MySQL 8.0, `LOAD DATA INFILE` is considered unsafe (see [Section 18.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#)).

18.4.1.19 Replication and Partitioning

Replication is supported between partitioned tables as long as they use the same partitioning scheme and otherwise have the same structure except where an exception is specifically allowed (see [Section 18.4.1.10, “Replication with Differing Table Definitions on Master and Slave”](#)).

Replication between tables having different partitioning is generally not supported. This because statements (such as `ALTER TABLE ... DROP PARTITION`) acting directly on partitions in such cases may produce different results on master and slave. In the case where a table is partitioned on the master but not on the slave, any statements operating on partitions on the master's copy of the slave fail on the slave. When the slave's copy of the table is partitioned but the master's copy is not, statements acting on partitions cannot be run on the master without causing errors there.

Due to these dangers of causing replication to fail entirely (on account of failed statements) and of inconsistencies (when the result of a partition-level SQL statement produces different results on master and slave), we recommend that insure that the partitioning of any tables to be replicated from the master is matched by the slave's versions of these tables.

18.4.1.20 Replication and REPAIR TABLE

When used on a corrupted or otherwise damaged table, it is possible for the `REPAIR TABLE` statement to delete rows that cannot be recovered. However, any such modifications of table data performed

by this statement are not replicated, which can cause master and slave to lose synchronization. For this reason, in the event that a table on the master becomes damaged and you use `REPAIR TABLE` to repair it, you should first stop replication (if it is still running) before using `REPAIR TABLE`, then afterward compare the master's and slave's copies of the table and be prepared to correct any discrepancies manually, before restarting replication.

18.4.1.21 Replication and Master or Slave Shutdowns

It is safe to shut down a master server and restart it later. When a slave loses its connection to the master, the slave tries to reconnect immediately and retries periodically if that fails. The default is to retry every 60 seconds. This may be changed with the `CHANGE MASTER TO` statement. A slave also is able to deal with network connectivity outages. However, the slave notices the network outage only after receiving no data from the master for `slave_net_timeout` seconds. If your outages are short, you may want to decrease `slave_net_timeout`. See [Section 18.3.2, “Handling an Unexpected Halt of a Replication Slave”](#).

An unclean shutdown (for example, a crash) on the master side can result in the master binary log having a final position less than the most recent position read by the slave, due to the master binary log file not being flushed. This can cause the slave not to be able to replicate when the master comes back up. Setting `sync_binlog=1` in the master `my.cnf` file helps to minimize this problem because it causes the master to flush its binary log more frequently.

Shutting down a slave cleanly is safe because it keeps track of where it left off. However, be careful that the slave does not have temporary tables open; see [Section 18.4.1.24, “Replication and Temporary Tables”](#). Unclean shutdowns might produce problems, especially if the disk cache was not flushed to disk before the problem occurred:

- For transactions, the slave commits and then updates `relay-log.info`. If a crash occurs between these two operations, relay log processing will have proceeded further than the information file indicates and the slave will re-execute the events from the last transaction in the relay log after it has been restarted.
- A similar problem can occur if the slave updates `relay-log.info` but the server host crashes before the write has been flushed to disk. To minimize the chance of this occurring, set `sync_relay_log_info=1` in the slave `my.cnf` file. Setting `sync_relay_log_info` to 0 causes no writes to be forced to disk and the server relies on the operating system to flush the file from time to time.

The fault tolerance of your system for these types of problems is greatly increased if you have a good uninterruptible power supply.

18.4.1.22 Replication and `max_allowed_packet`

`max_allowed_packet` sets an upper limit on the size of any single message between the MySQL server and clients, including replication slaves. If you are replicating large column values (such as might be found in `TEXT` or `BLOB` columns) and `max_allowed_packet` is too small on the master, the master fails with an error, and the slave shuts down the I/O thread. If `max_allowed_packet` is too small on the slave, this also causes the slave to stop the I/O thread.

Row-based replication currently sends all columns and column values for updated rows from the master to the slave, including values of columns that were not actually changed by the update. This means that, when you are replicating large column values using row-based replication, you must take care to set `max_allowed_packet` large enough to accommodate the largest row in any table to be replicated, even if you are replicating updates only, or you are inserting only relatively small values.

18.4.1.23 Replication and MEMORY Tables

When a master server shuts down and restarts, its `MEMORY` tables become empty. To replicate this effect to slaves, the first time that the master uses a given `MEMORY` table after startup, it logs an event

that notifies slaves that the table must to be emptied by writing a `DELETE` statement for that table to the binary log.

When a slave server shuts down and restarts, its `MEMORY` tables become empty. This causes the slave to be out of synchrony with the master and may lead to other failures or cause the slave to stop:

- Row-format updates and deletes received from the master may fail with `Can't find record in 'memory_table'`.
- Statements such as `INSERT INTO ... SELECT FROM memory_table` may insert a different set of rows on the master and slave.

The safe way to restart a slave that is replicating `MEMORY` tables is to first drop or delete all rows from the `MEMORY` tables on the master and wait until those changes have replicated to the slave. Then it is safe to restart the slave.

An alternative restart method may apply in some cases. When `binlog_format=ROW`, you can prevent the slave from stopping if you set `slave_exec_mode=IDEMPOTENT` before you start the slave again. This allows the slave to continue to replicate, but its `MEMORY` tables will still be different from those on the master. This can be okay if the application logic is such that the contents of `MEMORY` tables can be safely lost (for example, if the `MEMORY` tables are used for caching). `slave_exec_mode=IDEMPOTENT` applies globally to all tables, so it may hide other replication errors in non-`MEMORY` tables.

The size of `MEMORY` tables is limited by the value of the `max_heap_table_size` system variable, which is not replicated (see [Section 18.4.1.38, “Replication and Variables”](#)). A change in `max_heap_table_size` takes effect for `MEMORY` tables that are created or updated using `ALTER TABLE ... ENGINE = MEMORY` or `TRUNCATE TABLE` following the change, or for all `MEMORY` tables following a server restart. If you increase the value of this variable on the master without doing so on the slave, it becomes possible for a table on the master to grow larger than its counterpart on the slave, leading to inserts that succeed on the master but fail on the slave with `Table is full` errors. This is a known issue (Bug #48666). In such cases, you must set the global value of `max_heap_table_size` on the slave as well as on the master, then restart replication. It is also recommended that you restart both the master and slave MySQL servers, to insure that the new value takes complete (global) effect on each of them.

See [Section 16.3, “The MEMORY Storage Engine”](#), for more information about `MEMORY` tables.

18.4.1.24 Replication and Temporary Tables

The discussion in the following paragraphs does not apply when `binlog_format=ROW` because, in that case, temporary tables are not replicated; this means that there are never any temporary tables on the slave to be lost in the event of an unplanned shutdown by the slave. The remainder of this section applies only when using statement-based or mixed-format replication. Loss of replicated temporary tables on the slave can be an issue, whenever `binlog_format` is `STATEMENT` or `MIXED`, for statements involving temporary tables that can be logged safely using statement-based format. For more information about row-based replication and temporary tables, see [Row-based logging of temporary tables](#).

Safe slave shutdown when using temporary tables. Temporary tables are replicated except in the case where you stop the slave server (not just the slave threads) and you have replicated temporary tables that are open for use in updates that have not yet been executed on the slave. If you stop the slave server, the temporary tables needed by those updates are no longer available when the slave is restarted. To avoid this problem, do not shut down the slave while it has temporary tables open. Instead, use the following procedure:

1. Issue a `STOP SLAVE SQL_THREAD` statement.
2. Use `SHOW STATUS` to check the value of the `Slave_open_temp_tables` variable.
3. If the value is not 0, restart the slave SQL thread with `START SLAVE SQL_THREAD` and repeat the procedure later.

- When the value is 0, issue a `mysqladmin shutdown` command to stop the slave.

Temporary tables and replication options. By default, all temporary tables are replicated; this happens whether or not there are any matching `--replicate-do-db`, `--replicate-do-table`, or `--replicate-wild-do-table` options in effect. However, the `--replicate-ignore-table` and `--replicate-wild-ignore-table` options are honored for temporary tables. The exception is that to enable correct removal of temporary tables at the end of a session, a replication slave always replicates a `DROP TEMPORARY TABLE IF EXISTS` statement, regardless of any exclusion rules that would normally apply for the specified table.

A recommended practice when using statement-based or mixed-format replication is to designate a prefix for exclusive use in naming temporary tables that you do not want replicated, then employ a `--replicate-wild-ignore-table` option to match that prefix. For example, you might give all such tables names beginning with `norep` (such as `norepmytable`, `norepyourtable`, and so on), then use `--replicate-wild-ignore-table=norep%` to prevent them from being replicated.

18.4.1.25 Replication of the mysql System Database

Data modification statements made to tables in the `mysql` database are replicated according to the value of `binlog_format`; if this value is `MIXED`, these statements are replicated using row-based format. However, statements that would normally update this information indirectly—such as `GRANT`, `REVOKE`, and statements manipulating triggers, stored routines, and views—are replicated to slaves using statement-based replication.

18.4.1.26 Replication and the Query Optimizer

It is possible for the data on the master and slave to become different if a statement is written in such a way that the data modification is nondeterministic; that is, left up to the query optimizer. (In general, this is not a good practice, even outside of replication.) Examples of nondeterministic statements include `DELETE` or `UPDATE` statements that use `LIMIT` with no `ORDER BY` clause; see [Section 18.4.1.17](#), “Replication and LIMIT”, for a detailed discussion of these.

18.4.1.27 Replication and Reserved Words

You can encounter problems when you attempt to replicate from an older master to a newer slave and you make use of identifiers on the master that are reserved words in the newer MySQL version running on the slave. An example of this is using a table column named `virtual` on a 5.6 master that is replicating to a 5.7 or higher slave because `VIRTUAL` is a reserved word beginning in MySQL 5.7. Replication can fail in such cases with Error 1064 *You have an error in your SQL syntax. . . , even if a database or table named using the reserved word or a table having a column named using the reserved word is excluded from replication*. This is due to the fact that each SQL event must be parsed by the slave prior to execution, so that the slave knows which database object or objects would be affected; only after the event is parsed can the slave apply any filtering rules defined by `--replicate-do-db`, `--replicate-do-table`, `--replicate-ignore-db`, and `--replicate-ignore-table`.

To work around the problem of database, table, or column names on the master which would be regarded as reserved words by the slave, do one of the following:

- Use one or more `ALTER TABLE` statements on the master to change the names of any database objects where these names would be considered reserved words on the slave, and change any SQL statements that use the old names to use the new names instead.
- In any SQL statements using these database object names, write the names as quoted identifiers using backtick characters (```).

For listings of reserved words by MySQL version, see [Reserved Words](#), in the *MySQL Server Version Reference*. For identifier quoting rules, see [Section 9.2](#), “Schema Object Names”.

18.4.1.28 Slave Errors During Replication

If a statement produces the same error (identical error code) on both the master and the slave, the error is logged, but replication continues.

If a statement produces different errors on the master and the slave, the slave SQL thread terminates, and the slave writes a message to its error log and waits for the database administrator to decide what to do about the error. This includes the case that a statement produces an error on the master or the slave, but not both. To address the issue, connect to the slave manually and determine the cause of the problem. `SHOW SLAVE STATUS` is useful for this. Then fix the problem and run `START SLAVE`. For example, you might need to create a nonexistent table before you can start the slave again.

If this error code validation behavior is not desirable, some or all errors can be masked out (ignored) with the `--slave-skip-errors` option.

For nontransactional storage engines such as `MyISAM`, it is possible to have a statement that only partially updates a table and returns an error code. This can happen, for example, on a multiple-row insert that has one row violating a key constraint, or if a long update statement is killed after updating some of the rows. If that happens on the master, the slave expects execution of the statement to result in the same error code. If it does not, the slave SQL thread stops as described previously.

If you are replicating between tables that use different storage engines on the master and slave, keep in mind that the same statement might produce a different error when run against one version of the table, but not the other, or might cause an error for one version of the table, but not the other. For example, since `MyISAM` ignores foreign key constraints, an `INSERT` or `UPDATE` statement accessing an `InnoDB` table on the master might cause a foreign key violation but the same statement performed on a `MyISAM` version of the same table on the slave would produce no such error, causing replication to stop.

18.4.1.29 Replication of Server-Side Help Tables

The server maintains tables in the `mysql` database that store information for the `HELP` statement (see [Section 13.8.3, “HELP Syntax”](#)). These tables can be loaded manually as described at [Section 5.1.10, “Server-Side Help”](#).

Help table content is derived from the MySQL Reference Manual. There are versions of the manual specific to each MySQL release series, so help content is specific to each series as well. Normally, you load a version of help content that matches the server version. This has implications for replication. For example, you would load MySQL 5.6 help content into a MySQL 5.6 master server, but not necessarily replicate that content to a MySQL 5.7 slave server for which 5.7 help content is more appropriate.

This section describes how to manage help table content upgrades when your servers participate in replication. Server versions are one factor in this task. Another is that the help table structure may differ between the master and the slave.

Assume that help content is stored in a file named `fill_help_tables.sql`. In MySQL distributions, this file is located under the `share` or `share/mysql` directory, and the most recent version is always available for download from <http://dev.mysql.com/doc/index-other.html>.

To upgrade help tables, using the following procedure. Connection parameters are not shown for the `mysql` commands discussed here; in all cases, connect to the server using an account such as `root` that has privileges for modifying tables in the `mysql` database.

1. Upgrade your servers by running `mysql_upgrade`, first on the slaves and then on the master. This is the usual principle of upgrading slaves first.
2. Decide whether you want to replicate help table content from the master to its slaves. If not, load the content on the master and each slave individually. Otherwise, check for and resolve any incompatibilities between help table structure on the master and its slaves, then load the content into the master and let it replicate to the slaves.

More detail about these two methods of loading help table content follows.

Loading Help Table Content Without Replication to Slaves

To load help table content without replication, run this command on the master and each slave individually, using a `fill_help_tables.sql` file containing content appropriate to the server version:

```
mysql mysql < fill_help_tables.sql
```

Loading Help Table Content With Replication to Slaves

If you do want to replicate help table content, check for help table incompatibilities between your master and its slaves. The `url` column in the `help_category` and `help_topic` tables was originally `CHAR(128)`, but is `TEXT` in newer MySQL versions to accommodate longer URLs. To check help table structure, use this statement:

```
SELECT TABLE_NAME, COLUMN_NAME, COLUMN_TYPE
FROM INFORMATION_SCHEMA.COLUMNS
WHERE TABLE_SCHEMA = 'mysql'
AND COLUMN_NAME = 'url';
```

For tables with the old structure, the statement produces this result:

```
+-----+-----+-----+
| TABLE_NAME | COLUMN_NAME | COLUMN_TYPE |
+-----+-----+-----+
| help_category | url | char(128) |
| help_topic | url | char(128) |
+-----+-----+-----+
```

For tables with the new structure, the statement produces this result:

```
+-----+-----+-----+
| TABLE_NAME | COLUMN_NAME | COLUMN_TYPE |
+-----+-----+-----+
| help_category | url | text |
| help_topic | url | text |
+-----+-----+-----+
```

If the master and slave both have the old structure or both have the new structure, they are compatible and you can replicate help table content by executing this command on the master:

```
mysql mysql < fill_help_tables.sql
```

The table content will load into the master, then replicate to the slaves.

If the master and slave have incompatible help tables (one server has the old structure and the other has the new), you have a choice between not replicating help table content after all, or making the table structures compatible so that you can replicate the content.

- If you decide not to replicate the content after all, upgrade the master and slaves individually using `mysql` with the `--init-command` option, as described previously.
- If instead you decide to make the table structures compatible, upgrade the tables on the server that has the old structure. Suppose that your master server has the old table structure. Upgrade its tables to the new structure manually by executing these statements (binary logging is disabled here to prevent replication of the changes to the slaves, which already have the new structure):

```
SET sql_log_bin=0;
ALTER TABLE mysql.help_category ALTER COLUMN url TEXT;
ALTER TABLE mysql.help_topic ALTER COLUMN url TEXT;
```

Then run this command on the master:

```
mysql mysql < fill_help_tables.sql
```

The table content will load into the master, then replicate to the slaves.

18.4.1.30 Replication and Server SQL Mode

Using different server SQL mode settings on the master and the slave may cause the same `INSERT` statements to be handled differently on the master and the slave, leading the master and slave to diverge. For best results, you should always use the same server SQL mode on the master and on the slave. This advice applies whether you are using statement-based or row-based replication.

If you are replicating partitioned tables, using different SQL modes on the master and the slave is likely to cause issues. At a minimum, this is likely to cause the distribution of data among partitions to be different in the master's and slave's copies of a given table. It may also cause inserts into partitioned tables that succeed on the master to fail on the slave.

For more information, see [Section 5.1.8, “Server SQL Modes”](#). In particular, see [SQL Mode Changes in MySQL 5.7](#), which describes changes in MySQL 5.7 so that you can assess whether your applications will be affected.

18.4.1.31 Replication Retries and Timeouts

The global system variable `slave_transaction_retries` affects replication as follows: If the slave SQL thread fails to execute a transaction because of an `InnoDB` deadlock or because it exceeded the `InnoDB innodb_lock_wait_timeout` value, or the `NDB TransactionDeadlockDetectionTimeout` or `TransactionInactiveTimeout` value, the slave automatically retries the transaction `slave_transaction_retries` times before stopping with an error. The default value is 10. The total retry count can be seen in the output of `SHOW STATUS`; see [Section 5.1.7, “Server Status Variables”](#).

18.4.1.32 Replication and Time Zones

By default, master and slave servers assume that they are in the same time zone. If you are replicating between servers in different time zones, the time zone must be set on both master and slave. Otherwise, statements depending on the local time on the master are not replicated properly, such as statements that use the `NOW()` or `FROM_UNIXTIME()` functions. Set the time zone in which MySQL server runs by using the `--timezone=timezone_name` option of the `mysqld_safe` script or by setting the `TZ` environment variable. See also [Section 18.4.1.16, “Replication and System Functions”](#).

18.4.1.33 Replication and Transactions

Mixing transactional and nontransactional statements within the same transaction. In general, you should avoid transactions that update both transactional and nontransactional tables in a replication environment. You should also avoid using any statement that accesses both transactional (or temporary) and nontransactional tables and writes to any of them.

The server uses these rules for binary logging:

- If the initial statements in a transaction are nontransactional, they are written to the binary log immediately. The remaining statements in the transaction are cached and not written to the binary log until the transaction is committed. (If the transaction is rolled back, the cached statements are written to the binary log only if they make nontransactional changes that cannot be rolled back. Otherwise, they are discarded.)
- For statement-based logging, logging of nontransactional statements is affected by the `binlog_direct_non_transactional_updates` system variable. When this variable is `OFF`

(the default), logging is as just described. When this variable is `ON`, logging occurs immediately for nontransactional statements occurring anywhere in the transaction (not just initial nontransactional statements). Other statements are kept in the transaction cache and logged when the transaction commits. `binlog_direct_non_transactional_updates` has no effect for row-format or mixed-format binary logging.

Transactional, nontransactional, and mixed statements.

To apply those rules, the server considers a statement nontransactional if it changes only nontransactional tables, and transactional if it changes only transactional tables. In MySQL 8.0, a statement that references both nontransactional and transactional tables and updates *any* of the tables involved, is considered a “mixed” statement. (In previous MySQL release series, a statement that changed both nontransactional and transactional tables was considered mixed.) Mixed statements, like transactional statements, are cached and logged when the transaction commits.

A mixed statement that updates a transactional table is considered unsafe if the statement also performs either of the following actions:

- Updates or reads a transactional table
- Reads a nontransactional table and the transaction isolation level is less than `REPEATABLE_READ`

A mixed statement following the update of a transactional table within a transaction is considered unsafe if it performs either of the following actions:

- Updates any table and reads from any temporary table
- Updates a nontransactional table and `binlog_direct_non_trans_update` is `OFF`

For more information, see [Section 18.2.1.3, “Determination of Safe and Unsafe Statements in Binary Logging”](#).

Note

A mixed statement is unrelated to mixed binary logging format.

In situations where transactions mix updates to transactional and nontransactional tables, the order of statements in the binary log is correct, and all needed statements are written to the binary log even in case of a `ROLLBACK`. However, when a second connection updates the nontransactional table before the first connection transaction is complete, statements can be logged out of order because the second connection update is written immediately after it is performed, regardless of the state of the transaction being performed by the first connection.

Using different storage engines on master and slave. It is possible to replicate transactional tables on the master using nontransactional tables on the slave. For example, you can replicate an `InnoDB` master table as a `MyISAM` slave table. However, if you do this, there are problems if the slave is stopped in the middle of a `BEGIN ... COMMIT` block because the slave restarts at the beginning of the `BEGIN` block.

In MySQL 8.0, it is also safe to replicate transactions from `MyISAM` tables on the master to transactional tables—such as tables that use the `InnoDB` storage engine—on the slave. In such cases, an `AUTOCOMMIT=1` statement issued on the master is replicated, thus enforcing `AUTOCOMMIT` mode on the slave.

When the storage engine type of the slave is nontransactional, transactions on the master that mix updates of transactional and nontransactional tables should be avoided because they can cause inconsistency of the data between the master transactional table and the slave nontransactional table. That is, such transactions can lead to master storage engine-specific behavior with the possible effect of replication going out of synchrony. MySQL does not issue a warning about this currently, so extra care should be taken when replicating transactional tables from the master to nontransactional tables on the slaves.

Changing the binary logging format within transactions. The `binlog_format` system variable is read-only as long as a transaction is in progress.

Every transaction (including `autocommit` transactions) is recorded in the binary log as though it starts with a `BEGIN` statement, and ends with either a `COMMIT` or a `ROLLBACK` statement. In MySQL 8.0, this true is even for statements affecting tables that use a nontransactional storage engine (such as `MyISAM`).

18.4.1.34 Replication and Transaction Inconsistencies

Inconsistencies in the sequence of transactions that have been executed from the relay log can occur depending on your replication configuration. This section explains how to avoid inconsistencies and solve any problems they cause.

The following types of inconsistencies can exist:

- *Half-applied transactions.* A transaction which updates non-transactional tables has applied some but not all of its changes.
- *Gaps.* A gap is a transaction that has not been (fully) applied, even though some later transaction has been applied. Gaps can only appear when using a multi-threaded slave. To avoid gaps occurring, set `slave_preserve_commit_order=1`, which requires `slave_parallel_type=LOGICAL_CLOCK`, and that `log-bin` and `log-slave-updates` are also enabled.
- *Gap-free low-watermark position.* Even in the absence of gaps, it is possible that transactions after `Exec_master_log_pos` have not been applied. That is, all transactions up to point `N` have been applied, and no transactions after `N` have been applied, but `Exec_master_log_pos` has a value smaller than `N`. This can only happen on multi-threaded slaves. Enabling `slave_preserve_commit_order` does *not* prevent gap-free low-watermark positions.

The following scenarios are relevant to the existence of half-applied transactions, gaps, and gap-free low-watermark position inconsistencies:

1. While slave threads are running, there may be gaps and half-applied transactions.
2. `mysqld` shuts down. Both clean and unclean shutdown abort ongoing transactions and may leave gaps and half-applied transactions.
3. `KILL` of replication threads (the SQL thread when using a single-threaded slave, the coordinator thread when using a multi-threaded slave). This aborts ongoing transactions and may leave gaps and half-applied transactions.
4. Error in applier threads. This may leave gaps. If the error is in a mixed transaction, that transaction is half-applied. When using a multi-threaded slave, workers which have not received an error complete their queues, so it may take time to stop all threads.
5. `STOP SLAVE` when using a multi-threaded slave. After issuing `STOP SLAVE`, the slave waits for any gaps to be filled and then updates `Exec_master_log_pos`. This ensures it never leaves gaps or gap-free low-watermark positions, unless any of the cases above applies (in other words, before `STOP SLAVE` completes, either an error happens, or another thread issues `KILL`, or the server restarts. In these cases, `STOP SLAVE` returns successfully.)
6. If the last transaction in the relay log is only half-received and the multi-threaded slave coordinator has started to schedule the transaction to a worker, then `STOP SLAVE` waits up to 60 seconds for the transaction to be received. After this timeout, the coordinator gives up and aborts the transaction. If the transaction is mixed, it may be left half-completed.
7. `STOP SLAVE` when using a single-threaded slave. If the ongoing transaction only updates transactional tables, it is rolled back and `STOP SLAVE` stops immediately. If the ongoing transaction

is mixed, `STOP SLAVE` waits up to 60 seconds for the transaction to complete. After this timeout, it aborts the transaction, so it may be left half-completed.

The global variable `rpl_stop_slave_timeout` is unrelated to the process of stopping the replication threads. It only makes the client that issues `STOP SLAVE` return to the client, but the replication threads continue to try to stop.

If a replication channel has gaps, it has the following consequences:

1. The slave database is in a state that may never have existed on the master.
2. The field `Exec_master_log_pos` in `SHOW SLAVE STATUS` is only a "low-watermark". In other words, transactions appearing before the position are guaranteed to have committed, but transactions after the position may have committed or not.
3. `CHANGE MASTER TO` statements for that channel fail with an error, unless the applier threads are running and the `CHANGE MASTER TO` statement only sets receiver options.
4. If `mysqld` is started with `--relay-log-recovery`, no recovery is done for that channel, and a warning is printed.
5. If `mysqldump` is used with `--dump-slave`, it does not record the existence of gaps; thus it prints `CHANGE MASTER TO` with `RELAY_LOG_POS` set to the low-watermark position in `Exec_master_log_pos`.

After applying the dump on another server, and starting the replication threads, transactions appearing after the position are replicated again. Note that this is harmless if GTIDs are enabled (however, in that case it is not recommended to use `--dump-slave`).

If a replication channel has a gap-free low-watermark position, cases 2 to 5 above apply, but case 1 does not.

The gap-free low-watermark position information is persisted in binary format in the internal table `mysql.slave_worker_info`. `START SLAVE [SQL_THREAD]` always consults this information so that it applies only the correct transactions. This remains true even if `slave_parallel_workers` has been changed to 0 before `START SLAVE`, and even if `START SLAVE` is used with `UNTIL` clauses. `START SLAVE UNTIL SQL_AFTER_MTS_GAPS` only applies as many transactions as needed in order to fill in the gaps. If `START SLAVE` is used with `UNTIL` clauses that tell it to stop before it has consumed all the gaps, then it leaves remaining gaps.

Warning

`RESET SLAVE` removes the relay logs and resets the replication position. Thus issuing `RESET SLAVE` on a slave with gaps means the slave loses any information about the gaps, without correcting the gaps.

`slave-preserve-commit-order` ensures that there are no gaps. However, it is still possible that `Exec_master_log_pos` is just a gap-free low-watermark position in scenarios 1 to 4 above. That is, there may be transactions after `Exec_master_log_pos` which have been applied. Therefore the cases numbered 2 to 5 above (but not case 1) apply, even when `slave-preserve-commit-order` is enabled.

18.4.1.35 Replication and Triggers

With statement-based replication, triggers executed on the master also execute on the slave. With row-based replication, triggers executed on the master do not execute on the slave. Instead, the row changes on the master resulting from trigger execution are replicated and applied on the slave.

This behavior is by design. If under row-based replication the slave applied the triggers as well as the row changes caused by them, the changes would in effect be applied twice on the slave, leading to different data on the master and the slave.

If you want triggers to execute on both the master and the slave—perhaps because you have different triggers on the master and slave—you must use statement-based replication. However, to enable slave-side triggers, it is not necessary to use statement-based replication exclusively. It is sufficient to switch to statement-based replication only for those statements where you want this effect, and to use row-based replication the rest of the time.

A statement invoking a trigger (or function) that causes an update to an `AUTO_INCREMENT` column is not replicated correctly using statement-based replication. MySQL 8.0 marks such statements as unsafe. (Bug #45677)

A trigger can have triggers for different combinations of trigger event (`INSERT`, `UPDATE`, `DELETE`) and action time (`BEFORE`, `AFTER`), and multiple triggers are permitted.

For brevity, “multiple triggers” here is shorthand for “multiple triggers that have the same trigger event and action time.”

Upgrades. Suppose that you upgrade an old server that does not support multiple triggers (lower than 5.7.2) to a version that does (MySQL 5.7.2 or higher). If the new server is a replication master and has old slaves that do not support multiple triggers, an error occurs on those slaves if a trigger is created on the master for a table that already has a trigger with the same trigger event and action time. To avoid this problem, upgrade the slaves first, then upgrade the master.

Downgrades. If you downgrade a server that supports multiple triggers to an older version that does not, the downgrade has these effects:

- For each table that has triggers, all trigger definitions are in the `.TRG` file for the table. However, if there are multiple triggers with the same trigger event and action time, the server executes only one of them when the trigger event occurs. For information about `.TRG` files, see [Table Trigger Storage](#).
- If triggers for the table are added or dropped subsequent to the downgrade, the server rewrites the table's `.TRG` file. The rewritten file retains only one trigger per combination of trigger event and action time; the others are lost.

To avoid these problems, modify your triggers before downgrading. For each table that has multiple triggers per combination of trigger event and action time, convert each such set of triggers to a single trigger as follows:

1. For each trigger, create a stored routine that contains all the code in the trigger. Values accessed using `NEW` and `OLD` can be passed to the routine using parameters. If the trigger needs a single result value from the code, you can put the code in a stored function and have the function return the value. If the trigger needs multiple result values from the code, you can put the code in a stored procedure and return the values using `OUT` parameters.
2. Drop all triggers for the table.
3. Create one new trigger for the table that invokes the stored routines just created. The effect for this trigger is thus the same as the multiple triggers it replaces.

18.4.1.36 Replication and TRUNCATE TABLE

`TRUNCATE TABLE` is normally regarded as a DML statement, and so would be expected to be logged and replicated using row-based format when the binary logging mode is `ROW` or `MIXED`. However this caused issues when logging or replicating, in `STATEMENT` or `MIXED` mode, tables that used transactional storage engines such as `InnoDB` when the transaction isolation level was `READ COMMITTED` or `READ UNCOMMITTED`, which precludes statement-based logging.

`TRUNCATE TABLE` is treated for purposes of logging and replication as DDL rather than DML so that it can be logged and replicated as a statement. However, the effects of the statement as applicable to `InnoDB` and other transactional tables on replication slaves still follow the rules described in [Section 13.1.30, “TRUNCATE TABLE Syntax”](#) governing such tables. (Bug #36763)

18.4.1.37 Replication and User Name Length

The maximum length of MySQL user names is 32 characters in MySQL 5.7.8 or higher. Replication of user names longer than 16 characters to a slave that supports only shorter user names will fail. However, this should occur only when replicating from a newer master to an older slave, which is not a recommended configuration.

18.4.1.38 Replication and Variables

System variables are not replicated correctly when using `STATEMENT` mode, except for the following variables when they are used with session scope:

- `auto_increment_increment`
- `auto_increment_offset`
- `character_set_client`
- `character_set_connection`
- `character_set_database`
- `character_set_server`
- `collation_connection`
- `collation_database`
- `collation_server`
- `foreign_key_checks`
- `identity`
- `last_insert_id`
- `lc_time_names`
- `pseudo_thread_id`
- `sql_auto_is_null`
- `time_zone`
- `timestamp`
- `unique_checks`

When `MIXED` mode is used, the variables in the preceding list, when used with session scope, cause a switch from statement-based to row-based logging. See [Section 5.4.4.3, “Mixed Binary Logging Format”](#).

`sql_mode` is also replicated except for the `NO_DIR_IN_CREATE` mode; the slave always preserves its own value for `NO_DIR_IN_CREATE`, regardless of changes to it on the master. This is true for all replication formats.

However, when `mysqlbinlog` parses a `SET @@sql_mode = mode` statement, the full `mode` value, including `NO_DIR_IN_CREATE`, is passed to the receiving server. For this reason, replication of such a statement may not be safe when `STATEMENT` mode is in use.

The `default_storage_engine` system variable is not replicated, regardless of the logging mode; this is intended to facilitate replication between different storage engines.

The `read_only` system variable is not replicated. In addition, the enabling this variable has different effects with regard to temporary tables, table locking, and the `SET PASSWORD` statement in different MySQL versions.

The `max_heap_table_size` system variable is not replicated. Increasing the value of this variable on the master without doing so on the slave can lead eventually to `Table is full` errors on the slave when trying to execute `INSERT` statements on a `MEMORY` table on the master that is thus permitted to grow larger than its counterpart on the slave. For more information, see [Section 18.4.1.23, “Replication and MEMORY Tables”](#).

In statement-based replication, session variables are not replicated properly when used in statements that update tables. For example, the following sequence of statements will not insert the same data on the master and the slave:

```
SET max_join_size=1000;
INSERT INTO mytable VALUES(@@max_join_size);
```

This does not apply to the common sequence:

```
SET time_zone=...;
INSERT INTO mytable VALUES(CONVERT_TZ(..., ..., @@time_zone));
```

Replication of session variables is not a problem when row-based replication is being used, in which case, session variables are always replicated safely. See [Section 18.2.1, “Replication Formats”](#).

In MySQL 8.0, the following session variables are written to the binary log and honored by the replication slave when parsing the binary log, regardless of the logging format:

- `sql_mode`
- `foreign_key_checks`
- `unique_checks`
- `character_set_client`
- `collation_connection`
- `collation_database`
- `collation_server`
- `sql_auto_is_null`

Important

Even though session variables relating to character sets and collations are written to the binary log, replication between different character sets is not supported.

To help reduce possible confusion, we recommend that you always use the same setting for the `lower_case_table_names` system variable on both master and slave, especially when you are running MySQL on platforms with case-sensitive file systems.

18.4.1.39 Replication and Views

Views are always replicated to slaves. Views are filtered by their own name, not by the tables they refer to. This means that a view can be replicated to the slave even if the view contains a table that would normally be filtered out by `replication-ignore-table` rules. Care should therefore be taken to ensure that views do not replicate table data that would normally be filtered for security reasons.

Replication from a table to a same-named view is supported using statement-based logging, but not when using row-based logging. Trying to do so when row-based logging is in effect causes an error.

18.4.2 Replication Compatibility Between MySQL Versions

MySQL supports replication from one release series to the next higher release series. For example, you can replicate from a master running MySQL 5.6 to a slave running MySQL 5.7, from a master running MySQL 5.7 to a slave running MySQL 8.0, and so on.

However, you may encounter difficulties when replicating from an older master to a newer slave if the master uses statements or relies on behavior no longer supported in the version of MySQL used on the slave. For example, in MySQL 5.5, `CREATE TABLE ... SELECT` statements are permitted to change tables other than the one being created, but are no longer allowed to do so in MySQL 5.6 (see [Section 18.4.1.6, “Replication of CREATE TABLE ... SELECT Statements”](#)).

The use of more than two MySQL Server versions is not supported in replication setups involving multiple masters, regardless of the number of master or slave MySQL servers. This restriction applies not only to release series, but to version numbers within the same release series as well. For example, if you are using a chained or circular replication setup, you cannot use MySQL 8.0.1, MySQL 8.0.2, and MySQL 8.0.4 concurrently, although you could use any two of these releases together.

Important

It is strongly recommended to use the most recent release available within a given MySQL release series because replication (and other) capabilities are continually being improved. It is also recommended to upgrade masters and slaves that use early releases of a release series of MySQL to GA (production) releases when the latter become available for that release series.

Replication from newer masters to older slaves may be possible, but is generally not supported. This is due to a number of factors:

- **Binary log format changes.** The binary log format can change between major releases. While we attempt to maintain backward compatibility, this is not always possible.

This also has significant implications for upgrading replication servers; see [Section 18.4.3, “Upgrading a Replication Setup”](#), for more information.

- For more information about row-based replication, see [Section 18.2.1, “Replication Formats”](#).
- **SQL incompatibilities.** You cannot replicate from a newer master to an older slave using statement-based replication if the statements to be replicated use SQL features available on the master but not on the slave.

However, if both the master and the slave support row-based replication, and there are no data definition statements to be replicated that depend on SQL features found on the master but not on the slave, you can use row-based replication to replicate the effects of data modification statements even if the DDL run on the master is not supported on the slave.

For more information on potential replication issues, see [Section 18.4.1, “Replication Features and Issues”](#).

18.4.3 Upgrading a Replication Setup

When you upgrade servers that participate in a replication setup, the procedure for upgrading depends on the current server versions and the version to which you are upgrading. This section provides information about how upgrading affects replication. For general information about upgrading MySQL, see [Section 2.10.1, “Upgrading MySQL”](#)

When you upgrade a master to 8.0 from an earlier MySQL release series, you should first ensure that all the slaves of this master are using the same 8.0.x release. If this is not the case, you should first

upgrade the slaves. To upgrade each slave, shut it down, upgrade it to the appropriate 8.0.x version, restart it, and restart replication. Relay logs created by the slave after the upgrade are in 8.0 format.

Changes affecting operations in strict SQL mode may result in replication failure on an updated slave. For example, the server restricts insertion of a `DEFAULT` value of 0 for temporal data types in strict mode (`STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES`). A resulting incompatibility for replication if you use statement-based logging (`binlog_format=STATEMENT`) is that if a slave is upgraded, a nonupgraded master will execute statements without error that may fail on the slave and replication will stop. To deal with this, stop all new statements on the master and wait until the slaves catch up. Then upgrade the slaves. Alternatively, if you cannot stop new statements, temporarily change to row-based logging on the master (`binlog_format=ROW`) and wait until all slaves have processed all binary logs produced up to the point of this change. Then upgrade the slaves.

After the slaves have been upgraded, shut down the master, upgrade it to the same 8.0.x release as the slaves, and restart it. If you had temporarily changed the master to row-based logging, change it back to statement-based logging. The 8.0 master is able to read the old binary logs written prior to the upgrade and to send them to the 8.0 slaves. The slaves recognize the old format and handle it properly. Binary logs created by the master subsequent to the upgrade are in 8.0 format. These too are recognized by the 8.0 slaves.

In other words, when upgrading to MySQL 8.0, the slaves must be MySQL 8.0 before you can upgrade the master to 8.0. Note that downgrading from 8.0 to older versions does not work so simply: You must ensure that any 8.0 binary log or relay log has been fully processed, so that you can remove it before proceeding with the downgrade.

Some upgrades may require that you drop and re-create database objects when you move from one MySQL series to the next. For example, collation changes might require that table indexes be rebuilt. Such operations, if necessary, are detailed at [Section 2.10.1.1, “Changes Affecting Upgrades to MySQL 8.0”](#). It is safest to perform these operations separately on the slaves and the master, and to disable replication of these operations from the master to the slave. To achieve this, use the following procedure:

1. Stop all the slaves and upgrade them. Restart them with the `--skip-slave-start` option so that they do not connect to the master. Perform any table repair or rebuilding operations needed to re-create database objects, such as use of `REPAIR TABLE` or `ALTER TABLE`, or dumping and reloading tables or triggers.
2. Disable the binary log on the master. To do this without restarting the master, execute a `SET sql_log_bin = 0` statement. Alternatively, stop the master and restart it without the `--log-bin` option. If you restart the master, you might also want to disallow client connections. For example, if all clients connect using TCP/IP, use the `--skip-networking` option when you restart the master.
3. With the binary log disabled, perform any table repair or rebuilding operations needed to re-create database objects. The binary log must be disabled during this step to prevent these operations from being logged and sent to the slaves later.
4. Re-enable the binary log on the master. If you set `sql_log_bin` to 0 earlier, execute a `SET sql_log_bin = 1` statement. If you restarted the master to disable the binary log, restart it with `--log-bin`, and without `--skip-networking` so that clients and slaves can connect.
5. Restart the slaves, this time without the `--skip-slave-start` option.

If you are upgrading an existing replication setup from a version of MySQL that does not support global transaction identifiers to a version that does, you should not enable GTIDs on either the master or the slave before making sure that the setup meets all the requirements for GTID-based replication. For example `server_uuid`, which was added in MySQL 5.6, must exist for GTIDs to function correctly. See [Section 18.1.3.2, “Setting Up Replication Using GTIDs”](#), which contains information about converting existing replication setups to use GTID-based replication.

18.4.4 Troubleshooting Replication

If you have followed the instructions but your replication setup is not working, the first thing to do is *check the error log for messages*. Many users have lost time by not doing this soon enough after encountering problems.

If you cannot tell from the error log what the problem was, try the following techniques:

- Verify that the master has binary logging enabled by issuing a `SHOW MASTER STATUS` statement. If logging is enabled, `Position` is nonzero. If binary logging is not enabled, verify that you are running the master with the `--log-bin` option.
- Verify that the master and slave both were started with the `--server-id` option and that the ID value is unique on each server.
- Verify that the slave is running. Use `SHOW SLAVE STATUS` to check whether the `Slave_IO_Running` and `Slave_SQL_Running` values are both `Yes`. If not, verify the options that were used when starting the slave server. For example, `--skip-slave-start` prevents the slave threads from starting until you issue a `START SLAVE` statement.
- If the slave is running, check whether it established a connection to the master. Use `SHOW PROCESSLIST`, find the I/O and SQL threads and check their `State` column to see what they display. See [Section 18.2.2, “Replication Implementation Details”](#). If the I/O thread state says `Connecting to master`, check the following:
 - Verify the privileges for the user being used for replication on the master.
 - Check that the host name of the master is correct and that you are using the correct port to connect to the master. The port used for replication is the same as used for client network communication (the default is `3306`). For the host name, ensure that the name resolves to the correct IP address.
 - Check that networking has not been disabled on the master or slave. Look for the `skip-networking` option in the configuration file. If present, comment it out or remove it.
 - If the master has a firewall or IP filtering configuration, ensure that the network port being used for MySQL is not being filtered.
 - Check that you can reach the master by using `ping` or `traceroute/tracert` to reach the host.
- If the slave was running previously but has stopped, the reason usually is that some statement that succeeded on the master failed on the slave. This should never happen if you have taken a proper snapshot of the master, and never modified the data on the slave outside of the slave thread. If the slave stops unexpectedly, it is a bug or you have encountered one of the known replication limitations described in [Section 18.4.1, “Replication Features and Issues”](#). If it is a bug, see [Section 18.4.5, “How to Report Replication Bugs or Problems”](#), for instructions on how to report it.
- If a statement that succeeded on the master refuses to run on the slave, try the following procedure if it is not feasible to do a full database resynchronization by deleting the slave's databases and copying a new snapshot from the master:
 1. Determine whether the affected table on the slave is different from the master table. Try to understand how this happened. Then make the slave's table identical to the master's and run `START SLAVE`.
 2. If the preceding step does not work or does not apply, try to understand whether it would be safe to make the update manually (if needed) and then ignore the next statement from the master.
 3. If you decide that the slave can skip the next statement from the master, issue the following statements:

```
mysql> SET GLOBAL sql_slave_skip_counter = N;
```

```
mysql> START SLAVE;
```

The value of *N* should be 1 if the next statement from the master does not use `AUTO_INCREMENT` or `LAST_INSERT_ID()`. Otherwise, the value should be 2. The reason for using a value of 2 for statements that use `AUTO_INCREMENT` or `LAST_INSERT_ID()` is that they take two events in the binary log of the master.

See also [Section 13.4.2.5, “SET GLOBAL sql_slave_skip_counter Syntax”](#).

4. If you are sure that the slave started out perfectly synchronized with the master, and that no one has updated the tables involved outside of the slave thread, then presumably the discrepancy is the result of a bug. If you are running the most recent version of MySQL, please report the problem. If you are running an older version, try upgrading to the latest production release to determine whether the problem persists.

18.4.5 How to Report Replication Bugs or Problems

When you have determined that there is no user error involved, and replication still either does not work at all or is unstable, it is time to send us a bug report. We need to obtain as much information as possible from you to be able to track down the bug. Please spend some time and effort in preparing a good bug report.

If you have a repeatable test case that demonstrates the bug, please enter it into our bugs database using the instructions given in [Section 1.7, “How to Report Bugs or Problems”](#). If you have a “phantom” problem (one that you cannot duplicate at will), use the following procedure:

1. Verify that no user error is involved. For example, if you update the slave outside of the slave thread, the data goes out of synchrony, and you can have unique key violations on updates. In this case, the slave thread stops and waits for you to clean up the tables manually to bring them into synchrony. *This is not a replication problem. It is a problem of outside interference causing replication to fail.*
2. Run the slave with the `--log-slave-updates` and `--log-bin` options. These options cause the slave to log the updates that it receives from the master into its own binary logs.
3. Save all evidence before resetting the replication state. If we have no information or only sketchy information, it becomes difficult or impossible for us to track down the problem. The evidence you should collect is:
 - All binary log files from the master
 - All binary log files from the slave
 - The output of `SHOW MASTER STATUS` from the master at the time you discovered the problem
 - The output of `SHOW SLAVE STATUS` from the slave at the time you discovered the problem
 - Error logs from the master and the slave
4. Use `mysqlbinlog` to examine the binary logs. The following should be helpful to find the problem statement. `log_file` and `log_pos` are the `Master_Log_File` and `Read_Master_Log_Pos` values from `SHOW SLAVE STATUS`.

```
shell> mysqlbinlog --start-position=log_pos log_file | head
```

After you have collected the evidence for the problem, try to isolate it as a separate test case first. Then enter the problem with as much information as possible into our bugs database using the instructions at [Section 1.7, “How to Report Bugs or Problems”](#).

This section provides user documentation for MySQL Shell, which enables you to prototype code using the X DevAPI to communicate with a MySQL Server running the X Plugin.

MySQL Shell is an advanced command-line client and code editor for the MySQL Server. In addition to SQL, MySQL Shell also offers scripting capabilities for JavaScript and Python. When MySQL Shell is connected to the MySQL Server through the X Protocol, the X DevAPI can be used to work with both relational and document data.

19.1 MySQL Shell Features

The following features are available in MySQL Shell.

Interactive Code Execution

MySQL Shell provides an interactive code execution mode, where you type code at the MySQL Shell prompt and each entered statement is processed, with the result of the processing printed onscreen.

Supported Languages

MySQL Shell processes code in the following languages: JavaScript, Python and SQL. Any entered code is processed as one of these languages, based on the language that is currently active. There are also specific commands that are treated as “shell commands” which enable you to configure MySQL Shell or retrieve information. For more information see [Section 19.4.1, “MySQL Shell Commands”](#).

Batch Code Execution

In addition to the interactive execution of code, MySQL Shell can also take code from different sources and process it. This method of processing code in a non-interactive way is called *Batch Execution*.

As batch execution mode is intended for script processing of a single language, it is limited to having minimal non-formatted output and disabling the execution of commands. To avoid these limitations, use the `--interactive` command-line option, which tells MySQL Shell to execute the input as if it were an interactive session. In this mode the input is processed *line by line* just as if each line were typed in an interactive session. For more information see [Section 19.3.5, “Batch Mode Made Interactive”](#).

Output Formats

MySQL Shell provides output in different formats depending on how it is used: Tabbed, Table and JSON. For more information see [Section 19.3.3, “Output Formats”](#).

Multiple-line Support

Multiple-line code can be written using a command, enabling MySQL Shell to cache multiple lines and then execute them as a single statement. For more information see [Section 19.3.5.1, “Multiple-line Support”](#).

Application Log

MySQL Shell can be configured to log information about the execution process. For more information see [Section 19.5, “MySQL Shell Application Log”](#).

X DevAPI

Code written in MySQL Shell uses the X DevAPI, provided for Python and JavaScript. For general information, see [X DevAPI User Guide](#). For specific documentation on the implementation of the API see [JavaScript](#) and [Python](#).

X Protocol Support

MySQL Shell is designed to provide an integrated command-line client for all MySQL products which support X Protocol. The development features of MySQL Shell are designed for sessions using the X Protocol. MySQL Shell can also connect to MySQL Servers that do not support the X Protocol using the legacy MySQL Protocol. A minimal set of features from the X DevAPI are available for sessions created using the legacy MySQL protocol.

Global Session

Interaction with a MySQL Server is done through a Session object. For Python and JavaScript, a Session can be created through the `getSession` and `getNodeSession` functions of the `mysqlx` module. If a session is created in JavaScript mode using any of these methods, it is available only in JavaScript mode. The same happens if the session is created in Python mode. None of these sessions can be used in SQL mode.

For SQL Mode, the concept of Global Session is supported by the MySQL Shell. A Global Session is created when the connection information is passed to MySQL Shell using command-line options, or by using the `\connect` command.

The Global Session is used to execute statements in SQL mode and the same session is available in both Python or JavaScript modes. When a Global Session is created, a variable called `session` is set in the scripting languages, so you can execute code in the different languages by switching the active mode.

For more information, see [Section 19.2.1, “MySQL Shell Sessions”](#).

19.2 Getting Started with MySQL Shell

This section describes how to get started with MySQL Shell. This section assumes you have a MySQL Server running X Plugin and that you have installed MySQL Shell, see [Section 20.3, “Setting Up MySQL as a Document Store”](#).

19.2.1 MySQL Shell Sessions

This section explains the different types of sessions in MySQL Shell and how to create and configure them.

19.2.1.1 MySQL Shell Sessions Explained

MySQL Shell is a unified interface to operate MySQL Server through scripting languages such as JavaScript or Python. To maintain compatibility with previous versions, SQL can also be executed in certain modes. A connection to a MySQL server is required. In MySQL Shell these connections are handled by a *Session* object.

The following types of Session object are available:

- *XSession*: Use this session type for new application development. It offers the best integration with MySQL Server, and therefore, it is used by default. SQL execution is not supported and therefore it is not compatible with MySQL Shell's *SQL Mode*.
- *Node Session*: Use this session type for SQL execution on a MySQL Server with the X Protocol enabled. SQL execution is available with this session type, therefore it can be used in MySQL Shell's *SQL Mode*.

This session type should only be used when connecting *directly* to an X Protocol enabled MySQL Server.

- *Classic Session* Use this session type to interact with MySQL Servers that do not have the X Protocol enabled. SQL execution is available with this session type, therefore it can be used in MySQL Shell's *SQL Mode*.

The development API available for this type of session is very limited. For example, there are no CRUD operations, no collection handling, and binding is not supported.

19.2.1.2 Choosing a MySQL Shell Session Type

MySQL Shell creates an *XSession* object by default. To choose which type of session should be created, use one of these options:

- `--node` creates a Node Session.
- `--classic` creates a Classic Session.
- `--x` creates an *XSession*.

For more information, see [Section 19.2.2.1, “Connecting using a URI String”](#) and [Section 19.2.2.2, “Connecting using Individual Parameters”](#).

19.2.2 MySQL Shell Connections

MySQL Shell can be configured to connect to a MySQL Server using command options when starting the application, or from within MySQL Shell itself using the `\connect` command. The address of the MySQL Server which you want to connect to can be specified using individual parameters, such as user, hostname and port, or using a Uniform Resource Identifier (URI) in the format `user@host:port/schema`, such as `mike@myserver:33060/testDB`. The following sections describe these connection methods.

Important

Regardless of the method you choose to connect it is important to understand how passwords are handled by MySQL Shell. By default connections are assumed to require a password. The password is requested at the login prompt. To specify a password-less account use the `--password=` option and do not specify a password, or use a `:` after the `user` in a URI and do not specify a password.

If you do not specify parameters for a connection the following defaults are used:

- user defaults to the current system user name

- host defaults to localhost
- port defaults to the X Plugin port 33060 when using an X Session, and port 3306 when using a Classic session

MySQL Shell connections using X Protocol *always* use TCP, using Unix sockets is not supported. MySQL Shell connections using MySQL Protocol default to using Unix sockets when the following conditions are met:

- `--port` is not specified
- `--host` is not specified or it is equal to `localhost`
- `--socket` is provided with a path to a socket
- `--classic` is specified

If `--host` is specified but it is not `localhost`, a TCP connection is established. In this case, if `--port` is not specified the default value of 3306 is used. If the conditions are met for a socket connection but `--socket` is not specified then the default socket is used, see [Section 4.2.2, “Connecting to the MySQL Server”](#).

19.2.2.1 Connecting using a URI String

You configure the MySQL Server which MySQL Shell connects to by passing the connection data in string format using the `--uri` command option.

Use the following format:

```
[dbuser[:[dbpassword]]@]host[:port][/schema]
```

Descriptions of these options:

- `dbuser`: specifies the MySQL user account to be used for the authentication process.
- `dbpassword`: specifies the dbuser password to be used for the authentication process.

Warning

Storing the password in the URI is not recommended.

- `host`: specifies the host to which the session object connects. If not specified, `localhost` is used by default.
- `port`: specifies which port the target MySQL server is listening on for the connection. If not specified, 33060 is used by default for the X Protocol enabled sessions, and 3306 is the default for traditional MySQL protocol sessions.
- `schema`: specifies the database to be set as default when the session is established.

If no password is specified using the URI, which is recommended, then the password is prompted for. The following examples show how to use these command options:

- Connect with a Node Session at port 33065.

```
shell> mysqlsh --uri user@localhost:33065 --node
```

- Connect with a Classic Session.

```
shell> mysqlsh --uri user@localhost --classic
```

Although using a password-less account is not recommended, you can specify a user without a password using a `:` after the user name, for example:

```
shell> mysqlsh --uri user:@localhost
```

19.2.2.2 Connecting using Individual Parameters

In addition to specifying connection parameters using a URI, it is also possible to define the connection data using separate parameters for each value.

Use the following parameters:

- `--dbuser (-u) value`
- `--dbpassword value`
- `--host (-h) value`
- `--port (-P) value`
- `--schema (-D) value`
- `--password (-p)`
- `--socket (-S)`

The first 5 parameters match the tokens used in the URI format described at [Section 19.2.2.1, “Connecting using a URI String”](#).

The `--password` parameter indicates the user should connect *without* a password.

For consistency, the following aliases are supported for some parameters:

- `--user` is equivalent to `--dbuser`
- `--password` is equivalent to `--dbpassword`
- `--database` is equivalent to `--schema`

When parameters are specified in multiple ways, the following rules apply:

- If an argument is specified more than once the value of the last appearance is used.
- If both individual connection arguments and `--uri` are specified, the value of `--uri` is taken as the base and the values of the individual arguments override the specific component from the base URI.

Attempt to establish an XSession with a specified user at port 33065.

```
shell> mysqlsh -u user -h localhost -P 33065
```

Attempt to establish a Classic Session with a specified user.

```
shell> mysqlsh -u user -h localhost --classic
```

Attempt to establish a Node Session with a specified user.

```
shell> mysqlsh --node -u user -h localhost
```

19.2.2.3 Using SSL for Secure Connections

Using SSL is possible when connecting to an SSL enabled MySQL server.

To configure an SSL connection, use the following command options:

- `--ssl`: This enables or disables connections through SSL. If set to 0, the other SSL command options are ignored.
- `--ssl-ca=filename`: The path to a file in PEM format that contains a list of trusted SSL certificate authorities.
- `--ssl-cert=filename`: The name of the SSL certificate file in PEM format to use for establishing a secure connection.
- `--ssl-key=filename`: The name of the SSL key file in PEM format to use for establishing a secure connection.

The `--ssl` option is assumed to be 1 (enabled) if the other SSL options are set.

19.2.2.4 Connecting using both URI and Individual Parameters

When the `--uri` option is specified in combination with some of the individual parameters, the address specified by the `--uri` option is used as the base connection data and the values provided using individual parameters override the corresponding value from the URI. If the `--user` option is used, it would replace any user specified as part of a URI.

For example to establish an XSession and override `user` from the URI:

```
shell> mysqlsh --uri user@localhost:33065 --user otheruser
```

19.2.2.5 Creating a Session Using Shell Commands

If you open MySQL Shell without specifying connection parameters, MySQL Shell opens without an established global session. It is possible to establish a global session once MySQL Shell has been started using the following *Shell Commands*:

- `\connect URI`: Creates an XSession.
- `\connect -n URI`: Creates a Node Session.
- `\connect -c URI`: Creates a Classic Session.

Configure the connection using the URI parameter, which follows the same syntax as for the `--uri` command option. For additional information, see [Section 19.2.2.1, “Connecting using a URI String”](#).

For example:

```
mysql-js> \connect root@localhost
Creating XSession to root@localhost...
Enter password: ****
No default schema selected.
mysql-js>
```

Creating a Secure Session Using SSL

To establish an SSL connection, the URI parameter passed to the connect shell commands must include the SSL information as URL parameters. For example:

```
mysql-js> \connect root@localhost?ssl_ca=/path/to/ca/file&\
ssl_cert=/path/to/cert/file&ssl_key=/path/to/key/file
Creating XSession to root@localhost...
Enter password: ****
No default schema selected.
mysql-js>
```

19.2.2.6 Connections in JavaScript and Python

When a connection is made using the command options or by using any of the shell commands, a global session object is created. This session is global because once created, it can be used in any of the MySQL Shell execution modes.

Any global session object is available in JavaScript or Python modes because a variable called **session** holds a reference to it.

In SQL mode, both Node and Classic sessions can be used because they both expose SQL execution. In SQL mode an XSession cannot be used.

In addition to the global session object, sessions can be established and assigned to a different variable by using the functions available in the `mysql` and `mysqlx` JavaScript and Python modules.

For example, the following functions are provided by these modules:

- **`mysql.getSession(connectionData[, password])`**
- **`mysqlx.getNodeSession(connectionData[, password])`**
- **`mysql.getClassicSession(connectionData[, password])`**

The first of these functions is used to create an XSession which features the most comprehensive development API and supports X Protocol.

The second creates a Node Session which connects to a X Protocol enabled MySQL Server and allows SQL Execution.

The latter returns a Classic Session object which uses the traditional MySQL protocol and has a very limited development API.

`connectionData` can be either a URI as specified above or a dictionary containing the connection parameters. See [Section 19.2.2.1, “Connecting using a URI String”](#).

The following example shows how to create a Node Session using the X Protocol:

```
mysql-js> var mysqlx=require('mysqlx').mysqlx;
mysql-js> var session=mysqlx.getNodeSession('root@localhost');
mysql-js> print(session)
<NodeSession:root@localhost>
mysql-js>
```

The following example shows how to create a Node Session using the X Protocol so that you can execute SQL:

```
mysql-js> var mysqlx=require('mysqlx').mysqlx;
mysql-js> var session=mysqlx.getNodeSession({host: 'localhost', dbUser: 'root'});
mysql-js> print(session)
<NodeSession:root@localhost>
mysql-js>
```

The following example shows how to create a Classic Session:

```
mysql-js> var mysql=require('mysql').mysql;
mysql-js> var session = mysql.getClassicSession('root@localhost:3307');
mysql-js> print(session)
<ClassicSession:root@localhost:3307>
mysql-js>
```

Using SSL for Secure Connections

To establish an SSL connection, set the SSL information in the `connectionData` dictionary. For example:

```
mysql-js> var mysqlx=require('mysqlx').mysqlx;

mysql-js> var session=mysqlx.getNodeSession({host: 'localhost',
                                             dbUser: 'root',
                                             dbPassword: 'mypasswd',
                                             ssl_ca: "path_to_ca_file",
                                             ssl_cert: "path_to_cert_file",
                                             ssl_key: "path_to_key_file"});

mysql-js> print(session)
<NodeSession:root@localhost>
```

19.3 MySQL Shell Code Execution

This section explains how code execution works in MySQL Shell.

19.3.1 Interactive Code Execution

The default mode of MySQL Shell provides interactive execution of database operations that you type at the command prompt. These operations can be written in JavaScript, Python or SQL depending on the type of session being used. When executed, the results of the operation are displayed on-screen.

As with any other language interpreter, MySQL Shell is very strict regarding syntax. For example, the following JavaScript snippet reads and prints the documents in a collection:

```
var mysqlx = require('mysqlx').mysqlx;
var mySession = mysqlx.getSession('user:pwd@localhost');
var result = mySession.world_x.countryinfo.find().execute();
var record = result.fetchOne();
while(record){
  print(record);
  record = result.fetchOne();
}
```

As seen above, the call to `find()` is followed by the `execute()` function. CRUD database commands are only actually executed on the MySQL Server when `execute()` is called. However, when working with MySQL Shell interactively, `execute()` is implicitly called whenever you press **Return** on a statement. Then the results of the operation are fetched and displayed on-screen. The rules for when you need to call `execute()` or not are as follows:

- When using MySQL Shell in this way, calling `execute()` becomes optional on:
 - `Collection.add()`
 - `Collection.find()`
 - `Collection.remove()`
 - `Collection.modify()`
 - `Table.insert()`
 - `Table.select()`
 - `Table.delete()`
 - `Table.update()`

- `NodeSession.sql()`
- Automatic execution is disabled if the object is assigned to a variable. In such a case calling `execute()` is mandatory to perform the operation.
- When a line is processed and the function returns any of the available `Result` objects, the information contained in the Result object is automatically displayed on screen. The functions that return a Result object include:
 - The SQL execution and CRUD operations (listed above)
 - Transaction handling and drop functions of the session objects in both `mysql` and `mysqlx` modules:
 -
 - `startTransaction()`
 - `commit()`
 - `rollback()`
 - `dropSchema()`
 - `dropTable()`
 - `dropCollection()`
 - `dropView()`
 - `ClassicSession.runSql()`

Based on the above rules, the statements needed in the MySQL Shell in interactive mode to establish a session, query, and print the documents in a collection are:

```
mysql-js> var mysqlx = require('mysqlx').mysqlx;
mysql-js> var mySession = mysqlx.getSession('user:pwd@localhost');
```

No call to `execute()` is needed and the Result object is automatically printed.

```
mysql-js> mySession.world_x.countryinfo.find();
```

19.3.2 Batch Code Execution

As well as interactive code execution, MySQL Shell provides batch code execution from:

- A file loaded for processing.
- A file containing code that is redirected to the standard input for execution.
- Code from a different source that is redirected to the standard input for execution.

For example:

Loading SQL code from a file for batch processing.

```
shell> mysqlsh --file code.js
```

Redirecting a file to standard input for execution.

```
shell> mysqlsh < code.js
```

Redirecting code to standard input for execution.

```
shell> echo "show databases;" | mysqlsh --sql --uri root@192.168.1.141:33060
```

Executable Scripts

Starting with version 1.0.4, on Linux you can create executable scripts that run with MySQL Shell by including a `#!` line as the first line of the script. This line should provide the full path to MySQL Shell and include the `--file` option. For example:

```
#!/usr/local/mysql-shell/bin/mysqlsh --file
print("Hello World\n");
```

The script file must be marked as executable in the filesystem. Running the script invokes MySQL Shell and it executes the contents of the script.

19.3.3 Output Formats

The output of the commands processed on the server can be formatted in different ways. This section details the different available output formats.

19.3.3.1 Table Format

The table format is used by default when MySQL Shell is in interactive mode. The output is presented as a formatted table for a better view and to aid analysis.

```
mysql-sql> select * from sakila.actor limit 3;
+-----+-----+-----+-----+
| actor_id | first_name | last_name | last_update |
+-----+-----+-----+-----+
| 1 | PENELOPE | GUINNESS | 2006-02-15 4:34:33 |
| 2 | NICK | WAHLBERG | 2006-02-15 4:34:33 |
| 3 | ED | CHASE | 2006-02-15 4:34:33 |
+-----+-----+-----+-----+
3 rows in set (0.00 sec)

mysql-sql>
```

To get this output format when running in batch mode, use the `--table` command-line option.

19.3.3.2 Tab Separated Format

This format is used by default when running MySQL Shell in batch mode, to have better output for automated analysis.

```
>echo "select * from sakila.actor limit 3;" | mysqlsh --classic --uri root@192.168.1.141:33460
actor_id first_name last_name last_update
1 PENELOPE GUINNESS 2006-02-15 4:34:33
2 NICK WAHLBERG 2006-02-15 4:34:33
3 ED CHASE 2006-02-15 4:34:33
```

19.3.3.3 JSON Format Output

MySQL Shell supports the JSON format for output and it is available both in interactive and batch mode. This output format can be enabled using the `--json` command-line option:

JSON Format in Batch Mode

```
shell>echo "select * from sakila.actor limit 3;" | mysqlsh --json --sqlc --uri root@192.168.1.141:33060
{"duration":"0.00 sec","info":"","row_count":3,"rows":[[1,"PENELOPE","GUINNESS",{ "year":2006,"month":1,"day":15}]]}
```

```

shell>echo "select * from sakila.actor limit 3;" | mysqlsh --json=raw --sqlc --uri root@192.168.1.141:3306
{"duration":"0.00 sec","info":"","row_count":3,"rows":[[1,"PENELOPE","GUINNESS",{ "year":2006,"month":1,"day":15,"hour":4,"minute":34,"second":33.0}],["warning_count":0]}

shell>echo "select * from sakila.actor limit 3;" | mysqlsh --json=pretty --sqlc --uri root@192.168.1.141:3306

```

19.3.3.4 Result Metadata

When an operation is executed, in addition to any results returned, some additional information is available. This includes information such as the number of affected rows, warnings, duration, and so on, when any of these conditions is true:

- JSON format is being used for the output
- MySQL Shell is running in interactive mode.

19.3.4 Active Language

MySQL Shell can execute SQL, JavaScript or Python code, but only one language can be active at a time. The active mode determines how the executed statements are processed:

- If using SQL mode, statements are processed as SQL which means they are sent to the MySQL server for execution.
- If using JavaScript mode, statements are processed as JavaScript code.
- If using Python mode, statements are processed as Python code.

When running MySQL Shell in interactive mode, activate a specific language by entering the commands: `\sql`, `\js`, `\py`.

When running MySQL Shell in batch mode, activate a specific language by passing any of these command-line options: `--js`, `--py` or `--sql`. The default mode if none is specified is JavaScript.

Use MySQL Shell to execute the content of the file `code.sql` as SQL.

```
shell> mysqlsh --sql < code.sql
```

Use MySQL Shell to execute the content of the file `code.js` as JavaScript code.

```
shell> mysqlsh < code.js
```

Use MySQL Shell to execute the content of the file `code.py` as Python code.

```
shell> mysqlsh --py < code.py
```

19.3.5 Batch Mode Made Interactive

This section describes code execution in batch mode.

- In batch mode, all the command logic described above is not available, only valid code for the active language can be executed.
- When processing SQL code, it is executed statement by statement using the following logic: read/process/print result.
- When processing non-SQL code, it is loaded entirely from the input source and executed as a unit.

Use the `--interactive` (or `-i`) command-line option to configure MySQL Shell to process the input source as if it were being issued in interactive mode; this enables all the features provided by the Interactive mode to be used in batch processing.

Note

In this case, whatever the source is, it is read line by line and processed using the interactive pipeline.

19.3.5.1 Multiple-line Support

It is possible to specify statements over multiple lines. When in Python or JavaScript mode, multiple-line mode is automatically enabled when a block of statements starts like in function definitions, if/then statements, for loops, and so on. In SQL mode multiple line mode starts when the command `\` is issued.

Once multiple-line mode is started, the subsequently entered statements are cached.

For example:

```
mysql-sql> \  
... create procedure get_actors()  
... begin  
...   select first_name from sakila.actors;  
... end  
...  
mysql-sql>
```

19.4 Configuring MySQL Shell

This section explains how to configure MySQL Shell using commands executable from the interactive code editor and command-line options. For a description of MySQL Shell command-line options, see [Section 4.5.7, “mysqlsh — The MySQL Shell”](#).

19.4.1 MySQL Shell Commands

MySQL Shell provides commands which enable you to modify the execution environment of the code editor, for example to configure the active programming language or a MySQL Server connection. The following table lists the commands that are available regardless of the currently selected language. As commands need to be available independent of the *execution mode*, they start with an escape sequence, the `\` character.

Command	Alias/Shortcut	Description
<code>\help</code>	<code>\h</code> or <code>\?</code>	Prints help about MySQL Shell commands.
<code>\quit</code>	<code>\q</code> or <code>\exit</code>	Exit MySQL Shell.
<code>\</code>		In SQL mode, begin multiple-line mode. Code is cached and executed when an empty line is entered.
<code>\status</code>		Show the current MySQL Shell status.
<code>\js</code>		Switch execution mode to JavaScript.
<code>\py</code>		Switch execution mode to Python.
<code>\sql</code>		Switch execution mode to SQL.
<code>\connect</code>	<code>\c</code>	Connect to a MySQL Server with a URI using an XSession (X Protocol).
<code>\connect_node</code>	<code>\cn</code>	(Removed in version 1.0.4, use <code>\connect -n</code>) Connect to a MySQL Server with a URI using a Node session.
<code>\connect_classic</code>	<code>\cc</code>	(Removed in version 1.0.4, use <code>\connect -c</code>) Connect to a MySQL Server with a URI using a Classic session (MySQL Protocol).
<code>\use</code>		Specify the schema to use.
<code>\source</code>	<code>\.</code>	Execute a script file using the active language.
<code>\warnings</code>	<code>\W</code>	Show any warnings generated by a statement.
<code>\nowarnings</code>	<code>\w</code>	Do not show any warnings generated by a statement.
<code>\lsconn</code>	<code>\lsc</code>	Print the connection data for the stored sessions.
<code>\saveconn</code>	<code>\savec</code>	Save connection data of a session, optionally use <code>-f</code> to force overwriting an existing connection.
<code>\addconn</code>	<code>\addc</code>	(Removed in version 1.0.4, see <code>\saveconn</code>) Store the connection data of a session.
<code>\rmconn</code>		Removes a stored session.
<code>\chconn</code>		(Removed in version 1.0.4, see <code>\saveconn</code>) Updates a stored session.

Help Command

The `\help` command can be used with or without parameters. When used without parameters a general help is printed including information about:

- Available commands.
- Available commands for the active mode.

When used with a parameter, the parameter must be a valid command. If that is the case, help for that specific command is printed including:

- Description
- Supported aliases if any

- Additional help if any

For example:

```
\help connect
```

If the parameter is not a valid command, the general help is printed.

Connect Command

The `\connect` command is used to connect to a MySQL Server using an URI. This command creates an X Protocol connection by default.

For example:

```
\connect root@localhost:3306
```

If a password is required you are prompted for it.

Use the `-n` option to create a Node session, using the X Protocol to connect to a single server. For example:

```
\connect -n root@localhost:3306
```

Use the `-c` option to create a Classic session, enabling you to use the MySQL Protocol to issue SQL commands directly on a server. For example:

```
\connect -c root@localhost:3306
```

Source Command

The `\source` command is used to execute code from a script at a given path. For example:

```
\source /tmp/mydata.sql
```

It can be used to execute either SQL, JavaScript or Python code. The code in the file is executed using the active language, so to process SQL code the MySQL Shell must be in SQL mode.

Warning

As the code is executed using the active language, executing a script in a different language than the currently selected execution mode language could lead to unexpected results.

Use Command

The `\use` command enables you to choose which schema is active, for example:

```
\use schema_name
```

The `\use` command requires a global development session to be active. If the global development session is an XSession then the `\use` command only sets `db` to the object representing the `schema_name` but does not set a current schema on the database. If the global development session is one of NodeSession or ClassicSession the `\use` command sets the current schema to the specified `schema_name` and updates the `db` variable to the object that represents the selected schema.

19.5 MySQL Shell Application Log

This section explains the application log.

19.5.1 Application Log

MySQL Shell can be configured to generate an application log file with information about issues of varying severity. You can use this information to verify the state of MySQL Shell while it is running.

The location of the log file is the user configuration path and the file is named `mysqlsh.log`.

Log File on Windows

On Windows, the default path to the log file is `%APPDATA%\MySQL\mysqlsh\mysqlsh.log`

To find the location of `%APPDATA%` on your system, echo it from the command-line. For example:

```
C:>echo %APPDATA%
C:\Users\exampleuser\AppData\Roaming
```

On Windows, the path is determined by the result of gathering the `%APPDATA%` folder specific to that user, and then appending `MySQL\mysqlsh`. Using the above example, we end up with:

```
C:\Users\exampleuser\AppData\Roaming\MySQL\mysqlsh\mysqlsh.log
```

Log File on Unix-based Systems

For a machine running Unix, the default path is `~/mysqlsh/mysqlsh.log` where “~” represents the user's home directory. The environment variable `HOME` also represents the user's home directory. Appending `.mysqlsh` to the user's home directory determines the default path to the logs. For example:

```
C:>echo $HOME
/home/exampleuser
shell> less /home/exampleuser/.mysqlsh/mysqlsh.log
```

These paths can be overridden on all platforms by defining the environment variable `MYSQL_USER_CONFIG_PATH`. The value of this variable replaces `%APPDATA%` in Windows or `$HOME` in Unix.

By default, logging is disabled in MySQL Shell. To enable logging use the `--log-level` command-line option when starting MySQL Shell. For example:

```
shell> mysqlsh --log-level=4
```

The number assigned to `--log-level` controls the level of detail in the log. The following logging levels are supported:

Log Level	Meaning
1	None, the default
2	Internal Error
3	Error
4	Warning
5	Info
6	Debug
7	Debug2

Log Level	Meaning
8	Debug3

The log format is plain text and entries contain a timestamp and description of the problem, along with the log level from the above list. For example:

```
2016-04-05 22:23:01: Error: Default Domain: (shell):1:8: MySQLError: You have an error
in your SQL syntax; check the manual that corresponds to your MySQL server version for
the right syntax to use near '' at line 1 (1064) in session.sql("select * from t
limit").execute().all();
```

19.6 Customizing MySQL Shell

MySQL Shell offers the ability to customize the behavior and code execution environment through startup scripts, which are executed when the application is first run. Using such scripts enables you to:

- Add additional search paths for Python or JavaScript modules.
- Override the default prompt used by the Python and JavaScript modes.
- Define global functions or variables.
- Any other possible initialization through JavaScript or Python.

19.6.1 Working With Start-Up Scripts

When MySQL Shell enters either into JavaScript or Python mode, it searches for startup scripts to be executed. The startup scripts are JavaScript or Python specific scripts containing the instructions to be executed when the corresponding mode is initialized.

Startup scripts must be named as follows:

- For JavaScript mode: `mysqlshrc.js`
- For Python mode: `mysqlshrc.py`

MySQL Shell searches the following paths for these files (in order of execution).

On Windows:

1. `%PROGRAMDATA%MySQLmysqlshmysqlshrc.[js|py]`
2. `%MYSQLSH_HOME%sharedmysqlshmysqlshrc.[js|py]`
3. `<mysqlsh binary path>mysqlshrc.[js|py]`
4. `%APPDATA%MySQLmysqlshmysqlshrc.[js|py]`

On Linux and OSX:

1. `/etc/mysql/mysqlsh/mysqlshrc.[js|py]`
2. `$MYSQLSH_HOME/shared/mysqlsh/mysqlshrc.[js|py]`
3. `<mysqlsh binary path>/mysqlshrc.[js|py]`
4. `$HOME/.mysqlsh/mysqlshrc.[js|py]`

The environment variable `MYSQLSH_HOME` defines the root folder of a standard setup of MySQL Shell. If `MYSQLSH_HOME` is not defined it is automatically calculated based on the location of the MySQL Shell binary, therefore on many standard setups it is not required to define `MYSQLSH_HOME`.

If `MYSQLSH_HOME` is not defined and the MySQL Shell binary is not in a standard install folder structure, then the path defined in option 3 in the above lists is used. If using a standard install or if `MYSQLSH_HOME` points to a standard install folder structure, then the path defined in option 3 is not used.

Warning

The lists above also define the order of searching the paths, so if something is defined in two different scripts, the script executed later takes precedence.

19.6.2 Adding Module Search Paths

There are two ways to add additional module search paths:

- Through environment variables
- Through startup scripts

19.6.2.1 Environment Variables

Python uses the `PYTHONPATH` environment variable to allow extending the search paths for python modules. The value of this variable is a list of paths separated by:

- A colon character in Linux and OSX
- A semicolon character in Windows

To achieve this in JavaScript, MySQL Shell supports defining additional JavaScript module paths using the `MYSQLSH_JS_MODULE_PATH` environment variable. The value of this variable is a list of semicolon separated paths.

19.6.2.2 Startup Scripts

The addition of module search paths can be achieved for both languages through the corresponding startup script.

For Python modify the `mysqlshrc.py` file and append the required paths into the `sys.path` array.

```
# Import the sys module
import sys

# Append the additional module paths
sys.path.append('~/.custom/python')
sys.path.append('~/.other/custom/modules')
```

For JavaScript the same task is achieved by adding code into the `mysqlshrc.js` file to append the required paths into the predefined `shell.js_module_paths` array.

```
// Append the additional module paths
shell.js.module_paths[shell.js.module_paths.length] = '~/.custom/js';
shell.js.module_paths[shell.js.module_paths.length] = '~/.other/custom/modules';
```

19.6.3 Overriding the Default Prompt

MySQL Shell uses a default prompt for both Python (`mysql-py>`) and JavaScript (`mysql-js>`).

You can customize the language specific prompt using the `shell.custom_prompt()` function. This function must return a string that is used as the prompt. To have a custom prompt when MySQL Shell starts, define this function in a startup script. The following example shows how this functionality can be used.

In Python `shell.custom_prompt()` could be defined as:

```
# Import the sys module
from time import gmtime, strftime

def my_prompt():
    ret_val = strftime("%H:%M:%S", gmtime())

    if session and session.isOpen():
        data = shell.parseUri(session.getUri())

        ret_val = "%s-%s-%s-py> " % (ret_val, data.dbUser, data.host)
    else:
        ret_val = "%s-disconnected-py> " % ret_val

    return ret_val

shell.custom_prompt = my_prompt
```

In JavaScript `shell.custom_prompt()` could be defined as:

```
shell.custom_prompt = function(){
    var now = new Date();

    var ret_val = now.getHours().toString() + ":" + now.getMinutes().toString() + ":" + now.getSeconds().toString();

    if (session && session.isOpen()){
        var data = shell.parseUri(session.getUri());

        ret_val += "-" + data.dbUser + "-" + data.host + "-js> ";
    }
    else
        ret_val += "-disconnected-js> ";

    return ret_val;
}
```

The following example demonstrates using the custom prompt functions defined above in startup script. The prompts show the current system time, and if a session is open the current user and host:

```

20.7.2 X Plugin Options and Variables	2673
20.7.3 Monitoring X Plugin	2679

This chapter introduces an alternative way of working with MySQL as a document store, sometimes referred to as “using NoSQL”. If your intention is to use MySQL in a traditional (SQL) way, this chapter is probably not relevant to you.

Using MySQL as a document store is currently a preproduction feature to which this notice applies: [Section 20.1, “Preproduction Status — Legal Notice”](#).

Relational databases such as MySQL usually required a document schema to be defined before documents can be stored. The features described in this section enable you to use MySQL as a document store, which is a schema-less, and therefore schema-flexible, storage system for documents. When using MySQL as a document store, to create documents describing products you do not need to know and define all possible attributes of any products before storing them and operating with them. This differs from working with a relational database and storing products in a table, when all columns of the table must be known and defined before adding any products to the database. The features described in this chapter enable you to choose how you configure MySQL, using only the document store model, or combining the flexibility of the document store model with the power of the relational model.

These sections cover the usage of MySQL as a document store:

- The [Section 20.2, “Key Concepts”](#) section covers concepts like Document, Collection, Session, and Schema to help you understand how to use MySQL as a document store.
- The [Section 20.3, “Setting Up MySQL as a Document Store”](#) section explains how to configure X Plugin on a MySQL Server, so it can function as a document store, and how to install MySQL Shell to use as a client.

- The MySQL Shell is an interactive interface to MySQL supporting JavaScript, Python, or SQL modes. You can use the MySQL Shell to prototype applications, execute queries and update data. The *quick-start guides (tutorials)* help you to get started using MySQL Shell.

The quick-start guide for JavaScript is here: [Section 20.4, “Quick-Start Guide: MySQL Shell for JavaScript”](#).

The quick-start guide for Python is here: [Section 20.5, “Quick-Start Guide: MySQL Shell for Python”](#).

- [Chapter 19, MySQL Shell User Guide](#) provides more detailed information about using MySQL Shell.
- *X DevAPI User guide*.

Clients that communicate with a MySQL Server using the X Protocol can use the X DevAPI to develop applications. For example MySQL Shell and MySQL Connectors provide this ability by implementing the X DevAPI. X DevAPI offers a modern programming interface with a simple yet powerful design which provides support for established industry standard concepts. See [X DevAPI User Guide](#) for in-depth tutorials on using X DevAPI.

- The following MySQL Connectors support the X Protocol and enable you to use X DevAPI in your chosen language to develop applications that communicate with a MySQL Server functioning as a document store.
 - MySQL Shell X DevAPI and AdminAPI reference: [JavaScript](#) and [Python](#).
 - [MySQL Connector/J X DevAPI Reference](#)
 - [MySQL Connector/Node.js X DevAPI Reference](#)
 - [MySQL Connector/Net X DevAPI Reference](#)
 - [MySQL Connector/Python X DevAPI Reference](#)

Each implementation of X DevAPI provides library reference documentation, available at the above links.

20.1 Preproduction Status — Legal Notice

This documentation is in preproduction status and is intended for demonstration and preliminary use only. It may not be specific to the hardware on which you are using the software. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to this documentation and will not be responsible for any loss, costs, or damages incurred due to the use of this documentation.

20.2 Key Concepts

This section explains the concepts introduced as part of using MySQL as a document store.

Document

A Document is a set of key and value pairs, as represented by a JSON object. A Document is represented internally using the MySQL binary JSON object, through the JSON MySQL datatype. The values of fields can contain other documents, arrays, and lists of documents.

```
{
  "GNP": .6,
  "IndepYear": 1967,
  "Name": "Sealand",
  "_id": "SEA",
  "demographics": {
    "LifeExpectancy": 79,

```

```

    "Population": 27
  },
  "geography": {
    "Continent": "Europe",
    "Region": "British Islands",
    "SurfaceArea": 193
  },
  "government": {
    "GovernmentForm": "Monarchy",
    "HeadOfState": "Michael Bates"
  }
}

```

Collection

A Collection is a container that may be used to store Documents in a MySQL database.

CRUD Operations

Create, Read, Update and Delete (CRUD) operations are the four basic operations that can be performed on a database Collection or Table. In terms of MySQL this means:

- Create a new entry (insertion or addition)
- Read entries (queries)
- Update entries
- Delete entries

X Plugin

The MySQL Server plugin which enables communication using X Protocol. Supports clients that implement X DevAPI and enables you to use MySQL as a document store.

X Protocol

A protocol to communicate with a MySQL Server running X Plugin. X Protocol supports both CRUD and SQL operations, authentication via SASL, allows streaming (pipelining) of commands and is extensible on the protocol and the message layer.

20.3 Setting Up MySQL as a Document Store

This section describes how to install the X Plugin to enable MySQL Server to use the X Protocol and use MySQL Shell to act as a client to the server.

The prerequisite for using MySQL as a document store is the X Plugin, which implements the X Protocol. Without the X Plugin running, X Protocol clients cannot connect to the server. The X Plugin is supplied with MySQL (5.7.12 or higher) — installing it does not involve a separate download.

Setting up MySQL as a document store follows the steps outlined here:

1. **Install MySQL 8 or upgrade from MySQL 5.7.12 or lower.**

When the [installation](#) or upgrade is done, start the server. For server startup instructions, see [Section 2.9.2, “Starting the Server”](#).

Note

MySQL Installer enables you to perform this and the next step (Install the X Plugin) at the same time for new installations on Microsoft Windows. In the **Plugin and Extensions** screen, check mark the **Enable X Protocol/MySQL as a Document Store** check box. After the installation, verify that the X Plugin has been installed.

2. **Install the X Plugin.** A non-root account can be used to install the plugin as long as the account has `INSERT` privilege for the `mysql.plugin` table.

Always save your existing configuration settings before reconfiguring the server.

To install the built-in X Plugin, do one of the following:

- Using [MySQL Installer for Windows](#):
 - a. Launch MySQL Installer for Windows. MySQL Installer dashboard opens.
 - b. Click the **Reconfigure** quick action for MySQL Server. Use **Next** and **Back** to configure the following items:
 - In **Accounts and Roles**, confirm the current `root` account password.
 - In **Plugin and Extensions**, check mark the **Enable X Protocol/MySQL as a Document Store** check box. MySQL Installer provides a default port number and opens the firewall port for network access.
 - In **Apply Server Configuration**, click **Execute**.
 - Click **Finish** to close MySQL Installer.
 - c. [Install MySQL Shell](#).
- Using MySQL Shell:
 - a. [Install MySQL Shell](#).
 - b. Open a terminal window (command prompt on Windows) and navigate to the MySQL binaries location (for example, `/usr/bin/` on Linux).
 - c. Run the following command:

```
mysqlsh -u user -h localhost --classic --dba enableXProtocol
```

- Using the MySQL Client program:
 - a. Open a terminal window (command prompt on Windows) and navigate to the MySQL binaries location (for example, `/usr/bin/` on Linux).
 - b. Invoke the `mysql` command-line client:

```
mysql -u user -p
```

- c. Issue the following statement:

```
mysql> INSTALL PLUGIN mysqlx SONAME 'mysqlx.so';
```

Replace `mysqlx.so` with `mysqlx.dll` for Windows.

Important

The `mysql.session` user must exist before you can load X Plugin. `mysql.session` was added in MySQL version 8.0.2. If your data dictionary was initialized using an earlier version you must run the `mysql_upgrade` procedure. If the upgrade is not run, X Plugin fails to start with the error message `There was an error when trying to access the server with user:`

```
mysql.session@localhost. Make sure the user is
present in the server and that mysql_upgrade was ran
after a server update..
```

d. [Install MySQL Shell](#).

3. Verify that the X Plugin has been installed.

When the X Plugin is installed properly, it shows up in the list when you query for active plugins on the server with one of the following commands:

- MySQL Shell command:

```
mysqlsh -u user --sqlc -e "show plugins"
```

- MySQL Client program command:

```
mysql -u user -p -e "show plugins"
```

If you encounter problems with the X Plugin installation, or if you want to learn about alternative ways of installing, configuring, or uninstalling server plugins, see [Section 5.6.2, "Installing and Uninstalling Plugins"](#).

mysqlxsys@localhost User Account

Installing the X Plugin creates a `mysqlxsys@localhost` user account. If, for some reason, creating the user account fails, the X Plugin installation fails, too. Here is an explanation on what the `mysqlxsys@localhost` user account is for and what to do when its creation fails.

The X Plugin installation process uses the MySQL `root` user to create an internal account for the `mysqlxsys@localhost` user. The `mysqlxsys@localhost` account is used by the X Plugin for authentication of external users against the MySQL account system and for killing sessions when requested by a privileged user. The `mysqlxsys@localhost` account is created as locked, so it cannot be used to log in by external users. If for some reason the MySQL `root` account is not available, before you start the X Plugin installation you must manually create the `mysqlxsys@localhost` user by issuing the following statements in the `mysql` command-line client:

```
CREATE USER IF NOT EXISTS mysqlxsys@localhost IDENTIFIED WITH
mysql_native_password AS 'password' ACCOUNT LOCK;
GRANT SELECT ON mysql.user TO mysqlxsys@localhost;
GRANT SUPER ON *.* TO mysqlxsys@localhost;
```

Uninstalling the X Plugin

If you ever want to uninstall (deactivate) the X Plugin, issue the following statement in the `mysql` command-line client:

```
UNINSTALL PLUGIN mysqlx;
```

Do not use MySQL Shell to issue the previous statement. It works from MySQL Shell, but you get an error (code 1130). Also, uninstalling the plugin removes the `mysqlxsys` user.

20.3.1 Installing MySQL Shell

Important

For the Community version of MySQL Shell: Before installing MySQL Shell, make sure you have the Visual C++ Redistributable for Visual Studio 2015 (available at the [Microsoft Download Center](#)) installed on your Windows system.

This section describes how to download, install, and start MySQL Shell, which is an interactive JavaScript, Python, or SQL interface supporting development and administration for the MySQL Server. MySQL Shell is a component that you can install separately.

Requirements

MySQL Shell is available on Microsoft Windows, Linux, and OS X for 64-bit platforms. MySQL Shell requires that the built-in X Plugin be active. You can install the server plugin before or after you install MySQL Shell. For instructions, see [Installing the X Plugin](#).

20.3.1.1 Installing MySQL Shell on Microsoft Windows

Important

The Community version of MySQL Shell requires the [Visual C++ Redistributable for Visual Studio 2013](#) to work; make sure that is installed on your Windows system before installing MySQL Shell.

Note

MySQL Shell is currently not supplied with an MSI Installer. See [Installing MySQL Shell Binaries](#) for the manual install procedure.

To install MySQL Shell on Microsoft Windows using the MSI Installer, do the following:

1. Download the **Windows (x86, 64-bit), MSI Installer** package from <http://dev.mysql.com/downloads/shell/>.
2. When prompted, click **Run**.
3. Follow the steps in the Setup Wizard.

Figure 20.1 Installation of MySQL Shell on Windows

If you have installed MySQL without enabling the X Plugin, then later on decide you want to install the X Plugin, or if you are installing MySQL *without* using MySQL Installer, see [Installing the X Plugin](#).

20.3.1.2 Installing MySQL Shell on Linux

**Note**

Installation packages for MySQL Shell are available only for a limited number of Linux distributions, and only for 64-bit systems.

For supported Linux distributions, the easiest way to install MySQL Shell on Linux is to use the [MySQL APT repository](#) or [MySQL Yum repository](#). For systems not using the MySQL repositories, MySQL Shell can also be downloaded and installed directly.

Installing MySQL Shell with the MySQL APT Repository

**Note**

Installation of MySQL Shell using the MySQL APT repository is only supported on Ubuntu 14.04 LTS (“Trusty Tahr”) and Ubuntu 15.10 (“Wily Werewolf”).

For Linux distributions supported by the [MySQL APT repository](#), follow one of the paths below:

- If you do not yet have the [MySQL APT repository](#) as a software repository on your system, do the following:
 - Follow the steps given in [Adding the MySQL APT Repository](#), paying special attention to the following:
 - During the installation of the configuration package, when asked in the dialogue box to configure the repository, make sure you choose MySQL 5.7 (which is the default option) as the release series you want, and enable the **MySQL Preview Packages** component.
 - Make sure you do not skip the step for updating package information for the MySQL APT repository:

```
sudo apt-get update
```

- Install MySQL Shell with this command:

```
sudo apt-get install mysql-shell
```

- If you already have the [MySQL APT repository](#) as a software repository on your system, do the following:
 - Update package information for the MySQL APT repository:

```
sudo apt-get update
```

- Update the MySQL APT repository configuration package with the following command:

```
sudo apt-get install mysql-apt-config
```

When asked in the dialogue box to configure the repository, make sure you choose MySQL 5.7 (which is the default option) as the release series you want, and enable the **MySQL Preview Packages** component.

- Install MySQL Shell with this command:

```
sudo apt-get install mysql-shell
```

Installing MySQL Shell with the MySQL Yum Repository

For Linux distributions supported by the [MySQL Yum repository](#), follow these steps to install MySQL Shell:

- Do one of the following:
 - If you already have the [MySQL Yum repository](#) as a software repository on your system and the repository was configured with the new release package `mysql57-community-release`, skip to the next step (“Enable the MySQL Tools Preview subrepository...”).
 - If you already have the [MySQL Yum repository](#) as a software repository on your system but have configured the repository with the old release package `mysql-community-release`, it is easiest to install MySQL Shell by first reconfiguring the MySQL Yum repository with the new `mysql57-community-release` package. To do so, you need to remove your old release package first, with the following command :

```
sudo yum remove mysql-community-release
```

For dnf-enabled systems, do this instead:

```
sudo dnf erase mysql-community-release
```

Then, follow the steps given in [Adding the MySQL Yum Repository](#) to install the new release package, `mysql57-community-release`.

- If you do not yet have the [MySQL Yum repository](#) as a software repository on your system, follow the steps given in [Adding the MySQL Yum Repository](#).
- Enable the MySQL Tools Preview subrepository. You can do that by editing manually the `/etc/yum.repos.d/mysql-community.repo` file. This is an example of the subrepository's default entry in the file (the `baseurl` entry in your file might look different, depending on your Linux distribution):

```
[mysql-tools-preview]
name=MySQL Tools Preview
baseurl=http://repo.mysql.com/yum/mysql-tools-preview/el/6/$basearch/
enabled=0
gpgcheck=1
gpgkey=file:///etc/pki/rpm-gpg/RPM-GPG-KEY-mysql
```

Change the entry `enabled=0` to `enabled=1` to enable the subrepository.

- Install MySQL Shell with this command:

```
sudo yum install mysql-shell
```

For dnf-enabled systems, do this instead:

```
sudo dnf install mysql-shell
```

Installing MySQL Shell from Direct Downloads from the MySQL Developer Zone

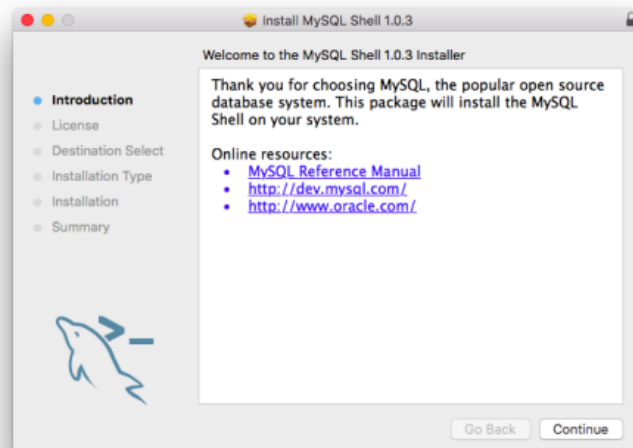

RPM, Debian, and source packages for installing MySQL Shell are also available for download at [Download MySQL Shell](#).

20.3.1.3 Installing MySQL Shell on OS X

To install MySQL Shell on OS X, do the following:

1. Download the package from <http://dev.mysql.com/downloads/shell/>.
2. Double-click the downloaded DMG to mount it. Finder opens.
3. Double-click the `.pkg` file shown in the Finder window.
4. Follow the steps in the installation wizard.

Figure 20.2 Installation of MySQL Shell on OS X

5. When the installer finishes, eject the DMG. (It can be deleted.)

20.3.2 Starting MySQL Shell

You need an account name and password to establish a session using MySQL Shell. Replace `user` with your account name.

On the same system where the server instance is running, open a terminal window (command prompt on Windows) and start MySQL Shell with the following command:

```
mysqlsh --uri user@localhost
```

You are prompted to input your password and then this establishes an X Session.

For instructions to get you started using MySQL Shell and MySQL as a document store, see the following quick-start guides:

- [Quick-Start Guide: MySQL Shell for JavaScript](#)
- [Quick-Start Guide: MySQL Shell for Python](#)

20.4 Quick-Start Guide: MySQL Shell for JavaScript

This quick-start guide provides instructions to begin prototyping database applications interactively with MySQL Shell. The guide includes the following topics:

- Introduction to MySQL functionality, MySQL Shell, and the `world_x` database sample.
- Operations to manage collections and documents.
- Operations to manage relational tables.

- Operations that apply to documents within tables.

Available Quick-Start Guides

- [MySQL Shell for Python](#)
- [MySQL for Visual Studio](#)

Related Information

- [Chapter 19, MySQL Shell User Guide](#) provides more in-depth information about MySQL Shell.
- [X DevAPI User Guide](#) provides more examples of using X DevAPI.

20.4.1 Introduction

The MySQL Shell for JavaScript quick start provides a short but comprehensive introduction to the database functionality including the new X DevAPI, which offers a modern, integrative way to work with relational and document data, without requiring SQL knowledge from application developers.

In MySQL, tables are the native data storage container type and collections are stored internally using tables.

JSON Documents and Collections

A JSON [document](#) is a data structure composed of field/value pairs stored within a [collection](#). The values of fields often contain other documents, arrays, and lists of documents.

```
{
  "GNP": .6,
  "IndepYear": 1967,
  "Name": "Sealand",
  "_id": "SEA",
  "demographics": {
    "LifeExpectancy": 79,
    "Population": 27
  },
  "geography": {
    "Continent": "Europe",
    "Region": "British Islands",
    "SurfaceArea": 193
  },
  "government": {
    "GovernmentForm": "Monarchy",
    "HeadOfState": "Michael Bates"
  }
}
```

Relational Tables

A [table](#) in MySQL enables you to store data organized in rows and columns. The structure of a table is defined by one or more columns with user-defined names and data types. Every row stored in the table has the same structure.

ID	Name	CountryCode	District	Info
1	Kabul	AFG	Kabul	{"Population": 1780000}
2	Qandahar	AFG	Qandahar	{"Population": 237500}
3	Herat	AFG	Herat	{"Population": 186800}
4	Mazar-e-Sharif	AFG	Balkh	{"Population": 127800}
5	Amsterdam	NLD	Noord-Holland	{"Population": 731200}
6	Rotterdam	NLD	Zuid-Holland	{"Population": 593321}

Related Information

- [Chapter 19, MySQL Shell User Guide](#) provides a general overview.
- See [X DevAPI User Guide](#) for development reference documentation.

20.4.2 Import Database Sample

The `world_x` database sample contains one JSON collection and a set of three relational tables:

- Collection
 - `countryinfo`: Information about countries in the world.
- Tables
 - `country`: Minimal information about countries of the world.
 - `city`: Information about some of the cities in those countries.
 - `countrylanguage`: Languages spoken in each country.

Requirements

You must install MySQL Shell with the X Protocol enabled. For instructions, see [Section 20.3, “Setting Up MySQL as a Document Store”](#).

Start the server before you load the `world_x` database for this guide.

Download world_x Database

To prepare the `world_x` database sample, follow these steps:

1. Download [world_x-db.zip](#).
2. Extract the installation archive to a temporary location such as `/tmp/`. Unpacking the archive results in a single file named `world_x.sql`.
3. Create the schema with the following command:

```
mysqlsh -u root --sql < /tmp/world_x-db/world_x.sql
Enter password: ****
```

Enter your password when prompted. A non-root account can be used as long as the account has privileges to create new databases.

Replace `/tmp/` with the path to the `world_x.sql` file on your system.

Related Information

- [Section 19.2.1, “MySQL Shell Sessions”](#) explains session types.
- See [Chapter 2, Installing and Upgrading MySQL](#) for general installation assistance.

20.4.3 MySQL Shell

MySQL Shell is a unified scripting interface to MySQL Server. It supports scripting in JavaScript and Python. JavaScript is the default processing mode. In most cases, you need an account to connect to the local MySQL server instance.

Start MySQL Shell

After you have installed and started MySQL server, connect MySQL Shell to the server instance. By default, MySQL Shell connects using the X Protocol.

On the same system where the server instance is running, open a terminal window and start MySQL Shell with the following command:

```
mysqlsh name@localhost/world_x
Creating a Session to 'root@localhost/world_x'
Enter password: ****
```

You may need to specify the path as appropriate.

In addition:

- `name` represents the user name of your MySQL account.
- MySQL Shell prompts you for your password.
- The default schema for this session is the `world_x` database. For instructions on setting up the `world_x` database sample, see [Section 20.4.2, “Import Database Sample”](#).

The `mysql-js>` prompt indicates that the active language for this session is JavaScript.

```
mysql-js>
```

When you run `mysqlsh` without the host argument, MySQL Shell attempts to connect to the server instance running on the localhost interface on port 33060. To specify a different host or port number, as well as other options, see the option descriptions at [Section 4.5.7, “mysqlsh — The MySQL Shell”](#).

MySQL Shell supports input-line editing as follows:

- **left-arrow** and **right-arrow** keys move horizontally within the current input line.
- **up-arrow** and **down-arrow** keys move up and down through the set of previously entered lines.
- **Backspace** deletes the character before the cursor and typing new characters enters them at the cursor position.
- **Enter** enters the current input line.

Get Help for MySQL Shell

Type `mysqlsh --help` at the prompt of your command interpreter for a list of command-line options.

```
mysqlsh --help
```

Type `\help` at the MySQL Shell prompt for a list of available commands and their descriptions.

```
mysql-js> \help
```

Type `\help` followed by a command name for detailed help about an individual MySQL Shell command. For example, to view help on the `\connect` command, type:

```
mysql-js> \help \connect
```

Quit MySQL Shell

To quit MySQL Shell, type the following command:

```
mysql-js> \quit
```

Related Information

- See [Section 19.3.1, “Interactive Code Execution”](#) for an explanation of how interactive code execution works in MySQL Shell.
- See [Section 19.2, “Getting Started with MySQL Shell”](#) to learn about session and connection alternatives.

20.4.4 Documents and Collections

In MySQL, collections contain JSON documents that you can add, find, update, and remove. Collections are containers within a schema that you create, list, and drop.

The examples in this section use the `countryinfo` collection in the `world_x` database. For instructions on setting up the `world_x` database sample, see [Section 20.4.2, “Import Database Sample”](#).

Documents

In MySQL, documents are represented as JSON objects. Internally, they are stored in an efficient binary format that enables fast lookups and updates.

- Simple document format for JavaScript:

```
{field1: "value", field2 : 10, "field 3": null}
```

An array of documents consists of a set of documents separated by commas and enclosed within [and] characters.

- Simple array of documents for JavaScript:

```
[ {Name: "Aruba", _id: "ABW"}, {Name: "Angola", _id: "AGO"} ]
```

MySQL supports the following JavaScript value types in JSON documents:

- numbers (integer and floating point)
- strings
- boolean (false and true)
- null
- arrays of more JSON values
- nested (or embedded) objects of more JSON values

Collections

Collections are containers for documents that share a purpose and possibly share one or more indexes. Each collection has a unique name and exists within a single schema.

The term schema is equivalent to a database, which means a group of database objects (as opposed to relational schema used to enforce structure and constraints over data). A schema does not enforce conformity on the documents in a collection.

In this quick-start guide:

- Basic objects include:

Object form	Description
<code>db</code>	<code>db</code> is a global variable assigned to the current active schema that you specified on the command line. You can type <code>db</code> in MySQL Shell to print a description of the object, which in this case will be the name of the schema it represents.
<code>db.getCollections()</code>	<code>db.getCollections()</code> holds a list of collections in the schema. Use the list to get references to collection objects, iterate over them, and so on.

- Basic operations scoped by collections include:

Operation form	Description
<code>db.name.add()</code>	The <code>add()</code> method inserts one document or a list of documents into the named collection.
<code>db.name.find()</code>	The <code>find()</code> method returns some or all documents in the named collection.
<code>db.name.modify()</code>	The <code>modify()</code> method updates documents in the named collection.
<code>db.name.remove()</code>	The <code>remove()</code> method deletes one document or a list of documents from the named collection.

Related Information

- See [Working with Collections](#) for a general overview.
- [CRUD EBNF Definitions](#) provides a complete list of operations.

20.4.4.1 Create, List, and Drop Collections

In MySQL Shell, you can create new collections, get a list of the existing collections in a schema, and remove an existing collection from a schema. Collection names are case-sensitive and each collection name must be unique.

Confirm the Schema

To show the value that is assigned to the schema variable, type `db`.

```
mysql-js> db
```

If the schema value is not `Schema:world_x`, then set the `db` variable as follows:

```
mysql-js> \use world_x
```

Create a Collection

To create a new collection in an existing schema, use the `createCollection()` method. The following example creates in the `world_x` database a collection called `flags`.

```
mysql-js> db.createCollection("flags")
```

The method returns a collection object.

```
<Collection:flags>
```

List Collections

To display all collections in the `world_x` database, use the `getCollections()` method on the schema object. Collections returned by the server appear between brackets.

```
mysql-js> db.getCollections()
[
  <Collection:countryinfo>,
  <Collection:flags>
]
```

Drop a Collection

To drop an existing collection from a database, use the `dropCollection()` method on the session object. For example, to drop the `flags` collection from the `world_x` database, type:

```
mysql-js> session.dropCollection("world_x", "flags")
Query OK (0.04 sec)
```

Related Information

- See [Section 19.2.2.6, “Connections in JavaScript and Python”](#) to learn more about the session object.
- See [Collection Objects](#) for more examples.

20.4.4.2 Add Documents

You can use the `add()` method to insert one document or a list documents into an existing collection using MySQL Shell. All examples in this section use the `countryinfo` collection.

Confirm the Schema

To show the value that is assigned to the schema variable, type `db`.

```
mysql-js> db
<Schema:world_x>
```

If the schema value is not `Schema:world_x`, then set the `db` variable as follows:

```
mysql-js> \use world_x
Schema `world_x` accessible through db.
```

Add a Document

Insert the following document into the `countryinfo` collection. Press **Enter** twice to insert the document.

```
mysql-js> db.countryinfo.add(
{
  GNP: .6,
  IndepYear: 1967,
  Name: "Sealand",
  _id: "SEA",
  demographics: {
    LifeExpectancy: 79,
    Population: 27
  },
  geography: {
    Continent: "Europe",
    Region: "British Islands",
    SurfaceArea: 193
  }
})
```

```

    },
    government: {
      GovernmentForm: "Monarchy",
      HeadOfState: "Michael Bates"
    }
  }
)
Query OK, 1 item affected (0.02 sec)

```

The method returns the status of the operation.

Each document requires an identifier field called `_id`. The value of the `_id` field must be unique among all documents in the same collection. If the document passed to the `add()` method does not contain the `_id` field, MySQL Shell automatically inserts a field into the document and sets the value to a generated universal unique identifier (UUID).

Related Information

- See [CollectionAddFunction](#) for the full syntax definition.

20.4.4.3 Find Documents

You can use the `find()` method to query for and return documents from a collection in a database. MySQL Shell provides additional methods to use with the `find()` method to filter and sort the returned documents.

MySQL provides the following operators to specify search conditions: `OR` (`|`), `AND` (`&&`), `XOR`, `IS`, `NOT`, `BETWEEN`, `IN`, `LIKE`, `!=`, `<>`, `>`, `>=`, `<`, `<=`, `&`, `|`, `<<`, `>>`, `+`, `-`, `*`, `/`, `~`, and `%`.

Find All Documents in a Collection

To return all documents in a collection, use the `find()` method without specifying search conditions. For example, the following operation returns all documents in the `countryinfo` collection.

```

mysql-js> db.countryinfo.find()
[
  {
    "GNP": 828,
    "IndepYear": null,
    "Name": "Aruba",
    "_id": "ABW",
    "demographics": {
      "LifeExpectancy": 78.4000015258789,
      "Population": 103000
    },
    "geography": {
      "Continent": "North America",
      "Region": "Caribbean",
      "SurfaceArea": 193
    },
    "government": {
      "GovernmentForm": "Nonmetropolitan Territory of The Netherlands",
      "HeadOfState": "Beatrix"
    }
    ...
  }
]
240 documents in set (0.00 sec)

```

The method produces results that contain operational information in addition to all documents in the collection.

An empty set (no matching documents) returns the following information:

```
Empty set (0.00 sec)
```

Filter Searches

You can include search conditions with the `find()` method. The syntax for expressions that form a search condition is the same as that of traditional [MySQL](#). You must enclose all expressions in quotes.

All examples in this section use the `countryinfo` collection in the `world_x` database. For the sake of brevity, some of the examples do not display output.

A simple search condition consists of the `_id` field and unique identifier of a document. The following example returns a single document matching the identifier string:

```
mysql-js> db.countryinfo.find("_id = 'AUS'")
[
  {
    "GNP": 351182,
    "IndepYear": 1901,
    "Name": "Australia",
    "_id": "AUS",
    "demographics": {
      "LifeExpectancy": 79.80000305175781,
      "Population": 18886000
    },
    "geography": {
      "Continent": "Oceania",
      "Region": "Australia and New Zealand",
      "SurfaceArea": 7741220
    },
    "government": {
      "GovernmentForm": "Constitutional Monarchy, Federation",
      "HeadOfState": "Elisabeth II"
    }
  }
]
1 document in set (0.01 sec)
```

The following example searches for all countries that have a GNP higher than \$500 billion. The `countryinfo` collection measures GNP in units of million.

```
mysql-js> db.countryinfo.find("GNP > 500000")
...[output removed]
10 documents in set (0.00 sec)
```

The `Population` field in the following query is embedded within the `demographics` object. To access the embedded field, use a period between `demographics` and `Population` to identify the relationship. Document and field names are case sensitive.

```
mysql-js> db.countryinfo.find("GNP > 500000 and demographics.Population < 10000000")
...[output removed]
6 documents in set (0.00 sec)
```

Arithmetic operators in the following expression are used to query for countries with a GNP per capita higher than \$30000. Search conditions can include arithmetic operators and most [MySQL](#) functions.

Note

Seven documents in the `countryinfo` collection have a population value of zero. Warning messages appear at the end of the output.

```
mysql-js> db.countryinfo.find("GNP*1000000/demographics.Population > 30000")
...[output removed]
9 documents in set, 7 warnings (0.00 sec)
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
```

```
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
```

You can separate a value from the search condition by using the `bind()` method. For example, instead of specifying a hard-coded country name as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `country`. Then include the placeholder and value in the `bind()` method as follows:

```
mysql-js> db.countryinfo.find("Name = :country").bind("country", "Italy")
[
  {
    "GNP": 1161755,
    "IndepYear": 1861,
    "Name": "Italy",
    "_id": "ITA",
    "demographics": {
      "LifeExpectancy": 79,
      "Population": 57680000
    },
    "geography": {
      "Continent": "Europe",
      "Region": "Southern Europe",
      "SurfaceArea": 301316
    },
    "government": {
      "GovernmentForm": "Republic",
      "HeadOfState": "Carlo Azeglio Ciampi"
    }
  }
]
1 document in set (0.01 sec)
```

Tip

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

Project Results

You can return specific fields of a document, instead of returning all the fields. The following example returns the GNP and Name fields of all documents in the `countryinfo` collection matching the search conditions.

Use the `fields()` method to pass the list of fields to return.

```
mysql-js> db.countryinfo.find("GNP > 5000000").fields(["GNP", "Name"])
[
  {
    "GNP": 8510700,
    "Name": "United States"
  }
]
1 document in set (0.00 sec)
```

In addition, you can alter the returned documents—adding, renaming, nesting and even computing new field values—with an expression that describes the document to return. For example, alter the names of the fields with the following expression to return only two documents.

```
mysql-js> db.countryinfo.find().
fields(mysqlx.expr('{ "Name": upper(Name), "GNPPerCapita": GNP*1000000/demographics.Population}')).
limit(2)
[
  {
    "GNPPerCapita": 8038.834951456311,
    "Name": "ARUBA"
  },
  {
    "GNPPerCapita": 263.0281690140845,
    "Name": "AFGHANISTAN"
  }
]
2 documents in set (0.00 sec)
```

Limit, Sort, and Skip Results

You can apply the `limit()`, `sort()`, and `skip()` methods to manage the number and order of documents returned by the `find()` method.

To specify the number of documents included in a result set, append the `limit()` method with a value to the `find()` method. The following query returns the first five documents in the `countryinfo` collection.

```
mysql-js> db.countryinfo.find().limit(5)
... [output removed]
5 documents in set (0.00 sec)
```

To specify an order for the results, append the `sort()` method to the `find()` method. Pass to the `sort()` method a list of one or more fields to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all documents by the `IndepYear` field and then returns the first eight documents in descending order.

```
mysql-js> db.countryinfo.find().sort(["IndepYear desc"]).limit(8)
... [output removed]
8 documents in set (0.00 sec)
```

By default, the `limit()` method starts from the first document in the collection. You can use the `skip()` method to change the starting document. For example, to ignore the first document and return the next eight documents matching the condition, pass to the `skip()` method a value of 1.

```
mysql-js> db.countryinfo.find().sort(["IndepYear desc"]).limit(8).skip(1)
... [output removed]
8 documents in set (0.00 sec)
```

Related Information

- The [MySQL Reference Manual](#) provides detailed documentation on functions and operators.
- See [CollectionFindFunction](#) for the full syntax definition.

20.4.4.4 Modify Documents

You can use the `modify()` method to update one or more documents in a collection. The X DevAPI provides additional methods for use with the `modify()` method to:

- Set and unset fields within documents.
- Append, insert, and delete arrays.

- Bind, limit, and sort the documents to be modified.

Set and Unset Fields

The `modify()` method works by filtering a collection to include only the documents to be modified and then applying the operations that you specify to those documents.

In the following example, the `modify()` method uses the search condition to identify the document to change and then the `set()` method replaces two values within the nested demographics object.

```
mysql-js> db.countryinfo.modify("_id = 'SEA'").
set("demographics", {LifeExpectancy: 78, Population: 28})
Query OK, 1 item affected (0.04 sec)
```

After you modify a document, use the `find()` method to verify the change.

To remove content from a document, use the `modify()` and `unset()` methods. For example, the following query removes the GNP from a document that matches the search condition.

```
mysql-js> db.countryinfo.modify("Name = 'Sealand'").unset("GNP")
Query OK, 1 item affected (0.01 sec)
```

Use the `find()` method to verify the change.

```
mysql-js> db.countryinfo.find("Name = 'Sealand'")
[
  {
    "IndepYear": 1967,
    "Name": "Sealand",
    "_id": "SEA",
    "demographics": {
      "LifeExpectancy": 78,
      "Population": 28
    },
    "geography": {
      "Continent": "Europe",
      "Region": "British Islands",
      "SurfaceArea": 193
    },
    "government": {
      "GovernmentForm": "Monarchy",
      "HeadOfState": "Michael Bates"
    }
  }
]
1 document in set (0.00 sec)
```

Append, Insert, and Delete Arrays

To append an element to an array field, or insert, or delete elements in an array, use the `arrayAppend()`, `arrayInsert()`, or `arrayDelete()` methods. The following examples modify the `countryinfo` collection to enable tracking of international airports.

The first example uses the `modify()` and `set()` methods to create a new `Airports` field in all documents.

Caution

Use care when you modify documents without specifying a search condition. This action will modify all documents in the collection.

```
mysql-js> db.countryinfo.modify("true").set("Airports", [])
Query OK, 240 items affected (0.07 sec)
```

With the `Airports` field added, the next example uses the `arrayAppend()` method to add a new airport to one of the documents. `$.Airports` in the following example represents the `Airports` field of the current document.

```
mysql-js> db.countryinfo.modify("Name = 'France'").arrayAppend("$.Airports", "ORY")
Query OK, 1 item affected (0.02 sec)
```

Use `db.countryinfo.find("Name = 'France'")` to see the change.

To insert an element at a different position in the array, use the `arrayInsert()` method to specify which index to insert in the path expression. In this case, the index is 0, or the first element in the array.

```
mysql-js> db.countryinfo.modify("Name = 'France'").arrayInsert("$.Airports[0]", "CDG")
Query OK, 1 item affected (0.04 sec)
```

To delete an element from the array, you must pass to the `arrayDelete()` method the index of the element to be deleted.

```
mysql-js> db.countryinfo.modify("Name = 'France'").arrayDelete("$.Airports[1]")
Query OK, 1 item affected (0.03 sec)
```

Related Information

- The [MySQL Reference Manual](#) provides instructions to help you search for and modify JSON values.
- See [CollectionModifyFunction](#) for the full syntax definition.

20.4.4.5 Remove Documents

You can use the `remove()` method to delete some or all documents from a collection in a database. The X DevAPI provides additional methods for use with the `remove()` method to filter and sort the documents to be removed.

Remove Documents Using Conditions

The example that follows passes a search condition to the `remove()` method. All documents matching the condition will be removed from the `countryinfo` collection. In this example, one document matches the condition.

```
mysql-js> db.countryinfo.remove("_id = 'SEA'")
Query OK, 1 item affected (0.02 sec)
```

Remove the First Document

To remove the first document in the `countryinfo` collection, use the `limit()` method with a value of 1.

```
mysql-js> db.countryinfo.remove("true").limit(1)
Query OK, 1 item affected (0.03 sec)
```

Remove the Last Document in an Order

The following example removes the last document in the `countryinfo` collection by country name.

```
mysql-js> db.countryinfo.remove("true").sort(["Name desc"]).limit(1)
Query OK, 1 item affected (0.02 sec)
```

Remove All Documents in a Collection

You can remove all documents in a collection. To do so, use the `remove("true")` method without specifying any search condition.

**Caution**

Use care when you remove documents without specifying a search condition. This action will delete all documents from the collection.

Related Information

- See [CollectionRemoveFunction](#) for the full syntax definition.
- See [Section 20.4.2, "Import Database Sample"](#) for instructions to recreate the `world_x` database.

20.4.4.6 Create and Drop Indexes

Indexes are used to find documents with specific field values quickly. Without an index, MySQL must begin with the first document and then read through the entire collection to find the relevant fields. The larger the collection, the more this costs. If a collection is large and queries on a specific field are common, then consider creating an index on a specific field inside a document.

For example, the following query will perform better with an index:

```
mysql-js> db.countryinfo.find("demographics.Population < 100")
...[output removed]
8 documents in set (0.00 sec)
```

The `createIndex()` method creates an index that you can define as nonunique or unique. Use the `field()` method to chain the fields that should be indexed. The `execute()` method is required to create or drop an index.

In MySQL, the `_id` field is equivalent to a primary key by default.

Add a Nonunique Index

To create a nonunique index, pass to the `createIndex()` method an index name. Duplicate index names are prohibited.

In the following example, the first parameter of the `field()` method specifies the Population field inside the demographics object and the next parameter indicates that the field should be indexed as an Integer numeric value. The last parameter indicates whether the field should require the NOT NULL constraint. If the value is `false`, the field can contain `NULL` values.

```
mysql-js> db.countryinfo.createIndex("pop").
field("demographics.Population", "INTEGER", false).execute()
Query OK (0.04 sec)
```

Add a Unique Index

To create a unique index, pass to the `createIndex()` method an index name and the `mysqlx.IndexType.UNIQUE` type. Country "Name" is another common field in the countryinfo collection to index. In the following example, `Text(40)` represents the number of characters to index and `true` indicates that the field cannot contain any `NULL` values.

```
mysql-js> db.countryinfo.createIndex("name", mysqlx.IndexType.UNIQUE).
field("Name", "TEXT(40)", true).execute()
Query OK (0.04 sec)
```

Drop an Index

To drop an index, pass to the `dropIndex()` method the name of the index to drop. For example, you can drop the "pop" index as follows:

```
mysql-js> db.countryinfo.dropIndex("pop").execute()
Query OK (0.58 sec)
```

Related Information

- See [Collection Index Management Functions](#) for the full syntax definition.

20.4.5 Relational Tables

You can use MySQL Shell to manipulate not just JSON documents, but also relational tables.

In MySQL, each relational table is associated with a particular storage engine. The examples in this section use `InnoDB` tables in the `world_x` database.

Confirm the Schema

To show the value that is assigned to the schema variable, type `db`.

```
mysql-js> db
```

If the schema value is not `Schema:world_x`, then set the `db` variable as follows:

```
mysql-js> \use world_x
```

Show All Tables

To display all relational tables in the `world_x` database, use the `getTables()` method on the schema object.

```
mysql-js> db.getTables()
{
  "city": <Table:city>,
  "country": <Table:country>,
  "countrylanguage": <Table:countrylanguage>
}
```

Basic Table Operations

Basic operations scoped by tables include:

Operation form	Description
<code>db.name.insert()</code>	The <code>insert()</code> method inserts one or more records into the named table.
<code>db.name.select()</code>	The <code>select()</code> method returns some or all records in the named table.
<code>db.name.update()</code>	The <code>update()</code> method updates records in the named table.
<code>db.name.delete()</code>	The <code>delete()</code> method deletes one or more records from the named table.

Related Information

- See [Working with Relational Tables](#) for a general overview.
- [CRUD EBNF Definitions](#) provides a complete list of operations.
- See [Section 20.4.2, "Import Database Sample"](#) for instructions on setting up the `world_x` database sample.

20.4.5.1 Insert Records into Tables

You can use the `insert()` method with the `values()` method to insert records into an existing relational table. The `insert()` method accepts individual columns or all columns in the table. Use one or more `values()` methods to specify the values to be inserted.

Insert a Complete Record

To insert a complete record, pass to the `insert()` method all columns in the table. Then pass to the `values()` method one value for each column in the table. For example, to add a new record to the city table in the `world_x` database, insert the following record and press **Enter** twice.

```
mysql-js> db.city.insert("ID", "Name", "CountryCode", "District", "Info").
values(null, "Olympia", "USA", "Washington", '{"Population": 5000}')
```

Query OK, 1 item affected (0.01 sec)

The city table has five columns: ID, Name, CountryCode, District, and Info. Each value must match the data type of the column it represents.

Insert a Partial Record

The following example inserts values into the ID, Name, and CountryCode columns of the city table.

```
mysql-js> db.city.insert("ID", "Name", "CountryCode").
values(null, "Little Falls", "USA").values(null, "Happy Valley", "USA")
```

Query OK, 2 item affected (0.03 sec)

When you specify columns using the `insert()` method, the number of values must match the number of columns. In the previous example, you must supply three values to match the three columns specified.

Related Information

- See [TableInsertFunction](#) for the full syntax definition.

20.4.5.2 Select Tables

You can use the `select()` method to query for and return records from a table in a database. The X DevAPI provides additional methods to use with the `select()` method to filter and sort the returned records.

MySQL provides the following operators to specify search conditions: `OR (| |)`, `AND (&&)`, `XOR`, `IS`, `NOT`, `BETWEEN`, `IN`, `LIKE`, `!=`, `<>`, `>`, `>=`, `<`, `<=`, `&`, `|`, `<<`, `>>`, `+`, `-`, `*`, `/`, `~`, and `%`.

Select All Records

To issue a query that returns all records from an existing table, use the `select()` method without specifying search conditions. The following example selects all records from the city table in the `world_x` database.

Note

Limit the use of the empty `select()` method to interactive statements. Always use explicit column-name selections in your application code.

```
mysql-js> db.city.select()
+-----+-----+-----+-----+-----+
| ID | Name | CountryCode | District | Info |
+-----+-----+-----+-----+-----+
| 1 | Kabul | AFG | Kabul | {"Population": 1780000} |
| 2 | Qandahar | AFG | Qandahar | {"Population": 237500} |
| 3 | Herat | AFG | Herat | {"Population": 186800} |
+-----+-----+-----+-----+-----+
```

```

...      ...      ...      ...      ...
| 4079 | Rafah      | PSE      | Rafah      | {"Population": 92020} |
+-----+-----+-----+-----+-----+
4082 rows in set (0.01 sec)

```

An empty set (no matching records) returns the following information:

```
Empty set (0.00 sec)
```

Filter Searches

To issue a query that returns a set of table columns, use the `select()` method and specify the columns to return between square brackets. This query returns the Name and CountryCode columns from the city table.

```
mysql-js> db.city.select(["Name", "CountryCode"])
+-----+-----+
| Name      | CountryCode |
+-----+-----+
| Kabul     | AFG         |
| Qandahar  | AFG         |
| Herat     | AFG         |
| Mazar-e-Sharif | AFG         |
| Amsterdam | NLD         |
...
| Rafah     | PSE         |
| Olympia   | USA         |
| Little Falls | USA         |
| Happy Valley | USA         |
+-----+-----+
4082 rows in set (0.00 sec)
```

To issue a query that returns rows matching specific search conditions, use the `where()` method to include those conditions. For example, the following example returns the names and country codes of the cities that start with the letter Z.

```
mysql-js> db.city.select(["Name", "CountryCode"]).where("Name like 'Z%')
+-----+-----+
| Name      | CountryCode |
+-----+-----+
| Zaanstad  | NLD         |
| Zoetermeer | NLD         |
| Zwolle    | NLD         |
| Zenica    | BIH         |
| Zagazig   | EGY         |
| Zaragoza  | ESP         |
| Zamboanga | PHL         |
| Zahedan   | IRN         |
| Zanzjan   | IRN         |
| Zabol     | IRN         |
| Zama      | JPN         |
| Zhezqazghan | KAZ         |
| Zhengzhou | CHN         |
...
| Zeleznogorsk | RUS         |
+-----+-----+
59 rows in set (0.00 sec)
```

You can separate a value from the search condition by using the `bind()` method. For example, instead of using "Name = 'Z%' " as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as *name*. Then include the placeholder and value in the `bind()` method as follows:

```
mysql-js> db.city.select(["Name", "CountryCode"]).
           where("Name like :name").bind("name", "Z%")
```

**Tip**

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

Project Results

To issue a query using the `AND` operator, add the operator between search conditions in the `where()` method.

```
mysql-js> db.city.select(["Name", "CountryCode"]).
           where("Name like 'Z%' and CountryCode = 'CHN'")
+-----+-----+
| Name          | CountryCode |
+-----+-----+
| Zhengzhou    | CHN         |
| Zibo         | CHN         |
| Zhangjiakou  | CHN         |
| Zhuzhou     | CHN         |
| Zhangjiang   | CHN         |
| Zigong       | CHN         |
| Zaozhuang    | CHN         |
| ...         | ...         |
| Zhangjiagang | CHN         |
+-----+-----+
22 rows in set (0.01 sec)
```

To specify multiple conditional operators, you can enclose the search conditions in parenthesis to change the operator precedence. The following example demonstrates the placement of `AND` and `OR` operators.

```
mysql-js> db.city.select(["Name", "CountryCode"]).
           where("Name like 'Z%' and (CountryCode = 'CHN' or CountryCode = 'RUS'")
+-----+-----+
| Name          | CountryCode |
+-----+-----+
| Zhengzhou    | CHN         |
| Zibo         | CHN         |
| Zhangjiakou  | CHN         |
| Zhuzhou     | CHN         |
| ...         | ...         |
| Zeleznogorsk | RUS         |
+-----+-----+
29 rows in set (0.01 sec)
```

Limit, Order, and Offset Results

You can apply the `limit()`, `orderBy()`, and `offset()` methods to manage the number and order of records returned by the `select()` method.

To specify the number of records included in a result set, append the `limit()` method with a value to the `select()` method. For example, the following query returns the first five records in the country table.

```
mysql-js> db.country.select(["Code", "Name"]).limit(5)
+-----+-----+
| Code | Name          |
+-----+-----+
| ABW  | Aruba         |
| AFG  | Afghanistan   |
```

```
| AGO | Angola |
| AIA | Anguilla |
| ALB | Albania |
+-----+-----+
5 rows in set (0.00 sec)
```

To specify an order for the results, append the `orderBy()` method to the `select()` method. Pass to the `orderBy()` method a list of one or more columns to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all records by the Name column and then returns the first three records in descending order .

```
mysql-js> db.country.select(["Code", "Name"]).orderBy(["Name desc"]).limit(3)
+-----+-----+
| Code | Name |
+-----+-----+
| ZWE | Zimbabwe |
| ZMB | Zambia |
| YUG | Yugoslavia |
+-----+-----+
3 rows in set (0.00 sec)
```

By default, the `limit()` method starts from the first record in the table. You can use the `offset()` method to change the starting record. For example, to ignore the first record and return the next three records matching the condition, pass to the `offset()` method a value of 1.

```
mysql-js> db.country.select(["Code", "Name"]).orderBy(["Name desc"]).limit(3).offset(1)
+-----+-----+
| Code | Name |
+-----+-----+
| ZMB | Zambia |
| YUG | Yugoslavia |
| YEM | Yemen |
+-----+-----+
3 rows in set (0.00 sec)
```

Related Information

- The [MySQL Reference Manual](#) provides detailed documentation on functions and operators.
- See [TableSelectFunction](#) for the full syntax definition.

20.4.5.3 Update Tables

You can use the `update()` method to modify one or more records in a table. The `update()` method works by filtering a query to include only the records to be updated and then applying the operations you specify to those records.

To replace a city name in the city table, pass to the `set()` method the new city name. Then, pass to the `where()` method the city name to locate and replace. The following example replaces the city Peking with Beijing.

```
mysql-js> db.city.update().set("Name", "Beijing").where("Name = 'Peking'")
Query OK, 1 item affected (0.04 sec)
```

Use the `select()` method to verify the change.

```
mysql-js> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).where("Name = 'Beijing'")
+-----+-----+-----+-----+-----+
| ID | Name | CountryCode | District | Info |
+-----+-----+-----+-----+-----+
| 1891 | Beijing | CHN | Peking | {"Population": 7472000} |
+-----+-----+-----+-----+-----+
```

```
1 row in set (0.00 sec)
```

Related Information

- See [TableUpdateFunction](#) for the full syntax definition.

20.4.5.4 Delete Tables

You can use the `delete()` method to remove some or all records from a table in a database. The X DevAPI provides additional methods to use with the `delete()` method to filter and order the records to be deleted.

Delete Records Using Conditions

The example that follows passes search conditions to the `delete()` method. All records matching the condition will be deleted from the city table. In this example, one record matches the condition.

```
mysql-js> db.city.delete().where("Name = 'Olympia'")
Query OK, 1 item affected (0.01 sec)
```

Delete the First Record

To delete the first record in the city table, use the `limit()` method with a value of 1.

```
mysql-js> db.city.delete().limit(1)
Query OK, 1 item affected (0.02 sec)
```

Delete All Records in a Table

You can delete all records in a table. To do so, use the `delete()` method without specifying a search condition.

Caution

Use care when you delete records without specifying a search condition. This action will delete all records from the table.

Related Information

- See [TableDeleteFunction](#) for the full syntax definition.
- See [Section 20.4.2, "Import Database Sample"](#) for instructions to recreate the `world_x` database.

20.4.6 Documents in Tables

In MySQL, a table may contain traditional relational data, JSON values, or both. You can combine traditional data with JSON documents by storing the documents in columns having a native `JSON` data type.

Examples in this section use the city table in the `world_x` database.

city Table Description

The city table has five columns (or fields).

Field	Type	Null	Key	Default	Extra
ID	int(11)	NO	PRI	null	auto_increment
Name	char(35)	NO			
CountryCode	char(3)	NO			
District	char(20)	NO			

Info	json	YES		null	
------	------	-----	--	------	--

Insert a Record

To insert a document into the column of a table, pass to the `values()` method a well-formed JSON document in the correct order. In the following example, a document is passed as the final value to be inserted into the Info column.

```
mysql-js> db.city.insert().
values(null, "San Francisco", "USA", "California", '{"Population":830000}')
Query OK, 1 item affected (0.01 sec)
```

Select a Record

You can issue a query with a search condition that evaluates document values in the expression.

```
mysql-js> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).
where("CountryCode = :country and Info->'$.Population' > 1000000").
bind('country', 'USA')
```

ID	Name	CountryCode	District	Info
3793	New York	USA	New York	{"Population": 8008278}
3794	Los Angeles	USA	California	{"Population": 3694820}
3795	Chicago	USA	Illinois	{"Population": 2896016}
3796	Houston	USA	Texas	{"Population": 1953631}
3797	Philadelphia	USA	Pennsylvania	{"Population": 1517550}
3798	Phoenix	USA	Arizona	{"Population": 1321045}
3799	San Diego	USA	California	{"Population": 1223400}
3800	Dallas	USA	Texas	{"Population": 1188580}
3801	San Antonio	USA	Texas	{"Population": 1144646}

9 rows in set (0.01 sec)

Related Information

- See [Working with Relational Tables and Documents](#) for a general overview.
- See [Section 11.6, “The JSON Data Type”](#) for a detailed description of the data type.

20.5 Quick-Start Guide: MySQL Shell for Python

This quick-start guide provides instructions to begin prototyping database applications interactively with MySQL Shell. The guide includes the following topics:

- Introduction to MySQL functionality, MySQL Shell, and the `world_x` database sample.
- Operations to manage collections and documents.
- Operations to manage relational tables.
- Operations that apply to documents within tables.

Available Quick-Start Guides

- [MySQL Shell for JavaScript](#)
- [MySQL for Visual Studio](#)

Related Information

- [Chapter 19, MySQL Shell User Guide](#) provides more in-depth information about MySQL Shell.

- [X DevAPI User Guide](#) provides more examples of using X DevAPI.

20.5.1 Introduction

The MySQL Shell for Python quick start provides a short but comprehensive introduction to the database functionality including the new X DevAPI, which offers a modern, integrative way to work with relational and document data, without requiring SQL knowledge from application developers.

In MySQL, tables are the native data storage container type and collections are stored internally using tables.

JSON Documents and Collections

A JSON [document](#) is a data structure composed of field/value pairs stored within a [collection](#). The values of fields often contain other documents, arrays, and lists of documents.

```
{
  "GNP": .6,
  "IndepYear": 1967,
  "Name": "Sealand",
  "_id": "SEA",
  "demographics": {
    "LifeExpectancy": 79,
    "Population": 27
  },
  "geography": {
    "Continent": "Europe",
    "Region": "British Islands",
    "SurfaceArea": 193
  },
  "government": {
    "GovernmentForm": "Monarchy",
    "HeadOfState": "Michael Bates"
  }
}
```

Relational Tables

A [table](#) in MySQL enables you to store data organized in rows and columns. The structure of a table is defined by one or more columns with user-defined names and data types. Every row stored in the table has the same structure.

ID	Name	CountryCode	District	Info
1	Kabul	AFG	Kabol	{"Population": 1780000}
2	Qandahar	AFG	Qandahar	{"Population": 237500}
3	Herat	AFG	Herat	{"Population": 186800}
4	Mazar-e-Sharif	AFG	Balkh	{"Population": 127800}
5	Amsterdam	NLD	Noord-Holland	{"Population": 731200}
6	Rotterdam	NLD	Zuid-Holland	{"Population": 593321}

Related Information

- [Chapter 19, MySQL Shell User Guide](#) provides a general overview.
- See [X DevAPI User Guide](#) for development reference documentation.

20.5.2 Import Database Sample

The `world_x` database sample contains one JSON collection and a set of three relational tables:

- Collection

- countryinfo: Information about countries in the world.
- Tables
 - country: Minimal information about countries of the world.
 - city: Information about some of the cities in those countries.
 - countrylanguage: Languages spoken in each country.

Requirements

You must install MySQL Shell with the X Protocol enabled. For instructions, see [Section 20.3, “Setting Up MySQL as a Document Store”](#).

Start the server before you load the `world_x` database for this guide.

Download world_x Database

To prepare the `world_x` database sample, follow these steps:

1. Download [world_x-db.zip](#).
2. Extract the installation archive to a temporary location such as `/tmp/`. Unpacking the archive results in a single file named `world_x.sql`.
3. Create the schema with the following command:

```
mysqlsh -u root --sql < /tmp/world_x-db/world_x.sql
Enter password: ****
```

Enter your password when prompted. A non-root account can be used as long as the account has privileges to create new databases.

Replace `/tmp/` with the path to the `world_x.sql` file on your system.

Related Information

- [Section 19.2.1, “MySQL Shell Sessions”](#) explains session types.
- See [Chapter 2, *Installing and Upgrading MySQL*](#) for general installation assistance.

20.5.3 MySQL Shell

MySQL Shell is a unified scripting interface to MySQL Server. It supports scripting in JavaScript and Python. JavaScript is the default processing mode. In most cases, you need an account to connect to the local MySQL server instance.

Start MySQL Shell

After you have installed and started MySQL server, connect MySQL Shell to the server instance. By default, MySQL Shell connects using the X Protocol.

On the same system where the server instance is running, open a terminal window and start MySQL Shell with the following command:

```
mysqlsh name@localhost/world_x --py
Creating a Session to name@localhost/world_x
Enter password: ****
```

You may need to specify the path as appropriate.

In addition:

- `name` represents the user name of your MySQL account.
- MySQL Shell prompts you for your password.
- The `--py` option starts MySQL Shell in Python mode. If you omit `--py`, MySQL Shell starts in JavaScript mode.
- The default schema for this session is the `world_x` database. For instructions on setting up the `world_x` database sample, see [Section 20.5.2, “Import Database Sample”](#).

The `mysql-py>` prompt indicates that the active language for this session is Python.

```
mysql-py>
```

When you run `mysqlsh` without the host argument, MySQL Shell attempts to connect to the server instance running on the localhost interface on port 33060. To specify a different host or port number, as well as other options, see the option descriptions at [Section 4.5.7, “mysqlsh — The MySQL Shell”](#).

MySQL Shell supports input-line editing as follows:

- **left-arrow** and **right-arrow** keys move horizontally within the current input line.
- **up-arrow** and **down-arrow** keys move up and down through the set of previously entered lines.
- **Backspace** deletes the character before the cursor and typing new characters enters them at the cursor position.
- **Enter** enters the current input line.

Get Help for MySQL Shell

Type `mysqlsh --help` at the prompt of your command interpreter for a list of command-line options.

```
mysqlsh --help
```

Type `\help` at the MySQL Shell prompt for a list of available commands and their descriptions.

```
mysql-py> \help
```

Type `\help` followed by a command name for detailed help about an individual MySQL Shell command. For example, to view help on the `\connect` command, type:

```
mysql-py> \help \connect
```

Quit MySQL Shell

To quit MySQL Shell, type the following command:

```
mysql-py> \quit
```

Related Information

- See [Section 19.3.1, “Interactive Code Execution”](#) for an explanation of how interactive code execution works in MySQL Shell.
- See [Section 19.2, “Getting Started with MySQL Shell”](#) to learn about session and connection alternatives.

20.5.4 Documents and Collections

In MySQL, collections contain JSON documents that you can add, find, update, and remove. Collections are containers within a schema that you create, list, and drop.

The examples in this section use the `countryinfo` collection in the `world_x` database. For instructions on setting up the `world_x` database sample, see [Section 20.5.2, “Import Database Sample”](#).

Documents

In MySQL, documents are represented as JSON objects. Internally, they are stored in an efficient binary format that enables fast lookups and updates.

- Simple document format for Python:

```
{"field1": "value", "field2" : 10, "field 3": null}
```

An array of documents consists of a set of documents separated by commas and enclosed within [and] characters.

- Simple array of documents for Python:

```
[{"Name": "Aruba", "_id": "ABW"}, {"Name": "Angola", "_id": "AGO"}]
```

MySQL supports the following Python value types in JSON documents:

- numbers (integer and floating point)
- strings
- boolean (False and True)
- None
- arrays of more JSON values
- nested (or embedded) objects of more JSON values

Collections

Collections are containers for documents that share a purpose and possibly share one or more indexes. Each collection has a unique name and exists within a single schema.

The term schema is equivalent to a database, which means a group of database objects (as opposed to relational schema used to enforce structure and constraints over data). A schema does not enforce conformity on the documents in a collection.

In this quick-start guide:

- Basic objects include:

Object form	Description
<code>db</code>	<code>db</code> is a global variable assigned to the current active schema that you specified on the command line. You can type <code>db</code> in MySQL Shell to print a description of the object, which in this case will be the name of the schema it represents.
<code>db.get_collections()</code>	<code>db.get_collections()</code> holds a list of collections in the schema. Use the list to get references to collection objects, iterate over them, and so on.

- Basic operations scoped by collections include:

Operation form	Description
<code>db.name.add()</code>	The <code>add()</code> method inserts one document or a list of documents into the named collection.
<code>db.name.find()</code>	The <code>find()</code> method returns some or all documents in the named collection.
<code>db.name.modify()</code>	The <code>modify()</code> method updates documents in the named collection.
<code>db.name.remove()</code>	The <code>remove()</code> method deletes one document or a list of documents from the named collection.

Related Information

- See [Working with Collections](#) for a general overview.
- [CRUD EBNF Definitions](#) provides a complete list of operations.

20.5.4.1 Create, List, and Drop Collections

In MySQL Shell, you can create new collections, get a list of the existing collections in a schema, and remove an existing collection from a schema. Collection names are case-sensitive and each collection name must be unique.

Confirm the Schema

To show the value that is assigned to the schema variable, type `db`.

```
mysql-py> db
```

If the schema value is not `Schema:world_x`, then set the `db` variable as follows:

```
mysql-py> \use world_x
```

Create a Collection

To create a new collection in an existing schema, use the `create_collection()` method. The following example creates in the `world_x` database a collection called `flags`.

```
mysql-py> db.create_collection("flags")
```

The method returns a collection object.

```
<Collection:flags>
```

List Collections

To display all collections in the `world_x` database, use the `get_collections()` method on the schema object. Collections returned by the server appear between brackets.

```
mysql-py> db.get_collections()
[
  <Collection:countryinfo>,
  <Collection:flags>
]
```

Drop a Collection

To drop an existing collection from a database, use the `drop_collection()` method on the session object. For example, to drop the `flags` collection from the `world_x` database, type:

```
mysql-py> session.drop_collection("world_x", "flags")
Query OK (0.04 sec)
```

Related Information

- See [Section 19.2.2.6, “Connections in JavaScript and Python”](#) to learn more about the session object.
- See [Collection Objects](#) for more examples.

20.5.4.2 Add Documents

You can use the `add()` method to insert one document or a list documents into an existing collection using MySQL Shell. All examples in this section use the `countryinfo` collection.

Confirm the Schema

To show the value that is assigned to the schema variable, type `db`.

```
mysql-py> db
<Schema:world_x>
```

If the schema value is not `Schema:world_x`, then set the `db` variable as follows:

```
mysql-py> \use world_x
Schema `world_x` accessible through db.
```

Add a Document

Insert the following document into the `countryinfo` collection. Press **Enter** twice to insert the document.

```
mysql-py> db.countryinfo.add(
{
  "GNP": .6,
  "IndepYear": 1967,
  "Name": "Sealand",
  "_id": "SEA",
  "demographics": {
    "LifeExpectancy": 79,
    "Population": 27
  },
  "geography": {
    "Continent": "Europe",
    "Region": "British Islands",
    "SurfaceArea": 193
  },
  "government": {
    "GovernmentForm": "Monarchy",
    "HeadOfState": "Michael Bates"
  }
}
)
Query OK, 1 item affected (0.02 sec)
```

The method returns the status of the operation.

Each document requires an identifier field called `_id`. The value of the `_id` field must be unique among all documents in the same collection. If the document passed to the `add()` method does not contain the `_id` field, MySQL Shell automatically inserts a field into the document and sets the value to a generated universal unique identifier (UUID).

Related Information

- See [CollectionAddFunction](#) for the full syntax definition.

20.5.4.3 Find Documents

You can use the `find()` method to query for and return documents from a collection in a database. MySQL Shell provides additional methods to use with the `find()` method to filter and sort the returned documents.

MySQL provides the following operators to specify search conditions: `OR (| |)`, `AND (&&)`, `XOR`, `IS`, `NOT`, `BETWEEN`, `IN`, `LIKE`, `!=`, `<>`, `>`, `>=`, `<`, `<=`, `&`, `|`, `<<`, `>>`, `+`, `-`, `*`, `/`, `~`, and `%`.

Find All Documents in a Collection

To return all documents in a collection, use the `find()` method without specifying search conditions. For example, the following operation returns all documents in the `countryinfo` collection.

```
mysql-py> db.countryinfo.find()
[
  {
    "GNP": 828,
    "IndepYear": null,
    "Name": "Aruba",
    "_id": "ABW",
    "demographics": {
      "LifeExpectancy": 78.4000015258789,
      "Population": 103000
    },
    "geography": {
      "Continent": "North America",
      "Region": "Caribbean",
      "SurfaceArea": 193
    },
    "government": {
      "GovernmentForm": "Nonmetropolitan Territory of The Netherlands",
      "HeadOfState": "Beatrix"
    }
    ...
  }
]
240 documents in set (0.00 sec)
```

The method produces results that contain operational information in addition to all documents in the collection.

An empty set (no matching documents) returns the following information:

```
Empty set (0.00 sec)
```

Filter Searches

You can include search conditions with the `find()` method. The syntax for expressions that form a search condition is the same as that of traditional [MySQL](#). You must enclose all expressions in quotes.

All examples in this section use the `countryinfo` collection in the `world_x` database. For the sake of brevity, some of the examples do not display output.

A simple search condition consists of the `_id` field and unique identifier of a document. The following example returns a single document matching the identifier string:

```
mysql-py> db.countryinfo.find("_id = 'AUS'")
[
  {
    "GNP": 351182,
    "IndepYear": 1901,
    "Name": "Australia",
    "_id": "AUS",
  }
]
```

```

    "demographics": {
      "LifeExpectancy": 79.80000305175781,
      "Population": 18886000
    },
    "geography": {
      "Continent": "Oceania",
      "Region": "Australia and New Zealand",
      "SurfaceArea": 7741220
    },
    "government": {
      "GovernmentForm": "Constitutional Monarchy, Federation",
      "HeadOfState": "Elisabeth II"
    }
  }
]
1 document in set (0.01 sec)

```

The following example searches for all countries that have a GNP higher than \$500 billion. The countryinfo collection measures GNP in units of million.

```

mysql-py> db.countryinfo.find("GNP > 500000")
...[output removed]
10 documents in set (0.00 sec)

```

The Population field in the following query is embedded within the demographics object. To access the embedded field, use a period between demographics and Population to identify the relationship. Document and field names are case sensitive.

```

mysql-py> db.countryinfo.find("GNP > 500000 and demographics.Population < 100000000")
...[output removed]
6 documents in set (0.00 sec)

```

Arithmetic operators in the following expression are used to query for countries with a GNP per capita higher than \$30000. Search conditions can include arithmetic operators and most MySQL functions.

Note

Seven documents in the countryinfo collection have a population value of zero. Warning messages appear at the end of the output.

```

mysql-py> db.countryinfo.find("GNP*1000000/demographics.Population > 30000")
...[output removed]
9 documents in set, 7 warnings (0.00 sec)
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0
Warning (Code 1365): Division by 0

```

You can separate a value from the search condition by using the `bind()` method. For example, instead of specifying a hard-coded country name as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `country`. Then include the placeholder and value in the `bind()` method as follows:

```

mysql-py> db.countryinfo.find("Name = :country").bind("country", "Italy")
[
  {
    "GNP": 1161755,
    "IndepYear": 1861,
    "Name": "Italy",
    "_id": "ITA",
    "demographics": {
      "LifeExpectancy": 79,

```

```

    "Population": 57680000
  },
  "geography": {
    "Continent": "Europe",
    "Region": "Southern Europe",
    "SurfaceArea": 301316
  },
  "government": {
    "GovernmentForm": "Republic",
    "HeadOfState": "Carlo Azeglio Ciampi"
  }
}
]
1 document in set (0.01 sec)

```

Tip

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

Project Results

You can return specific fields of a document, instead of returning all the fields. The following example returns the GNP and Name fields of all documents in the `countryinfo` collection matching the search conditions.

Use the `fields()` method to pass the list of fields to return.

```

mysql-py> db.countryinfo.find("GNP > 5000000").fields(["GNP", "Name"])
[
  {
    "GNP": 8510700,
    "Name": "United States"
  }
]
1 document in set (0.00 sec)

```

In addition, you can alter the returned documents—adding, renaming, nesting and even computing new field values—with an expression that describes the document to return. For example, alter the names of the fields with the following expression to return only two documents.

```

mysql-py> db.countryinfo.find().\
fields(mysqlx.expr('{ "Name": upper(Name), "GNPPerCapita": GNP*1000000/demographics.Population}')).\
limit(2)
[
  {
    "GNPPerCapita": 8038.834951456311,
    "Name": "ARUBA"
  },
  {
    "GNPPerCapita": 263.0281690140845,
    "Name": "AFGHANISTAN"
  }
]
2 documents in set (0.00 sec)

```

Limit, Sort, and Skip Results

You can apply the `limit()`, `sort()`, and `skip()` methods to manage the number and order of documents returned by the `find()` method.

To specify the number of documents included in a result set, append the `limit()` method with a value to the `find()` method. The following query returns the first five documents in the `countryinfo` collection.

```
mysql-py> db.countryinfo.find().limit(5)
... [output removed]
5 documents in set (0.00 sec)
```

To specify an order for the results, append the `sort()` method to the `find()` method. Pass to the `sort()` method a list of one or more fields to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all documents by the `IndepYear` field and then returns the first eight documents in descending order.

```
mysql-py> db.countryinfo.find().sort(["IndepYear desc"]).limit(8)
... [output removed]
8 documents in set (0.00 sec)
```

By default, the `limit()` method starts from the first document in the collection. You can use the `skip()` method to change the starting document. For example, to ignore the first document and return the next eight documents matching the condition, pass to the `skip()` method a value of 1.

```
mysql-py> db.countryinfo.find().sort(["IndepYear desc"]).limit(8).skip(1)
... [output removed]
8 documents in set (0.00 sec)
```

Related Information

- The [MySQL Reference Manual](#) provides detailed documentation on functions and operators.
- See [CollectionFindFunction](#) for the full syntax definition.

20.5.4.4 Modify Documents

You can use the `modify()` method to update one or more documents in a collection. The X DevAPI provides additional methods for use with the `modify()` method to:

- Set and unset fields within documents.
- Append, insert, and delete arrays.
- Bind, limit, and sort the documents to be modified.

Set and Unset Fields

The `modify()` method works by filtering a collection to include only the documents to be modified and then applying the operations that you specify to those documents.

In the following example, the `modify()` method uses the search condition to identify the document to change and then the `set()` method replaces two values within the nested `demographics` object.

```
mysql-py> db.countryinfo.modify("_id = 'SEA'").\
set("demographics", {"LifeExpectancy": 78, "Population": 28})
Query OK, 1 item affected (0.04 sec)
```

After you modify a document, use the `find()` method to verify the change.

To remove content from a document, use the `modify()` and `unset()` methods. For example, the following query removes the `GNP` from a document that matches the search condition.

```
mysql-py> db.countryinfo.modify("Name = 'Sealand').unset("GNP")
Query OK, 1 item affected (0.01 sec)
```

Use the `find()` method to verify the change.

```
mysql-py> db.countryinfo.find("Name = 'Sealand'")
[
  {
    "IndepYear": 1967,
    "Name": "Sealand",
    "_id": "SEA",
    "demographics": {
      "LifeExpectancy": 78,
      "Population": 28
    },
    "geography": {
      "Continent": "Europe",
      "Region": "British Islands",
      "SurfaceArea": 193
    },
    "government": {
      "GovernmentForm": "Monarchy",
      "HeadOfState": "Michael Bates"
    }
  }
]
1 document in set (0.00 sec)
```

Append, Insert, and Delete Arrays

To append an element to an array field, or insert, or delete elements in an array, use the `array_append()`, `array_insert()`, or `array_delete()` methods. The following examples modify the `countryinfo` collection to enable tracking of international airports.

The first example uses the `modify()` and `set()` methods to create a new `Airports` field in all documents.

Caution

Use care when you modify documents without specifying a search condition. This action will modify all documents in the collection.

```
mysql-py> db.countryinfo.modify(True).set("Airports", [])
Query OK, 240 items affected (0.07 sec)
```

With the `Airports` field added, the next example uses the `array_append()` method to add a new airport to one of the documents. `$.Airports` in the following example represents the `Airports` field of the current document.

```
mysql-py> db.countryinfo.modify("Name = 'France').array_append("$.Airports", "ORY")
Query OK, 1 item affected (0.02 sec)
```

Use `db.countryinfo.find("Name = 'France')` to see the change.

To insert an element at a different position in the array, use the `array_insert()` method to specify which index to insert in the path expression. In this case, the index is 0, or the first element in the array.

```
mysql-py> db.countryinfo.modify("Name = 'France').array_insert("$.Airports[0]", "CDG")
Query OK, 1 item affected (0.04 sec)
```

To delete an element from the array, you must pass to the `array_delete()` method the index of the element to be deleted.

```
mysql-py> db.countryinfo.modify("Name = 'France'").array_delete("$.Airports[1]")
Query OK, 1 item affected (0.03 sec)
```

Related Information

- The [MySQL Reference Manual](#) provides instructions to help you search for and modify JSON values.
- See [CollectionModifyFunction](#) for the full syntax definition.

20.5.4.5 Remove Documents

You can use the `remove()` method to delete some or all documents from a collection in a database. The X DevAPI provides additional methods for use with the `remove()` method to filter and sort the documents to be removed.

Remove Documents Using Conditions

The example that follows passes a search condition to the `remove()` method. All documents matching the condition will be removed from the `countryinfo` collection. In this example, one document matches the condition.

```
mysql-py> db.countryinfo.remove("_id = 'SEA'")
Query OK, 1 item affected (0.02 sec)
```

Remove the First Document

To remove the first document in the `countryinfo` collection, use the `limit()` method with a value of 1.

```
mysql-py> db.countryinfo.remove(True).limit(1)
Query OK, 1 item affected (0.03 sec)
```

Remove the Last Document in an Order

The following example removes the last document in the `countryinfo` collection by country name.

```
mysql-py> db.countryinfo.remove(True).sort(["Name desc"]).limit(1)
Query OK, 1 item affected (0.02 sec)
```

Remove All Documents in a Collection

You can remove all documents in a collection. To do so, use the `remove(True)` method without specifying a search condition.

Caution

Use care when you remove documents without specifying a search condition. This action will delete all documents from the collection.

Related Information

- See [CollectionRemoveFunction](#) for the full syntax definition.
- See [Section 20.5.2, “Import Database Sample”](#) for instructions to recreate the `world_x` database.

20.5.4.6 Create and Drop Indexes

Indexes are used to find documents with specific field values quickly. Without an index, MySQL must begin with the first document and then read through the entire collection to find the relevant fields. The larger the collection, the more this costs. If a collection is large and queries on a specific field are common, then consider creating an index on a specific field inside a document.

For example, the following query will perform better with an index:

```
mysql-js> db.countryinfo.find("demographics.Population < 100")
...[output removed]
8 documents in set (0.00 sec)
```

The `create_index()` method creates an index that you can define as nonunique or unique. Use the `field()` method to chain the fields that should be indexed. The `execute()` method is required to create or drop an index.

In MySQL, the `_id` field is equivalent to a primary key by default.

Add a Nonunique Index

To create a nonunique index, pass to the `create_index()` method an index name. Duplicate index names are prohibited.

In the following example, the first parameter of the `field()` method specifies the Population field inside the demographics object and the next parameter indicates that the field should be indexed as an Integer numeric value. The last parameter indicates whether the field should require the NOT NULL constraint. If the value is `False`, the field can contain `NULL` values.

```
mysql-js> db.countryinfo.create_index("pop").\
field("demographics.Population", "INTEGER", False).execute()
Query OK (0.04 sec)
```

Add a Unique Index

To create a unique index, pass to the `create_index()` method an index name and the `mysqlx.IndexType.UNIQUE` type. Country "Name" is another common field in the countryinfo collection to index. In the following example, `Text(40)` represents the number of characters to index and `True` indicates that the field cannot contain any `NULL` values.

```
mysql-js> db.countryinfo.create_index("name", mysqlx.IndexType.UNIQUE).\
field("Name", "TEXT(40)", True).execute()
Query OK (0.04 sec)
```

Drop an Index

To drop an index, pass to the `drop_index()` method the name of the index to drop. For example, you can drop the "pop" index as follows:

```
mysql-js> db.countryinfo.drop_index("pop").execute()
Query OK (0.58 sec)
```

Related Information

- See [Collection Index Management Functions](#) for the full syntax definition.

20.5.5 Relational Tables

You can use MySQL Shell to manipulate not just JSON documents, but also relational tables.

In MySQL, each relational table is associated with a particular storage engine. The examples in this section use `InnoDB` tables in the `world_x` database.

Confirm the Schema

To show the value that is assigned to the schema variable, type `db`.

```
mysql-py> db
<Schema:world_x>
```

If the schema value is not the `Schema:world_x` database, then set the `db` variable as follows:

```
mysql-py> \use world_x
Schema `world_x` accessible through db.
```

Show All Tables

To display all relational tables in the `world_x` database, use the `get_tables()` method on the schema object.

```
mysql-py> db.get_tables()
{
  "city": <Table:city>,
  "country": <Table:country>,
  "countrylanguage": <Table:countrylanguage>
}
```

Basic Table Operations

Basic operations scoped by tables include:

Operation form	Description
<code>db.name.insert()</code>	The <code>insert()</code> method inserts one or more records into the named table.
<code>db.name.select()</code>	The <code>select()</code> method returns some or all records in the named table.
<code>db.name.update()</code>	The <code>update()</code> method updates records in the named table.
<code>db.name.delete()</code>	The <code>delete()</code> method deletes one or more records from the named table.

Related Information

- See [Working with Relational Tables](#) for a general overview.
- [CRUD EBNF Definitions](#) provides a complete list of operations.
- See [Section 20.5.2, "Import Database Sample"](#) for instructions on setting up the `world_x` database sample.

20.5.5.1 Insert Records into Tables

You can use the `insert()` method with the `values()` method to insert records into an existing relational table. The `insert()` method accepts individual columns or all columns in the table. Use one or more `values()` methods to specify the values to be inserted.

Insert a Complete Record

To insert a complete record, pass to the `insert()` method all columns in the table. Then pass to the `values()` method one value for each column. For example, to add a new record to the city table in the `world_x` database, insert the following record and press **Enter** twice.

```
mysql-py> db.city.insert("ID", "Name", "CountryCode", "District", "Info").\
values(None, "Olympia", "USA", "Washington", '{"Population": 5000}')
```

Query OK, 1 item affected (0.01 sec)

The city table has five columns: ID, Name, CountryCode, District, and Info. Each value must match the data type of the column it represents.

Insert a Partial Record

The following example inserts values into the ID, Name, and CountryCode columns of the city table.

```
mysql-py> db.city.insert("ID", "Name", "CountryCode").\
values(None, "Little Falls", "USA").values(None, "Happy Valley", "USA")
Query OK, 2 item affected (0.03 sec)
```

When you specify columns using the `insert()` method, the number of values must match the number of columns. In the previous example, you must supply three values to match the three columns specified.

Related Information

- See [TableInsertFunction](#) for the full syntax definition.

20.5.5.2 Select Tables

You can use the `select()` method to query for and return records from a table in a database. The X DevAPI provides additional methods to use with the `select()` method to filter and sort the returned records.

MySQL provides the following operators to specify search conditions: `OR (| |)`, `AND (&&)`, `XOR`, `IS`, `NOT`, `BETWEEN`, `IN`, `LIKE`, `!=`, `<>`, `>`, `>=`, `<`, `<=`, `&`, `|`, `<<`, `>>`, `+`, `-`, `*`, `/`, `~`, and `%`.

Select All Records

To issue a query that returns all records from an existing table, use the `select()` method without specifying search conditions. The following example selects all records from the city table in the `world_x` database.

Note

Limit the use of the empty `select()` method to interactive statements. Always use explicit column-name selections in your application code.

```
mysql-py> db.city.select()
+-----+-----+-----+-----+-----+
| ID   | Name      | CountryCode | District | Info                                     |
+-----+-----+-----+-----+-----+
| 1    | Kabul     | AFG         | Kabul   | {"Population": 1780000}                |
| 2    | Qandahar  | AFG         | Qandahar | {"Population": 237500}                 |
| 3    | Herat     | AFG         | Herat   | {"Population": 186800}                 |
| ...  | ...       | ...         | ...     | ...                                     |
| 4079 | Rafah     | PSE         | Rafah   | {"Population": 92020}                  |
+-----+-----+-----+-----+-----+
4082 rows in set (0.01 sec)
```

An empty set (no matching records) returns the following information:

```
Empty set (0.00 sec)
```

Filter Searches

To issue a query that returns a set of table columns, use the `select()` method and specify the columns to return between square brackets. This query returns the Name and CountryCode columns from the city table.

```
mysql-py> db.city.select(["Name", "CountryCode"])
+-----+-----+
| Name          | CountryCode |
+-----+-----+
| Kabul         | AFG         |
| Qandahar     | AFG         |
| Herat        | AFG         |
| Mazar-e-Sharif | AFG         |
| Amsterdam    | NLD         |
| ...          | ...         |
| Rafah        | PSE         |
| Olympia      | USA         |
| Little Falls | USA         |
| Happy Valley | USA         |
+-----+-----+
4082 rows in set (0.00 sec)
```

To issue a query that returns rows matching specific search conditions, use the `where()` method to include those conditions. For example, the following example returns the names and country codes of the cities that start with the letter Z.

```
mysql-py> db.city.select(["Name", "CountryCode"]).where("Name like 'Z%')
+-----+-----+
| Name          | CountryCode |
+-----+-----+
| Zaanstad      | NLD         |
| Zoetermeer   | NLD         |
| Zwolle        | NLD         |
| Zenica        | BIH         |
| Zagazig       | EGY         |
| Zaragoza      | ESP         |
| Zamboanga     | PHL         |
| Zahedan       | IRN         |
| Zanzan        | IRN         |
| Zabol         | IRN         |
| Zama          | JPN         |
| Zhezqazghan   | KAZ         |
| Zhengzhou     | CHN         |
| ...          | ...         |
| Zeleznogorsk | RUS         |
+-----+-----+
59 rows in set (0.00 sec)
```

You can separate a value from the search condition by using the `bind()` method. For example, instead of using `"Name = 'Z%' "` as the condition, substitute a named placeholder consisting of a colon followed by a name that begins with a letter, such as `name`. Then include the placeholder and value in the `bind()` method as follows:

```
mysql-py> db.city.select(["Name", "CountryCode"]).\
           where("Name like :name").bind("name", "Z%")
```

Tip

Within a program, binding enables you to specify placeholders in your expressions, which are filled in with values before execution and can benefit from automatic escaping, as appropriate.

Always use binding to sanitize input. Avoid introducing values in queries using string concatenation, which can produce invalid input and, in some cases, can cause security issues.

Project Results

To issue a query using the `AND` operator, add the operator between search conditions in the `where()` method.

```
mysql-py> db.city.select(["Name", "CountryCode"]).\
           where("Name like 'Z%' and CountryCode = 'CHN'")
+-----+-----+
| Name          | CountryCode |
+-----+-----+
| Zhengzhou    | CHN         |
| Zibo         | CHN         |
| Zhangjiakou  | CHN         |
| Zhuzhou     | CHN         |
| Zhangjiang   | CHN         |
| Zigong       | CHN         |
| Zaozhuang    | CHN         |
| ...          | ...         |
| Zhangjiagang | CHN         |
+-----+-----+
22 rows in set (0.01 sec)
```

To specify multiple conditional operators, you can enclose the search conditions in parenthesis to change the operator precedence. The following example demonstrates the placement of **AND** and **OR** operators.

```
mysql-py> db.city.select(["Name", "CountryCode"]).\
           where("Name like 'Z%' and (CountryCode = 'CHN' or CountryCode = 'RUS'")
+-----+-----+
| Name          | CountryCode |
+-----+-----+
| Zhengzhou    | CHN         |
| Zibo         | CHN         |
| Zhangjiakou  | CHN         |
| Zhuzhou     | CHN         |
| ...          | ...         |
| Zeleznogorsk | RUS         |
+-----+-----+
29 rows in set (0.01 sec)
```

Limit, Order, and Offset Results

You can apply the `limit()`, `order_by()`, and `offset()` methods to manage the number and order of records returned by the `select()` method.

To specify the number of records included in a result set, append the `limit()` method with a value to the `select()` method. For example, the following query returns the first five records in the country table.

```
mysql-py> db.country.select(["Code", "Name"]).limit(5)
+-----+-----+
| Code | Name          |
+-----+-----+
| ABW  | Aruba         |
| AFG  | Afghanistan  |
| AGO  | Angola        |
| AIA  | Anguilla      |
| ALB  | Albania       |
+-----+-----+
5 rows in set (0.00 sec)
```

To specify an order for the results, append the `order_by()` method to the `select()` method. Pass to the `order_by()` method a list of one or more columns to sort by and, optionally, the descending (`desc`) or ascending (`asc`) attribute as appropriate. Ascending order is the default order type.

For example, the following query sorts all records by the Name column and then returns the first three records in descending order .

```
mysql-py> db.country.select(["Code", "Name"]).order_by(["Name desc"]).limit(3)
+-----+-----+
| Code | Name |
+-----+-----+
| ZWE  | Zimbabwe |
| ZMB  | Zambia |
| YUG  | Yugoslavia |
+-----+-----+
3 rows in set (0.00 sec)
```

By default, the `limit()` method starts from the first record in the table. You can use the `offset()` method to change the starting record. For example, to ignore the first record and return the next three records matching the condition, pass to the `offset()` method a value of 1.

```
mysql-py> db.country.select(["Code", "Name"]).order_by(["Name desc"]).limit(3).offset(1)
+-----+-----+
| Code | Name |
+-----+-----+
| ZMB  | Zambia |
| YUG  | Yugoslavia |
| YEM  | Yemen |
+-----+-----+
3 rows in set (0.00 sec)
```

Related Information

- The [MySQL Reference Manual](#) provides detailed documentation on functions and operators.
- See [TableSelectFunction](#) for the full syntax definition.

20.5.5.3 Update Tables

You can use the `update()` method to modify one or more records in a table. The `update()` method works by filtering a query to include only the records to be updated and then applying the operations you specify to those records.

To replace a city name in the city table, pass to the `set()` method the new city name. Then, pass to the `where()` method the city name to locate and replace. The following example replaces the city Peking with Beijing.

```
mysql-py> db.city.update().set("Name", "Beijing").where("Name = 'Peking'")
Query OK, 1 item affected (0.04 sec)
```

Use the `select()` method to verify the change.

```
mysql-py> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).where("Name = 'Beijing'")
+-----+-----+-----+-----+-----+
| ID | Name | CountryCode | District | Info |
+-----+-----+-----+-----+-----+
| 1891 | Beijing | CHN | Peking | {"Population": 7472000} |
+-----+-----+-----+-----+-----+
1 row in set (0.00 sec)
```

Related Information

- See [TableUpdateFunction](#) for the full syntax definition.

20.5.5.4 Delete Tables

You can use the `delete()` method to remove some or all records from a table in a database. The X DevAPI provides additional methods to use with the `delete()` method to filter and order the records to be deleted.

Delete Records Using Conditions

The example that follows passes search conditions to the `delete()` method. All records matching the condition will be deleted from the city table. In this example, one record matches the condition.

```
mysql-py> db.city.delete().where("Name = 'Olympia'")
Query OK, 1 item affected (0.01 sec)
```

Delete the First Record

To delete the first record in the city table, use the `limit()` method with a value of 1.

```
mysql-py> db.city.delete().limit(1)
Query OK, 1 item affected (0.02 sec)
```

Delete All Records in a Table

You can delete all records in a table. To do so, use the `delete()` method without specifying a search condition.

Caution

Use care when you delete records without specifying a search condition. This action will delete all records from the table.

Related Information

- See [TableDeleteFunction](#) for the full syntax definition.
- See [Section 20.5.2, “Import Database Sample”](#) for instructions to recreate the `world_x` database.

20.5.6 Documents in Tables

In MySQL, a table may contain traditional relational data, JSON values, or both. You can combine traditional data with JSON documents by storing the documents in columns having a native `JSON` data type.

Examples in this section use the city table in the `world_x` database.

city Table Description

The city table has five columns (or fields).

Field	Type	Null	Key	Default	Extra
ID	int(11)	NO	PRI	null	auto_increment
Name	char(35)	NO			
CountryCode	char(3)	NO			
District	char(20)	NO			
Info	json	YES		null	

Insert a Record

To insert a document into the column of a table, pass to the `values()` method a well-formed JSON document in the correct order. In the following example, a document is passed as the final value to be inserted into the Info column.

```
mysql-py> db.city.insert().\
values(None, "San Francisco", "USA", "California", '{"Population":830000}')
```

```
Query OK, 1 item affected (0.01 sec)
```

Select a Record

You can issue a query with a search condition that evaluates document values in the expression.

```
mysql-py> db.city.select(["ID", "Name", "CountryCode", "District", "Info"]).\
  where("CountryCode = :country and Info->'$.Population' > 1000000").\
  bind('country', 'USA')
```

ID	Name	CountryCode	District	Info
3793	New York	USA	New York	{"Population": 8008278}
3794	Los Angeles	USA	California	{"Population": 3694820}
3795	Chicago	USA	Illinois	{"Population": 2896016}
3796	Houston	USA	Texas	{"Population": 1953631}
3797	Philadelphia	USA	Pennsylvania	{"Population": 1517550}
3798	Phoenix	USA	Arizona	{"Population": 1321045}
3799	San Diego	USA	California	{"Population": 1223400}
3800	Dallas	USA	Texas	{"Population": 1188580}
3801	San Antonio	USA	Texas	{"Population": 1144646}

```
9 rows in set (0.01 sec)
```

Related Information

- See [Working with Relational Tables and Documents](#) for a general overview.
- See [Section 11.6, "The JSON Data Type"](#) for a detailed description of the data type.

20.6 Quick-Start Guide: MySQL for Visual Studio

This section explains how to use MySQL Shell to script a server using MySQL for Visual Studio.

Introduction

MySQL for Visual Studio provides access to MySQL objects and data without forcing developers to leave Visual Studio. Designed and developed as a Visual Studio package, MySQL for Visual Studio integrates directly into Server Explorer providing a seamless experience for setting up new connections and working with database objects.

The following MySQL for Visual Studio features are available as of version 2.0.2:

- JavaScript and Python code editors, where scripts in those languages can be executed to query data from a MySQL database.
- Better integration with the Server Explorer to open MySQL, JavaScript, and Python code editors directly from a connected MySQL instance.
- A newer user interface for displaying query results, where different views are presented from result sets returned by a MySQL Server like:
 - Multiple tabs for each result set returned by an executed query.
 - Results view, where the information can be seen in grid, tree, or text representation for JSON results.
 - Field types view, where information about the columns of a result set is shown, such as names, data types, character sets, and more.
 - Query statistics view, displaying information about the executed query such as execution times, processed rows, index and temporary tables usage, and more.

- Execution plan view, displaying an explanation of the query execution done internally by the MySQL Server.

Getting Started

The requirements are MySQL for Visual Studio 2.0.2 or higher, and Visual Studio 2010 or higher. X DevAPI support requires MySQL Server 5.7.12 or higher with the X plugin enabled.

Opening a Code Editor

Before opening a code editor that can execute queries against a MySQL server, a connection needs to be established:

1. Open the Server Explorer pane through the View menu, or with **Control + W, K**.
2. Right-click on the Data Connections node, select **Add Connection....**
3. In the **Add Connection** dialog, make sure the MySQL Data Provider is being used and fill in all the information.

Note

To enter the port number, click **Advanced...** and set the Port among the list of connection properties.

4. Click **Test Connection** to ensure you have a valid connection, then click **OK**.
5. Right-click your newly created connection, select **New MySQL Script** and then the language for the code editor you want to open.

For existing MySQL connections, to create a new editor you need only to do the last step.

Using the Code Editor

The MySQL script editors have a toolbar at the top where information about the session is displayed, along with the actions that can be executed.

Note

Note the first two buttons in the toolbar represent a way to connect or disconnect from a MySQL server. If the editor was opened from the Server Explorer, the connection will be already established for the new editor window.

The third button is the **Run** button, the script contained in the editor window is executed by clicking it and results from the script execution are displayed below the script window.

Note

Some commands in the MySQL Shell can be executed without appending `execute()` while in interactive mode. In MySQL for Visual Studio, these commands do require `execute()`. In other words, append ".execute()" to execute commands.

20.7 X Plugin

X Plugin extends MySQL Server to be able to function as a document store. Running X Plugin enables MySQL Server to communicate with clients using the X Protocol, which is designed to expose the ACID compliant storage abilities of MySQL as a document store. Documents are stored in JSON format and

enable schema-less storage. Using the X DevAPI you can use a NoSQL-like syntax to execute Create, Read, Update, Delete (CRUD) operations against these documents.

This section explains how to configure and monitor the X Plugin in MySQL Server.

20.7.1 Using Secure Connections with X Plugin

This section explains how to configure X Plugin to use secure connections. For more background information, see [Section 6.4, “Using Secure Connections”](#).

X Plugin has its own SSL settings which can differ from those used with MySQL Server. This means that X Plugin can be configured with a different SSL key, certificate, and certificate authorities file than MySQL Server. Similarly, X Plugin has its own SSL status variables calculated independently from the MySQL Server SSL related variables. By default the X Plugin SSL configuration is taken from the `mysqlx_ssl_*` variables, described at [Section 20.7.2.2, “X Plugin System Variables and Options”](#). If no configuration is provided using the `mysqlx_ssl_*` variables, X Plugin falls back to using the MySQL Server SSL system variables. This means you can choose to either have separate SSL configurations for MySQL Protocol and X Protocol connections by configuring each separately, or share the SSL configuration between MySQL Protocol and X Protocol connections by only configuring the `ssl-*` variables.

On a server with X Plugin installed, to configure MySQL Protocol and X Protocol connections with separate SSL configurations use both the `ssl-*` and `mysqlx-ssl-*` variables in `my.cnf`:

```
[mysqld]
ssl-ca=ca1.pem
ssl-cert=server-cert1.pem
ssl-key=server-key1.pem

mysqlx-ssl-ca=ca2.pem
mysqlx-ssl-cert=server-cert2.pem
mysqlx-ssl-key=server-key2.pem
```

The available `mysqlx_ssl_*` variables mirror the SSL variables in MySQL Server, so the files and techniques described for configuring MySQL Server to use SSL at [Section 6.4.4, “Configuring MySQL to Use Secure Connections”](#) are relevant to configuring X Plugin to use secure connections. An exception to this rule is the `mysqlx_ssl` variable, which defaults to `1` whenever any of the other X Protocol SSL related variables is configured. In other words, if you configure any of the `mysqlx_ssl_*` variables there is no need to configure `mysqlx_ssl`.

You can configure the TLS versions used by X Protocol SSL connections using the `tls_version` system variable. The TLS version used by MySQL Protocol and X Protocol connections is therefore the same TLS version.

Encryption per connection is optional, but a specific user can be forced to use encryption for X Protocol and MySQL Protocol connections. You configure such a user by issuing a `GRANT` statement with the `REQUIRE` option. For more details see [Section 13.7.1.6, “GRANT Syntax”](#). Alternatively all X Protocol and MySQL Protocol connections can be forced to use encryption by setting `require_secure_transport`.

20.7.2 X Plugin Options and Variables

This section describes the command options and system variables which configure X Plugin. If values specified at startup time are incorrect, X Plugin could fail to initialize properly and the server does not load it. In this case, the server could also produce error messages for other X Plugin settings because it cannot recognize them.

20.7.2.1 X Plugin Option and Variable Reference

This table provides an overview of the command options, and system and status variables provided by X Plugin.

Table 20.1 X Plugin Option and Variable Reference

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynamic
Mysqlx_address				Yes	Global	No
mysqlx_bind_address	Yes	Yes	Yes		Global	No
Mysqlx_bytes_received				Yes	Both	No
Mysqlx_bytes_sent				Yes	Both	No
mysqlx_connect_timeout	Yes	Yes	Yes		Global	Yes
Mysqlx_connection_accept_errors				Yes	Both	No
Mysqlx_connection_errors				Yes	Both	No
Mysqlx_connections_accepted				Yes	Global	No
Mysqlx_connections_closed				Yes	Global	No
Mysqlx_connections_rejected				Yes	Global	No
Mysqlx_crud_create_view				Yes	Both	No
Mysqlx_crud_delete				Yes	Both	No
Mysqlx_crud_drop_view				Yes	Both	No
Mysqlx_crud_find				Yes	Both	No
Mysqlx_crud_insert				Yes	Both	No
Mysqlx_crud_modify_view				Yes	Both	No
Mysqlx_crud_update				Yes	Both	No
Mysqlx_errors_sent				Yes	Both	No
Mysqlx_errors_unknown_message_type				Yes	Both	No
Mysqlx_expect_close				Yes	Both	No
Mysqlx_expect_open				Yes	Both	No
mysqlx_idle_worker_read_timeout	Yes	Yes				
Mysqlx_init_error				Yes	Both	No
mysqlx_max_allowed_packet	Yes	Yes				
mysqlx_max_connections	Yes	Yes	Yes		Global	Yes
mysqlx_min_worker_reads	Yes	Yes				
Mysqlx_notice_other_sent				Yes	Both	No
Mysqlx_notice_warning_sent				Yes	Both	No
Mysqlx_port				Yes	Global	No
mysqlx_port	Yes	Yes	Yes		Global	No
mysqlx_port_open_timeout	Yes	Yes	Yes		Global	No
Mysqlx_rows_sent				Yes	Both	No
Mysqlx_sessions				Yes	Global	No
Mysqlx_sessions_accepted				Yes	Global	No
Mysqlx_sessions_closed				Yes	Global	No
Mysqlx_sessions_fatal_error				Yes	Global	No
Mysqlx_sessions_killed				Yes	Global	No
Mysqlx_sessions_rejected				Yes	Global	No
Mysqlx_socket				Yes	Global	No
mysqlx-socket	Yes	Yes	Yes		Global	No

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynamic
mysqlx_socket	Yes	Yes	Yes		Global	No
mysqlx_ssl	Yes	Yes	Yes		Global	No
Mysqlx_ssl_accept_renegotiates				Yes	Global	No
Mysqlx_ssl_accepts				Yes	Global	No
Mysqlx_ssl_active				Yes	Both	No
mysqlx_ssl_ca	Yes	Yes	Yes		Global	No
mysqlx_ssl_capath	Yes	Yes	Yes		Global	No
mysqlx_ssl_cert	Yes	Yes	Yes		Global	No
Mysqlx_ssl_cipher				Yes	Both	No
mysqlx_ssl_cipher	Yes	Yes				
Mysqlx_ssl_cipher_list				Yes	Both	No
mysqlx_ssl_crl	Yes	Yes	Yes		Global	No
mysqlx_ssl_crlpath	Yes	Yes	Yes		Global	No
Mysqlx_ssl_ctx_verify_depth				Yes	Both	No
Mysqlx_ssl_ctx_verify_mode				Yes	Both	No
Mysqlx_ssl_finished_accepts				Yes	Global	No
mysqlx_ssl_key	Yes	Yes	Yes		Global	No
Mysqlx_ssl_server_not_after				Yes	Global	No
Mysqlx_ssl_server_not_before				Yes	Global	No
Mysqlx_ssl_verify_depth				Yes	Global	No
Mysqlx_ssl_verify_mode				Yes	Global	No
Mysqlx_ssl_version				Yes	Both	No
Mysqlx_stmt_create_collection				Yes	Both	No
Mysqlx_stmt_create_collection_index				Yes	Both	No
Mysqlx_stmt_disable_notices				Yes	Both	No
Mysqlx_stmt_drop_collection				Yes	Both	No
Mysqlx_stmt_drop_collection_index				Yes	Both	No
Mysqlx_stmt_enable_notices				Yes	Both	No
Mysqlx_stmt_ensure_collection				Yes	Both	No
Mysqlx_stmt_execute_mysqlx				Yes	Both	No
Mysqlx_stmt_execute_sql				Yes	Both	No
Mysqlx_stmt_execute_xplugin				Yes	Both	No
Mysqlx_stmt_kill_client				Yes	Both	No
Mysqlx_stmt_list_clients				Yes	Both	No
Mysqlx_stmt_list_notices				Yes	Both	No
Mysqlx_stmt_list_objects				Yes	Both	No
Mysqlx_stmt_ping				Yes	Both	No
Mysqlx_worker_threads				Yes	Global	No
Mysqlx_worker_threads_active				Yes	Global	No

20.7.2.2 X Plugin System Variables and Options

The following command options configure X Plugin:

- `--mysqlx_port[=value]`

Command-Line Format	<code>--mysqlx-port=#</code>	
System Variable	Name	<code>mysqlx_port</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	33060
	Min Value	1
	Max Value	65535

Specifies the port where the X Plugin listens for connections. This option is only read at start up, therefore to change it on a running server requires a restart.

- `--mysqlx_connect_timeout[=value]`

Command-Line Format	<code>--mysqlx-connect-timeout=#</code>	
System Variable	Name	<code>mysqlx_connect_timeout</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	30
	Min Value	1
	Max Value	18446744073709551615

Number of seconds to wait for the first packet to be received from newly connected clients. This option is dynamically changeable.

- `mysqlx_idle_worker_thread_timeout[=value]`

Command-Line Format	<code>--mysqlx-idle-worker-thread-timeout=#</code>	
Permitted Values	Type	integer
	Default	60
	Min Value	0
	Max Value	18446744073709551615

- `mysqlx_max_allowed_packet[=value]`

Command-Line Format	<code>--mysqlx-max-allowed-packet=#</code>	
Permitted Values	Type	integer
	Default	1048576
	Min Value	0
	Max Value	18446744073709551615

Maximum size of a network packet that X Plugin can process. This option is dynamically changeable.

- `mysqlx_max_connections[=value]`

Command-Line Format	<code>--mysqlx-max-connections=#</code>	
System Variable	Name	<code>mysqlx_max_connections</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	100
	Min Value	1
	Max Value	18446744073709551615

Maximum number of concurrent client connections the X Plugin can accept. This option is dynamically changeable. When modifying this variable, if the new value is smaller than the current number of connections, the new limit is only taken into account for new connections.

- `mysqlx_min_worker_threads[=value]`

Command-Line Format	<code>--mysqlx-min-worker-threads=#</code>	
Permitted Values	Type	integer
	Default	2
	Min Value	1
	Max Value	18446744073709551615

The minimum number of worker threads the X Plugin uses for handling client requests. The maximum number of worker threads is limited implicitly by `--mysqlx_max_connections`. This option is dynamically changeable.

- `--mysqlx_ssl[=value]`

Command-Line Format	<code>--mysqlx-ssl=#</code>	
System Variable	Name	<code>mysqlx_ssl</code>
	Variable Scope	Global

	Dynamic Variable	No
Permitted Values	Type	integer

The equivalent of `ssl` for X Plugin, see that variable for more information.

- `--mysqlx_ssl_ca[=value]`

Command-Line Format	<code>--mysqlx-ssl-ca=file_name</code>	
System Variable	Name	<code>mysqlx_ssl_ca</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	file name

The equivalent of `ssl_ca` for X Plugin, see that variable for more information.

- `--mysqlx_ssl_capath[=value]`

Command-Line Format	<code>--mysqlx-ssl-capath=dir_name</code>	
System Variable	Name	<code>mysqlx_ssl_capath</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	directory name

The equivalent of `ssl_capath` for X Plugin, see that variable for more information.

- `--mysqlx_ssl_cert[=value]`

Command-Line Format	<code>--mysqlx-ssl-cert</code>	
System Variable	Name	<code>mysqlx_ssl_key</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	file name

The equivalent of `ssl_cert` for X Plugin, see that variable for more information.

- `--mysqlx_ssl_cipher[=value]`

Command-Line Format	<code>--mysqlx-ssl-cipher=name</code>	
Permitted Values	Type	string

The equivalent of `ssl_cipher` for X Plugin, see that variable for more information.

- `--mysqlx_ssl_crl[=value]`

Command-Line Format	<code>--mysqlx-ssl-crl=file_name</code>	
System Variable	Name	<code>mysqlx_ssl_crl</code>

	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	file name

The equivalent of `ssl_crl` for X Plugin, see that variable for more information.

- `--mysqlx_ssl_crlpath[=value]`

Command-Line Format	<code>--mysqlx-ssl-crlpath=directory_name</code>	
System Variable	Name	<code>mysqlx_ssl_crlpath</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	directory name

The equivalent of `ssl_crlpath` for X Plugin, see that variable for more information.

- `--mysqlx_ssl_key[=value]`

Command-Line Format	<code>--mysqlx-ssl-key=file_name</code>	
System Variable	Name	<code>mysqlx_ssl_key</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	file name

The equivalent of `ssl_key` for X Plugin, see that variable for more information.

20.7.3 Monitoring X Plugin

This section describes how to monitor X Plugin. There are two available methods of monitoring, using Performance Schema tables or status variables.

20.7.3.1 Status Variables for X Plugin

The status variables have the following meanings.

- `MySQLx_bytes_sent`

The number of bytes sent through the network.

- `MySQLx_bytes_received`

The number of bytes received through the network.

- `MySQLx_stmt_execute_sql`

The number of StmtExecute requests received for the SQL namespace.

- `MySQLx_stmt_execute_xplugin`

The number of StmtExecute requests received for the X Plugin namespace.

- `Mysqlx_stmt_create_collection`
The number of create collection statements received.
- `Mysqlx_stmt_create_collection_index`
The number of create collection index statements received.
- `Mysqlx_stmt_drop_collection`
The number of drop collection statements received.
- `Mysqlx_stmt_drop_collection_index`
The number of drop collection index statements received.
- `Mysqlx_stmt_list_objects`
The number of list object statements received.
- `Mysqlx_stmt_enable_notices`
The number of enable notice statements received.
- `Mysqlx_stmt_disable_notices`
The number of disable notice statements received.
- `Mysqlx_stmt_list_notices`
The number of list notice statements received.
- `Mysqlx_stmt_list_clients`
The number of list client statements received.
- `Mysqlx_stmt_kill_client`
The number of kill client statements received.
- `Mysqlx_stmt_ping`
The number of ping statements received.
- `Mysqlx_crud_insert`
The number of insert requests received.
- `Mysqlx_crud_update`
The number of update requests received.
- `Mysqlx_crud_delete`
The number of delete requests received.
- `Mysqlx_crud_find`
The number of find requests received.
- `Mysqlx_expect_open`
The number of expectation blocks opened.
- `Mysqlx_expect_close`

The number of expectation blocks closed.

- `Mysqlx_rows_sent`

The number of rows sent back to clients.

- `Mysqlx_notice_warning_sent`

The number of warning notices sent back to clients.

- `Mysqlx_notice_other_sent`

The number of other types of notices sent back to clients.

- `Mysqlx_ssl_cipher`

The current SSL cipher (empty for non-SSL connections).

- `Mysqlx_ssl_cipher_list`

A list of possible SSL ciphers (empty for non-SSL connections).

- `Mysqlx_ssl_verify_depth`

The certificate verification depth for SSL connections.

- `Mysqlx_ssl_verify_mode`

The certificate verification mode for SSL connections.

- `Mysqlx_ssl_version`

The name of the protocol used for SSL connections.

- `Mysqlx_sessions`

The number of sessions that have been opened.

- `Mysqlx_sessions_closed`

The number of sessions that have been closed.

- `Mysqlx_sessions_fatal_error`

The number of sessions that have closed with a fatal error.

- `Mysqlx_init_error`

The number of errors during initialisation.

- `Mysqlx_sessions_accepted`

The number of session attempts which have been accepted.

- `Mysqlx_sessions_rejected`

The number of session attempts which have been rejected.

- `Mysqlx_sessions_killed`

The number of sessions which have been killed.

- `Mysqlx_connections_closed`

The number of connections which have been closed.

- [Mysqlx_connections_accepted](#)

The number of connections which have been accepted.

- [Mysqlx_connections_rejected](#)

The number of connections which have been rejected.

- [Mysqlx_connection_accept_errors](#)

The number of connections which have caused accept errors.

- [Mysqlx_connection_errors](#)

The number of connections which have caused errors.

- [Mysqlx_worker_threads](#)

The number of worker threads available.

- [Mysqlx_worker_threads_active](#)

The number of worker threads currently used.

- [Mysqlx_ssl_active](#)

If SSL is active.

- [Mysqlx_ssl_ctx_verify_depth](#)

The certificate verification depth limit currently set in ctx.

- [Mysqlx_ssl_ctx_verify_mode](#)

The certificate verification mode currently set in ctx.

- [Mysqlx_ssl_finished_accepts](#)

The number of successful SSL connections to the server.

- [Mysqlx_ssl_accepts](#)

The number of accepted SSL connections.

- [Mysqlx_ssl_server_not_after](#)

The last date for which the SSL certificate is valid.

- [Mysqlx_ssl_server_not_before](#)

The first date for which the SSL certificate is valid.

- [Mysqlx_ssl_accept_renegotiates](#)

The number of negotiations needed to establish the connection.

- [Mysqlx_errors_sent](#)

The number of errors sent to clients.

This chapter explains MySQL Group Replication and how to install, configure and monitor groups. MySQL Group Replication is a MySQL Server plugin that enables you to create elastic, highly-available, fault-tolerant replication topologies.

Groups can operate in a single-primary mode with automatic primary election, where only one server accepts updates at a time. Alternatively, for more advanced users, groups can be deployed in multi-primary mode, where all servers can accept updates, even if they are issued concurrently.

There is a built-in group membership service that keeps the view of the group consistent and available for all servers at any given point in time. Servers can leave and join the group and the view is updated accordingly. Sometimes servers can leave the group unexpectedly, in which case the failure detection mechanism detects this and notifies the group that the view has changed. This is all automatic.

The chapter is structured as follows:

- [Section 21.1, “Group Replication Background”](#) provides an introduction to groups and how Group Replication works.

- [Section 21.2, “Getting Started”](#) explains how to configure multiple MySQL Server instances to create a group.
- [Section 21.3, “Monitoring Group Replication”](#) explains how to monitor a group.
- [Section 21.5, “Group Replication Security”](#) explains how to secure a group.
- [Section 21.9, “Group Replication Technical Details”](#) provides in-depth information about how Group Replication works.

21.1 Group Replication Background

This section provides background information on MySQL Group Replication.

The most common way to create a fault-tolerant system is to resort to making components redundant, in other words the component can be removed and the system should continue to operate as expected. This creates a set of challenges that raise complexity of such systems to a whole different level. Specifically, replicated databases have to deal with the fact that they require maintenance and administration of several servers instead of just one. Moreover, as servers are cooperating together to create the group several other classic distributed systems problems have to be dealt with, such as network partitioning or split brain scenarios.

Therefore, the ultimate challenge is to fuse the logic of the database and data replication with the logic of having several servers coordinated in a consistent and simple way. In other words, to have multiple servers agreeing on the state of the system and the data on each and every change that the system goes through. This can be summarized as having servers reaching agreement on each database state transition, so that they all progress as one single database or alternatively that they eventually converge to the same state. Meaning that they need to operate as a (distributed) state machine.

MySQL Group Replication provides distributed state machine replication with strong coordination between servers. Servers coordinate themselves automatically when they are part of the same group. The group can operate in a single-primary mode with automatic primary election, where only one server accepts updates at a time. Alternatively, for more advanced users the group can be deployed in multi-primary mode, where all servers can accept updates, even if they are issued concurrently. This power comes at the expense of applications having to work around the limitations imposed by such deployments.

There is a built-in group membership service that keeps the view of the group consistent and available for all servers at any given point in time. Servers can leave and join the group and the view is updated accordingly. Sometimes servers can leave the group unexpectedly, in which case the failure detection mechanism detects this and notifies the group that the view has changed. This is all automatic.

For a transaction to commit, the majority of the group have to agree on the order of a given transaction in the global sequence of transactions. Deciding to commit or abort a transaction is done by each server individually, but all servers make the same decision. If there is a network partition, resulting in a split where members are unable to reach agreement, then the system does not progress until this issue is resolved. Hence there is also a built-in, automatic, split-brain protection mechanism.

All of this is powered by the provided group communication protocols. These provide a failure detection mechanism, a group membership service, and safe and completely ordered message delivery. All these properties are key to creating a system which ensures that data is consistently replicated across the group of servers. At the very core of this technology lies an implementation of the Paxos algorithm. It acts as the group communication systems engine.

21.1.1 Replication Technologies

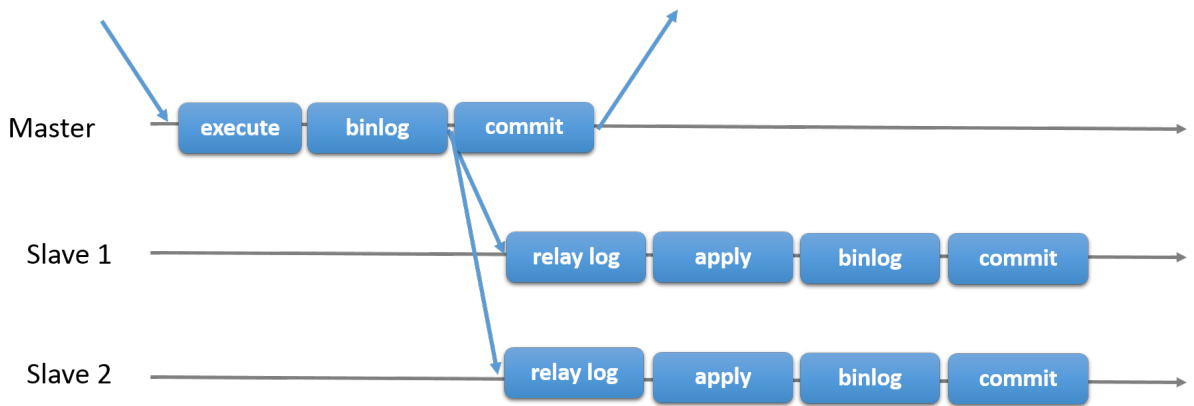

Before getting into the details of MySQL Group Replication, this section introduces some background concepts and an overview of how things work. This provides some context to help understand what

is required for Group Replication and what the differences are between classic asynchronous MySQL Replication and Group Replication.

21.1.1.1 Primary-Secondary Replication

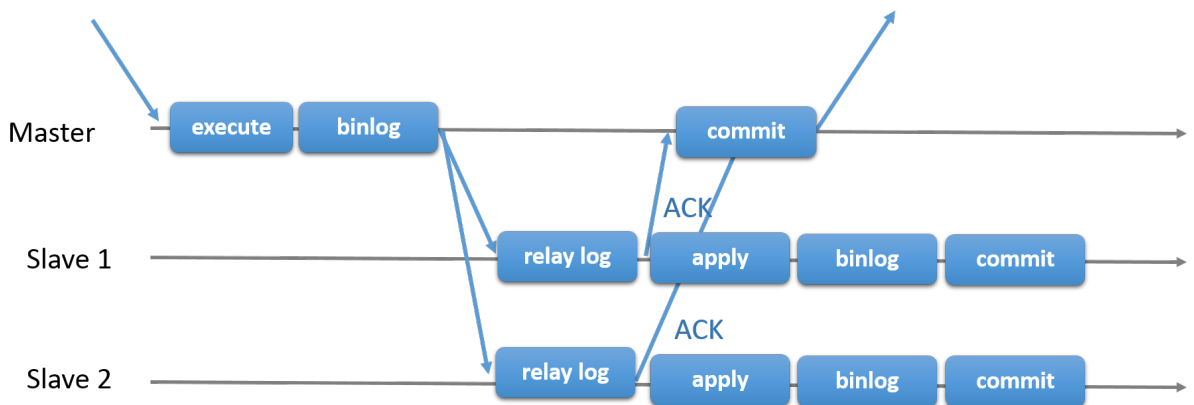

Traditional MySQL Replication provides a simple Primary-Secondary approach to replication. There is a primary (master) and there is one or more secondaries (slaves). The primary executes transactions, commits them and then they are later (thus asynchronously) sent to the secondaries to be either re-executed (in statement-based replication) or applied (in row-based replication). It is a shared-nothing system, where all servers have a full copy of the data by default.

Figure 21.1 MySQL Asynchronous Replication

There is also semisynchronous replication, which adds one synchronization step to the protocol. This means that the Primary waits, at commit time, for the secondary to acknowledge that it has *received* the transaction. Only then does the Primary resume the commit operation.

Figure 21.2 MySQL Semisynchronous Replication

In the two pictures above, you can see a diagram of the classic asynchronous MySQL Replication protocol (and its semisynchronous variant as well). Blue arrows represent messages exchanged between servers or messages exchanged between servers and the client application.

21.1.1.2 Group Replication

Group Replication is a technique that can be used to implement fault-tolerant systems. The replication group is a set of servers that interact with each other through message passing. The communication layer provides a set of guarantees such as atomic message and total order message delivery. These are very powerful properties that translate into very useful abstractions that one can resort to build more advanced database replication solutions.

MySQL Group Replication builds on top of such properties and abstractions and implements a multi-master update everywhere replication protocol. In essence, a replication group is formed by multiple servers and each server in the group may execute transactions independently. But all read-write (RW) transactions commit only after they have been approved by the group. Read-only (RO) transactions need no coordination within the group and thus commit immediately. In other words, for any RW transaction the group needs to decide whether it commits or not, thus the commit operation is not a unilateral decision from the originating server. To be precise, when a transaction is ready to commit at the originating server, the server atomically broadcasts the write values (rows changed) and the correspondent write set (unique identifiers of the rows that were updated). Then a global total order is established for that transaction. Ultimately, this means that all servers receive the same set of transactions in the same order. As a consequence, all servers apply the same set of changes in the same order, therefore they remain consistent within the group.

However, there may be conflicts between transactions that execute concurrently on different servers. Such conflicts are detected by inspecting the write sets of two different and concurrent transactions, in a process called *certification*. If two concurrent transactions, that executed on different servers, update the same row, then there is a conflict. The resolution procedure states that the transaction that was ordered first commits on all servers, whereas the transaction ordered second aborts, and thus is rolled back on the originating server and dropped by the other servers in the group. This is in fact a distributed first commit wins rule.

Figure 21.3 MySQL Group Replication Protocol

Finally, Group Replication is a shared-nothing replication scheme where each server has its own entire copy of the data.

The Figure above depicts the MySQL Group Replication protocol and by comparing it to MySQL Replication (or even MySQL semisynchronous replication) you can see some differences. Note that some underlying consensus and Paxos related messages are missing from this picture for the sake of clarity.

21.1.2 Group Replication Use Cases

Group Replication enables you to create fault-tolerant systems with redundancy by replicating the system state throughout a set of servers. Consequently, even if some of the servers fail, as long it is not all or a majority, the system is still available, and all it could have degraded performance or scalability, it is still available. Server failures are isolated and independent. They are tracked by a group membership service which relies on a distributed failure detector that is able to signal when any servers leave the group, either voluntarily or due to an unexpected halt. There is a distributed recovery procedure to ensure that when servers join the group they are brought up to date automatically. There is no need for server fail-over, and the multi-master update everywhere nature ensures that not

even updates are blocked in the event of a single server failure. Therefore MySQL Group Replication guarantees that the database service is continuously available.

It is important to understand that although the database service is available, in the event of a server crash, those clients connected to it must be redirected, or failed over, to a different server. This is not something Group Replication attempts to resolve. A connector, load balancer, router, or some form of middleware are more suitable to deal with this issue.

To summarize, MySQL Group Replication provides a highly available, highly elastic, dependable MySQL service.

21.1.2.1 Examples of Use Case Scenarios

The following examples are typical use cases for Group Replication.

- *Elastic Replication* - Environments that require a very fluid replication infrastructure, where the number of servers has to grow or shrink dynamically and with as few side-effects as possible. For instance, database services for the cloud.
- *Highly Available Shards* - Sharding is a popular approach to achieve write scale-out. Use MySQL Group Replication to implement highly available shards, where each shard maps to a replication group.
- *Alternative to Master-Slave replication* - In certain situations, using a single master server makes it a single point of contention. Writing to an entire group may prove more scalable under certain circumstances.
- *Autonomic Systems* - Additionally, you can deploy MySQL Group Replication purely for the automation that is built into the replication protocol (described already in this and previous chapters).

21.1.3 Group Replication Details

This section presents details about some of the services that Group Replication builds on.

21.1.3.1 Failure Detection

There is a failure detection mechanism provided that is able to find and report which servers are silent and as such assumed to be dead. At a high level, the failure detector is a distributed service that provides information about which servers may be dead (suspicions). Later if the group agrees that the suspicions are probably true, then the group decides that a given server has indeed failed. This means that the remaining members in the group take a coordinated decision to exclude a given member.

Suspicions are triggered when servers go mute. When server A does not receive messages from server B during a given period, a timeout occurs and a suspicion is raised.

If a server gets isolated from the rest of the group, then it suspects that all others have failed. Being unable to secure agreement with the group (as it cannot secure a quorum), its suspicion does not have consequences. When a server is isolated from the group in this way, it is unable to execute any local transactions.

21.1.3.2 Group Membership

MySQL Group Replication relies on a group membership service. This is built into the plugin. It defines which servers are online and participating in the group. The list of online servers is often referred to as a *view*. Therefore, every server in the group has a consistent view of which are the members participating actively in the group at a given moment in time.

Servers have to agree not only on transaction commits, but also which is the current view. Therefore, if servers agree that a new server becomes part of the group, then the group itself is reconfigured to

integrate that server in it, triggering a view change. The opposite also happens, if a server leaves the group, voluntarily or not, then the group dynamically rearranges its configuration and a view change is triggered.

Note though that when a member leaves voluntarily, it first initiates a dynamic group reconfiguration. This triggers a procedure, where all members have to agree on the new view without the leaving server. However, if a member leaves involuntarily (for example it has stopped unexpectedly or the network connection is down) then the failure detection mechanism realizes this fact and a reconfiguration of the group is proposed, this one without the failed member. As mentioned this requires agreement from the majority of servers in the group. If the group is not able to reach agreement (for example it partitioned in such a way that there is no majority of servers online), then the system is not be able to dynamically change the configuration and as such, blocks to prevent a split-brain situation. Ultimately, this means that the administrator needs to step in and fix this.

21.1.3.3 Fault-tolerance

MySQL Group Replication builds on an implementation of the Paxos distributed algorithm to provide distributed coordination between servers. As such, it requires a majority of servers to be active to reach quorum and thus make a decision. This has direct impact on the number of failures the system can tolerate without compromising itself and its overall functionality. The number of servers (n) needed to tolerate f failures is then $n = 2 \times f + 1$.

In practice this means that to tolerate one failure the group must have three servers in it. As such if one server fails, there are still two servers to form a majority (two out of three) and allow the system to continue to make decisions automatically and progress. However, if a second server fails *involuntarily*, then the group (with one server left) blocks, because there is no majority to reach a decision.

The following is a small table illustrating the formula above.

Group Size	Majority	Instant Failures Tolerated
1	1	0
2	2	0
3	2	1
4	3	1
5	3	2
6	4	2
7	4	3

The next Chapter covers technical aspects of Group Replication.

21.2 Getting Started

MySQL Group Replication is provided as a plugin to MySQL server, and each server in a group requires configuration and installation of the plugin. This section provides a detailed tutorial with the steps required to create a replication group with at least three servers.

21.2.1 Deploying Group Replication in Single-Primary Mode

Each of the server instances in a group can run on an independent physical machine, or on the same machine. This section explains how to create a replication group with three MySQL Server instances on one physical machine. This means that three data directories are needed, one per server instance, and that you need to configure each instance independently.

Figure 21.4 Group Architecture

This tutorial explains how to get and deploy MySQL Server with the Group Replication plugin, how to configure each server instance before creating a group, and how to use Performance Schema monitoring to verify that everything is working correctly.

21.2.1.1 Deploying Instances for Group Replication

The first step is to deploy three instances of MySQL Server. Group Replication is a built-in MySQL plugin provided with MySQL Server 5.7.17 and later. For more background information on MySQL plugins, see [Section 5.6, “MySQL Server Plugins”](#). This procedure assumes that MySQL Server was downloaded and unpacked into the directory named `mysql-5.7`. The following procedure uses one physical machine, therefore each MySQL server instance requires a specific data directory for the instance. Create the data directories in a directory named `data` and initialize each one.

```
mkdir data
mysql-5.7/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-5.7 --datadir=$PWD/data/s1
mysql-5.7/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-5.7 --datadir=$PWD/data/s2
mysql-5.7/bin/mysqld --initialize-insecure --basedir=$PWD/mysql-5.7 --datadir=$PWD/data/s3
```

Inside `data/s1`, `data/s2`, `data/s3` is an initialized data directory, containing the mysql system database and related tables and much more. To learn more about the initialization procedure, see [Section 2.9.1.1, “Initializing the Data Directory Manually Using mysqld”](#).

Warning

Do not use `--initialize-insecure` in production environments, it is only used here to simplify the tutorial. For more information on security settings, see [Section 21.5, “Group Replication Security”](#).

21.2.1.2 Configuring an Instance for Group Replication

This section explains the configuration settings required for MySQL Server instances that you want to use for Group Replication. For background information, see [Section 21.7.2, “Group Replication Limitations”](#).

Group Replication Server Settings

To install and use the Group Replication plugin you must configure the MySQL Server instance correctly. It is recommended to store the configuration in the instance's configuration file. See [Section 4.2.6, "Using Option Files"](#) for more information. Unless stated otherwise, what follows is the configuration for the first instance in the group, referred to as *s1* in this procedure. The following section shows an example server configuration.

```
[mysqld]

# server configuration
datadir=<full_path_to_data>/data/s1
basedir=<full_path_to_bin>/mysql-5.7/

port=24801
socket=<full_path_to_sock_dir>/s1.sock
```

These settings configure MySQL server to use the data directory created earlier and which port the server should open and start listening for incoming connections.

Note

The non-default port of 24801 is used because in this tutorial the three server instances use the same hostname. In a setup with three different machines this would not be required.

Replication Framework

The following settings configure replication according to the MySQL Group Replication requirements.

```
server_id=1
gtid_mode=ON
enforce_gtid_consistency=ON
master_info_repository=TABLE
relay_log_info_repository=TABLE
binlog_checksum=NONE
log_slave_updates=ON
log_bin=binlog
binlog_format=ROW
```

These settings configure the server to use the unique identifier number 1, to enable global transaction identifiers and to store replication metadata in system tables instead of files. Additionally, it instructs the server to turn on binary logging, use row-based format and disable binary log event checksums. For more details see [Section 21.7.2, "Group Replication Limitations"](#).

Group Replication Settings

At this point the `my.cnf` file ensures that the server is configured and is instructed to instantiate the replication infrastructure under a given configuration. The following section configures the Group Replication settings for the server.

```
transaction_write_set_extraction=XXHASH64
loose-group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaaa"
loose-group_replication_start_on_boot=off
loose-group_replication_local_address="127.0.0.1:24901"
loose-group_replication_group_seeds="127.0.0.1:24901,127.0.0.1:24902,127.0.0.1:24903"
loose-group_replication_bootstrap_group= off
```

Note

The `loose-` prefix used for the `group_replication` variables above instructs the server to continue to start if the Group Replication plugin has not been loaded at the time the server is started.

- *Line 1* instructs the server that for each transaction it has to collect the write set and encode it as a hash using the XXHASH64 hashing algorithm.
- *Line 2* tells the plugin that the group that it is joining, or creating, is named "aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa".
- *Line 3* instructs the plugin to not start operations automatically when the server starts.
- *Line 4* tells the plugin to use the IP address 127.0.0.1, or localhost, and port 24901 for incoming connections from other members in the group.

Important

The server listens on this port for member-to-member connections. This port must not be used for user applications at all, it must be reserved for communication between different members of the group while running Group Replication.

The local address configured by `group_replication_local_address` must be accessible to all group members. For example, if each server instance is on a different machine use the IP and port of the machine, such as 10.0.0.1:33061. The recommended port for `group_replication_local_address` is 33061, but in this tutorial we use three server instances running on one machine, thus ports 24901 to 24903 are used.

- *Line 5* tells the plugin that the following members on those hosts and ports should be contacted in case it needs to join the group. These are seed members, which are used when this member wants to connect to the group. Upon joining the server contacts one of them first (seed) and then it asks the group to reconfigure to allow the joiner to be accepted in the group. Note that this option does *not* need to list all members in the group, but rather a list of servers that should be contacted in case this server wishes to join the group.

The server that starts the group does not make use of this option, since it is the initial server and as such, it is in charge of bootstrapping the group. The second server joining asks the one and only member in the group to join and then the group expands. The third server joining can ask any of these two to join, and then the group expands again. Subsequent servers repeat this procedure when joining.

Warning

When joining multiple servers at the same time, make sure that they point to seed members that are already in the group. Do not use members that are also joining the group as seeds, because they may not yet be in the group when contacted.

It is good practice to start the bootstrap member first, and let it create the group. Then make it the seed member for the rest of the members that are joining. This ensures that there is a group formed when joining the rest of the members.

Creating a group and joining multiple members at the same time is not supported. It may work, but chances are that the operations race and then the act of joining the group ends up in an error or a time out.

- *Line 6* instructs the plugin whether to bootstrap the group or not.

Important

This option must only be used on one server instance at any time, usually the first time you bootstrap the group (or in case the entire group is brought down and back up again). If you bootstrap the group multiple times, for example when multiple server instances have this option set, then they could create an

artificial split brain scenario, in which two distinct groups with the same name exist. Disable this option after the first server instance comes online.

Configuration for all servers in the group is quite similar. You need to change the specifics about each server (for example `server_id`, `datadir`, `group_replication_local_address`). This is illustrated later in this tutorial.

21.2.1.3 User Credentials

Group Replication uses the asynchronous replication protocol to achieve distributed recovery, synchronizing group members before joining them to the group. The distributed recovery process relies on a replication channel named `group_replication_recovery` which is used to transfer transactions between group members. Therefore you need to set up a replication user with the correct permissions so that Group Replication can establish direct member-to-member recovery replication channels.

Start the server:

```
mysql-5.7/bin/mysqld --defaults-file=data/s1/s1.cnf
```

Create a MySQL user with the `REPLICATION-SLAVE` privilege. This process should *not* be captured in the binary log to avoid the changes being propagated to other server instances. In the following example the user `rpl_user` with the password `rpl_pass` is shown. When configuring your servers use a suitable user name and password. Connect to server `s1` and issue the following statements:

```
mysql> SET SQL_LOG_BIN=0;
Query OK, 0 rows affected (0,00 sec)

mysql> CREATE USER rpl_user@'%' IDENTIFIED BY 'rpl_pass';
Query OK, 0 rows affected (0,00 sec)

mysql> GRANT REPLICATION SLAVE ON *.* TO rpl_user@'%';
Query OK, 0 rows affected, 1 warning (0,00 sec)

mysql> FLUSH PRIVILEGES;
Query OK, 0 rows affected (0,00 sec)

mysql> SET SQL_LOG_BIN=1;
Query OK, 0 rows affected (0,00 sec)
```

Once the user has been configured as above, use the `CHANGE MASTER TO` statement to configure the server to use the given credentials for the `group_replication_recovery` replication channel the next time it needs to recover its state from another member. Issue the following, replacing `rpl_user` and `rpl_pass` with the values used when creating the user.

```
mysql> CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='rpl_pass' \\\
FOR CHANNEL 'group_replication_recovery';
Query OK, 0 rows affected, 2 warnings (0,01 sec)
```

Distributed recovery is the first step taken by a server that joins the group. If these credentials are not set correctly as shown, the server cannot run the recovery process and gain synchrony with the other group members, and hence ultimately cannot join the group. Similarly, if the member cannot correctly identify the other members via the server's `hostname` the recovery process can fail. It is recommended that operating systems running MySQL have a properly configured unique `hostname`, either using DNS or local settings. This `hostname` can be verified in the `Member_host` column of the `performance_schema.replication_group_members` table. If multiple group members externalize a default `hostname` set by the operating system, there is a chance of the member not resolving to the correct member address and not being able to join the group. In such a situation use `report_host` to configure a unique `hostname` to be externalized by each of the servers.

21.2.1.4 Launching Group Replication

Once server `s1` has been configured and started, install the Group Replication plugin. Connect to the server and issue the following command:

```
INSTALL PLUGIN group_replication SONAME 'group_replication.so';
```

Important

The `mysql.session` user must exist before you can load Group Replication. `mysql.session` was added in MySQL version 8.0.2. If your data dictionary was initialized using an earlier version you must run the `mysql_upgrade` procedure. If the upgrade is not run, Group Replication fails to start with the error message `There was an error when trying to access the server with user: mysql.session@localhost`. Make sure the user is present in the server and that `mysql_upgrade` was ran after a server update..

To check that the plugin was installed successfully, issue `SHOW PLUGINS;` and check the output. It should show something like this:

```
mysql> SHOW PLUGINS;
+-----+-----+-----+-----+-----+
| Name                | Status | Type                | Library                | License                |
+-----+-----+-----+-----+-----+
| binlog              | ACTIVE | STORAGE ENGINE     | NULL                  | PROPRIETARY          |
| (...)              |       |                     |                       |                       |
| group_replication  | ACTIVE | GROUP REPLICATION  | group_replication.so | PROPRIETARY          |
+-----+-----+-----+-----+-----+
```

To start the group, instruct server `s1` to bootstrap the group and then start Group Replication. This bootstrap should only be done by a single server, the one that starts the group and only once. This is why the value of the bootstrap configuration option was not saved in the configuration file. If it is saved in the configuration file, upon restart the server automatically bootstraps a second group with the same name. This would result in two distinct groups with the same name. The same reasoning applies to stopping and restarting the plugin with this option set to `ON`.

```
SET GLOBAL group_replication_bootstrap_group=ON;
START GROUP_REPLICATION;
SET GLOBAL group_replication_bootstrap_group=OFF;
```

Once the `START GROUP_REPLICATION` statement returns, the group has been started. You can check that the group is now created and that there is one member in it:

```
mysql> SELECT * FROM performance_schema.replication_group_members;
+-----+-----+-----+-----+-----+
| CHANNEL_NAME        | MEMBER_ID                | MEMBER_HOST | MEMBER_PORT | MEMBER_STATUS |
+-----+-----+-----+-----+-----+
| group_replication_applier | ce9be252-2b71-11e6-b8f4-00212844f856 | myhost      | 24801      | ONLINE        |
+-----+-----+-----+-----+-----+
1 row in set (0,00 sec)
```

The information in this table confirms that there is a member in the group with the unique identifier `ce9be252-2b71-11e6-b8f4-00212844f856`, that it is `ONLINE` and is at `myhost` listening for client connections on port `24801`.

For the purpose of demonstrating that the server is indeed in a group and that it is able to handle load, create a table and add some content to it.

```
mysql> CREATE DATABASE test;
Query OK, 1 row affected (0,00 sec)

mysql> use test
Database changed
mysql> CREATE TABLE t1 (c1 INT PRIMARY KEY, c2 TEXT NOT NULL);
Query OK, 0 rows affected (0,00 sec)

mysql> INSERT INTO t1 VALUES (1, 'Luis');
Query OK, 1 row affected (0,01 sec)
```

Check the content of table `t1` and the binary log.

```
mysql> SELECT * FROM t1;
+-----+-----+
| c1 | c2 |
+-----+-----+
| 1 | Luis |
+-----+-----+
1 row in set (0,00 sec)

mysql> SHOW BINLOG EVENTS;
+-----+-----+-----+-----+-----+-----+
| Log_name | Pos | Event_type | Server_id | End_log_pos | Info |
+-----+-----+-----+-----+-----+-----+
| binlog.000001 | 4 | Format_desc | 1 | 123 | Server ver: 5.7.17-gr080-log, Binlog ver |
| binlog.000001 | 123 | Previous_gtid | 1 | 150 | |
| binlog.000001 | 150 | Gtid | 1 | 211 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa |
| binlog.000001 | 211 | Query | 1 | 270 | BEGIN |
| binlog.000001 | 270 | View_change | 1 | 369 | view_id=14724817264259180:1 |
| binlog.000001 | 369 | Query | 1 | 434 | COMMIT |
| binlog.000001 | 434 | Gtid | 1 | 495 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa |
| binlog.000001 | 495 | Query | 1 | 585 | CREATE DATABASE test |
| binlog.000001 | 585 | Gtid | 1 | 646 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa |
| binlog.000001 | 646 | Query | 1 | 770 | use `test`; CREATE TABLE t1 (c1 INT PRIM |
| binlog.000001 | 770 | Gtid | 1 | 831 | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa |
| binlog.000001 | 831 | Query | 1 | 899 | BEGIN |
| binlog.000001 | 899 | Table_map | 1 | 942 | table_id: 108 (test.t1) |
| binlog.000001 | 942 | Write_rows | 1 | 984 | table_id: 108 flags: STMT_END_F |
| binlog.000001 | 984 | Xid | 1 | 1011 | COMMIT /* xid=38 */ |
+-----+-----+-----+-----+-----+-----+
15 rows in set (0,00 sec)
```

As seen above, the database and the table objects were created and their corresponding DDL statements were written to the binary log. Also, the data was inserted into the table and written to the binary log. The importance of the binary log entries is illustrated in the following section when the group grows and distributed recovery is executed as new members try to catch up and become online.

21.2.1.5 Adding Instances to the Group

At this point, the group has one member in it, server `s1`, which has some data in it. It is now time to expand the group by adding the other two servers configured previously.

Adding a Second Instance

In order to add a second instance, server `s2`, first create the configuration file for it. The configuration is similar to the one used for server `s1`, except for things such as the location of the data directory, the ports that `s2` is going to be listening on or its `server_id`. These different lines are highlighted in the listing below.

```
[mysqld]

# server configuration
datadir=<full_path_to_data>/data/s2
basedir=<full_path_to_bin>/mysql-5.7/
```

```

port=24802
socket=<full_path_to_sock_dir>/s2.sock

#
# Replication configuration parameters
#
server_id=2
gtid_mode=ON
enforce_gtid_consistency=ON
master_info_repository=TABLE
relay_log_info_repository=TABLE
binlog_checksum=NONE
log_slave_updates=ON
log_bin=binlog
binlog_format=ROW

#
# Group Replication configuration
#
transaction_write_set_extraction=XXHASH64
loose-group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa"
loose-group_replication_start_on_boot=off
loose-group_replication_local_address= "127.0.0.1:24902"
loose-group_replication_group_seeds= "127.0.0.1:24901,127.0.0.1:24902,127.0.0.1:24903"
loose-group_replication_bootstrap_group= off

```

Similar to the procedure for server s1, with the configuration file in place you launch the server.

```
mysql-5.7/bin/mysqld --defaults-file=data/s2/s2.cnf
```

Then configure the recovery credentials as follows. The commands are the same as used when setting up server s1 as the user is shared within the group. Issue the following statements on s2.

```

SET SQL_LOG_BIN=0;
CREATE USER rpl_user@'%';
GRANT REPLICATION SLAVE ON *.* TO rpl_user@%' IDENTIFIED BY 'rpl_pass';
SET SQL_LOG_BIN=1;
CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='rpl_pass' \
FOR CHANNEL 'group_replication_recovery';

```

Install the Group Replication plugin and start the process of joining the server to the group. The following example installs the plugin in the same way as used while deploying server s1.

```
mysql> INSTALL PLUGIN group_replication SONAME 'group_replication.so';
Query OK, 0 rows affected (0,01 sec)
```

Add server s2 to the group.

```
mysql> START GROUP_REPLICATION;
Query OK, 0 rows affected (44,88 sec)
```

Unlike the previous steps that were the same as those executed on s1, here there is a difference in that you do *not* issue `SET GLOBAL group_replication_bootstrap_group=ON;` before starting Group Replication, because the group has already been created and bootstrapped by server s1. At this point server s2 only needs to be added to the already existing group.

Tip

When Group Replication starts successfully and the server joins the group, if the `super_read_only` variable is set to 1 then the `super_read_only` variable is set to 0. By setting `super_read_only` to 1 in the member's configuration file, you can ensure that servers which fail when starting Group Replication for any reason do not accept transactions.

Checking the `performance_schema.replication_group_members` table again shows that there are now two *ONLINE* servers in the group.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
+-----+-----+-----+-----+-----+
| CHANNEL_NAME          | MEMBER_ID          | MEMBER_HOST | MEMBER_PORT | MEMBER_STATUS |
+-----+-----+-----+-----+-----+
| group_replication_applier | 395409e1-6dfa-11e6-970b-00212844f856 | myhost      | 24801       | ONLINE        |
| group_replication_applier | ac39f1e6-6dfa-11e6-a69d-00212844f856 | myhost      | 24802       | ONLINE        |
+-----+-----+-----+-----+-----+
2 rows in set (0,00 sec)
```

As server s2 is also marked as *ONLINE*, it must have already caught up with server s1 automatically. Verify that it has indeed synchronized with server s1 as follows.

```
mysql> SHOW DATABASES LIKE 'test';
+-----+
| Database (test) |
+-----+
| test            |
+-----+
1 row in set (0,00 sec)

mysql> SELECT * FROM test.t1;
+----+----+
| c1 | c2  |
+----+----+
| 1  | Luis |
+----+----+
1 row in set (0,00 sec)

mysql> SHOW BINLOG EVENTS;
+-----+-----+-----+-----+-----+-----+
| Log_name      | Pos | Event_type | Server_id | End_log_pos | Info |
+-----+-----+-----+-----+-----+-----+
| binlog.000001 | 4   | Format_desc | 2         | 123         | Server ver: 5.7.17-log, Binlog ver: 4 |
| binlog.000001 | 123 | Previous_gtids | 2         | 150         | |
| binlog.000001 | 150 | Gtid       | 1         | 211         | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa |
| binlog.000001 | 211 | Query      | 1         | 270         | BEGIN |
| binlog.000001 | 270 | View_change | 1         | 369         | view_id=14724832985483517:1 |
| binlog.000001 | 369 | Query      | 1         | 434         | COMMIT |
| binlog.000001 | 434 | Gtid       | 1         | 495         | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa |
| binlog.000001 | 495 | Query      | 1         | 585         | CREATE DATABASE test |
| binlog.000001 | 585 | Gtid       | 1         | 646         | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa |
| binlog.000001 | 646 | Query      | 1         | 770         | use `test`; CREATE TABLE t1 (c1 INT PRI |
| binlog.000001 | 770 | Gtid       | 1         | 831         | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa |
| binlog.000001 | 831 | Query      | 1         | 890         | BEGIN |
| binlog.000001 | 890 | Table_map | 1         | 933         | table_id: 108 (test.t1) |
| binlog.000001 | 933 | Write_rows | 1         | 975         | table_id: 108 flags: STMT_END_F |
| binlog.000001 | 975 | Xid        | 1         | 1002        | COMMIT /* xid=30 */ |
| binlog.000001 | 1002 | Gtid       | 1         | 1063        | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaaa |
| binlog.000001 | 1063 | Query      | 1         | 1122        | BEGIN |
| binlog.000001 | 1122 | View_change | 1         | 1261        | view_id=14724832985483517:2 |
| binlog.000001 | 1261 | Query      | 1         | 1326        | COMMIT |
+-----+-----+-----+-----+-----+-----+
19 rows in set (0,00 sec)
```

As seen above, the second server has been added to the group and it has replicated the changes from server s1 automatically. According to the distributed recovery procedure, this means that just after joining the group and immediately before being declared online, server s2 has connected to server s1 automatically and fetched the missing data from it. In other words, it copied transactions from the binary log of s1 that it was missing, up to the point in time that it joined the group.

Adding Additional Instances

Adding additional instances to the group is essentially the same sequence of steps as adding the second server, except that the configuration has to be changed as it had to be for server s2. To summarise the required commands:

1. Create the configuration file

```
[mysqld]

# server configuration
datadir=<full_path_to_data>/data/s3
basedir=<full_path_to_bin>/mysql-5.7/

port=24803
socket=<full_path_to_sock_dir>/s3.sock

#
# Replication configuration parameters
#
server_id=3
gtid_mode=ON
enforce_gtid_consistency=ON
master_info_repository=TABLE
relay_log_info_repository=TABLE
binlog_checksum=NONE
log_slave_updates=ON
log_bin=binlog
binlog_format=ROW

#
# Group Replication configuration
#
transaction_write_set_extraction=XXHASH64
loose-group_replication_group_name="aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaaa"
loose-group_replication_start_on_boot=off
loose-group_replication_local_address= "127.0.0.1:24903"
loose-group_replication_group_seeds= "127.0.0.1:24901,127.0.0.1:24902,127.0.0.1:24903"
loose-group_replication_bootstrap_group= off
```

2. Start the server

```
mysql-5.7/bin/mysqld --defaults-file=data/s3/s3.cnf
```

3. Configure the recovery credentials for the group_replication_recovery channel.

```
SET SQL_LOG_BIN=0;
CREATE USER rpl_user@'%';
GRANT REPLICATION SLAVE ON *.* TO rpl_user@%' IDENTIFIED BY 'rpl_pass';
FLUSH PRIVILEGES;
SET SQL_LOG_BIN=1;
CHANGE MASTER TO MASTER_USER='rpl_user', MASTER_PASSWORD='rpl_pass' \\\
FOR CHANNEL 'group_replication_recovery';
```

4. Install the Group Replication plugin and start it.

```
INSTALL PLUGIN group_replication SONAME 'group_replication.so';
START GROUP_REPLICATION;
```

At this point server s3 is booted and running, has joined the group and caught up with the other servers in the group. Consulting the `performance_schema.replication_group_members` table again confirms this is the case.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
+-----+-----+-----+-----+-----+
| CHANNEL_NAME | MEMBER_ID | MEMBER_HOST | MEMBER_PORT | MEMBER_ROLE |
+-----+-----+-----+-----+-----+
| group_replication_applier | 395409e1-6dfa-11e6-970b-00212844f856 | myhost | 24801 | ONLINE |
| group_replication_applier | 7eb217ff-6df3-11e6-966c-00212844f856 | myhost | 24803 | ONLINE |
| group_replication_applier | ac39f1e6-6dfa-11e6-a69d-00212844f856 | myhost | 24802 | ONLINE |
+-----+-----+-----+-----+-----+
3 rows in set (0,00 sec)
```

Issuing this same query on server s2 or server s1 yields the same result. Also, you can verify that server s3 has also caught up:

```
mysql> SHOW DATABASES LIKE 'test';
+-----+
| Database (test) |
+-----+
| test            |
+-----+
1 row in set (0,00 sec)

mysql> SELECT * FROM test.t1;
+-----+
| c1 | c2 |
+-----+
| 1  | Luis |
+-----+
1 row in set (0,00 sec)

mysql> SHOW BINLOG EVENTS;
+-----+
| Log_name          | Pos | Event_type      | Server_id | End_log_pos | Info
+-----+
| binlog.000001    | 4   | Format_desc     | 3         | 123         | Server ver: 5.7.17-log, Binlog ver: 4
| binlog.000001    | 123 | Previous_gtids | 3         | 150         |
| binlog.000001    | 150 | Gtid            | 1         | 211         | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaa
| binlog.000001    | 211 | Query           | 1         | 270         | BEGIN
| binlog.000001    | 270 | View_change     | 1         | 369         | view_id=14724832985483517:1
| binlog.000001    | 369 | Query           | 1         | 434         | COMMIT
| binlog.000001    | 434 | Gtid            | 1         | 495         | SET @@SESSION.GTID_NEXT= 'aaaaaaaa-aaa
| binlog.000001    | 495 | Query           | 1         | 585         | CREATE DATABASE test

```

21.3 Monitoring Group Replication

Use the Performance Schema tables to monitor Group Replication, assuming that the Performance Schema is enabled. Group Replication adds the following tables:

- [performance_schema.replication_group_member_stats](#)
- [performance_schema.replication_group_members](#)

These Performance Schema replication tables also show information about Group Replication:

- [performance_schema.replication_connection_status](#)
- [performance_schema.replication_applier_status](#)

The replication channels created by the Group Replication plugin are named:

- [group_replication_recovery](#) - This channel is used for the replication changes that are related to the distributed recovery phase.

- [group_replication_applier](#) - This channel is used for the incoming changes from the group. This is the channel used to apply transactions coming directly from the group.

The following sections describe the information available in each of these tables.

21.3.1 Replication_group_member_stats

Each member in a replication group certifies and applies transactions received by the group. Statistics regarding the certifier and applier procedures are useful to understand how the applier queue is growing, how many conflicts have been found, how many transactions were checked, which transactions are committed everywhere, and so on.

The [performance_schema.replication_group_member_stats](#) table provides group-level information related to the certification process, and also statistics for the transactions received and originated by each individual member of the replication group. The information is shared between all the server instances that are members of the replication group, so information on all the group members can be queried from any member. Note that refreshing of statistics for remote members is controlled by the message period specified in the [group_replication_flow_control_period](#) option, so these can differ slightly from the locally collected statistics for the member where the query is made.

Table 21.1 replication_group_member_stats

Field	Description
Channel_name	The name of the Group Replication channel.
Member_id	The member server UUID. This has a different value for each member in the group. This also serves as a key since it is unique to each member.
Count_transactions_in_queue	The number of transactions in the queue pending conflict detection checks. Once the transactions have been checked for conflicts, if they pass the check, they are queued to be applied as well.
Count_transactions_checked	The number of transactions that have been checked for conflicts.
Count_conflicts_detected	The number of transactions that did not pass the conflict detection check.
Count_transactions_rows_validating	The current size of the conflict detection database (against which each transaction is certified).
Transactions_committed_all_members	The transactions that have been successfully committed on all members of the replication group. This is updated at a fixed time interval.
Last_conflict_free_transaction	The transaction identifier of the last conflict free transaction checked.
Count_transactions_remote_in_applier_queue	The number of transactions that this member has received from the replication group which are waiting to be applied.
Count_transactions_remote_applied	The number of transactions that this member has received from the replication group which have been applied.
Count_transactions_local_proposed	The number of transactions that this member originated and sent to the replication group for coordination.
Count_transactions_local_rollback	The number of transactions that this member originated that were rolled back after being sent to the replication group.

These fields are important for monitoring the performance of the members connected in the group. For example, suppose that one of the group's members is delayed and is not able to keep up to date

with the other members of the group. In this case you might see a large number of transactions in the queue. Based on this information, you could decide to either remove the member from the group, or delay the processing of transactions on the other members of the group in order to reduce the number of queued transactions. This information can also help you to decide how to adjust the flow control of the Group Replication plugin.

21.3.2 Replication_group_members

This table is used for monitoring the status of the different server instances that are tracked in the current view, or in other words are part of the group and as such are tracked by the membership service. The information is shared between all the server instances that are members of the replication group, so information on all the group members can be queried from any member.

Table 21.2 replication_group_members

Field	Description
Channel_name	The name of the Group Replication channel.
Member_id	The member server UUID. This has a different value for each member in the group. This also serves as a key because it is unique to each member.
Member_host	The network address of the group member.
Member_port	The MySQL connection port on which the group member is listening.
Member_state	The current state of the group member (which can be ONLINE , ERROR , RECOVERING , OFFLINE or UNREACHABLE).
Member_role	The role of the member in the group, either PRIMARY or SECONDARY .
Member_version	The MySQL version of the group member.

For more information about the [Member_host](#) value and its impact on the distributed recovery process, see [Section 21.2.1.3, "User Credentials"](#).

21.3.3 Replication_connection_status

When connected to a group, some fields in this table show information regarding Group Replication. For instance, the transactions that have been received from the group and queued in the applier queue (the relay log).

Table 21.3 replication_connection_status

Field	Description
Channel_name	The name of the Group Replication channel.
Group_name	Shows the value of the name of the group. It is always a valid UUID.
Source_UUID	Shows the identifier for the group. It is similar to the group name and it is used as the UUID for all the transactions that are generated during group replication.
Service_state	Shows whether the member is a part of the group or not. The possible values of service state can be {ON, OFF and CONNECTING};
Received_transaction_set	Transactions in this GTID set have been received by this member of the group.

21.3.4 Replication_applier_status

The state of the Group Replication related channels and threads can be observed using the regular replication_applier_status table as well. If there are many different worker threads applying transactions, then the worker tables can also be used to monitor what each worker thread is doing.

Table 21.4 replication_applier_status

Field	Description
Channel_name	The name of the Group Replication channel.
Service_state	Shows whether the applier service is ON or OFF.
Remaining_delay	Shows whether there is some applier delay configured.
Count_transactions_retries	The number of retries performed while applying a transaction.
Received_transaction_set	Transactions in this GTID set have been received by this member of the group.

21.3.5 Group Replication Server States

The table [replication_group_members](#) is updated whenever there is a view change, for example when the configuration of the group is dynamically changed. At that point, servers exchange some of their metadata to synchronize themselves and continue to cooperate together.

There are various states that a server instance can be in. If servers are communicating properly, all report the same states for all servers. However, if there is a network partition, or a server leaves the group, then different information may be reported, depending on which server is queried. Note that if the server has left the group then obviously it cannot report updated information about other servers' state. If there is a partition, such that quorum is lost, servers are not able to coordinate between themselves. As a consequence, they cannot guess what the status of different servers is. Therefore, instead of guessing their state they report that some servers are unreachable.

Table 21.5 Server State

Field	Description	Group Synchronized
ONLINE	The member is ready to serve as a fully functional group member, meaning that the client can connect and start executing transactions.	Yes
RECOVERING	The member is in the process of becoming an active member of the group and is currently going through the recovery process, receiving state information from a donor.	No
OFFLINE	The plugin is loaded but the member does not belong to any group.	No
ERROR	The state of the member. Whenever there is an error on the recovery phase or while applying changes, the server enters this state.	No
UNREACHABLE	Whenever the local failure detector suspects that a given server is not reachable, because maybe it has crashed or was disconnected involuntarily, it shows that server's state as 'unreachable'.	No

Important

Once an instance enters **ERROR** state, the [super_read_only](#) option is set to **ON**. To leave the **ERROR** state you must manually configure the instance with [super_read_only=OFF](#).

Note that Group Replication is *not* synchronous, but eventually synchronous. More precisely, transactions are delivered to all group members in the same order, but their execution is not synchronized, meaning that after a transaction is accepted to be committed, each member commits at its own pace.

21.4 Group Replication Operations

This section describes the different modes of deploying Group Replication, explains common operations for managing groups and provides information about how to tune your groups .

21.4.1 Deploying in Multi-Primary or Single-Primary Mode

Group Replication operates in the following different modes:

- single-primary mode
- multi-primary mode

The default mode is single-primary. It is not possible to have members of the group deployed in different modes, for example one configured in multi-primary mode while another one is in single-primary mode. To switch between modes, the group and not the server, needs to be restarted with a different operating configuration. Regardless of the deployed mode, Group Replication does not handle client-side fail-over, that must be handled by the application itself, a connector or a middleware framework such as a proxy or router.

When deployed in multi-primary mode, statements are checked to ensure they are compatible with the mode. The following checks are made when Group Replication is deployed in multi-master mode:

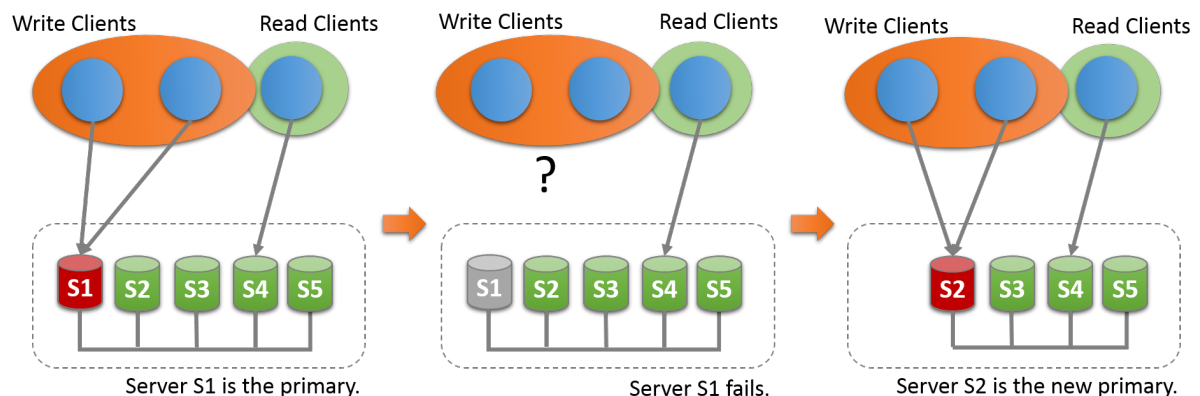

- If a transaction is executed under the SERIALIZABLE isolation level, then its commit fails when synchronizing itself with the group.
- If a transaction executes against a table that has foreign keys with cascading constraints, then the transaction fails to commit when synchronizing itself with the group.

These checks can be deactivated by setting the option `group_replication_enforce_update_everywhere_checks` to `FALSE`. When deploying in single-primary mode, this option *must* be set to `FALSE`.

21.4.1.1 Single-Primary Mode

In this mode the group has a single-primary server that is set to read-write mode. All the other members in the group are set to read-only mode (with `super-read-only=ON`). This happens automatically. The primary is typically the first server to bootstrap the group, all other servers that join automatically learn about the primary server and are set to read only.

Figure 21.5 New Primary Election

When in single-primary mode, some of the checks deployed in multi-primary mode are disabled, because the system enforces that only a single writer server is in the group at a time. For example, changes to tables that have cascading foreign keys are allowed, whereas in multi-primary mode they are not. Upon primary member failure, an automatic primary election mechanism chooses the next primary member. The method of choosing the next primary depends on the server's `server_uuid` variable and the `group_replication_member_weight` variable.

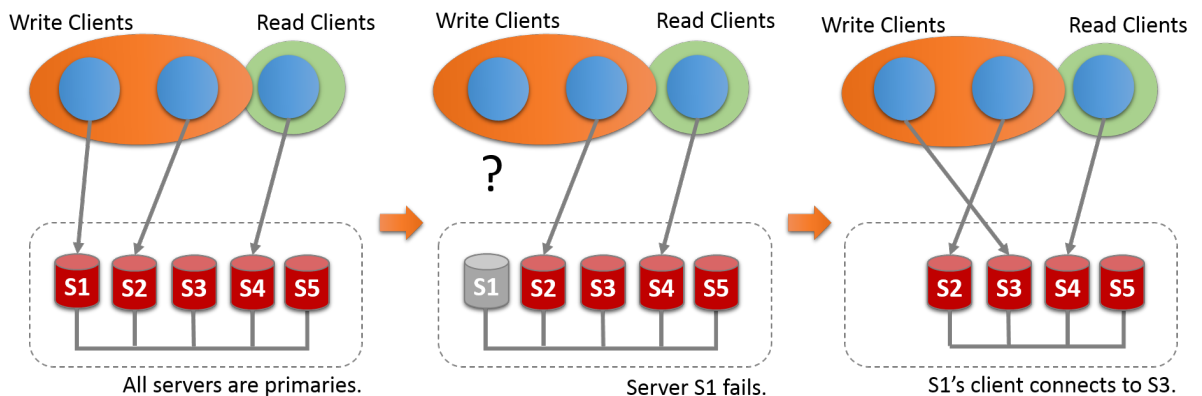

In the event that the primary member leaves the group, then an election is performed and a new primary is chosen from the remaining servers in the group. This election is performed by looking at the new view, and ordering the potential new primaries based on the value of `group_replication_member_weight`. The member with the highest value for `group_replication_member_weight` is elected as the new primary. In the event that multiple servers have the same `group_replication_member_weight`, the servers are then prioritised based on their `server_uuid` in lexicographical order and by picking the first one. Once a new primary is elected, it is automatically set to read-write and the other secondaries remain as secondaries, and as such, read-only.

It is a good practice to wait for the new primary to apply its replication related relay-log before re-routing the client applications to it.

21.4.1.2 Multi-Primary Mode

In multi-primary mode, there is no notion of a single primary. There is no need to engage an election procedure since there is no server playing any special role.

Figure 21.6 Client Failover

All servers are set to read-write mode when joining the group.

21.4.1.3 Finding the Primary

The following example shows how to find out which server is currently the primary when deployed in single-primary mode.

```
mysql> SELECT VARIABLE_VALUE FROM performance_schema.global_status WHERE VARIABLE_NAME= 'group_replicat
+-----+
| VARIABLE_VALUE |
+-----+
| 69e1a3b8-8397-11e6-8e67-bf68cbc061a4 |
+-----+
1 row in set (0,00 sec)
```

21.4.2 Tuning Recovery

Whenever a new member joins a replication group, it connects to a suitable donor and fetches the data that it has missed up until the point it is declared online. This critical component in Group Replication is

fault tolerant and configurable. The following section explains how recovery works and how to tune the settings

Donor Selection

A random donor is selected from the existing online members in the group. This way there is a good chance that the same server is not selected more than once when multiple members enter the group.

If the connection to the selected donor fails, a new connection is automatically attempted to a new candidate donor. Once the connection retry limit is reached the recovery procedure terminates with an error.

Note

A donor is picked randomly from the list of online members in the current view.

Enhanced Automatic Donor Switchover

The other main point of concern in recovery as a whole is to make sure that it copes with failures. Hence, Group Replication provides robust error detection mechanisms. In earlier versions of Group Replication, when reaching out to a donor, recovery could only detect connection errors due to authentication issues or some other problem. The reaction to such problematic scenarios was to switch over to a new donor thus a new connection attempt was made to a different member.

This behavior was extended to also cover other failure scenarios:

- *Purged data scenarios* - If the selected donor contains some purged data that is needed for the recovery process then an error occurs. Recovery detects this error and a new donor is selected.
- *Duplicated data* - If a joiner already contains some data that conflicts with the data coming from the selected donor during recovery then an error occurs. This could be caused by some errant transactions present in the joiner.

One could argue that recovery should fail instead of switching over to another donor, but in heterogeneous groups there is chance that other members share the conflicting transactions and others do not. For that reason, upon error, recovery selects another donor from the group.

- *Other errors* - If any of the recovery threads fail (receiver or applier threads fail) then an error occurs and recovery switches over to a new donor.

Note

In case of some persistent failures or even transient failures recovery automatically retries connecting to the same or a new donor.

Donor Connection Retries

The recovery data transfer relies on the binary log and existing MySQL replication framework, therefore it is possible that some transient errors could cause errors in the receiver or applier threads. In such cases, the donor switch over process has retry functionality, similar to that found in regular replication.

Number of Attempts

The number of attempts a joiner makes when trying to connect to a donor from the pool of donors is 10. This is configured through the `group_replication_recovery_retry_count` plugin variable. The following command sets the maximum number of attempts to connect to a donor to 10.

```
SET GLOBAL group_replication_recovery_retry_count= 10;
```

Note that this accounts for the global number of attempts that the joiner makes connecting to each one of the suitable donors.

Sleep Routines

The `group_replication_recovery_reconnect_interval` plugin variable defines how much time the recovery process should sleep between donor connection attempts. This variable has its default set to 60 seconds and you can change this value dynamically. The following command sets the recovery donor connection retry interval to 120 seconds.

```
SET GLOBAL group_replication_recovery_reconnect_interval= 120;
```

Note, however, that recovery does not sleep after every donor connection attempt. As the joiner is connecting to different servers and not to the same one over and over again, it can assume that the problem that affects server A maybe not affect server B. As such, recovery suspends only when it has gone through all the possible donors. Once the joiner has tried to connect to all the suitable donors in the group and none remains, the recovery process sleeps for the number of seconds configured by the `group_replication_recovery_reconnect_interval` variable.

21.4.3 Network Partitioning

The group needs to achieve consensus whenever a change that needs to be replicated happens. This is the case for regular transactions but is also required for group membership changes and some internal messaging that keeps the group consistent. Consensus requires a majority of group members to agree on a given decision. When a majority of group members is lost, the group is unable to progress and blocks because it cannot secure majority or quorum.

Quorum may be lost when there are multiple involuntary failures, causing a majority of servers to be removed abruptly from the group. For example in a group of 5 servers, if 3 of them become silent at once, the majority is compromised and thus no quorum can be achieved. In fact, the remaining two are not able to tell if the other 3 servers have crashed or whether a network partition has isolated these 2 alone and therefore the group cannot be reconfigured automatically.

On the other hand, if servers exit the group voluntarily, they instruct the group that it should reconfigure itself. In practice, this means that a server that is leaving tells others that it is going away. This means that other members can reconfigure the group properly, the consistency of the membership is maintained and the majority is recalculated. For example, in the above scenario of 5 servers where 3 leave at once, if the 3 leaving servers warn the group that they are leaving, one by one, then the membership is able to adjust itself from 5 to 2, and at the same time, securing quorum while that happens.

Note

Loss of quorum is by itself a side-effect of bad planning. Plan the group size for the number of expected failures (regardless whether they are consecutive, happen all at once or are sporadic).

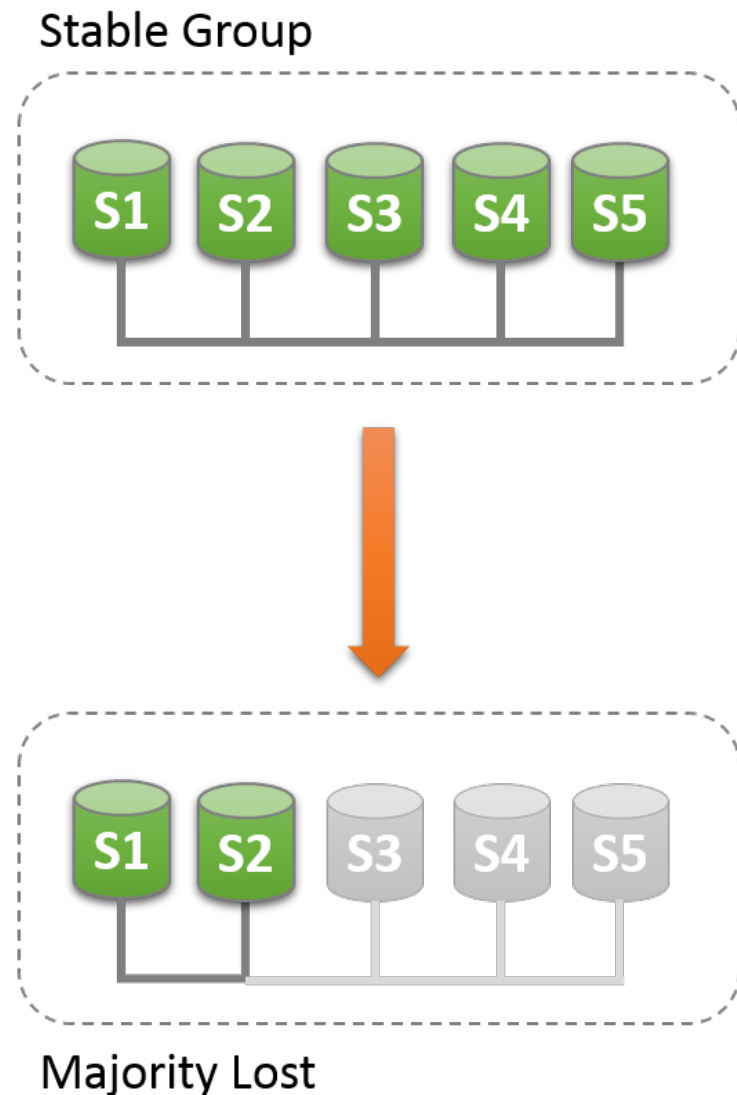

The following sections explain what to do if the system partitions in such a way that no quorum is automatically achieved by the servers in the group.

21.4.3.1 Detecting Partitions

The `replication_group_members` performance schema table presents the status of each server in the current view from the perspective of this server. The majority of the time the system does not run into partitioning, and therefore the table shows information that is consistent across all servers in the group. In other words, the status of each server on this table is agreed by all in the current view. However, if there is network partitioning, and quorum is lost, then the table shows the status

UNREACHABLE for those servers that it cannot contact. This information is exported by the local failure detector built into Group Replication.

Figure 21.7 Losing Quorum

To understand this type of network partition the following section describes a scenario where there are initially 5 servers working together correctly, and the changes that then happen to the group once only 2 servers are online. The scenario is depicted in the figure.

As such, lets assume that there is a group with these 5 servers in it:

- Server s1 with member identifier `199b2df7-4aaf-11e6-bb16-28b2bd168d07`
- Server s2 with member identifier `199bb88e-4aaf-11e6-babe-28b2bd168d07`
- Server s3 with member identifier `1999b9fb-4aaf-11e6-bb54-28b2bd168d07`
- Server s4 with member identifier `19ab72fc-4aaf-11e6-bb51-28b2bd168d07`
- Server s5 with member identifier `19b33846-4aaf-11e6-ba81-28b2bd168d07`

Initially the group is running fine and the servers are happily communicating with each other. You can verify this by logging into s1 and looking at its `replication_group_members` performance schema table. For example:

```
mysql> SELECT * FROM performance_schema.replication_group_members;
+-----+-----+-----+-----+-----+
| CHANNEL_NAME          | MEMBER_ID          | MEMBER_HOST | MEMBER_PORT | MEMBER_STATUS |
+-----+-----+-----+-----+-----+
| group_replication_applier | 1999b9fb-4aaf-11e6-bb54-28b2bd168d07 | 127.0.0.1 | 13002 | ONLINE |
| group_replication_applier | 199b2df7-4aaf-11e6-bb16-28b2bd168d07 | 127.0.0.1 | 13001 | ONLINE |
| group_replication_applier | 199bb88e-4aaf-11e6-babe-28b2bd168d07 | 127.0.0.1 | 13000 | ONLINE |
| group_replication_applier | 19ab72fc-4aaf-11e6-bb51-28b2bd168d07 | 127.0.0.1 | 13003 | ONLINE |
| group_replication_applier | 19b33846-4aaf-11e6-ba81-28b2bd168d07 | 127.0.0.1 | 13004 | ONLINE |
+-----+-----+-----+-----+-----+
5 rows in set (0,00 sec)
```

However, moments later there is a catastrophic failure and servers s3, s4 and s5 stop unexpectedly. A few seconds after this, looking again at the `replication_group_members` table on s1 shows that it is still online, but several others members are not. In fact, as seen below they are marked as `UNREACHABLE`. Moreover, the system could not reconfigure itself to change the membership, because the majority has been lost.

```
mysql> SELECT * FROM performance_schema.replication_group_members;
+-----+-----+-----+-----+-----+
| CHANNEL_NAME          | MEMBER_ID          | MEMBER_HOST | MEMBER_PORT | MEMBER_STATUS |
+-----+-----+-----+-----+-----+
| group_replication_applier | 1999b9fb-4aaf-11e6-bb54-28b2bd168d07 | 127.0.0.1 | 13002 | UNREACHABLE |
| group_replication_applier | 199b2df7-4aaf-11e6-bb16-28b2bd168d07 | 127.0.0.1 | 13001 | ONLINE |
| group_replication_applier | 199bb88e-4aaf-11e6-babe-28b2bd168d07 | 127.0.0.1 | 13000 | ONLINE |
| group_replication_applier | 19ab72fc-4aaf-11e6-bb51-28b2bd168d07 | 127.0.0.1 | 13003 | UNREACHABLE |
| group_replication_applier | 19b33846-4aaf-11e6-ba81-28b2bd168d07 | 127.0.0.1 | 13004 | UNREACHABLE |
+-----+-----+-----+-----+-----+
5 rows in set (0,00 sec)
```

The table shows that s1 is now in a group that has no means of progressing without external intervention, because a majority of the servers are unreachable. In this particular case, the group membership list needs to be reset to allow the system to proceed, which is explained in this section. Alternatively, you could also choose to stop Group Replication on s1 and s2 (or stop completely s1 and s2), figure out what happened with s3, s4 and s5 and then restart Group Replication (or the servers).

21.4.3.2 Unblocking a Partition

Group replication enables you to reset the group membership list by forcing a specific configuration. For instance in the case above, where s1 and s2 are the only servers online, you could chose to force a membership configuration consisting of only s1 and s2. This requires checking some information about s1 and s2 and then using the `group_replication_force_members` variable.

Figure 21.8 Forcing a New Membership

Suppose that you are back in the situation where s1 and s2 are the only servers left in the group. Servers s3, s4 and s5 have left the group unexpectedly. To make servers s1 and s2 continue, you want to force a membership configuration that contains only s1 and s2.

Warning

This procedure uses `group_replication_force_members` and should be considered a last resort remedy. It *must* be used with extreme care and only for overriding loss of quorum. If misused, it could create an artificial split-brain scenario or block the entire system altogether.

Recall that the system is blocked and the current configuration is the following (as perceived by the local failure detector on s1):

```
mysql> SELECT * FROM performance_schema.replication_group_members;
```

CHANNEL_NAME	MEMBER_ID	MEMBER_HOST	MEMBER_PORT	MEMBER_STATUS
group_replication_applier	1999b9fb-4aaf-11e6-bb54-28b2bd168d07	127.0.0.1	13002	UNREACHABLE
group_replication_applier	199b2df7-4aaf-11e6-bb16-28b2bd168d07	127.0.0.1	13001	ONLINE
group_replication_applier	199bb88e-4aaf-11e6-babe-28b2bd168d07	127.0.0.1	13000	ONLINE

```
| group_replication_applier | 19ab72fc-4aaf-11e6-bb51-28b2bd168d07 | 127.0.0.1 | 13003 | UNREAC
| group_replication_applier | 19b33846-4aaf-11e6-ba81-28b2bd168d07 | 127.0.0.1 | 13004 | UNREAC
+-----+-----+-----+-----+-----+
5 rows in set (0,00 sec)
```

The first thing to do is to check what is the peer address (group communication identifier) for s1 and s2. Log in to s1 and s2 and get that information as follows.

```
mysql> SELECT @@group_replication_local_address;
+-----+
| @@group_replication_local_address |
+-----+
| 127.0.0.1:10000 |
+-----+
1 row in set (0,00 sec)
```

Then log in to s2 and do the same thing:

```
mysql> SELECT @@group_replication_local_address;
+-----+
| @@group_replication_local_address |
+-----+
| 127.0.0.1:10001 |
+-----+
1 row in set (0,00 sec)
```

Once you know the group communication addresses of s1 (127.0.0.1:10000) and s2 (127.0.0.1:10001), you can use that on one of the two servers to inject a new membership configuration, thus overriding the existing one that has lost quorum. To do that on s1:

```
mysql> SET GLOBAL group_replication_force_members="127.0.0.1:10000,127.0.0.1:10001";
Query OK, 0 rows affected (7,13 sec)
```

This unblocks the group by forcing a different configuration. Check [replication_group_members](#) on both s1 and s2 to verify the group membership after this change. First on s1.

```
mysql> select * from performance_schema.replication_group_members;
+-----+-----+-----+-----+-----+
| CHANNEL_NAME | MEMBER_ID | MEMBER_HOST | MEMBER_PORT | MEMBER
+-----+-----+-----+-----+-----+
| group_replication_applier | b5ffe505-4ab6-11e6-b04b-28b2bd168d07 | 127.0.0.1 | 13000 | ONLINE
| group_replication_applier | b60907e7-4ab6-11e6-afb7-28b2bd168d07 | 127.0.0.1 | 13001 | ONLINE
+-----+-----+-----+-----+-----+
2 rows in set (0,00 sec)
```

And then on s2.

```
mysql> select * from performance_schema.replication_group_members;
+-----+-----+-----+-----+-----+
| CHANNEL_NAME | MEMBER_ID | MEMBER_HOST | MEMBER_PORT | MEMBER
+-----+-----+-----+-----+-----+
| group_replication_applier | b5ffe505-4ab6-11e6-b04b-28b2bd168d07 | 127.0.0.1 | 13000 | ONLINE
| group_replication_applier | b60907e7-4ab6-11e6-afb7-28b2bd168d07 | 127.0.0.1 | 13001 | ONLINE
+-----+-----+-----+-----+-----+
2 rows in set (0,00 sec)
```

When forcing a new membership configuration, make sure that whatever servers are going to be forced out of the group are indeed stopped. In the scenario depicted above, if s3, s4 and s5 are not really unreachable but instead are online, they may have formed their own functional partition (they are 3 out of 5, hence they have the majority). In that case, forcing a group membership list with s1 and s2 could create an artificial split-brain situation. Therefore it is important before forcing a new membership configuration to ensure that the servers to be excluded are indeed shutdown and if they are not, shut them down before proceeding.

21.5 Group Replication Security

This section explains how to secure a group, securing the connections between members of a group, or by establishing a security perimeter using address whitelisting.

21.5.1 IP Address Whitelisting

The Group Replication plugin has a configuration option to determine from which hosts an incoming Group Communication connection can be accepted. This option is called `group_replication_ip_whitelist`. If you set this option on a server `s1`, then when server `s2` is establishing a connection to `s1` for the purpose of engaging group communication, then `s1` first checks the whitelist before accepting the connection from `s2`. If `s2` is in the whitelist, then `s1` accepts the connection, otherwise `s1` rejects the connection attempt by `s2`.

Note

By default, if not specified explicitly, the whitelist is automatically set to the private network addresses that the server has network interfaces on.

If you do not configure any whitelist, the server automatically sets the whitelist to the private networks that the server has an interface on. This means that a server, even if it has interfaces on public IPs, does not by default allow connections from external hosts.

Whenever the IP whitelist is set to `AUTOMATIC`, an entry in the error log can be emitted in such case, similar to:

```
2016-07-07T06:40:49.320686Z 4 [Note] Plugin group_replication reported: 'Added automatically \\
IP ranges 10.120.40.237/18,10.178.59.44/22,127.0.0.1/8 to the whitelist'
```

You can improve the security of the group further by manually setting the list of IP addresses permitted for group communication connections to come from. The list can be specified in CIDR notation or as simple IP addresses. A comma must separate each entry. For example:

```
mysql> STOP GROUP_REPLICATION;
mysql> SET GLOBAL group_replication_ip_whitelist="10.120.40.237/18,10.178.59.44/22,127.0.0.1/8";
mysql> START GROUP_REPLICATION;
```

Note

The localhost IP address (127.0.0.1) is always added to the whitelist. If not explicitly, it is implicitly and automatically added.

21.5.2 Secure Socket Layer Support (SSL)

MySQL Group Replication supports both OpenSSL and YaSSL builds of MySQL Server.

Group communication connections as well as recovery connections, are secured using SSL. The following sections explain how to configure connections.

Configuring SSL for Recovery

Recovery is performed through a regular asynchronous replication connection. Once the donor is selected, the joiner establishes an asynchronous replication connection. This is all automatic.

However, a user that requires an SSL connection must have been created before the joiner connects to the donor. Typically, this is set up at the time one is provisioning a server to join the group.

```
donor> SET SQL_LOG_BIN=0;
donor> CREATE USER 'rec_ssl_user'@'%' REQUIRE SSL;
donor> GRANT replication slave ON *.* TO 'rec_ssl_user'@'%';
donor> SET SQL_LOG_BIN=1;
```

Assuming that all servers already in the group have a replication user set up to use SSL, you configure the joiner to use those credentials when connecting to the donor. That is done according to the values of the SSL options provided for the Group Replication plugin.

```
new_member> SET GLOBAL group_replication_recovery_use_ssl=1;
new_member> SET GLOBAL group_replication_recovery_ssl_ca= '../cacert.pem';
new_member> SET GLOBAL group_replication_recovery_ssl_cert= '../client-cert.pem';
new_member> SET GLOBAL group_replication_recovery_ssl_key= '../client-key.pem';
```

And by configuring the recovery channel to use the credentials of the user that requires an SSL connection.

```
new_member> CHANGE MASTER TO MASTER_USER="rec_ssl_user" FOR CHANNEL "group_replication_recovery";
new_member> START GROUP_REPLICATION;
```

Configuring SSL for Group Communication

Secure sockets can be used to establish communication between members in a group. The configuration for this depends on the server's SSL configuration. As such, if the server has SSL configured, the Group Replication plugin also has SSL configured. For more information on the options for configuring the server SSL, see [Section 6.4.5, “Command Options for Secure Connections”](#). The options which configure Group Replication are shown in the following table.

Table 21.6 SSL Options

Server Configuration	Plugin Configuration Description
ssl_key	Path of key file. To be used as client and server certificate.
ssl_cert	Path of certificate file. To be used as client and server certificate.
ssl_ca	Path of file with SSL CAs that are trusted.
ssl_caphath	Path of directory containing certificates for SSL CAs that are trusted.
ssl_crl	Path of file containing the certificate revocation lists.
ssl_crlpath	Path of directory containing revoked certificate lists files.
ssl_cipher	Permitted ciphers to use while encrypting data over the connection.
tls_version	Secure communication will use this version and its protocols.

These options are MySQL Server configuration options which Group Replication relies on for its configuration. In addition there is the following Group Replication specific option to configure SSL on the plugin itself.

- `group_replication_ssl_mode` - specifies the security state of the connection between Group Replication members.

Table 21.7 group_replication_ssl_mode configuration values

Value	Description
<code>DISABLED</code>	Establish an unencrypted connection (<i>default</i>).
<code>REQUIRED</code>	Establish a secure connection if the server supports secure connections.
<code>VERIFY_CA</code>	Like <code>REQUIRED</code> , but additionally verify the server TLS certificate against the configured Certificate Authority (CA) certificates.

Value	Description
VERIFY_IDENTITY	Like VERIFY_CA, but additionally verify that the server certificate matches the host to which the connection is attempted.

The following example shows an example my.cnf file section used to configure SSL on a server and how activate it for Group Replication.

```
[mysqld]
ssl_ca = "cacert.pem"
ssl_capath = "../ca_directory"
ssl_cert = "server-cert.pem"
ssl_cipher = "DHE-RSA-AES256-SHA"
ssl_crl = "crl-server-revoked.crl"
ssl_crlpath = "../crl_directory"
ssl_key = "server-key.pem"
group_replication_ssl_mode= REQUIRED
```

The only plugin specific configuration option that is listed is `group_replication_ssl_mode`. This option activates the SSL communication between members of the group, by configuring the SSL framework with the `ssl_*` parameters that are provided to the server.

21.5.3 Virtual Private Networks (VPN)

There is nothing preventing Group Replication from operating over a virtual private network. At its core, it just relies on an IPv4 socket to establish connections between servers for the purpose of propagating messages between them.

21.6 Group Replication System Variables

These are the system variables that are specific to the Group Replication plugin. Every configuration option is prefixed with "group_replication".

Important

Although most variables are described as dynamic and can be changed while the server is running, most changes only take effect upon restarting the Group Replication plugin. Variables which can be changed without requiring a restart of the plugin are specifically noted as such in this section.

- `group_replication_group_name`

Command-Line Format	<code>--group-replication-group-name=value</code>	
System Variable	Name	<code>group_replication_group_name</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	string

The name of the group which this server instance belongs to. Must be a valid UUID.

- `group_replication_start_on_boot`

Command-Line Format	<code>--group-replication-start-on-boot=value</code>	
System Variable	Name	<code>group_replication_start_on_boot</code>
	Variable Scope	Global

	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	ON

Whether the server should start Group Replication or not during server start.

- `group_replication_local_address`

Command-Line Format	<code>--group-replication-local-address=value</code>	
System Variable	Name	<code>group_replication_local_address</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	string

The local address as a `host:port` formatted string.

- `group_replication_member_weight`

Introduced	8.0.2	
Command-Line Format	<code>--group-replication-member-weight=value</code>	
System Variable	Name	<code>group_replication_member_weight</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	50
	Min Value	0
	Max Value	100

A percentage weight that can be assigned to members to influence the chance of the member being elected as primary in the event that the existing primary leaves the group. Assign numeric weights to members to ensure that specific members are elected, for example during scheduled maintenance of the primary or to ensure certain hardware is prioritised in the event of failover.

- `group_replication_group_seeds`

Command-Line Format	<code>--group-replication-group-seeds=value</code>	
System Variable	Name	<code>group_replication_group_seeds</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	string

A list of peer addresses as a comma separated list such as `host1:port1,host2:port2`. Each address is validated when starting Group Replication and the list must contain at least one valid address. Any invalid host names could cause `START GROUP_REPLICATION` to fail.

- `group_replication_force_members`

Command-Line Format	<code>--group-replication-force-members=value</code>	
System Variable	Name	<code>group_replication_force_members</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	string

A list of peer addresses as a comma separated list such as `host1:port1,host2:port2`. This option is used to force a new group membership, in which the excluded members do not receive a new view and are blocked. You need to manually kill the excluded servers. Any invalid host names in the list could cause subsequent `START GROUP_REPLICATION` statements to fail because they could block group membership.

- `group_replication_bootstrap_group`

Command-Line Format	<code>--group-replication-bootstrap-group=value</code>	
System Variable	Name	<code>group_replication_bootstrap_group</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	<code>OFF</code>

Configure this server to bootstrap the group. This option must only be set on one server and only when starting the group for the first time or restarting the entire group. After the group has been bootstrapped, set this option to `OFF`. It should be set to `OFF` both dynamically and in the configuration files. Starting two servers or restarting one server with this option set while the group is running may lead to an artificial split brain situation, where two independent groups with the same name are bootstrapped.

- `group_replication_poll_spin_loops`

Command-Line Format	<code>--group-replication-poll-spin-loops=value</code>	
System Variable	Name	<code>group_replication_poll_spin_loops</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values (32-bit platforms)	Type	integer
	Default	0
	Min Value	0
	Max Value	4294967295

Permitted Values (64-bit platforms)	Type	integer
	Default	0
	Min Value	0
	Max Value	18446744073709547520

The number of times the group communication thread waits for the communication engine mutex to be released before the thread waits for more incoming network messages.

- [group_replication_recovery_retry_count](#)

Command-Line Format	<code>--group-replication-recovery-retry-count=value</code>	
System Variable	Name	group_replication_recovery_retry_count
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	10
	Min Value	0
	Max Value	31536000

The number of times that the member that is joining tries to connect to the available donors before giving up.

- [group_replication_recovery_reconnect_interval](#)

Command-Line Format	<code>--group-replication-recovery-reconnect-interval=value</code>	
System Variable	Name	group_replication_recovery_reconnect_interval
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	60
	Min Value	0
	Max Value	0

The sleep time, in seconds, between reconnection attempts when no donor was found in the group.

- [group_replication_recovery_use_ssl](#)

Command-Line Format	<code>--group-replication-recovery-use-ssl=value</code>	
System Variable	Name	group_replication_recovery_use_ssl
	Variable Scope	Global

	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	OFF

Whether Group Replication recovery connection should use SSL or not.

- [group_replication_recovery_ssl_ca](#)

Command-Line Format	<code>--group-replication-recovery-ssl-ca=value</code>	
System Variable	Name	group_replication_recovery_ssl_ca
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	string

The path to a file that contains a list of trusted SSL certificate authorities.

- [group_replication_recovery_ssl_capath](#)

Command-Line Format	<code>--group-replication-recovery-ssl-capath=value</code>	
System Variable	Name	group_replication_recovery_ssl_capath
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	string

The path to a directory that contains trusted SSL certificate authority certificates.

- [group_replication_recovery_ssl_cert](#)

Command-Line Format	<code>--group-replication-recovery-ssl-cert=value</code>	
System Variable	Name	group_replication_recovery_ssl_cert
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	string

The name of the SSL certificate file to use for establishing a secure connection.

- [group_replication_recovery_ssl_key](#)

Command-Line Format	<code>--group-replication-recovery-ssl-key=value</code>	
System Variable	Name	group_replication_recovery_ssl_key
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	string

The name of the SSL key file to use for establishing a secure connection.

- `group_replication_recovery_ssl_cipher`

Command-Line Format	<code>--group-replication-recovery-ssl-cipher=value</code>	
System Variable	Name	<code>group_replication_recovery_ssl_cipher</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	string

A list of permissible ciphers to use for SSL encryption.

- `group_replication_recovery_ssl_crl`

Command-Line Format	<code>--group-replication-recovery-ssl-crl=value</code>	
System Variable	Name	<code>group_replication_recovery_ssl_crl</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	string

The path to a directory that contains files containing certificate revocation lists.

- `group_replication_recovery_ssl_crlpath`

Command-Line Format	<code>--group-replication-recovery-ssl-crlpath=value</code>	
System Variable	Name	<code>group_replication_recovery_ssl_crlpath</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	string

The path to a directory that contains files containing certificate revocation lists.

- `group_replication_recovery_ssl_verify_server_cert`

Command-Line Format	<code>--group-replication-recovery-ssl-verify-server-cert=value</code>	
System Variable	Name	<code>group_replication_recovery_ssl_verify_server_cert</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	OFF

- `group_replication_recovery_complete_at`

Command-Line Format	<code>--group-replication-recovery-complete-at=value</code>	
System Variable	Name	<code>group_replication_recovery_complete_at</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	enumeration
	Default	<code>TRANSACTIONS_APPLIED</code>
	Valid Values	<code>TRANSACTIONS_CERTIFIED</code> <code>TRANSACTIONS_APPLIED</code>

Recovery policies when handling cached transactions after state transfer. This option specifies whether a member is marked online after it has received all transactions that it missed before it joined the group (`TRANSACTIONS_CERTIFIED`) or after it has received and applied them (`TRANSACTIONS_APPLIED`).

- `group_replication_components_stop_timeout`

Command-Line Format	<code>--group-replication-components-stop-timeout=value</code>	
System Variable	Name	<code>group_replication_components_stop_timeout</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	<code>31536000</code>

Timeout, in seconds, that Group Replication waits for each of the components when shutting down.

- `group_replication_allow_local_lower_version_join`

Command-Line Format	<code>--group-replication-allow-local-lower-version-join=value</code>	
System Variable	Name	<code>group_replication_allow_local_lower_version_join</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	<code>OFF</code>

Allow the current server to join the group even if it has a lower plugin version than the group.

- `group_replication_allow_local_disjoint_gtids_join`

Command-Line Format	<code>--group-replication-allow-local-disjoint-gtids-join=value</code>	
System Variable	Name	<code>group_replication_allow_local_disjoint_gtids_join</code>

	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	OFF

Allow the current server to join the group even if it has transactions not present in the group.

Warning

Use caution when enabling this option as incorrect usage could lead to inconsistencies in the group.

- [group_replication_auto_increment_increment](#)

Command-Line Format	<code>--group-replication-auto-increment-increment=value</code>	
System Variable	Name	group_replication_auto_increment_increment
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	7
	Min Value	1
	Max Value	65535

Determines the interval between successive column values for transactions that execute on this server instance.

- [group_replication_compression_threshold](#)

Command-Line Format	<code>--group-replication-compression-threshold=value</code>	
System Variable	Name	group_replication_compression_threshold
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	1000000
	Min Value	0
	Max Value	4294967296

The value in bytes above which (LZ4) compression is enforced. When set to zero, deactivates compression.

Command-Line Format	<code>--group-replication-gtid-assignment-block-size=value</code>	
System Variable	Name	<code>group_replication_gtid_assignment_block_size</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values (32-bit platforms)	Type	integer
	Default	1000000
	Min Value	1
	Max Value	4294967295
Permitted Values (64-bit platforms)	Type	integer
	Default	1000000
	Min Value	1
	Max Value	18446744073709547520

The number of consecutive GTIDs that are reserved for each member. Each member consumes its blocks and reserves more when needed.

- `group_replication_ssl_mode`

Command-Line Format	<code>--group-replication-ssl-mode=value</code>	
System Variable	Name	<code>group_replication_ssl_mode</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	enumeration
	Default	DISABLED
	Valid Values	DISABLED
		REQUIRED
		VERIFY_CA
VERIFY_IDENTITY		

Specifies the security state of the connection between Group Replication members.

- `group_replication_single_primary_mode`

Command-Line Format	<code>--group-replication-single-primary-mode=value</code>	
System Variable	Name	<code>group_replication_single_primary_mode</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean

	Default	ON
--	----------------	----

Instructs the group to automatically pick a single server to be the one that handles read/write workload. This server is the PRIMARY and all others are SECONDARIES.

- `group_replication_transaction_size_limit`

Command-Line Format	<code>--group-replication-transaction-size-limit=value</code>	
System Variable	Name	<code>group_replication_transaction_size_limit</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	0
	Min Value	0
	Max Value	2147483647
Permitted Values (>= 8.0.2)	Type	integer
	Default	150000000
	Min Value	0
	Max Value	2147483647

Configures the maximum transaction size in bytes which the group accepts. Transactions larger than this size are rolled back. Use this option to avoid large transactions causing the group to fail. A large transaction can cause problems for a group, either in terms of memory allocation or network bandwidth consumption, which may cause the failure detector to trigger because a given member is unreachable while it is busy processing the large transaction. When set to 0 there is no limit to the size of transactions the group accepts, and there may be the risk of large transactions causing the group to fail. Adjust the value of this variable depending on the size of workload you require from the group.

- `group_replication_unreachable_majority_timeout`

Introduced	8.0.2	
Command-Line Format	<code>--group-replication-unreachable-majority-timeout=value</code>	
System Variable	Name	<code>group_replication_unreachable_majority_timeout</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	0
	Min Value	0
	Max Value	31536000

Configures how long members that suffer a network partition and cannot connect to the majority wait before leaving the group. By default set to 0, which means that members that find themselves in a minority due to a network partition wait forever to connect the group. In a group of 5 servers (S1,S2,S3,S4,S5), if there is a disconnection between (S1,S2) and (S3,S4,S5) there is a network partition. The first group (S1,S2) is now in a minority because it cannot contact more than half of the group. While the majority group (S3,S4,S5) remains running, the minority group waits forever for a network reconnection. Any transactions processed by the minority group are blocked until Group Replication is stopped using `STOP GROUP REPLICATION` on the members of the minority.

If configured to a number of seconds, members wait for this amount of time after losing contact with the majority of members before leaving the group. All pending transactions processed by the minority are rolled back and the servers in the minority partition move to the `ERROR` state and set themselves to `super_read_only=ON` mode.

Warning

When you have a symmetric group, with just two members for example (S0,S2), if there is a network partition and there is no majority, after the configured timeout all members shut down and enter `ERROR` state.

- `group_replication_enforce_update_everywhere_checks`

Command-Line Format	<code>--group-replication-enforce-update-everywhere-checks=value</code>	
System Variable	Name	<code>group_replication_enforce_update_everywhere_checks</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	boolean
	Default	<code>OFF</code>

Enable or disable strict consistency checks for multi-primary update everywhere.

- `group_replication_flow_control_mode`

Command-Line Format	<code>--group-replication-flow-control-mode=value</code>	
System Variable	Name	<code>group_replication_flow_control_mode</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	enumeration
	Default	<code>QUOTA</code>
	Valid Values	<code>DISABLED</code> <code>QUOTA</code>

Specifies the mode used for flow control. This variable can be changed without resetting Group Replication.

- `group_replication_flow_control_hold_percent`

Command-Line Format	<code>--group-replication-flow-control-hold-percent=value</code>	
System Variable	Name	<code>group_replication_flow_control_hold_percent</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	10
	Min Value	0
	Max Value	100

Defines what percentage of the group quota remains unused to allow a cluster under flow control to catch up on backlog. A value of 0 implies that no part of the quota is reserved for catching up on the work backlog.

- `group_replication_flow_control_certifier_threshold`

Command-Line Format	<code>--group-replication-flow-control-certifier-threshold=value</code>	
System Variable	Name	<code>group_replication_flow_control_certifier_threshold</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	25000
	Min Value	0
	Max Value	2147483648

Specifies the number of waiting transactions in the certifier queue that trigger flow control. This variable can be changed without resetting Group Replication.

- `group_replication_flow_control_applier_threshold`

Command-Line Format	<code>--group-replication-flow-control-applier-threshold=value</code>	
System Variable	Name	<code>group_replication_flow_control_applier_threshold</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	25000
	Min Value	0

	Max Value	2147483648
--	------------------	------------

Specifies the number of waiting transactions in the applier queue that trigger flow control. This variable can be changed without resetting Group Replication.

- `group_replication_flow_control_max_commit_quota`

Introduced	8.0.2	
Command-Line Format	<code>--group-replication-flow-control-max-commit-quota=value</code>	
System Variable	Name	<code>group_replication_flow_control_max_commit_quota</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	0
	Min Value	0
	Max Value	2147483648

Defines the maximum flow control quota of the group, or the maximum available quota for any period while flow control is enabled. A value of 0 implies that there is no maximum quota set. Cannot be smaller than `group_replication_flow_control_min_quota` and `group_replication_flow_control_min_recovery_quota`.

- `group_replication_flow_control_member_quota_percent`

Introduced	8.0.2	
Command-Line Format	<code>--group-replication-flow-control-member-quota-percent=value</code>	
System Variable	Name	<code>group_replication_flow_control_member_quota_percent</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	0
	Min Value	0
	Max Value	100

Defines the percentage of the quota that a member should assume is available for itself when calculating the quotas. A value of 0 implies that the quota should be split equally between members that were writers in the last period.

- `group_replication_flow_control_min_quota`

Command-Line Format	<code>--group-replication-flow-control-min-quota=value</code>	
System Variable	Name	<code>group_replication_flow_control_min_quota</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	0
	Min Value	0
	Max Value	2147483648

Controls the lowest flow control quota that can be assigned to a member, independently of the calculated minimum quota executed in the last period. A value of 0 implies that there is no minimum quota. Cannot be larger than `group_replication_flow_control_max_commit_quota`.

- `group_replication_flow_control_min_recovery_quota`

Introduced	8.0.2	
Command-Line Format	<code>--group-replication-flow-control-min-recovery-quota=value</code>	
System Variable	Name	<code>group_replication_flow_control_min_recovery_quota</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	0
	Min Value	0
	Max Value	2147483648

Controls the lowest quota that can be assigned to a member because of another recovering member in the group, independently of the calculated minimum quota executed in the last period. A value of 0 implies that there is no minimum quota. Cannot be larger than `group_replication_flow_control_max_commit_quota`.

- `group_replication_flow_control_period`

Introduced	8.0.2	
Command-Line Format	<code>--group-replication-flow-control-period=value</code>	
System Variable	Name	<code>group_replication_flow_control_period</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	1

	Min Value	1
	Max Value	60

Defines how many seconds to wait between flow control iterations, in which flow control messages are sent and flow control management tasks are run.

- `group_replication_flow_control_release_percent`

Introduced	8.0.2	
Command-Line Format	<code>--group-replication-flow-control-release-percent=value</code>	
System Variable	Name	<code>group_replication_flow_control_release_percent</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	integer
	Default	50
	Min Value	0
	Max Value	1000

Defines how the group quota should be released when flow control no longer needs to throttle the writer members, with this percentage being the quota increase per flow control period. A value of 0 implies that once the flow control thresholds are within limits the quota is released in a single flow control iteration. The range allows the quota to be released at up to 10 times current quota, as that allows a greater degree of adaptation, mainly when the flow control period is large and the quotas are very small.

- `group_replication_ip_whitelist`

Command-Line Format	<code>--group-replication-ip-whitelist=value</code>	
System Variable	Name	<code>group_replication_recovery_ip_whitelist</code>
	Variable Scope	Global
	Dynamic Variable	Yes
Permitted Values	Type	string
	Default	<code>AUTOMATIC</code>

Specifies which hosts are permitted to connect to the group. By default set to `AUTOMATIC`, which permits connections from private subnetworks active on the host. Active interfaces on the host are scanned and those with addresses on private subnetworks are automatically added to the permitted list. Alternatively you can specify the permitted hosts using a comma separated list of IPv4 addresses or subnet CIDR notation. For example `192.168.1.0/24,10.0.0.1`.

Note

Address 127.0.0.1 is always permitted to connect, even when not specified using `group_replication_ip_whitelist`.

21.7 Requirements and Limitations

This section lists and explains the requirements and limitations of Group Replication.

21.7.1 Group Replication Requirements

Server instances that you want to use for Group Replication must satisfy the following requirements.

Infrastructure

- **InnoDB Storage Engine.** Data must be stored in the [InnoDB](#) transactional storage engine. Transactions are executed optimistically and then, at commit time, are checked for conflicts. If there are conflicts, in order to maintain consistency across the group, some transactions are rolled back. This means that a transactional storage engine is required. Moreover, [InnoDB](#) provides some additional functionality that enables better management and handling of conflicts when operating together with Group Replication.
- **Primary Keys.** Every table that is to be replicated by the group must have an explicit primary key defined. Primary keys play an extremely important role in determining which transactions conflict by identifying exactly which rows each transaction has modified.
- **IPv4 Network.** The group communication engine used by MySQL Group Replication only supports IPv4. Therefore, Group Replication requires an IPv4 network infrastructure.
- **Network Performance.** Group Replication is designed to be deployed in a cluster environment where server instances are very close to each other, and is impacted by both network latency as well as network bandwidth.

Server Instance Configuration

The following options must be configured on server instances that are members of a group.

- **Binary Log Active.** Set `--log-bin[=log_file_name]`. MySQL Group Replication replicates binary log contents, therefore the binary log needs to be turned on for it to operate. See [Section 5.4.4, “The Binary Log”](#).
- **Slave Updates Logged.** Set `--log-slave-updates`. Servers need to log binary logs that are applied through the replication applier. Servers in the group need to log all transactions that they receive and apply from the group. This is required because recovery is conducted by relying on binary logs from participants in the group. Therefore, copies of each transaction need to exist on every server, even for those transactions that were not initiated on the server itself.
- **Binary Log Row Format.** Set `--binlog-format=row`. Group Replication relies on row-based replication format to propagate changes consistently among the servers in the group. It relies on row-based infrastructure to be able to extract the necessary information to detect conflicts among transactions that execute concurrently in different servers in the group. See [Section 18.2.1, “Replication Formats”](#).
- **Global Transaction Identifiers On.** Set `--gtid-mode=ON`. Group Replication uses global transaction identifiers to track exactly which transactions have been committed on every server instance and thus be able to infer which servers have executed transactions that could conflict with already committed transactions elsewhere. In other words, explicit transaction identifiers are a fundamental part of the framework to be able to determine which transactions may conflict. See [Section 18.1.3, “Replication with Global Transaction Identifiers”](#).
- **Replication Information Repositories.** Set `--master-info-repository=TABLE` and `--relay-log-info-repository=TABLE`. The replication applier needs to have the master information and relay log metadata written to the `mysql.slave_master_info` and `mysql.slave_relay_log_info` system tables. This ensures the Group Replication plugin

has consistent recoverability and transactional management of the replication metadata. See [Section 18.2.4.2, “Slave Status Logs”](#).

- **Transaction Write Set Extraction.** Set `--transaction-write-set-extraction=XXHASH64` so that while collecting rows to log them to the binary log, the server collects the write set as well. The write set is based on the primary keys of each row and is a simplified and compact view of a tag that uniquely identifies the row that was changed. This tag is then used for detecting conflicts.
- **Multi-threaded Appliers.** Group Replication members can be configured as multi-threaded appliers, enabling transactions to be applied in parallel. Set `--slave-parallel-workers=N` (where `N` is the number of parallel applier threads), `--slave-preserve-commit-order=1`, and `--slave-parallel-type=LOGICAL_CLOCK`. Setting `--slave-parallel-workers=N` enables the multi-threaded applier on the member. Group Replication relies on consistency mechanisms built around the guarantee that all participating members receive and apply committed transaction in the same order, so you must also set `--slave-preserve-commit-order=1` to ensure that the final commit of parallel transactions is in the same order as the original transactions. Finally, in order to determine which transactions can be executed in parallel, the relay log must contain transaction parent information generated with `--slave-parallel-type=LOGICAL_CLOCK`. Attempting to add a member with `--slave-parallel-workers` set to greater than 0 without also setting the other two options, generates an error and the instance is prevented from joining.

21.7.2 Group Replication Limitations

The following known limitations exist for Group Replication.

- **Replication Event Checksums.** Due to a design limitation of replication event checksums, Group Replication cannot currently make use of them. Therefore set `--binlog-checksum=NONE`.
- **Gap Locks.** The certification process does not take into account [gap locks](#), as information about gap locks is not available outside of [InnoDB](#). See [Gap Locks](#) for more information.

Note

Unless you rely on [REPEATABLE READ](#) semantics in your applications, we recommend using the [READ COMMITTED](#) isolation level with Group Replication. InnoDB does not use gap locks in [READ COMMITTED](#), which aligns the local conflict detection within InnoDB with the distributed conflict detection performed by Group Replication.

- **Table Locks and Named Locks.** The certification process does not take into account table locks (see [Section 13.3.5, “LOCK TABLES and UNLOCK TABLES Syntax”](#)) or named locks (see [GET_LOCK\(\)](#)).
- **SERIALIZABLE Isolation Level.** [SERIALIZABLE](#) isolation level is not supported in multi-primary groups by default. Setting a transaction isolation level to [SERIALIZABLE](#) configures Group Replication to refuse to commit the transaction.
- **Concurrent DDL versus DML Operations.** Concurrent data definition statements and data manipulation statements executing against the same object but on different servers is not supported when using multi-primary mode. During execution of Data Definition Language (DDL) statements on an object, executing concurrent Data Manipulation Language (DML) on the same object but on a different server instance has the risk of conflicting DDL executing on different instances not being detected.
- **Foreign Keys with Cascading Constraints.** Multi-primary mode groups (members all configured with `group_replication_single_primary_mode=OFF`) do not support tables with multi-level foreign key dependencies, specifically tables that have defined [CASCADING foreign key constraints](#). This is because foreign key constraints that result in cascading operations executed by a multi-primary mode group can result in undetected conflicts and

lead to inconsistent data across the members of the group. Therefore we recommend setting `group_replication_enforce_update_everywhere_checks=ON` on server instances used in multi-primary mode groups to avoid undetected conflicts.

In single-primary mode this is not a problem as it does not allow concurrent writes to multiple members of the group and thus there is no risk of undetected conflicts.

- **Very Large Transactions.** Individual transactions that result in GTID contents which are large enough that it cannot be copied between group members over the network within a 5 second window can cause failures in the group communication. To avoid this issue try and limit the size of your transactions as much as possible. For example, split up files used with `LOAD DATA INFILE` into smaller chunks.

21.8 Frequently Asked Questions

This section provides answers to frequently asked questions.

What is the maximum number of MySQL servers in a group?

A group can consist of maximum 9 servers. Attempting to add another server to a group with 9 members causes the request to join to be refused.

How are servers in a group connected?

Servers in a group connect to the other servers in the group by opening a peer-to-peer TCP connection. These connections are only used for internal communication and message passing between servers in the group.

What is the `group_replication_bootstrap_group` option used for?

The bootstrap flag instructs a member to *create* a group and act as the initial seed server. The second member joining the group needs to ask the member that bootstrapped the group to dynamically change the configuration in order for it to be added to the group.

A member needs to bootstrap the group in two scenarios. When the group is originally created, or when shutting down and restarting the entire group.

How do I set credentials for the recovery procedure?

You pre-configure the Group Replication recovery channel credentials using the `CHANGE MASTER TO` statement.

Can I scale-out my write-load using Group Replication?

Not directly, but MySQL Group replication is a shared nothing full replication solution, where all servers in the group replicate the same amount of data. Therefore if one member in the group writes N bytes to storage as the result of a transaction commit operation, then roughly N bytes are written to storage on other members as well, because the transaction is replicated everywhere.

However, given that other members do not have to do the same amount of processing that the original member had to do when it originally executed the transaction, they apply the changes faster. Transactions are replicated in a format that is used to apply row transformations only, without having to re-execute transactions again (row-based format).

Furthermore, given that changes are propagated and applied in row-based format, this means that they are received in an optimized and compact format, and likely reducing the number of IO operations required when compared to the originating member.

Does Group Replication require more network bandwidth and CPU, when compared to simple replication and under the same workload?

To summarize, you can scale-out processing, by spreading conflict free transactions throughout different members in the group. And you can likely scale-out a small fraction of your IO operations, since remote servers receive only the necessary changes to read-modify-write changes to stable storage.

Does Group Replication require more network bandwidth and CPU, when compared to simple replication and under the same workload?

Some additional load is expected because servers need to be constantly interacting with each other for synchronization purposes. It is difficult to quantify how much more data. It also depends on the size of the group (three servers puts less stress on the bandwidth requirements than nine servers in the group).

Also the memory and CPU footprint are larger, because more complex work is done for the server synchronization part and for the group messaging.

Can I deploy Group Replication across wide-area networks?

Yes, but the network connection between each member *must* be reliable and have suitable performance. Low latency, high bandwidth network connections are a requirement for optimal performance.

If network bandwidth alone is an issue, then [Section 21.9.7.2, "Message Compression"](#) can be used to lower the bandwidth required. However, if the network drops packets, leading to re-transmissions and higher end-to-end latency, throughput and latency are both negatively affected.

Warning

When the network round-trip time (RTT) between any group members is 2 seconds or more you could encounter problems as the built-in failure detection mechanism could be incorrectly triggered.

Do members automatically rejoin a group in case of temporary connectivity problems?

This depends on the reason for the connectivity problem. If the connectivity problem is transient and the reconnection is quick enough that the failure detector is not aware of it, then the server may not be removed from the group. If it is a "long" connectivity problem, then the failure detector eventually suspects a problem and the server is removed from the group.

Once a server is removed from the group, you need to join it back again. In other words, after a server is removed explicitly from the group you need to rejoin it manually (or have a script doing it automatically).

When is a member excluded from a group?

If the member becomes silent, the other members remove it from the group configuration. In practice this may happen when the member has crashed or there is a network disconnection.

The failure is detected after a given timeout elapses for a given member and a new configuration without the silent member in it is created.

What happens when one node is significantly lagging behind?

There is no method for defining policies for when to expel members automatically from the group. You need to find out why a member is lagging behind and fix that or remove the member from the group.

Otherwise, if the server is so slow that it triggers the flow control, then the entire group slows down as well. The flow control can be configured according to the your needs.

Upon suspicion of a problem in the group, is there a special member responsible for triggering a reconfiguration?

No, there is no special member in the group in charge of triggering a reconfiguration.

Any member can suspect that there is a problem. All members need to (automatically) agree that a given member has failed. One member is in charge of expelling it from the group, by triggering a reconfiguration. Which member is responsible for expelling the member is not something you can control or set.

Can I use Group Replication for sharding?

Group Replication is designed to provide highly available replica sets; data and writes are duplicated on each member in the group. For scaling beyond what a single system can provide, you need an orchestration and sharding framework built around a number of Group Replication sets, where each replica set maintains and manages a given shard or partition of your total dataset. This type of setup, often called a “sharded cluster”, allows you to scale reads and writes linearly and without limit.

How do I use Group Replication with SELinux?

If SELinux is enabled, which you can verify using `sestatus -v`, then you need to enable the use of the Group Replication communication port, configured by `group_replication_local_address`, for `mysqld` so that it can bind to it and listen there. To see which ports MySQL is currently allowed to use, issue `semanage port -l | grep mysqld`. Assuming the port configured is 6606, add the necessary port to those permitted by SELinux by issuing `semanage port -a -t mysqld_port_t -p tcp 6606`.

How do I use Group Replication with iptables?

If iptables is enabled, then you need to open up the Group Replication port for communication between the machines. To see the current rules in place on each machine, issue `iptables -L`. Assuming the port configured is 6606, enable communication over the necessary port by issuing `iptables -A INPUT -p tcp --dport 6606 -j ACCEPT`.

How do I recover the relay log for a replication channel used by a group member?

The replication channels used by Group Replication behave in the same way as replication channels used in master to slave replication, and as such rely on the relay log. In the event of a change of the `relay_log` variable, or when the option is not set and the host name changes, there is a chance of errors. See [Section 18.2.4.1, “The Slave Relay Log”](#) for a recovery procedure in this situation. Alternatively, another way of fixing the issue specifically in Group Replication is to issue a `STOP GROUP_REPLICATION` statement and then a `START GROUP_REPLICATION` statement to restart the instance. The Group Replication plugin creates the `group_replication_applier` channel again.

21.9 Group Replication Technical Details

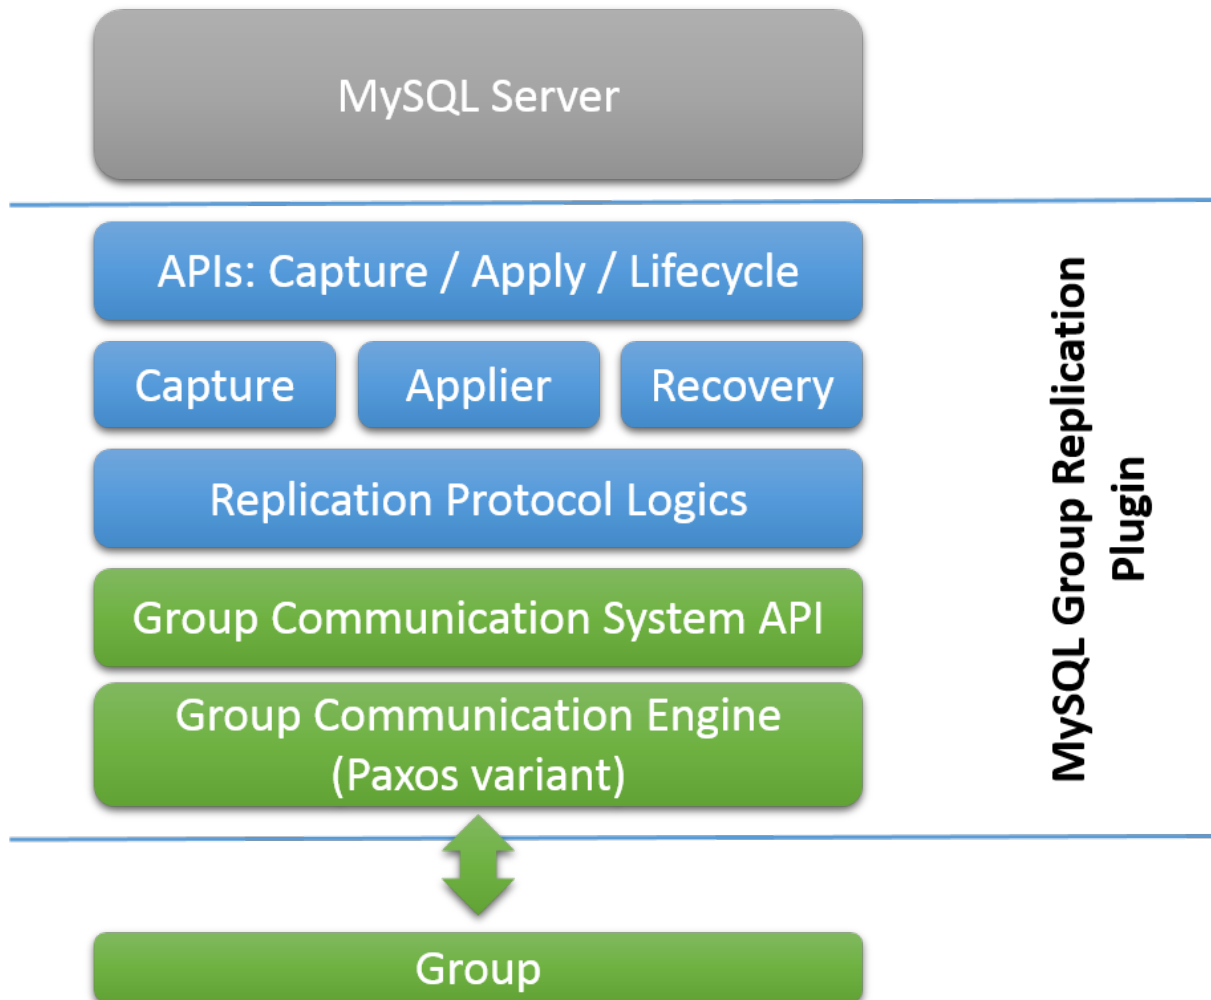

This section provides more technical details about MySQL Group Replication.

21.9.1 Group Replication Plugin Architecture

MySQL Group Replication is a MySQL plugin and it builds on the existing MySQL replication infrastructure, taking advantage of features such as the binary log, row-based logging, and global

transaction identifiers. It integrates with current MySQL frameworks, such as the performance schema or plugin and service infrastructures. The following figure presents a block diagram depicting the overall architecture of MySQL Group Replication.

Figure 21.9 Group Replication Plugin Block Diagram

Starting from the top of the figure, there is a set of APIs that control how the Group Replication plugin interacts with MySQL Server (the gray box). There are interfaces to make information flow from the server to the plugin and vice versa. Such interfaces isolate the server core from the plugin and are mostly hooks placed in the transaction execution pipeline. In one direction, from server to the plugin, there are notifications such as the server is starting, the server is recovering, the server is ready to accept connections, the server is about to commit a transaction, and so on. In the other direction, the plugin instructs the server to commit or abort ongoing transactions, queue transactions in the relay-log, and so on.

Below the API block is a set of components that react when a notification is routed to them. The capture component is responsible for keeping track of context related to transactions that are executing. The applier component is responsible for executing remote transactions on the database. The recovery component manages distributed recovery and is responsible for getting a server that is joining the group up to date by selecting the donor, orchestrating the catch up procedure and reacting on donor failures.

Continuing down the stack, the replication protocol module contains the specific logic of the replication protocol. It handles conflict detection, receives and propagates transactions to the group.

The first green box is the Group Communication API. It is a high level API abstracting the properties required to build a replicated state machine (details in the Background chapter). Therefore it decouples the implementation of the messaging layer from the remaining upper layers of the plugin. The MySQL Group Replication plugin contains an implementation of a Paxos based group communication engine.

21.9.2 The Group

In MySQL Group Replication, a set of servers forms a replication group. A group has a name, which takes the form of a UUID. The group is dynamic and servers can leave (either voluntarily or involuntarily) and join it at any time. The group adjusts itself whenever servers join or leave.

If a server joins the group, it automatically brings itself up to date by fetching the missing state from an existing server. This state is transferred by means of Asynchronous MySQL replication. If a server leaves the group, for instance it was taken down for maintenance, the remaining servers notice that it has left and reconfigure the group automatically. The group membership service described at [Section 21.1.3.2, “Group Membership”](#) powers all of this.

21.9.3 Data Manipulation Statements

As there are no primary servers (masters) for any particular data set, every server in the group is allowed to execute transactions at any time, even transactions that change state (RW transactions).

Any server may execute a transaction without any *a priori* coordination. But, at commit time, it coordinates with the rest of the servers in the group to reach a decision on the fate of that transaction. This coordination serves two purposes: (i) check whether the transaction should commit or not; (ii) and propagate the changes so that other servers can apply the transaction as well.

As a transaction is sent through an atomic broadcast, either all servers in the group receive the transaction or none do. If they receive it, then they all receive it in the same order with respect to other transactions that were sent before. Conflict detection is carried out by inspecting and comparing write sets of transactions. Thus, they are detected at the row level. Conflict resolution follows the first committer wins rule. If t1 and t2 execute concurrently at different sites, because t2 is ordered before t1, and both changed the same row, then t2 wins the conflict and t1 aborts. In other words, t1 was trying to change data that had been rendered stale by t2.

Note

If two transactions are bound to conflict more often than not, then it is a good practice to start them on the same server. They then have a chance to synchronize on the local lock manager instead of aborting later in the replication protocol.

21.9.4 Data Definition Statements

Care needs to be taken when executing data definition statements also commonly known as data definition language (DDL). Given that MySQL does not support atomic or transactional DDL, one cannot optimistically execute DDL statements and later roll back if needs be. Consequently, the lack of atomicity does not fit directly into the optimistic replication paradigm that Group Replication is based on.

Therefore, more care needs to be taken when replicating data definition statements. Schema changes and changes to the data that the object contains need to be handled through the same server while the schema operation has not yet completed and replicated everywhere. Failure to do so, may result in data inconsistency.

Note

If the group is deployed in single-primary mode, then this is not a problem, because all changes are performed through the same server, the primary.

**Warning**

MySQL DDL execution is not atomic or transactional. The server executes and commits without securing group agreement first. As such, you must route DDL and DML for the same object through the same server, while the DDL is executing and has not replicated everywhere yet.

21.9.5 Distributed Recovery

This section describes the process through which a joining member catches up with the remaining servers, called the distributed recovery phase.

21.9.5.1 Group Replication Basics

The Group Replication distributed recovery procedure can be summarized as the process through which a new server gets missing data from a online server in the group, while listening for events happening in the group. During recovery a server listens to membership events and also to the transactions that are happening while recovery is happening. This is a high level summary. The following sections provide additional detail, by describing the two phases of the procedure.

Phase 1

In the first phase, the joiner (joining server), will select one of the online servers on the group to be the *donor* of the state that it is missing. The donor is responsible for handing the joiner all the data it is missing up to the moment it has joined the group. This is achieved by relying on a standard asynchronous replication channel, established between donor and joiner. Through that channel, binary logs flow up until the point that the view change happened when the joiner became part of the group. While the joiner receives binary logs from the donor, it is also applying them.

Furthermore, while the binary logs transfer is ongoing, the joiner is also caching every transaction that is exchanged within the group. I.e., it is listening for transactions that are happening after it joined the group and while it is applying the missing state from the donor. When the first phase ends and the replication channel to the donor is closed, the joiner then starts phase two: the catch up.

Phase 2

In this phase, the joiner proceeds to the execution of the cached transactions and when the number of transactions queued for execution finally reaches zero, then the member is declared online.

Resilience

The recovery procedure withstands donor failures while the joiner is fetching binary logs from it. In such cases, whenever a donor fails during phase 1, the joiner fails over to a new donor and resumes from that one. When that happens the joiner closes the connection to the failed joiner explicitly and opens a connection to a new donor. This happens automatically.

21.9.5.2 Recovering From a Point-in-time

To synchronize the joiner with the donor up to a specific point in time, the joiner and donor make use of the MySQL global transaction identifiers (GTIDs) mechanism. However, that is not enough, since that only provides a mean to realize which transactions the joiner is missing. It does not help marking a specific point in time to which the joiner must catch up, nor does it help conveying certification information. This is where the binary log view markers come into play. They mark view changes in the binary log stream, and also contain additional metadata information, provisioning the joiner with missing certification related data.

View and View Changes

To explain the concept of view change markers, it is important to understand what a view and a view change are.

A *view* corresponds to a group of members participating actively in the current configuration, in other words at a specific point in time. They are correct and online in the system.

A *view change* occurs when a modification to the group configuration happens, such as a member joining or leaving. Any group membership change results in an independent view change communicated to all members at the same logical point in time.

A *view identifier* uniquely identifies a view. It is generated whenever a view change happens

At the group communication layer, view changes with their associated view ids are then boundaries between the data exchanged before and after a member joins. This concept is implemented through a new binary log event: the "view change log event". The view id thus becomes a marker as well for transactions transmitted before and after changes happen in the group membership.

The view identifier itself is built from two parts: (i) one that is randomly generated and (ii) a monotonically increasing integer. The first part is generated when the group is created, and remains unchanged while there is at least one member in the group. The second part is incremented every time a view change happens.

The reason for this heterogeneous pair that makes up the view id is the need to unambiguously mark group changes whenever a member joins or leaves but also whenever all members leave the group and no information remains of what view the group was in. In fact, the sole use of monotonic increasing identifiers could lead to the reuse of the same id after full group shutdowns, destroying the uniqueness of the binary log data markers that recovery depends on. To summarize, the first part identifies whenever the group was started from the beginning and the incremental part when the group changed from that point on.

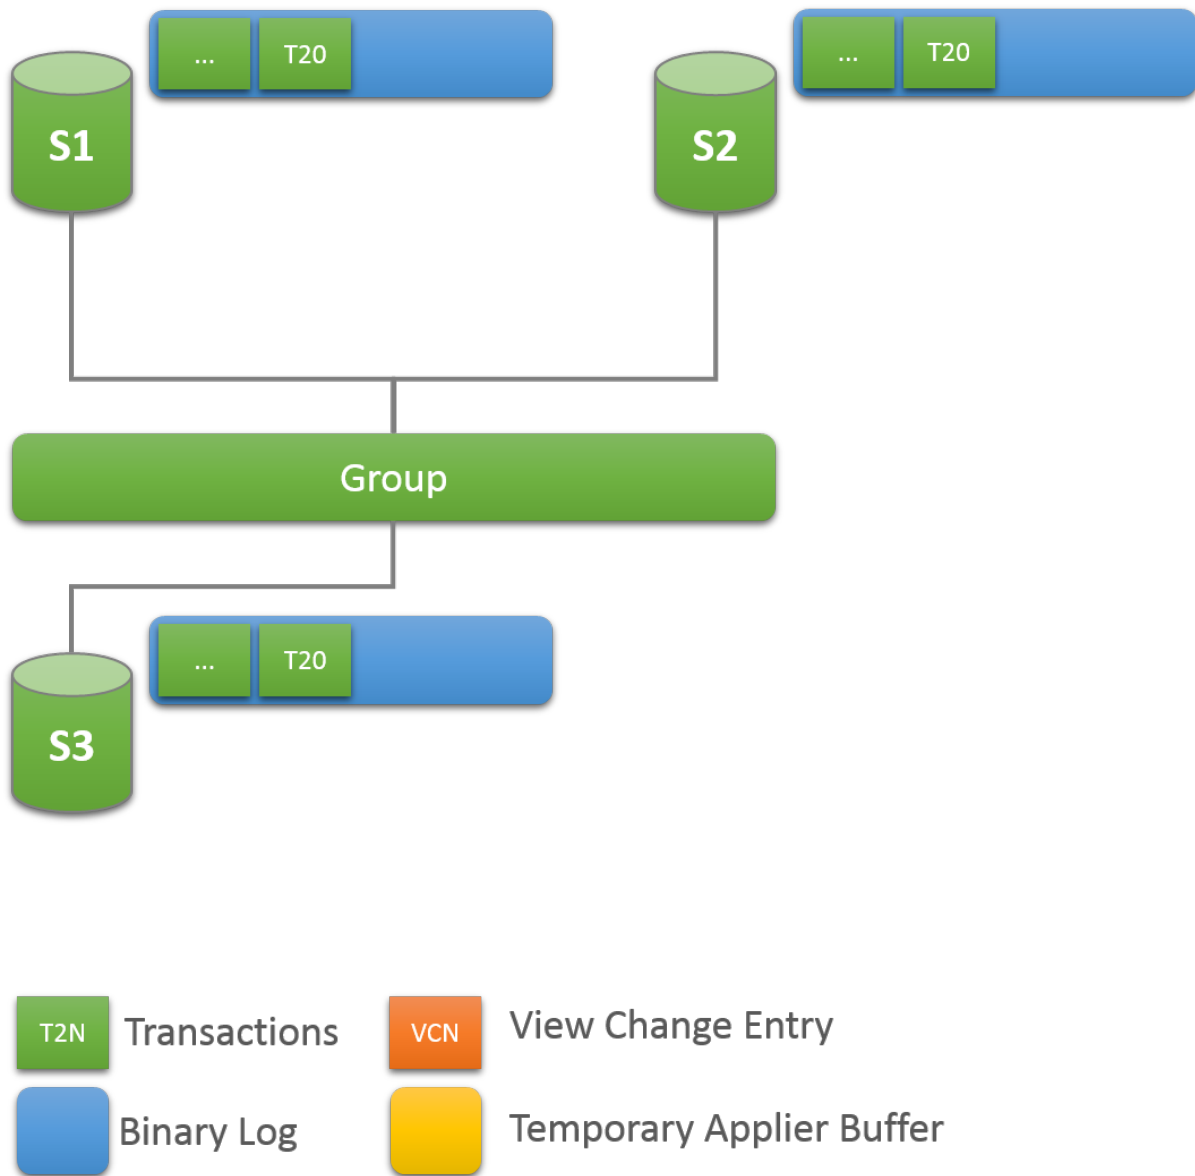

21.9.5.3 View Changes

This section explains the process which controls how the view change identifier is incorporated into a binary log event and written to the log, The following steps are taken:

Begin: Stable Group

All servers are online and processing incoming transactions from the group. Some servers may be a little behind in terms of transactions replicated, but eventually they converge. The group acts as one distributed and replicated database.

Figure 21.10 Stable Group

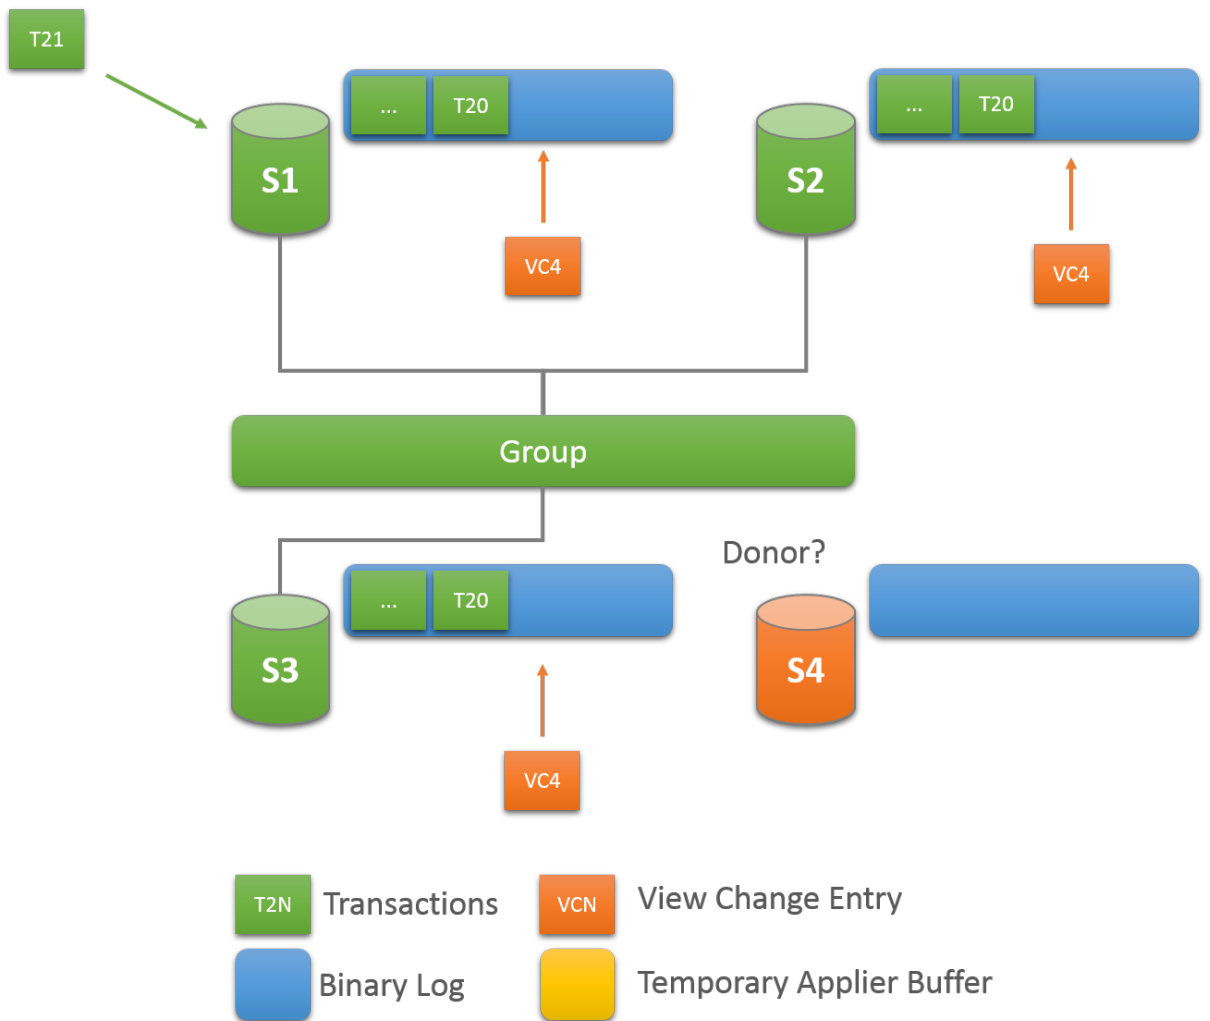

View Change: a Member Joins

Whenever a new member joins the group and therefore a view change is performed, every online server queues a view change log event for execution. This is queued because before the view change, several transactions can be queued on the server to be applied and as such, these belong to the old view. Queuing the view change event after them guarantees a correct marking of when this happened.

Meanwhile, the joiner selects the donor from the list of online servers as stated by the membership service through the view abstraction. A member joins on view 4 and the online members write a View change event to the binary log.

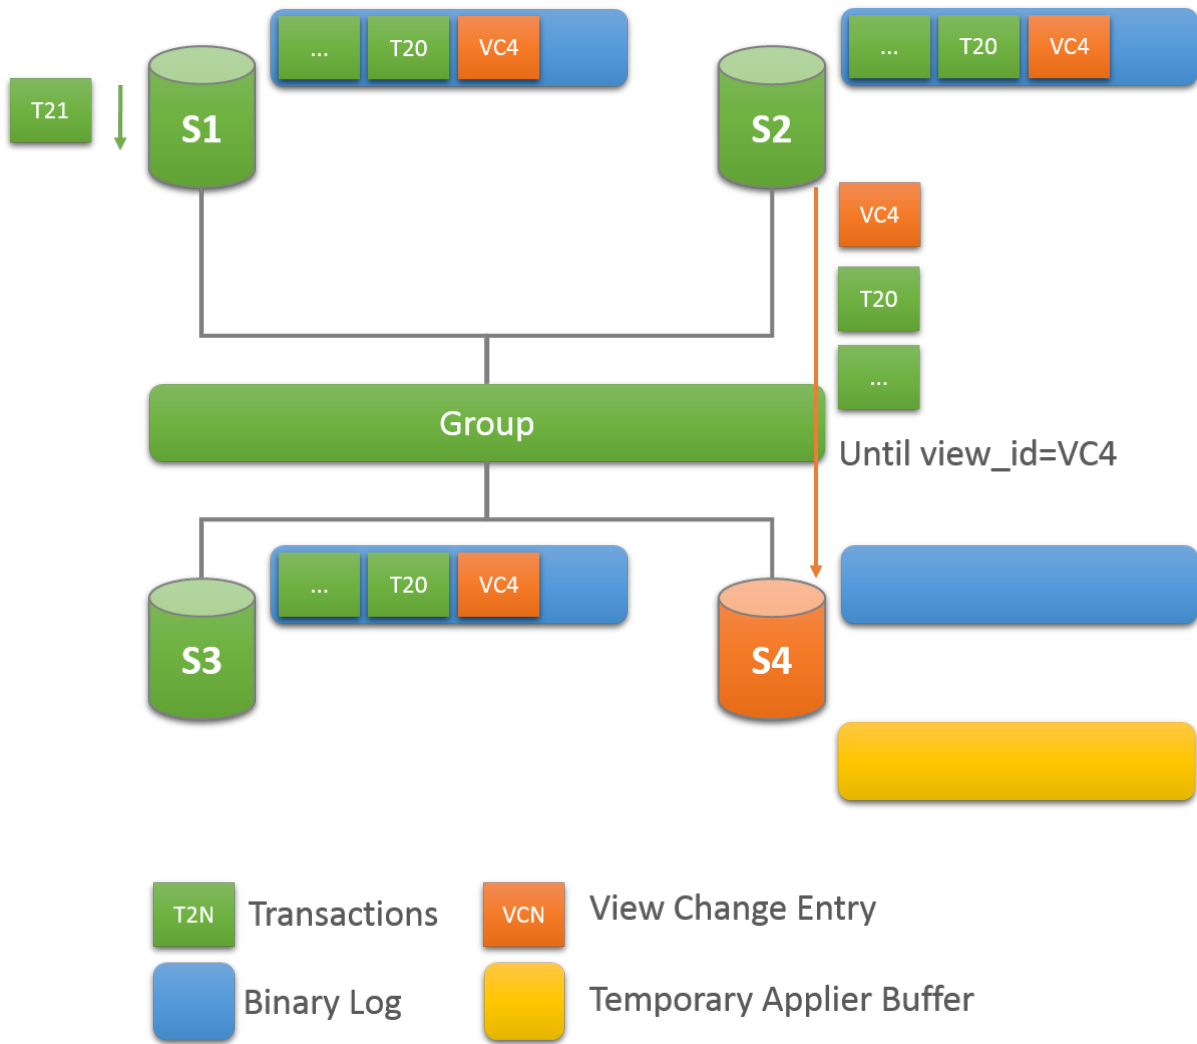

Figure 21.11 A Member Joins

State Transfer: Catching Up

Once the joiner has chosen which server in the group is to be the donor, a new asynchronous replication connection is established between the two and the state transfer begins (phase 1). This interaction with the donor continues until the joiner's applier thread processes the view change log event that corresponds to the view change triggered when the joiner came into the group. In other words, the joiner replicates from the donor, until it gets to the marker with the view identifier which matches the view marker it is already in.

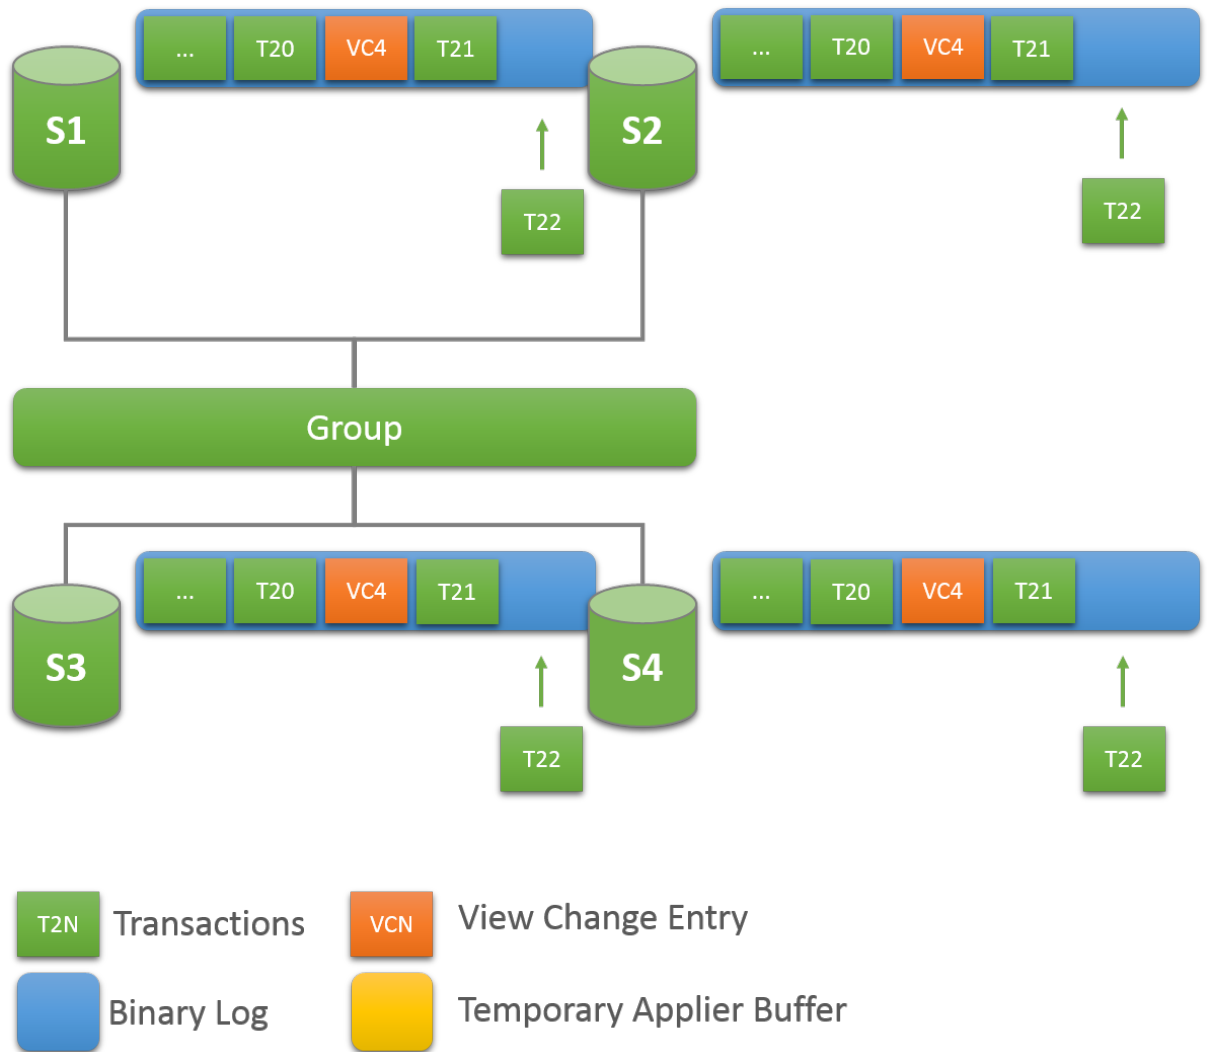

Figure 21.12 State Transfer: Catching Up

As view identifiers are transmitted to all members in the group at the same logical time, the joiner knows at which view identifier it should stop replicating. This avoids complex GTID set calculations because the view id clearly marks which data belongs to each group view.

While the joiner is replicating from the donor, it is also caching incoming transactions from the group. Eventually, it stops replicating from the donor and switches to applying those that are cached.

Figure 21.13 Queued Transactions

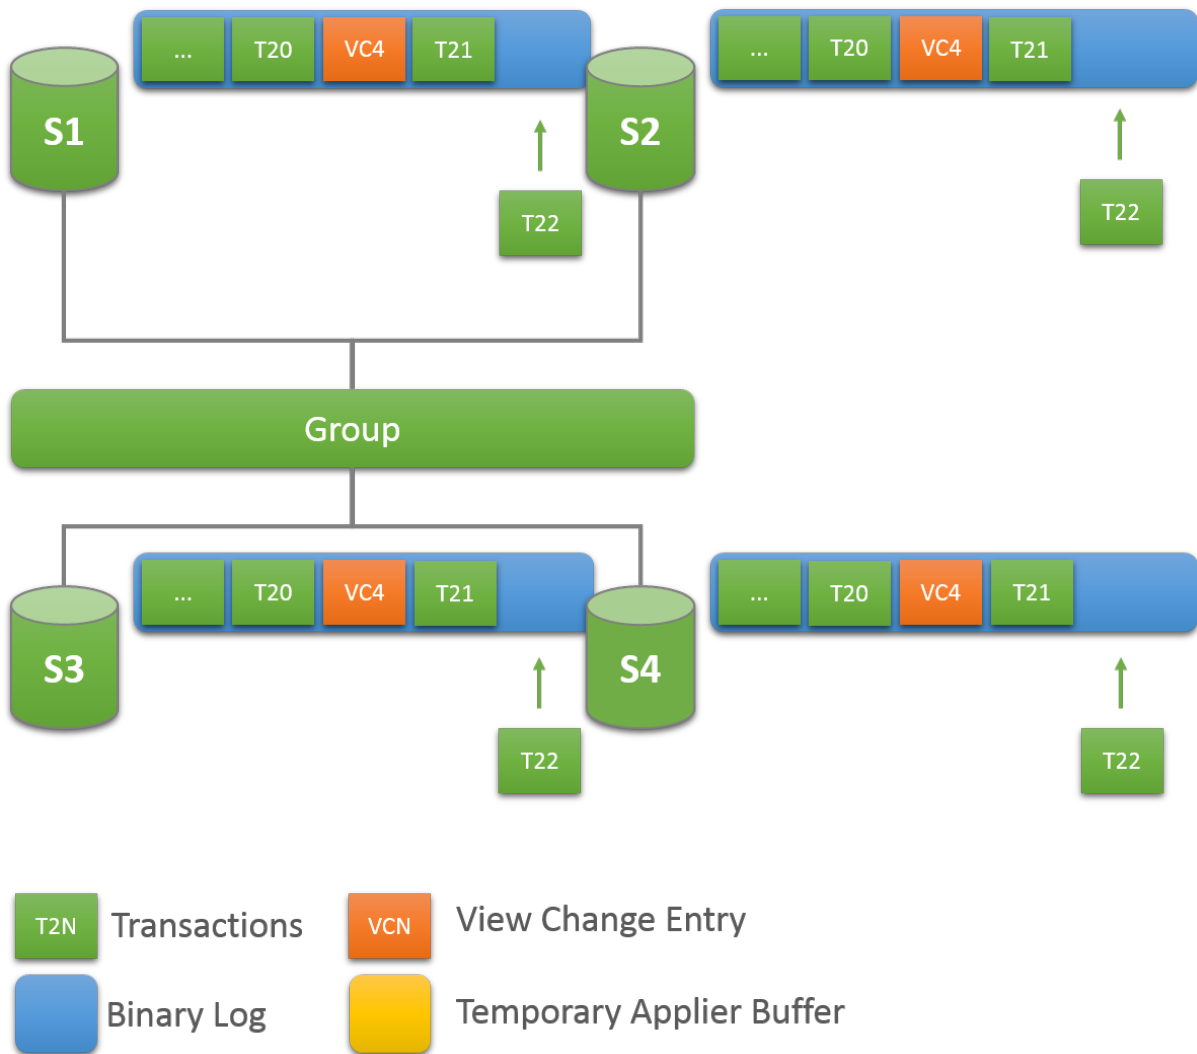

Finish: Caught Up

When the joiner recognizes a view change log event with the expected view identifier, the connection to the donor is terminated and it starts applying the cached transactions. An important point to understand is the final recovery procedure. Although it acts as a marker in the binary log, delimiting view changes, the view change log event also plays another role. It conveys the certification information as perceived by all servers when the joiner entered the group, in other words the last view change. Without it, the joiner would not have the necessary information to be able to certify (detect conflicts) subsequent transactions.

The duration of the catch up (phase 2) is not deterministic, because it depends on the workload and the rate of incoming transactions to the group. This process is completely online and the joiner does not block any other server in the group while it is catching up. Therefore the number of transactions the joiner is behind when it moves to phase 2 can, for this reason, vary and thus increase or decrease according to the workload.

When the joiner's queued transactions reach zero and its stored data is equal to the other members, its public state changes to online.

Figure 21.14 Instance Online

21.9.5.4 Usage Advice and Limitations of Distributed Recovery

Distributed recovery does have some limitations. It is based on classic asynchronous replication and as such it may be slow if the joiner is not provisioned at all or is provisioned with a very old backup image. This means that if the data to transfer is too big at phase 1, the server may take a very long time to recover. As such, the recommendation is that before adding a server to the group, one should provision it with a fairly recent snapshot of a server already in the group. This minimizes the length of phase 1 and reduces the impact on the donor server, since it has to save and transfer less binary logs.

Warning

It is recommended that a server is provisioned before it is added to a group. That way, one minimizes the time spent on the recovery step.

21.9.6 Observability

There is a lot of automation built into the Group Replication plugin. Nonetheless, you might sometimes need to understand what is happening behind the scenes. This is where the instrumentation of Group Replication and Performance Schema becomes important. The entire state of the system (including the view, conflict statistics and service states) can be queried through performance_schema tables. The distributed nature of the replication protocol and the fact that server instances agree and thus synchronize on transactions and metadata makes it simpler to inspect the state of the group. For

example, you can connect to a single server in the group and obtain both local and global information by issuing select statements on the Group Replication related Performance Schema tables. For more information, see [Section 21.3, “Monitoring Group Replication”](#).

21.9.7 Group Replication Performance

This section explains how to use the available configuration options to gain the best performance from your group.

21.9.7.1 Fine Tuning the Group Communication Thread

The group communication thread (GCT) runs in a loop while the Group Replication plugin is loaded. The GCT receives messages from the group and from the plugin, handles quorum and failure detection related tasks, sends out some keep alive messages and also handles the incoming and outgoing transactions from/to the server/group. The GCT waits for incoming messages in a queue. When there are no messages, the GCT waits. By configuring this wait to be a little longer (doing an active wait) before actually going to sleep can prove to be beneficial in some cases. This is because the alternative is for the operating system to switch out the GCT from the processor and do a context switch.

To force the GCT do an active wait, use the `group_replication_poll_spin_loops` option, which makes the GCT loop, doing nothing relevant for the configured number of loops, before actually polling the queue for the next message.

For example:

```
mysql> SET GLOBAL group_replication_poll_spin_loops= 10000;
```

21.9.7.2 Message Compression

When network bandwidth is a bottleneck, message compression can provide up to 30-40% throughput improvement at the group communication level. This is especially important within the context of large groups of servers under load.

Table 21.8 LZ4 Compression Ratios for Different Binary Log Formats.

Workload	Ratio	
	ROW	STMT
mysqlslapd	4,5	4,1
sysbench	3,4	2,9

The TCP peer-to-peer nature of the interconnections between N participants on the group makes the sender send the same amount of data N times. Furthermore, binary logs are likely to exhibit a high compression ratio (see table above). This makes compression a compelling feature for workloads that contain large transaction.

Figure 21.15 Compression Support

Compression happens at the group communication engine level, before the data is handed over to the group communication thread, so it happens within the context of the mysql user session thread. Transaction payloads may be compressed before being sent out to the group and decompressed when received. Compression is conditional and depends on a configured threshold. By default compression is enabled.

In addition, there is no requirement that all servers in the group have compression enabled to be able to work together. Upon receiving a message, the member checks the message envelope to verify whether it is compressed or not. If needed, then the member decompresses the transaction, before delivering it to the upper layer.

The compression algorithm used is LZ4. Compression is enabled by default with threshold of 1000000 bytes. The compression threshold, in bytes, may be set to something larger than default. In that case, only transactions that have a payload larger than the threshold are compressed. Below is an example of how to set a compression threshold.

```
STOP GROUP_REPLICATION;
SET GLOBAL group_replication_compression_threshold= 2097152;
START GROUP_REPLICATION;
```

This sets the compression threshold to 2MB. If a transaction generates a replication message with a payload larger than 2MB, for example a binary log transaction entry larger than 2MB, then it is compressed. To disable compression set threshold to 0.

21.9.7.3 Flow Control

Group Replication ensures that a transaction only commits after a majority of the members in a group have received it and agreed on the relative order between all transactions that were sent concurrently.

This approach works well if the total number of writes to the group does not exceed the write capacity of any member in the group. If it does and some of the members have less write throughput than others, particularly less than the writer members, those members can start lagging behind of the writers.

Having some members lagging behind the group brings some problematic consequences, particularly, the reads on such members may externalize very old data. Depending on why the member is lagging behind, other members in the group may have to save more or less replication context to be able to fulfil potential data transfer requests from the slow member.

There is however a mechanism in the replication protocol to avoid having too much distance, in terms of transactions applied, between fast and slow members. This is known as the flow control mechanism. It tries to address several goals:

1. to keep the members close enough to make buffering and de-synchronization between members a small problem;
2. to adapt quickly to changing conditions like different workloads or more writers in the group;
3. to give each member a fair share of the available write capacity;
4. to not reduce throughput more than strictly necessary to avoid wasting resources.

Given the design of Group Replication, the decision whether to throttle or not may be decided taking into account two work queues: (i) the *certification* queue; (ii) and on the binary log *applier* queue. Whenever the size of one of these queues exceeds the user-defined threshold, the throttling mechanism is triggered. Only configure: (i) whether to do flow control at the certifier or at the applier level, or both; and (ii) what is the threshold for each queue.

The flow control depends on two basic mechanisms:

1. the monitoring of members to collect some statistics on throughput and queue sizes of all group members to make educated guesses on what is the maximum write pressure each member should be subjected to;
2. the throttling of members that are trying to write beyond their fair-share of the available capacity at each moment in time.

Probes and Statistics

The monitoring mechanism works by having each member deploying a set of probes to collect information about its work queues and throughput. It then propagates that information to the group periodically to share that data with the other members.

Such probes are scattered throughout the plugin stack and allow one to establish metrics, such as:

- the certifier queue size;
- the replication applier queue size;
- the total number of transactions certified;
- the total number of remote transactions applied in the member;
- the total number of local transactions.

Once a member receives a message with statistics from another member, it calculates additional metrics regarding how many transactions were certified, applied and locally executed in the last monitoring period.

Monitoring data is shared with others in the group periodically. The monitoring period must be high enough to allow the other members to decide on the current write requests, but low enough that it has minimal impact on group bandwidth. The information is shared every second, and this period is sufficient to address both concerns.

Group Replication Throttling

Based on the metrics gathered across all servers in the group, a throttling mechanism kicks in and decides whether to limit the rate a member is able to execute/commit new transactions.

Therefore, metrics acquired from all members are the basis for calculating the capacity of each member: if a member has a large queue (for certification or the applier thread), then the capacity to execute new transactions should be close to ones certified or applied in the last period.

The lowest capacity of all the members in the group determines the real capacity of the group, while the number of local transactions determines how many members are writing to it, and, consequently, how many members should that available capacity be shared with.

This means that every member has an established write quota based on the available capacity, in other words a number of transactions it can safely issue for the next period. The writer-quota will be enforced by the throttling mechanism if the queue size of the certifier or the binary log applier exceeds a user-defined threshold.

The quota is reduced by the number of transactions that were delayed in the last period, and then also further reduced by 10% to allow the queue that triggered the problem to reduce its size. In order to avoid large jumps in throughput once the queue size goes beyond the threshold, the throughput is only allowed to grow by the same 10% per period after that.

The current throttling mechanism does not penalize transactions below quota, but delays finishing those transactions that exceed it until the end of the monitoring period. As a consequence, if the quota is very small for the write requests issued some transactions may have latencies close to the monitoring period.

Chapter 22 Partitioning

22.6.1 Partitioning Keys, Primary Keys, and Unique Keys	2807
22.6.2 Partitioning Limitations Relating to Storage Engines	2811
22.6.3 Partitioning Limitations Relating to Functions	2811

This chapter discusses *user-defined partitioning*. In MySQL 8.0, partitioning support is provided by the [InnoDB](#) storage engine. (The [NDB](#) storage engine used by MySQL Cluster also provides partitioning support, but [NDB](#) is not included in MySQL 8.0.)

MySQL 8.0 does not currently support partitioning of tables using any storage engine other than [InnoDB](#), such as [MyISAM](#). An attempt to create a partitioned tables using a storage engine that does not supply native partitioning support fails with `ER_CHECK_NOT_IMPLEMENTED`.

MySQL 8.0 Community binaries provided by Oracle include partitioning support provided by the [InnoDB](#) storage engine. For information about partitioning support offered in MySQL Enterprise Edition binaries, see [Chapter 29, MySQL Enterprise Edition](#).

If you are compiling MySQL 8.0 from source, configuring the build with [InnoDB](#) support is sufficient to produce binaries with partition support for [InnoDB](#) tables. For more information, see [Section 2.8, “Installing MySQL from Source”](#).

Nothing further needs to be done to enable partitioning support by [InnoDB](#) (for example, no special entries are required in the `my.cnf` file).

It is not possible to disable partitioning support by the [InnoDB](#) storage engine.

See [Section 22.1, “Overview of Partitioning in MySQL”](#), for an introduction to partitioning and partitioning concepts.

Several types of partitioning are supported, as well as subpartitioning; see [Section 22.2, “Partitioning Types”](#), and [Section 22.2.6, “Subpartitioning”](#).

[Section 22.3, “Partition Management”](#), covers methods of adding, removing, and altering partitions in existing partitioned tables.

[Section 22.3.4, “Maintenance of Partitions”](#), discusses table maintenance commands for use with partitioned tables.

The `PARTITIONS` table in the `INFORMATION_SCHEMA` database provides information about partitions and partitioned tables. See [Section 24.13, “The INFORMATION_SCHEMA PARTITIONS Table”](#), for more information; for some examples of queries against this table, see [Section 22.2.7, “How MySQL Partitioning Handles NULL”](#).

For known issues with partitioning in MySQL 8.0, see [Section 22.6, “Restrictions and Limitations on Partitioning”](#).

**Note**

Table partitioning differs from partitioning as used by window functions. For information about the latter, see [Section 12.19, “Window Functions”](#).

You may also find the following resources to be useful when working with partitioned tables.

Additional Resources. Other sources of information about user-defined partitioning in MySQL include the following:

This is the official discussion forum for those interested in or experimenting with MySQL Partitioning technology. It features announcements and updates from MySQL developers and others. It is monitored by members of the Partitioning Development and Documentation Teams.

- [Mikael Ronström's Blog](#)

MySQL Partitioning Architect and Lead Developer Mikael Ronström frequently posts articles here concerning his work with MySQL Partitioning and MySQL Cluster.

- [PlanetMySQL](#)

A MySQL news site featuring MySQL-related blogs, which should be of interest to anyone using my MySQL. We encourage you to check here for links to blogs kept by those working with MySQL Partitioning, or to have your own blog added to those covered.

22.1 Overview of Partitioning in MySQL

This section provides a conceptual overview of partitioning in MySQL 8.0.

For information on partitioning restrictions and feature limitations, see [Section 22.6, “Restrictions and Limitations on Partitioning”](#).

The SQL standard does not provide much in the way of guidance regarding the physical aspects of data storage. The SQL language itself is intended to work independently of any data structures or media underlying the schemas, tables, rows, or columns with which it works. Nonetheless, most advanced database management systems have evolved some means of determining the physical location to be used for storing specific pieces of data in terms of the file system, hardware or even both. In MySQL, the `InnoDB` storage engine has long supported the notion of a tablespace (see [Section 15.7, “InnoDB Tablespaces”](#)), and the MySQL Server, even prior to the introduction of partitioning, could be configured to employ different physical directories for storing different databases (see [Section 8.12.2, “Using Symbolic Links”](#), for an explanation of how this is done).

Partitioning takes this notion a step further, by enabling you to distribute portions of individual tables across a file system according to rules which you can set largely as needed. In effect, different portions of a table are stored as separate tables in different locations. The user-selected rule by which the division of data is accomplished is known as a *partitioning function*, which in MySQL can be the modulus, simple matching against a set of ranges or value lists, an internal hashing function, or a linear

hashing function. The function is selected according to the partitioning type specified by the user, and takes as its parameter the value of a user-supplied expression. This expression can be a column value, a function acting on one or more column values, or a set of one or more column values, depending on the type of partitioning that is used.

In the case of `RANGE`, `LIST`, and `[LINEAR] HASH` partitioning, the value of the partitioning column is passed to the partitioning function, which returns an integer value representing the number of the partition in which that particular record should be stored. This function must be nonconstant and nonrandom. It may not contain any queries, but may use an SQL expression that is valid in MySQL, as long as that expression returns either `NULL` or an integer `intval` such that

```
-MAXVALUE <= intval <= MAXVALUE
```

(`MAXVALUE` is used to represent the least upper bound for the type of integer in question. `-MAXVALUE` represents the greatest lower bound.)

For `[LINEAR] KEY`, `RANGE COLUMNS`, and `LIST COLUMNS` partitioning, the partitioning expression consists of a list of one or more columns.

For `[LINEAR] KEY` partitioning, the partitioning function is supplied by MySQL.

For more information about permitted partitioning column types and partitioning functions, see [Section 22.2, “Partitioning Types”](#), as well as [Section 13.1.15, “CREATE TABLE Syntax”](#), which provides partitioning syntax descriptions and additional examples. For information about restrictions on partitioning functions, see [Section 22.6.3, “Partitioning Limitations Relating to Functions”](#).

This is known as *horizontal partitioning*—that is, different rows of a table may be assigned to different physical partitions. MySQL 8.0 does not support *vertical partitioning*, in which different columns of a table are assigned to different physical partitions. There are no plans at this time to introduce vertical partitioning into MySQL.

For creating partitioned tables, you must use a storage engine that supports them. In MySQL 8.0, all partitions of the same partitioned table must use the same storage engine. However, there is nothing preventing you from using different storage engines for different partitioned tables on the same MySQL server or even in the same database.

In MySQL 8.0, the only storage engine that supports partitioning is `InnoDB`. Partitioning cannot be used with storage engines that do not support it; these include the `MyISAM`, `MERGE`, `CSV`, and `FEDERATED` storage engines.

When creating a partitioned table, the default storage engine is used just as when creating any other table; to override this behavior, it is necessary only to use the `[STORAGE] ENGINE` option just as you would for a table that is not partitioned. The target storage engine must provide native partitioning support, or the statement fails. You should keep in mind that `[STORAGE] ENGINE` (and other table options) need to be listed *before* any partitioning options are used in a `CREATE TABLE` statement. This example shows how to create a table that is partitioned by hash into 6 partitions and which uses the `InnoDB` storage engine (regardless of the value of `default_storage_engine`):

```
CREATE TABLE ti (id INT, amount DECIMAL(7,2), tr_date DATE)
ENGINE=INNODB
PARTITION BY HASH( MONTH(tr_date) )
PARTITIONS 6;
```

Each `PARTITION` clause can include a `[STORAGE] ENGINE` option, but in MySQL 8.0 this has no effect.

Unless otherwise specified, the remaining examples in this discussion assume that `default_storage_engine` is `InnoDB`.

**Important**

Partitioning applies to all data and indexes of a table; you cannot partition only the data and not the indexes, or vice versa, nor can you partition only a portion of the table.

Data and indexes for each partition can be assigned to a specific directory using the `DATA DIRECTORY` and `INDEX DIRECTORY` options for the `PARTITION` clause of the `CREATE TABLE` statement used to create the partitioned table.

InnoDB supports the `DATA DIRECTORY` and `INDEX DIRECTORY` options for individual partitions and subpartitions.

All columns used in the table's partitioning expression must be part of every unique key that the table may have, including any primary key. This means that a table such as this one, created by the following SQL statement, cannot be partitioned:

```
CREATE TABLE tnp (
  id INT NOT NULL AUTO_INCREMENT,
  ref BIGINT NOT NULL,
  name VARCHAR(255),
  PRIMARY KEY pk (id),
  UNIQUE KEY uk (name)
);
```

Because the keys `pk` and `uk` have no columns in common, there are no columns available for use in a partitioning expression. Possible workarounds in this situation include adding the `name` column to the table's primary key, adding the `id` column to `uk`, or simply removing the unique key altogether. See [Section 22.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#), for more information.

In addition, `MAX_ROWS` and `MIN_ROWS` can be used to determine the maximum and minimum numbers of rows, respectively, that can be stored in each partition. See [Section 22.3, “Partition Management”](#), for more information on these options.

Some advantages of partitioning are listed here:

- Partitioning makes it possible to store more data in one table than can be held on a single disk or file system partition.
- Data that loses its usefulness can often be easily removed from a partitioned table by dropping the partition (or partitions) containing only that data. Conversely, the process of adding new data can in some cases be greatly facilitated by adding one or more new partitions for storing specifically that data.
- Some queries can be greatly optimized in virtue of the fact that data satisfying a given `WHERE` clause can be stored only on one or more partitions, which automatically excludes any remaining partitions from the search. Because partitions can be altered after a partitioned table has been created, you can reorganize your data to enhance frequent queries that may not have been often used when the partitioning scheme was first set up. This ability to exclude non-matching partitions (and thus any rows they contain) is often referred to as *partition pruning*. For more information, see [Section 22.4, “Partition Pruning”](#).

In addition, MySQL 8.0 supports explicit partition selection for queries. For example, `SELECT * FROM t PARTITION (p0,p1) WHERE c < 5` selects only those rows in partitions `p0` and `p1` that match the `WHERE` condition. In this case, MySQL does not check any other partitions of table `t`; this can greatly speed up queries when you already know which partition or partitions you wish to examine. Partition selection is also supported for the data modification statements `DELETE`, `INSERT`, `REPLACE`, `UPDATE`, and `LOAD DATA`, `LOAD XML`. See the descriptions of these statements for more information and examples.

Other benefits usually associated with partitioning include those in the following list. These features are not currently implemented in MySQL Partitioning, but are high on our list of priorities.

- Queries involving aggregate functions such as `SUM()` and `COUNT()` can easily be parallelized. A simple example of such a query might be `SELECT salesperson_id, COUNT(orders) as order_total FROM sales GROUP BY salesperson_id;` By “parallelized,” we mean that the query can be run simultaneously on each partition, and the final result obtained merely by summing the results obtained for all partitions.
- Achieving greater query throughput in virtue of spreading data seeks over multiple disks.

22.2 Partitioning Types

This section discusses the types of partitioning which are available in MySQL 8.0. These include the types listed here:

- **RANGE partitioning.** This type of partitioning assigns rows to partitions based on column values falling within a given range. See [Section 22.2.1, “RANGE Partitioning”](#). For information about an extension to this type, `RANGE COLUMNS`, see [Section 22.2.3.1, “RANGE COLUMNS partitioning”](#).
- **LIST partitioning.** Similar to partitioning by `RANGE`, except that the partition is selected based on columns matching one of a set of discrete values. See [Section 22.2.2, “LIST Partitioning”](#). For information about an extension to this type, `LIST COLUMNS`, see [Section 22.2.3.2, “LIST COLUMNS partitioning”](#).
- **HASH partitioning.** With this type of partitioning, a partition is selected based on the value returned by a user-defined expression that operates on column values in rows to be inserted into the table. The function may consist of any expression valid in MySQL that yields a nonnegative integer value. An extension to this type, `LINEAR HASH`, is also available. See [Section 22.2.4, “HASH Partitioning”](#).
- **KEY partitioning.** This type of partitioning is similar to partitioning by `HASH`, except that only one or more columns to be evaluated are supplied, and the MySQL server provides its own hashing function. These columns can contain other than integer values, since the hashing function supplied by MySQL guarantees an integer result regardless of the column data type. An extension to this type, `LINEAR KEY`, is also available. See [Section 22.2.5, “KEY Partitioning”](#).

A very common use of database partitioning is to segregate data by date. Some database systems support explicit date partitioning, which MySQL does not implement in 8.0. However, it is not difficult in MySQL to create partitioning schemes based on `DATE`, `TIME`, or `DATETIME` columns, or based on expressions making use of such columns.

When partitioning by `KEY` or `LINEAR KEY`, you can use a `DATE`, `TIME`, or `DATETIME` column as the partitioning column without performing any modification of the column value. For example, this table creation statement is perfectly valid in MySQL:

```
CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
  joined DATE NOT NULL
)
PARTITION BY KEY(joined)
PARTITIONS 6;
```

In MySQL 8.0, it is also possible to use a `DATE` or `DATETIME` column as the partitioning column using `RANGE COLUMNS` and `LIST COLUMNS` partitioning.

Other partitioning types require a partitioning expression that yields an integer value or `NULL`. If you wish to use date-based partitioning by `RANGE`, `LIST`, `HASH`, or `LINEAR HASH`, you can simply employ a function that operates on a `DATE`, `TIME`, or `DATETIME` column and returns such a value, as shown here:

```
CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
  joined DATE NOT NULL
)
PARTITION BY RANGE( YEAR(joined) ) (
  PARTITION p0 VALUES LESS THAN (1960),
  PARTITION p1 VALUES LESS THAN (1970),
  PARTITION p2 VALUES LESS THAN (1980),
  PARTITION p3 VALUES LESS THAN (1990),
  PARTITION p4 VALUES LESS THAN MAXVALUE
);
```

Additional examples of partitioning using dates may be found in the following sections of this chapter:

- [Section 22.2.1, “RANGE Partitioning”](#)
- [Section 22.2.4, “HASH Partitioning”](#)
- [Section 22.2.4.1, “LINEAR HASH Partitioning”](#)

For more complex examples of date-based partitioning, see the following sections:

- [Section 22.4, “Partition Pruning”](#)
- [Section 22.2.6, “Subpartitioning”](#)

MySQL partitioning is optimized for use with the `TO_DAYS()`, `YEAR()`, and `TO_SECONDS()` functions. However, you can use other date and time functions that return an integer or `NULL`, such as `WEEKDAY()`, `DAYOFYEAR()`, or `MONTH()`. See [Section 12.7, “Date and Time Functions”](#), for more information about such functions.

It is important to remember—regardless of the type of partitioning that you use—that partitions are always numbered automatically and in sequence when created, starting with 0. When a new row is inserted into a partitioned table, it is these partition numbers that are used in identifying the correct partition. For example, if your table uses 4 partitions, these partitions are numbered 0, 1, 2, and 3. For the `RANGE` and `LIST` partitioning types, it is necessary to ensure that there is a partition defined for each partition number. For `HASH` partitioning, the user-supplied expression must evaluate to an integer value greater than 0. For `KEY` partitioning, this issue is taken care of automatically by the hashing function which the MySQL server employs internally.

Names of partitions generally follow the rules governing other MySQL identifiers, such as those for tables and databases. However, you should note that partition names are not case-sensitive. For example, the following `CREATE TABLE` statement fails as shown:

```
mysql> CREATE TABLE t2 (val INT)
-> PARTITION BY LIST(val)(
->   PARTITION mypart VALUES IN (1,3,5),
->   PARTITION MyPart VALUES IN (2,4,6)
-> );
ERROR 1488 (HY000): Duplicate partition name mypart
```

Failure occurs because MySQL sees no difference between the partition names `mypart` and `MyPart`.

When you specify the number of partitions for the table, this must be expressed as a positive, nonzero integer literal with no leading zeros, and may not be an expression such as `0.8E+01` or `6-2`, even if it evaluates to an integer value. Decimal fractions are not permitted.

In the sections that follow, we do not necessarily provide all possible forms for the syntax that can be used for creating each partition type; for this information, see [Section 13.1.15, “CREATE TABLE Syntax”](#).

22.2.1 RANGE Partitioning

A table that is partitioned by range is partitioned in such a way that each partition contains rows for which the partitioning expression value lies within a given range. Ranges should be contiguous but not overlapping, and are defined using the `VALUES LESS THAN` operator. For the next few examples, suppose that you are creating a table such as the following to hold personnel records for a chain of 20 video stores, numbered 1 through 20:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
);
```

Note

The `employees` table used here has no primary or unique keys. While the examples work as shown for purposes of the present discussion, you should keep in mind that tables are extremely likely in practice to have primary keys, unique keys, or both, and that allowable choices for partitioning columns depend on the columns used for these keys, if any are present. For a discussion of these issues, see [Section 22.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#).

This table can be partitioned by range in a number of ways, depending on your needs. One way would be to use the `store_id` column. For instance, you might decide to partition the table 4 ways by adding a `PARTITION BY RANGE` clause as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
  PARTITION p0 VALUES LESS THAN (6),
  PARTITION p1 VALUES LESS THAN (11),
  PARTITION p2 VALUES LESS THAN (16),
  PARTITION p3 VALUES LESS THAN (21)
);
```

In this partitioning scheme, all rows corresponding to employees working at stores 1 through 5 are stored in partition `p0`, to those employed at stores 6 through 10 are stored in partition `p1`, and so on. Each partition is defined in order, from lowest to highest. This is a requirement of the `PARTITION BY RANGE` syntax; you can think of it as being analogous to a series of `if ... elseif ...` statements in C or Java in this regard.

It is easy to determine that a new row containing the data `(72, 'Mitchell', 'Wilson', '1998-06-25', NULL, 13)` is inserted into partition `p2`, but what happens when your chain adds a 21st store? Under this scheme, there is no rule that covers a row whose `store_id` is greater than 20, so an error results because the server does not know where to place it. You can keep this from occurring by using a “catchall” `VALUES LESS THAN` clause in the `CREATE TABLE` statement that provides for all values greater than the highest value explicitly named:

```
CREATE TABLE employees (
```

```

id INT NOT NULL,
fname VARCHAR(30),
lname VARCHAR(30),
hired DATE NOT NULL DEFAULT '1970-01-01',
separated DATE NOT NULL DEFAULT '9999-12-31',
job_code INT NOT NULL,
store_id INT NOT NULL
)
PARTITION BY RANGE (store_id) (
PARTITION p0 VALUES LESS THAN (6),
PARTITION p1 VALUES LESS THAN (11),
PARTITION p2 VALUES LESS THAN (16),
PARTITION p3 VALUES LESS THAN MAXVALUE
);

```

(As with the other examples in this chapter, we assume that the default storage engine is [InnoDB](#).)

Note

Another way to avoid an error when no matching value is found is to use the [IGNORE](#) keyword as part of the [INSERT](#) statement. For an example, see [Section 22.2.2, “LIST Partitioning”](#). Also see [Section 13.2.6, “INSERT Syntax”](#), for general information about [IGNORE](#).

[MAXVALUE](#) represents an integer value that is always greater than the largest possible integer value (in mathematical language, it serves as a *least upper bound*). Now, any rows whose `store_id` column value is greater than or equal to 16 (the highest value defined) are stored in partition `p3`. At some point in the future—when the number of stores has increased to 25, 30, or more—you can use an [ALTER TABLE](#) statement to add new partitions for stores 21-25, 26-30, and so on (see [Section 22.3, “Partition Management”](#), for details of how to do this).

In much the same fashion, you could partition the table based on employee job codes—that is, based on ranges of `job_code` column values. For example—assuming that two-digit job codes are used for regular (in-store) workers, three-digit codes are used for office and support personnel, and four-digit codes are used for management positions—you could create the partitioned table using the following statement:

```

CREATE TABLE employees (
id INT NOT NULL,
fname VARCHAR(30),
lname VARCHAR(30),
hired DATE NOT NULL DEFAULT '1970-01-01',
separated DATE NOT NULL DEFAULT '9999-12-31',
job_code INT NOT NULL,
store_id INT NOT NULL
)
PARTITION BY RANGE (job_code) (
PARTITION p0 VALUES LESS THAN (100),
PARTITION p1 VALUES LESS THAN (1000),
PARTITION p2 VALUES LESS THAN (10000)
);

```

In this instance, all rows relating to in-store workers would be stored in partition `p0`, those relating to office and support staff in `p1`, and those relating to managers in partition `p2`.

It is also possible to use an expression in [VALUES LESS THAN](#) clauses. However, MySQL must be able to evaluate the expression's return value as part of a [LESS THAN \(<\)](#) comparison.

Rather than splitting up the table data according to store number, you can use an expression based on one of the two [DATE](#) columns instead. For example, let us suppose that you wish to partition based on the year that each employee left the company; that is, the value of [YEAR\(separated\)](#). An example of a [CREATE TABLE](#) statement that implements such a partitioning scheme is shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY RANGE ( YEAR(separated) ) (
  PARTITION p0 VALUES LESS THAN (1991),
  PARTITION p1 VALUES LESS THAN (1996),
  PARTITION p2 VALUES LESS THAN (2001),
  PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

In this scheme, for all employees who left before 1991, the rows are stored in partition `p0`; for those who left in the years 1991 through 1995, in `p1`; for those who left in the years 1996 through 2000, in `p2`; and for any workers who left after the year 2000, in `p3`.

It is also possible to partition a table by `RANGE`, based on the value of a `TIMESTAMP` column, using the `UNIX_TIMESTAMP()` function, as shown in this example:

```
CREATE TABLE quarterly_report_status (
  report_id INT NOT NULL,
  report_status VARCHAR(20) NOT NULL,
  report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
)
PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) (
  PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),
  PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),
  PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),
  PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-10-01 00:00:00') ),
  PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),
  PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),
  PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),
  PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),
  PARTITION p8 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),
  PARTITION p9 VALUES LESS THAN (MAXVALUE)
);
```

Any other expressions involving `TIMESTAMP` values are not permitted. (See Bug #42849.)

Range partitioning is particularly useful when one or more of the following conditions is true:

- You want or need to delete “old” data. If you are using the partitioning scheme shown previously for the `employees` table, you can simply use `ALTER TABLE employees DROP PARTITION p0`; to delete all rows relating to employees who stopped working for the firm prior to 1991. (See [Section 13.1.7, “ALTER TABLE Syntax”](#), and [Section 22.3, “Partition Management”](#), for more information.) For a table with a great many rows, this can be much more efficient than running a `DELETE` query such as `DELETE FROM employees WHERE YEAR(separated) <= 1990`;
- You want to use a column containing date or time values, or containing values arising from some other series.
- You frequently run queries that depend directly on the column used for partitioning the table. For example, when executing a query such as `EXPLAIN SELECT COUNT(*) FROM employees WHERE separated BETWEEN '2000-01-01' AND '2000-12-31' GROUP BY store_id`;, MySQL can quickly determine that only partition `p2` needs to be scanned because the remaining partitions cannot contain any records satisfying the `WHERE` clause. See [Section 22.4, “Partition Pruning”](#), for more information about how this is accomplished.

A variant on this type of partitioning is `RANGE COLUMNS` partitioning. Partitioning by `RANGE COLUMNS` makes it possible to employ multiple columns for defining partitioning ranges that apply both to placement of rows in partitions and for determining the inclusion or exclusion of specific partitions

when performing partition pruning. See [Section 22.2.3.1, “RANGE COLUMNS partitioning”](#), for more information.

Partitioning schemes based on time intervals. If you wish to implement a partitioning scheme based on ranges or intervals of time in MySQL 8.0, you have two options:

1. Partition the table by [RANGE](#), and for the partitioning expression, employ a function operating on a [DATE](#), [TIME](#), or [DATETIME](#) column and returning an integer value, as shown here:

```
CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
  joined DATE NOT NULL
)
PARTITION BY RANGE( YEAR(joined) ) (
  PARTITION p0 VALUES LESS THAN (1960),
  PARTITION p1 VALUES LESS THAN (1970),
  PARTITION p2 VALUES LESS THAN (1980),
  PARTITION p3 VALUES LESS THAN (1990),
  PARTITION p4 VALUES LESS THAN MAXVALUE
);
```

In MySQL 8.0, it is also possible to partition a table by [RANGE](#) based on the value of a [TIMESTAMP](#) column, using the [UNIX_TIMESTAMP\(\)](#) function, as shown in this example:

```
CREATE TABLE quarterly_report_status (
  report_id INT NOT NULL,
  report_status VARCHAR(20) NOT NULL,
  report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
)
PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) (
  PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),
  PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),
  PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),
  PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-10-01 00:00:00') ),
  PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),
  PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),
  PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),
  PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),
  PARTITION p8 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),
  PARTITION p9 VALUES LESS THAN (MAXVALUE)
);
```

In MySQL 8.0, any other expressions involving [TIMESTAMP](#) values are not permitted. (See [Bug #42849](#).)

Note

It is also possible in MySQL 8.0 to use [UNIX_TIMESTAMP\(timestamp_column\)](#) as a partitioning expression for tables that are partitioned by [LIST](#). However, it is usually not practical to do so.

2. Partition the table by [RANGE COLUMNS](#), using a [DATE](#) or [DATETIME](#) column as the partitioning column. For example, the `members` table could be defined using the `joined` column directly, as shown here:

```
CREATE TABLE members (
  firstname VARCHAR(25) NOT NULL,
  lastname VARCHAR(25) NOT NULL,
  username VARCHAR(16) NOT NULL,
  email VARCHAR(35),
  joined DATE NOT NULL
```

```

)
PARTITION BY RANGE COLUMNS(joined) (
  PARTITION p0 VALUES LESS THAN ('1960-01-01'),
  PARTITION p1 VALUES LESS THAN ('1970-01-01'),
  PARTITION p2 VALUES LESS THAN ('1980-01-01'),
  PARTITION p3 VALUES LESS THAN ('1990-01-01'),
  PARTITION p4 VALUES LESS THAN MAXVALUE
);

```

**Note**

The use of partitioning columns employing date or time types other than `DATE` or `DATETIME` is not supported with `RANGE COLUMNS`.

22.2.2 LIST Partitioning

List partitioning in MySQL is similar to range partitioning in many ways. As in partitioning by `RANGE`, each partition must be explicitly defined. The chief difference between the two types of partitioning is that, in list partitioning, each partition is defined and selected based on the membership of a column value in one of a set of value lists, rather than in one of a set of contiguous ranges of values. This is done by using `PARTITION BY LIST(expr)` where *expr* is a column value or an expression based on a column value and returning an integer value, and then defining each partition by means of a `VALUES IN (value_list)`, where *value_list* is a comma-separated list of integers.

**Note**

In MySQL 8.0, it is possible to match against only a list of integers (and possibly `NULL`—see [Section 22.2.7, “How MySQL Partitioning Handles NULL”](#)) when partitioning by `LIST`.

However, other column types may be used in value lists when employing `LIST COLUMN` partitioning, which is described later in this section.

Unlike the case with partitions defined by range, list partitions do not need to be declared in any particular order. For more detailed syntactical information, see [Section 13.1.15, “CREATE TABLE Syntax”](#).

For the examples that follow, we assume that the basic definition of the table to be partitioned is provided by the `CREATE TABLE` statement shown here:

```

CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
);

```

(This is the same table used as a basis for the examples in [Section 22.2.1, “RANGE Partitioning”](#). As with the other partitioning examples, we assume that the `default_storage_engine` is `InnoDB`.)

Suppose that there are 20 video stores distributed among 4 franchises as shown in the following table.

Region	Store ID Numbers
North	3, 5, 6, 9, 17
East	1, 2, 10, 11, 19, 20
West	4, 12, 13, 14, 18

Region	Store ID Numbers
Central	7, 8, 15, 16

To partition this table in such a way that rows for stores belonging to the same region are stored in the same partition, you could use the `CREATE TABLE` statement shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY LIST(store_id) (
  PARTITION pNorth VALUES IN (3,5,6,9,17),
  PARTITION pEast VALUES IN (1,2,10,11,19,20),
  PARTITION pWest VALUES IN (4,12,13,14,18),
  PARTITION pCentral VALUES IN (7,8,15,16)
);
```

This makes it easy to add or drop employee records relating to specific regions to or from the table. For instance, suppose that all stores in the West region are sold to another company. In MySQL 8.0, all rows relating to employees working at stores in that region can be deleted with the query `ALTER TABLE employees TRUNCATE PARTITION pWest`, which can be executed much more efficiently than the equivalent `DELETE FROM employees WHERE store_id IN (4,12,13,14,18)`; (Using `ALTER TABLE employees DROP PARTITION pWest` would also delete all of these rows, but would also remove the partition `pWest` from the definition of the table; you would need to use an `ALTER TABLE ... ADD PARTITION` statement to restore the table's original partitioning scheme.)

As with `RANGE` partitioning, it is possible to combine `LIST` partitioning with partitioning by hash or key to produce a composite partitioning (subpartitioning). See [Section 22.2.6, “Subpartitioning”](#).

Unlike the case with `RANGE` partitioning, there is no “catch-all” such as `MAXVALUE`; all expected values for the partitioning expression should be covered in `PARTITION ... VALUES IN (...)` clauses. An `INSERT` statement containing an unmatched partitioning column value fails with an error, as shown in this example:

```
mysql> CREATE TABLE h2 (
->   c1 INT,
->   c2 INT
-> )
-> PARTITION BY LIST(c1) (
->   PARTITION p0 VALUES IN (1, 4, 7),
->   PARTITION p1 VALUES IN (2, 5, 8)
-> );
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO h2 VALUES (3, 5);
ERROR 1525 (HY000): Table has no partition for value 3
```

When inserting multiple rows using a single `INSERT` statement into a single `InnoDB` table, `InnoDB` considers the statement a single transaction, so that the presence of any unmatched values causes the statement to fail completely, and so no rows are inserted.

You can cause this type of error to be ignored by using the `IGNORE` keyword. If you do so, rows containing unmatched partitioning column values are not inserted, but any rows with matching values are inserted, and no errors are reported:

```
mysql> TRUNCATE h2;
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM h2;
Empty set (0.00 sec)

mysql> INSERT IGNORE INTO h2 VALUES (2, 5), (6, 10), (7, 5), (3, 1), (1, 9);
Query OK, 3 rows affected (0.00 sec)
Records: 5 Duplicates: 2 Warnings: 0

mysql> SELECT * FROM h2;
+-----+-----+
| c1    | c2    |
+-----+-----+
| 7    | 5     |
| 1    | 9     |
| 2    | 5     |
+-----+-----+
3 rows in set (0.00 sec)
```

MySQL 8.0 also provides support for `LIST COLUMNS` partitioning, a variant of `LIST` partitioning that enables you to use columns of types other than integer types for partitioning columns, and to use multiple columns as partitioning keys. For more information, see [Section 22.2.3.2, “LIST COLUMNS partitioning”](#).

22.2.3 COLUMNS Partitioning

The next two sections discuss *COLUMNS partitioning*, which are variants on `RANGE` and `LIST` partitioning. `COLUMNS` partitioning enables the use of multiple columns in partitioning keys. All of these columns are taken into account both for the purpose of placing rows in partitions and for the determination of which partitions are to be checked for matching rows in partition pruning.

In addition, both `RANGE COLUMNS` partitioning and `LIST COLUMNS` partitioning support the use of non-integer columns for defining value ranges or list members. The permitted data types are shown in the following list:

- All integer types: `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT (INTEGER)`, and `BIGINT`. (This is the same as with partitioning by `RANGE` and `LIST`.)

Other numeric data types (such as `DECIMAL` or `FLOAT`) are not supported as partitioning columns.

- `DATE` and `DATETIME`.

Columns using other data types relating to dates or times are not supported as partitioning columns.

- The following string types: `CHAR`, `VARCHAR`, `BINARY`, and `VARBINARY`.

`TEXT` and `BLOB` columns are not supported as partitioning columns.

The discussions of `RANGE COLUMNS` and `LIST COLUMNS` partitioning in the next two sections assume that you are already familiar with partitioning based on ranges and lists as supported in MySQL 5.1 and later; for more information about these, see [Section 22.2.1, “RANGE Partitioning”](#), and [Section 22.2.2, “LIST Partitioning”](#), respectively.

22.2.3.1 RANGE COLUMNS partitioning

Range columns partitioning is similar to range partitioning, but enables you to define partitions using ranges based on multiple column values. In addition, you can define the ranges using columns of types other than integer types.

`RANGE COLUMNS` partitioning differs significantly from `RANGE` partitioning in the following ways:

- `RANGE COLUMNS` does not accept expressions, only names of columns.

- `RANGE COLUMNS` accepts a list of one or more columns.

`RANGE COLUMNS` partitions are based on comparisons between *tuples* (lists of column values) rather than comparisons between scalar values. Placement of rows in `RANGE COLUMNS` partitions is also based on comparisons between tuples; this is discussed further later in this section.

- `RANGE COLUMNS` partitioning columns are not restricted to integer columns; string, `DATE` and `DATETIME` columns can also be used as partitioning columns. (See [Section 22.2.3, “COLUMNS Partitioning”](#), for details.)

The basic syntax for creating a table partitioned by `RANGE COLUMNS` is shown here:

```
CREATE TABLE table_name
PARTITIONED BY RANGE COLUMNS(column_list) (
    PARTITION partition_name VALUES LESS THAN (value_list)[,
    PARTITION partition_name VALUES LESS THAN (value_list)[,
    ...]
)

column_list:
    column_name[, column_name][, ...]

value_list:
    value[, value][, ...]
```

Note

Not all `CREATE TABLE` options that can be used when creating partitioned tables are shown here. For complete information, see [Section 13.1.15, “CREATE TABLE Syntax”](#).

In the syntax just shown, *column_list* is a list of one or more columns (sometimes called a *partitioning column list*), and *value_list* is a list of values (that is, it is a *partition definition value list*). A *value_list* must be supplied for each partition definition, and each *value_list* must have the same number of values as the *column_list* has columns. Generally speaking, if you use *N* columns in the `COLUMNS` clause, then each `VALUES LESS THAN` clause must also be supplied with a list of *N* values.

The elements in the partitioning column list and in the value list defining each partition must occur in the same order. In addition, each element in the value list must be of the same data type as the corresponding element in the column list. However, the order of the column names in the partitioning column list and the value lists does not have to be the same as the order of the table column definitions in the main part of the `CREATE TABLE` statement. As with table partitioned by `RANGE`, you can use `MAXVALUE` to represent a value such that any legal value inserted into a given column is always less than this value. Here is an example of a `CREATE TABLE` statement that helps to illustrate all of these points:

```
mysql> CREATE TABLE rcx (
->     a INT,
->     b INT,
->     c CHAR(3),
->     d INT
-> )
-> PARTITION BY RANGE COLUMNS(a,d,c) (
->     PARTITION p0 VALUES LESS THAN (5,10,'ggg'),
->     PARTITION p1 VALUES LESS THAN (10,20,'mmm'),
->     PARTITION p2 VALUES LESS THAN (15,30,'sss'),
->     PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
-> );
Query OK, 0 rows affected (0.15 sec)
```

Table `rcx` contains the columns `a`, `b`, `c`, `d`. The partitioning column list supplied to the `COLUMNS` clause uses 3 of these columns, in the order `a`, `d`, `c`. Each value list used to define a partition contains

3 values in the same order; that is, each value list tuple has the form `(INT, INT, CHAR(3))`, which corresponds to the data types used by columns `a`, `d`, and `c` (in that order).

Placement of rows into partitions is determined by comparing the tuple from a row to be inserted that matches the column list in the `COLUMNS` clause with the tuples used in the `VALUES LESS THAN` clauses to define partitions of the table. Because we are comparing tuples (that is, lists or sets of values) rather than scalar values, the semantics of `VALUES LESS THAN` as used with `RANGE COLUMNS` partitions differs somewhat from the case with simple `RANGE` partitions. In `RANGE` partitioning, a row generating an expression value that is equal to a limiting value in a `VALUES LESS THAN` is never placed in the corresponding partition; however, when using `RANGE COLUMNS` partitioning, it is sometimes possible for a row whose partitioning column list's first element is equal in value to the that of the first element in a `VALUES LESS THAN` value list to be placed in the corresponding partition.

Consider the `RANGE` partitioned table created by this statement:

```
CREATE TABLE r1 (
  a INT,
  b INT
)
PARTITION BY RANGE (a) (
  PARTITION p0 VALUES LESS THAN (5),
  PARTITION p1 VALUES LESS THAN (MAXVALUE)
);
```

If we insert 3 rows into this table such that the column value for `a` is 5 for each row, all 3 rows are stored in partition `p1` because the `a` column value is in each case not less than 5, as we can see by executing the proper query against the `INFORMATION_SCHEMA.PARTITIONS` table:

```
mysql> INSERT INTO r1 VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT PARTITION_NAME, TABLE_ROWS
  -> FROM INFORMATION_SCHEMA.PARTITIONS
  -> WHERE TABLE_NAME = 'r1';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0              |            0 |
| p1              |            3 |
+-----+-----+
2 rows in set (0.00 sec)
```

Now consider a similar table `rc1` that uses `RANGE COLUMNS` partitioning with both columns `a` and `b` referenced in the `COLUMNS` clause, created as shown here:

```
CREATE TABLE rc1 (
  a INT,
  b INT
)
PARTITION BY RANGE COLUMNS(a, b) (
  PARTITION p0 VALUES LESS THAN (5, 12),
  PARTITION p3 VALUES LESS THAN (MAXVALUE, MAXVALUE)
);
```

If we insert exactly the same rows into `rc1` as we just inserted into `r1`, the distribution of the rows is quite different:

```
mysql> INSERT INTO rc1 VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT PARTITION_NAME, TABLE_ROWS
```

```
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'rc1';
+-----+-----+-----+
| TABLE_SCHEMA | PARTITION_NAME | TABLE_ROWS |
+-----+-----+-----+
| p             | p0             | 2           |
| p             | p1             | 1           |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

This is because we are comparing rows rather than scalar values. We can compare the row values inserted with the limiting row value from the `VALUES THAN LESS THAN` clause used to define partition `p0` in table `rc1`, like this:

```
mysql> SELECT (5,10) < (5,12), (5,11) < (5,12), (5,12) < (5,12);
+-----+-----+-----+
| (5,10) < (5,12) | (5,11) < (5,12) | (5,12) < (5,12) |
+-----+-----+-----+
| 1               | 1               | 0               |
+-----+-----+-----+
1 row in set (0.00 sec)
```

The 2 tuples `(5,10)` and `(5,11)` evaluate as less than `(5,12)`, so they are stored in partition `p0`. Since 5 is not less than 5 and 12 is not less than 12, `(5,12)` is considered not less than `(5,12)`, and is stored in partition `p1`.

The `SELECT` statement in the preceding example could also have been written using explicit row constructors, like this:

```
SELECT ROW(5,10) < ROW(5,12), ROW(5,11) < ROW(5,12), ROW(5,12) < ROW(5,12);
```

For more information about the use of row constructors in MySQL, see [Section 13.2.11.5, “Row Subqueries”](#).

For a table partitioned by `RANGE COLUMNS` using only a single partitioning column, the storing of rows in partitions is the same as that of an equivalent table that is partitioned by `RANGE`. The following `CREATE TABLE` statement creates a table partitioned by `RANGE COLUMNS` using 1 partitioning column:

```
CREATE TABLE rx (
  a INT,
  b INT
)
PARTITION BY RANGE COLUMNS (a) (
  PARTITION p0 VALUES LESS THAN (5),
  PARTITION p1 VALUES LESS THAN (MAXVALUE)
);
```

If we insert the rows `(5,10)`, `(5,11)`, and `(5,12)` into this table, we can see that their placement is the same as it is for the table `r` we created and populated earlier:

```
mysql> INSERT INTO rx VALUES (5,10), (5,11), (5,12);
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT PARTITION_NAME, TABLE_ROWS
-> FROM INFORMATION_SCHEMA.PARTITIONS
-> WHERE TABLE_NAME = 'rx';
+-----+-----+-----+
| TABLE_SCHEMA | PARTITION_NAME | TABLE_ROWS |
+-----+-----+-----+
| p             | p0             | 0           |
| p             | p1             | 3           |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

It is also possible to create tables partitioned by `RANGE COLUMNS` where limiting values for one or more columns are repeated in successive partition definitions. You can do this as long as the tuples of column values used to define the partitions are strictly increasing. For example, each of the following `CREATE TABLE` statements is valid:

```
CREATE TABLE rc2 (
  a INT,
  b INT
)
PARTITION BY RANGE COLUMNS(a,b) (
  PARTITION p0 VALUES LESS THAN (0,10),
  PARTITION p1 VALUES LESS THAN (10,20),
  PARTITION p2 VALUES LESS THAN (10,30),
  PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);

CREATE TABLE rc3 (
  a INT,
  b INT
)
PARTITION BY RANGE COLUMNS(a,b) (
  PARTITION p0 VALUES LESS THAN (0,10),
  PARTITION p1 VALUES LESS THAN (10,20),
  PARTITION p2 VALUES LESS THAN (10,30),
  PARTITION p3 VALUES LESS THAN (10,35),
  PARTITION p4 VALUES LESS THAN (20,40),
  PARTITION p5 VALUES LESS THAN (MAXVALUE,MAXVALUE)
);
```

The following statement also succeeds, even though it might appear at first glance that it would not, since the limiting value of column `b` is 25 for partition `p0` and 20 for partition `p1`, and the limiting value of column `c` is 100 for partition `p1` and 50 for partition `p2`:

```
CREATE TABLE rc4 (
  a INT,
  b INT,
  c INT
)
PARTITION BY RANGE COLUMNS(a,b,c) (
  PARTITION p0 VALUES LESS THAN (0,25,50),
  PARTITION p1 VALUES LESS THAN (10,20,100),
  PARTITION p2 VALUES LESS THAN (10,30,50)
  PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
);
```

When designing tables partitioned by `RANGE COLUMNS`, you can always test successive partition definitions by comparing the desired tuples using the `mysql` client, like this:

```
mysql> SELECT (0,25,50) < (10,20,100), (10,20,100) < (10,30,50);
+-----+-----+
| (0,25,50) < (10,20,100) | (10,20,100) < (10,30,50) |
+-----+-----+
| 1 | 1 |
+-----+-----+
1 row in set (0.00 sec)
```

If a `CREATE TABLE` statement contains partition definitions that are not in strictly increasing order, it fails with an error, as shown in this example:

```
mysql> CREATE TABLE rcf (
->   a INT,
->   b INT,
->   c INT
-> )
-> PARTITION BY RANGE COLUMNS(a,b,c) (
```

```
-> PARTITION p0 VALUES LESS THAN (0,25,50),
-> PARTITION p1 VALUES LESS THAN (20,20,100),
-> PARTITION p2 VALUES LESS THAN (10,30,50),
-> PARTITION p3 VALUES LESS THAN (MAXVALUE,MAXVALUE,MAXVALUE)
-> );
ERROR 1493 (HY000): VALUES LESS THAN value must be strictly increasing for each partition
```

When you get such an error, you can deduce which partition definitions are invalid by making “less than” comparisons between their column lists. In this case, the problem is with the definition of partition `p2` because the tuple used to define it is not less than the tuple used to define partition `p3`, as shown here:

```
mysql> SELECT (0,25,50) < (20,20,100), (20,20,100) < (10,30,50);
+-----+-----+
| (0,25,50) < (20,20,100) | (20,20,100) < (10,30,50) |
+-----+-----+
| 1 | 0 |
+-----+-----+
1 row in set (0.00 sec)
```

It is also possible for `MAXVALUE` to appear for the same column in more than one `VALUES LESS THAN` clause when using `RANGE COLUMNS`. However, the limiting values for individual columns in successive partition definitions should otherwise be increasing, there should be no more than one partition defined where `MAXVALUE` is used as the upper limit for all column values, and this partition definition should appear last in the list of `PARTITION ... VALUES LESS THAN` clauses. In addition, you cannot use `MAXVALUE` as the limiting value for the first column in more than one partition definition.

As stated previously, it is also possible with `RANGE COLUMNS` partitioning to use non-integer columns as partitioning columns. (See [Section 22.2.3, “COLUMNS Partitioning”](#), for a complete listing of these.) Consider a table named `employees` (which is not partitioned), created using the following statement:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
);
```

Using `RANGE COLUMNS` partitioning, you can create a version of this table that stores each row in one of four partitions based on the employee's last name, like this:

```
CREATE TABLE employees_by_lname (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT NOT NULL,
  store_id INT NOT NULL
)
PARTITION BY RANGE COLUMNS (lname) (
  PARTITION p0 VALUES LESS THAN ('g'),
  PARTITION p1 VALUES LESS THAN ('m'),
  PARTITION p2 VALUES LESS THAN ('t'),
  PARTITION p3 VALUES LESS THAN (MAXVALUE)
);
```

Alternatively, you could cause the `employees` table as created previously to be partitioned using this scheme by executing the following `ALTER TABLE` statement:

```
ALTER TABLE employees PARTITION BY RANGE COLUMNS (lname) (
```

```

PARTITION p0 VALUES LESS THAN ('g'),
PARTITION p1 VALUES LESS THAN ('m'),
PARTITION p2 VALUES LESS THAN ('t'),
PARTITION p3 VALUES LESS THAN (MAXVALUE)
);

```

**Note**

Because different character sets and collations have different sort orders, the character sets and collations in use may effect which partition of a table partitioned by [RANGE COLUMNS](#) a given row is stored in when using string columns as partitioning columns. In addition, changing the character set or collation for a given database, table, or column after such a table is created may cause changes in how rows are distributed. For example, when using a case-sensitive collation, 'and' sorts before 'Andersen', but when using a collation that is case insensitive, the reverse is true.

For information about how MySQL handles character sets and collations, see [Section 10.1, “Character Set Support”](#).

Similarly, you can cause the `employees` table to be partitioned in such a way that each row is stored in one of several partitions based on the decade in which the corresponding employee was hired using the `ALTER TABLE` statement shown here:

```

ALTER TABLE employees PARTITION BY RANGE COLUMNS (hired) (
  PARTITION p0 VALUES LESS THAN ('1970-01-01'),
  PARTITION p1 VALUES LESS THAN ('1980-01-01'),
  PARTITION p2 VALUES LESS THAN ('1990-01-01'),
  PARTITION p3 VALUES LESS THAN ('2000-01-01'),
  PARTITION p4 VALUES LESS THAN ('2010-01-01'),
  PARTITION p5 VALUES LESS THAN (MAXVALUE)
);

```

See [Section 13.1.15, “CREATE TABLE Syntax”](#), for additional information about `PARTITION BY RANGE COLUMNS` syntax.

22.2.3.2 LIST COLUMNS partitioning

MySQL 8.0 provides support for `LIST COLUMNS` partitioning. This is a variant of `LIST` partitioning that enables the use of multiple columns as partition keys, and for columns of data types other than integer types to be used as partitioning columns; you can use string types, `DATE`, and `DATETIME` columns. (For more information about permitted data types for `COLUMNS` partitioning columns, see [Section 22.2.3, “COLUMNS Partitioning”](#).)

Suppose that you have a business that has customers in 12 cities which, for sales and marketing purposes, you organize into 4 regions of 3 cities each as shown in the following table:

Region	Cities
1	Oskarshamn, Högsby, Mönsterås
2	Vimmerby, Hultsfred, Västervik
3	Nässjö, Eksjö, Vetlanda
4	Uppvidinge, Alvesta, Växjö

With `LIST COLUMNS` partitioning, you can create a table for customer data that assigns a row to any of 4 partitions corresponding to these regions based on the name of the city where a customer resides, as shown here:

```

CREATE TABLE customers_1 (

```

```

first_name VARCHAR(25),
last_name VARCHAR(25),
street_1 VARCHAR(30),
street_2 VARCHAR(30),
city VARCHAR(15),
renewal DATE
)
PARTITION BY LIST COLUMNS(city) (
PARTITION pRegion_1 VALUES IN('Oskarshamn', 'Högsby', 'Mönsterås'),
PARTITION pRegion_2 VALUES IN('Vimmerby', 'Hultsfred', 'Västervik'),
PARTITION pRegion_3 VALUES IN('Nässjö', 'Eksjö', 'Vetlanda'),
PARTITION pRegion_4 VALUES IN('Uppvidinge', 'Alvesta', 'Växjö')
);

```

As with partitioning by [RANGE COLUMNS](#), you do not need to use expressions in the [COLUMNS \(\)](#) clause to convert column values into integers. (In fact, the use of expressions other than column names is not permitted with [COLUMNS \(\)](#).)

It is also possible to use [DATE](#) and [DATETIME](#) columns, as shown in the following example that uses the same name and columns as the [customers_1](#) table shown previously, but employs [LIST COLUMNS](#) partitioning based on the [renewal](#) column to store rows in one of 4 partitions depending on the week in February 2010 the customer's account is scheduled to renew:

```

CREATE TABLE customers_2 (
first_name VARCHAR(25),
last_name VARCHAR(25),
street_1 VARCHAR(30),
street_2 VARCHAR(30),
city VARCHAR(15),
renewal DATE
)
PARTITION BY LIST COLUMNS(renewal) (
PARTITION pWeek_1 VALUES IN('2010-02-01', '2010-02-02', '2010-02-03',
'2010-02-04', '2010-02-05', '2010-02-06', '2010-02-07'),
PARTITION pWeek_2 VALUES IN('2010-02-08', '2010-02-09', '2010-02-10',
'2010-02-11', '2010-02-12', '2010-02-13', '2010-02-14'),
PARTITION pWeek_3 VALUES IN('2010-02-15', '2010-02-16', '2010-02-17',
'2010-02-18', '2010-02-19', '2010-02-20', '2010-02-21'),
PARTITION pWeek_4 VALUES IN('2010-02-22', '2010-02-23', '2010-02-24',
'2010-02-25', '2010-02-26', '2010-02-27', '2010-02-28')
);

```

This works, but becomes cumbersome to define and maintain if the number of dates involved grows very large; in such cases, it is usually more practical to employ [RANGE](#) or [RANGE COLUMNS](#) partitioning instead. In this case, since the column we wish to use as the partitioning key is a [DATE](#) column, we use [RANGE COLUMNS](#) partitioning, as shown here:

```

CREATE TABLE customers_3 (
first_name VARCHAR(25),
last_name VARCHAR(25),
street_1 VARCHAR(30),
street_2 VARCHAR(30),
city VARCHAR(15),
renewal DATE
)
PARTITION BY RANGE COLUMNS(renewal) (
PARTITION pWeek_1 VALUES LESS THAN('2010-02-09'),
PARTITION pWeek_2 VALUES LESS THAN('2010-02-15'),
PARTITION pWeek_3 VALUES LESS THAN('2010-02-22'),
PARTITION pWeek_4 VALUES LESS THAN('2010-03-01')
);

```

See [Section 22.2.3.1, “RANGE COLUMNS partitioning”](#), for more information.

In addition (as with [RANGE COLUMNS](#) partitioning), you can use multiple columns in the [COLUMNS \(\)](#) clause.

See [Section 13.1.15, “CREATE TABLE Syntax”](#), for additional information about `PARTITION BY LIST COLUMNS()` syntax.

22.2.4 HASH Partitioning

Partitioning by `HASH` is used primarily to ensure an even distribution of data among a predetermined number of partitions. With range or list partitioning, you must specify explicitly which partition a given column value or set of column values should be stored in; with hash partitioning, this decision is taken care of for you, and you need only specify a column value or expression based on a column value to be hashed and the number of partitions into which the partitioned table is to be divided.

To partition a table using `HASH` partitioning, it is necessary to append to the `CREATE TABLE` statement a `PARTITION BY HASH (expr)` clause, where `expr` is an expression that returns an integer. This can simply be the name of a column whose type is one of MySQL's integer types. In addition, you most likely want to follow this with `PARTITIONS num`, where `num` is a positive integer representing the number of partitions into which the table is to be divided.

Note

For simplicity, the tables in the examples that follow do not use any keys. You should be aware that, if a table has any unique keys, every column used in the partitioning expression for this table must be part of every unique key, including the primary key. See [Section 22.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#), for more information.

The following statement creates a table that uses hashing on the `store_id` column and is divided into 4 partitions:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY HASH(store_id)
PARTITIONS 4;
```

If you do not include a `PARTITIONS` clause, the number of partitions defaults to `1`; using the `PARTITIONS` keyword without a number following it results in a syntax error.

You can also use an SQL expression that returns an integer for `expr`. For instance, you might want to partition based on the year in which an employee was hired. This can be done as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY HASH( YEAR(hired) )
PARTITIONS 4;
```

`expr` must return a nonconstant, nonrandom integer value (in other words, it should be varying but deterministic), and must not contain any prohibited constructs as described in [Section 22.6, “Restrictions and Limitations on Partitioning”](#). You should also keep in mind that this expression is evaluated each time a row is inserted or updated (or possibly deleted); this means that very complex

expressions may give rise to performance issues, particularly when performing operations (such as batch inserts) that affect a great many rows at one time.

The most efficient hashing function is one which operates upon a single table column and whose value increases or decreases consistently with the column value, as this allows for “pruning” on ranges of partitions. That is, the more closely that the expression varies with the value of the column on which it is based, the more efficiently MySQL can use the expression for hash partitioning.

For example, where `date_col` is a column of type `DATE`, then the expression `TO_DAYS(date_col)` is said to vary directly with the value of `date_col`, because for every change in the value of `date_col`, the value of the expression changes in a consistent manner. The variance of the expression `YEAR(date_col)` with respect to `date_col` is not quite as direct as that of `TO_DAYS(date_col)`, because not every possible change in `date_col` produces an equivalent change in `YEAR(date_col)`. Even so, `YEAR(date_col)` is a good candidate for a hashing function, because it varies directly with a portion of `date_col` and there is no possible change in `date_col` that produces a disproportionate change in `YEAR(date_col)`.

By way of contrast, suppose that you have a column named `int_col` whose type is `INT`. Now consider the expression `POW(5-int_col,3) + 6`. This would be a poor choice for a hashing function because a change in the value of `int_col` is not guaranteed to produce a proportional change in the value of the expression. Changing the value of `int_col` by a given amount can produce widely differing changes in the value of the expression. For example, changing `int_col` from 5 to 6 produces a change of `-1` in the value of the expression, but changing the value of `int_col` from 6 to 7 produces a change of `-7` in the expression value.

In other words, the more closely the graph of the column value versus the value of the expression follows a straight line as traced by the equation $y=cx$ where c is some nonzero constant, the better the expression is suited to hashing. This has to do with the fact that the more nonlinear an expression is, the more uneven the distribution of data among the partitions it tends to produce.

In theory, pruning is also possible for expressions involving more than one column value, but determining which of such expressions are suitable can be quite difficult and time-consuming. For this reason, the use of hashing expressions involving multiple columns is not particularly recommended.

When `PARTITION BY HASH` is used, the storage engine determines which partition of `num` partitions to use based on the modulus of the result of the expression. In other words, for a given expression `expr`, the partition in which the record is stored is partition number N , where $N = \text{MOD}(\text{expr}, \text{num})$. Suppose that table `t1` is defined as follows, so that it has 4 partitions:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY HASH( YEAR(col3) )
PARTITIONS 4;
```

If you insert a record into `t1` whose `col3` value is `'2005-09-15'`, then the partition in which it is stored is determined as follows:

```
MOD( YEAR( '2005-09-01' ), 4 )
= MOD( 2005, 4 )
= 1
```

MySQL 8.0 also supports a variant of `HASH` partitioning known as *linear hashing* which employs a more complex algorithm for determining the placement of new rows inserted into the partitioned table. See [Section 22.2.4.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm.

The user-supplied expression is evaluated each time a record is inserted or updated. It may also—depending on the circumstances—be evaluated when records are deleted.

22.2.4.1 LINEAR HASH Partitioning

MySQL also supports linear hashing, which differs from regular hashing in that linear hashing utilizes a linear powers-of-two algorithm whereas regular hashing employs the modulus of the hashing function's value.

Syntactically, the only difference between linear-hash partitioning and regular hashing is the addition of the `LINEAR` keyword in the `PARTITION BY` clause, as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30),
  hired DATE NOT NULL DEFAULT '1970-01-01',
  separated DATE NOT NULL DEFAULT '9999-12-31',
  job_code INT,
  store_id INT
)
PARTITION BY LINEAR HASH( YEAR(hired) )
PARTITIONS 4;
```

Given an expression *expr*, the partition in which the record is stored when linear hashing is used is partition number *N* from among *num* partitions, where *N* is derived according to the following algorithm:

1. Find the next power of 2 greater than *num*. We call this value *V*; it can be calculated as:

```
V = POWER(2, CEILING(LOG(2, num)))
```

(Suppose that *num* is 13. Then `LOG(2, 13)` is 3.7004397181411. `CEILING(3.7004397181411)` is 4, and `V = POWER(2, 4)`, which is 16.)

2. Set $N = F(\textit{column_list}) \& (V - 1)$.
3. While $N \geq \textit{num}$:
 - Set $V = V / 2$
 - Set $N = N \& (V - 1)$

Suppose that the table `t1`, using linear hash partitioning and having 6 partitions, is created using this statement:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
PARTITION BY LINEAR HASH( YEAR(col3) )
PARTITIONS 6;
```

Now assume that you want to insert two records into `t1` having the `col3` column values `'2003-04-14'` and `'1998-10-19'`. The partition number for the first of these is determined as follows:

```
V = POWER(2, CEILING( LOG(2,6) )) = 8
N = YEAR('2003-04-14') & (8 - 1)
  = 2003 & 7
  = 3

(3 >= 6 is FALSE: record stored in partition #3)
```

The number of the partition where the second record is stored is calculated as shown here:

```
V = 8
N = YEAR('1998-10-19') & (8 - 1)
  = 1998 & 7
  = 6
```

```
(6 >= 6 is TRUE: additional step required)

N = 6 & ((8 / 2) - 1)
  = 6 & 3
  = 2

(2 >= 6 is FALSE: record stored in partition #2)
```

The advantage in partitioning by linear hash is that the adding, dropping, merging, and splitting of partitions is made much faster, which can be beneficial when dealing with tables containing extremely large amounts (terabytes) of data. The disadvantage is that data is less likely to be evenly distributed between partitions as compared with the distribution obtained using regular hash partitioning.

22.2.5 KEY Partitioning

Partitioning by key is similar to partitioning by hash, except that where hash partitioning employs a user-defined expression, the hashing function for key partitioning is supplied by the MySQL server. This internal hashing function is based on the same algorithm as `PASSWORD()`.

The syntax rules for `CREATE TABLE ... PARTITION BY KEY` are similar to those for creating a table that is partitioned by hash. The major differences are listed here:

- `KEY` is used rather than `HASH`.
- `KEY` takes only a list of zero or more column names. Any columns used as the partitioning key must comprise part or all of the table's primary key, if the table has one. Where no column name is specified as the partitioning key, the table's primary key is used, if there is one. For example, the following `CREATE TABLE` statement is valid in MySQL 8.0:

```
CREATE TABLE k1 (
  id INT NOT NULL PRIMARY KEY,
  name VARCHAR(20)
)
PARTITION BY KEY()
PARTITIONS 2;
```

If there is no primary key but there is a unique key, then the unique key is used for the partitioning key:

```
CREATE TABLE k1 (
  id INT NOT NULL,
  name VARCHAR(20),
  UNIQUE KEY (id)
)
PARTITION BY KEY()
PARTITIONS 2;
```

However, if the unique key column were not defined as `NOT NULL`, then the previous statement would fail.

In both of these cases, the partitioning key is the `id` column, even though it is not shown in the output of `SHOW CREATE TABLE` or in the `PARTITION_EXPRESSION` column of the `INFORMATION_SCHEMA.PARTITIONS` table.

Unlike the case with other partitioning types, columns used for partitioning by `KEY` are not restricted to integer or `NULL` values. For example, the following `CREATE TABLE` statement is valid:

```
CREATE TABLE tm1 (
  s1 CHAR(32) PRIMARY KEY
)
PARTITION BY KEY(s1)
PARTITIONS 10;
```

The preceding statement would *not* be valid, were a different partitioning type to be specified. (In this case, simply using `PARTITION BY KEY()` would also be valid and have the same effect as `PARTITION BY KEY(s1)`, since `s1` is the table's primary key.)

For additional information about this issue, see [Section 22.6, “Restrictions and Limitations on Partitioning”](#).

Important

For a key-partitioned table, you cannot execute an `ALTER TABLE DROP PRIMARY KEY`, as doing so generates the error `ERROR 1466 (HY000): Field in list of fields for partition function not found in table.`

It is also possible to partition a table by linear key. Here is a simple example:

```
CREATE TABLE tk (
  col1 INT NOT NULL,
  col2 CHAR(5),
  col3 DATE
)
PARTITION BY LINEAR KEY (col1)
PARTITIONS 3;
```

The `LINEAR` keyword has the same effect on `KEY` partitioning as it does on `HASH` partitioning, with the partition number being derived using a powers-of-two algorithm rather than modulo arithmetic. See [Section 22.2.4.1, “LINEAR HASH Partitioning”](#), for a description of this algorithm and its implications.

22.2.6 Subpartitioning

Subpartitioning—also known as *composite partitioning*—is the further division of each partition in a partitioned table. Consider the following `CREATE TABLE` statement:

```
CREATE TABLE ts (id INT, purchased DATE)
PARTITION BY RANGE( YEAR(purchased) )
SUBPARTITION BY HASH( TO_DAYS(purchased) )
SUBPARTITIONS 2 (
  PARTITION p0 VALUES LESS THAN (1990),
  PARTITION p1 VALUES LESS THAN (2000),
  PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

Table `ts` has 3 `RANGE` partitions. Each of these partitions—`p0`, `p1`, and `p2`—is further divided into 2 subpartitions. In effect, the entire table is divided into $3 * 2 = 6$ partitions. However, due to the action of the `PARTITION BY RANGE` clause, the first 2 of these store only those records with a value less than 1990 in the `purchased` column.

It is possible to subpartition tables that are partitioned by `RANGE` or `LIST`. Subpartitions may use either `HASH` or `KEY` partitioning. This is also known as *composite partitioning*.

Note

`SUBPARTITION BY HASH` and `SUBPARTITION BY KEY` generally follow the same syntax rules as `PARTITION BY HASH` and `PARTITION BY KEY`, respectively. An exception to this is that `SUBPARTITION BY KEY` (unlike `PARTITION BY KEY`) does not currently support a default column, so the column used for this purpose must be specified, even if the table has an explicit primary key. This is a known issue which we are working to address; see [Issues with subpartitions](#), for more information and an example.

It is also possible to define subpartitions explicitly using [SUBPARTITION](#) clauses to specify options for individual subpartitions. For example, a more verbose fashion of creating the same table `ts` as shown in the previous example would be:

```
CREATE TABLE ts (id INT, purchased DATE)
  PARTITION BY RANGE( YEAR(purchased) )
  SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990) (
      SUBPARTITION s0,
      SUBPARTITION s1
    ),
    PARTITION p1 VALUES LESS THAN (2000) (
      SUBPARTITION s2,
      SUBPARTITION s3
    ),
    PARTITION p2 VALUES LESS THAN MAXVALUE (
      SUBPARTITION s4,
      SUBPARTITION s5
    )
  );
```

Some syntactical items of note are listed here:

- Each partition must have the same number of subpartitions.
- If you explicitly define any subpartitions using [SUBPARTITION](#) on any partition of a partitioned table, you must define them all. In other words, the following statement will fail:

```
CREATE TABLE ts (id INT, purchased DATE)
  PARTITION BY RANGE( YEAR(purchased) )
  SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990) (
      SUBPARTITION s0,
      SUBPARTITION s1
    ),
    PARTITION p1 VALUES LESS THAN (2000),
    PARTITION p2 VALUES LESS THAN MAXVALUE (
      SUBPARTITION s2,
      SUBPARTITION s3
    )
  );
```

This statement would still fail even if it used [SUBPARTITIONS 2](#).

- Each [SUBPARTITION](#) clause must include (at a minimum) a name for the subpartition. Otherwise, you may set any desired option for the subpartition or allow it to assume its default setting for that option.
- Subpartition names must be unique across the entire table. For example, the following [CREATE TABLE](#) statement is valid:

```
CREATE TABLE ts (id INT, purchased DATE)
  PARTITION BY RANGE( YEAR(purchased) )
  SUBPARTITION BY HASH( TO_DAYS(purchased) ) (
    PARTITION p0 VALUES LESS THAN (1990) (
      SUBPARTITION s0,
      SUBPARTITION s1
    ),
    PARTITION p1 VALUES LESS THAN (2000) (
      SUBPARTITION s2,
      SUBPARTITION s3
    ),
    PARTITION p2 VALUES LESS THAN MAXVALUE (
      SUBPARTITION s4,
      SUBPARTITION s5
    )
  );
```

);

22.2.7 How MySQL Partitioning Handles NULL

Partitioning in MySQL does nothing to disallow `NULL` as the value of a partitioning expression, whether it is a column value or the value of a user-supplied expression. Even though it is permitted to use `NULL` as the value of an expression that must otherwise yield an integer, it is important to keep in mind that `NULL` is not a number. MySQL's partitioning implementation treats `NULL` as being less than any non-`NULL` value, just as `ORDER BY` does.

This means that treatment of `NULL` varies between partitioning of different types, and may produce behavior which you do not expect if you are not prepared for it. This being the case, we discuss in this section how each MySQL partitioning type handles `NULL` values when determining the partition in which a row should be stored, and provide examples for each.

Handling of `NULL` with `RANGE` partitioning. If you insert a row into a table partitioned by `RANGE` such that the column value used to determine the partition is `NULL`, the row is inserted into the lowest partition. Consider these two tables in a database named `p`, created as follows:

```
mysql> CREATE TABLE t1 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY RANGE(c1) (
->   PARTITION p0 VALUES LESS THAN (0),
->   PARTITION p1 VALUES LESS THAN (10),
->   PARTITION p2 VALUES LESS THAN MAXVALUE
-> );
Query OK, 0 rows affected (0.09 sec)

mysql> CREATE TABLE t2 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY RANGE(c1) (
->   PARTITION p0 VALUES LESS THAN (-5),
->   PARTITION p1 VALUES LESS THAN (0),
->   PARTITION p2 VALUES LESS THAN (10),
->   PARTITION p3 VALUES LESS THAN MAXVALUE
-> );
Query OK, 0 rows affected (0.09 sec)
```

You can see the partitions created by these two `CREATE TABLE` statements using the following query against the `PARTITIONS` table in the `INFORMATION_SCHEMA` database:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+
| t1          | p0              | 0           | 0              | 0            |
| t1          | p1              | 0           | 0              | 0            |
| t1          | p2              | 0           | 0              | 0            |
| t2          | p0              | 0           | 0              | 0            |
| t2          | p1              | 0           | 0              | 0            |
| t2          | p2              | 0           | 0              | 0            |
| t2          | p3              | 0           | 0              | 0            |
+-----+-----+-----+-----+-----+
7 rows in set (0.00 sec)
```

(For more information about this table, see [Section 24.13, “The INFORMATION_SCHEMA PARTITIONS Table”](#).) Now let us populate each of these tables with a single row containing a `NULL` in the column used as the partitioning key, and verify that the rows were inserted using a pair of `SELECT` statements:

```
mysql> INSERT INTO t1 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM t1;
+-----+-----+
| id   | name |
+-----+-----+
| NULL | mothra |
+-----+-----+
1 row in set (0.00 sec)

mysql> SELECT * FROM t2;
+-----+-----+
| id   | name |
+-----+-----+
| NULL | mothra |
+-----+-----+
1 row in set (0.00 sec)
```

You can see which partitions are used to store the inserted rows by rerunning the previous query against `INFORMATION_SCHEMA.PARTITIONS` and inspecting the output:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 't_';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+
| t1          | p0             | 1           | 20             | 20           |
| t1          | p1             | 0           | 0              | 0            |
| t1          | p2             | 0           | 0              | 0            |
| t2          | p0             | 1           | 20             | 20           |
| t2          | p1             | 0           | 0              | 0            |
| t2          | p2             | 0           | 0              | 0            |
| t2          | p3             | 0           | 0              | 0            |
+-----+-----+-----+-----+-----+
7 rows in set (0.01 sec)
```

You can also demonstrate that these rows were stored in the lowest-numbered partition of each table by dropping these partitions, and then re-running the `SELECT` statements:

```
mysql> ALTER TABLE t1 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> ALTER TABLE t2 DROP PARTITION p0;
Query OK, 0 rows affected (0.16 sec)

mysql> SELECT * FROM t1;
Empty set (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

(For more information on `ALTER TABLE ... DROP PARTITION`, see [Section 13.1.7, “ALTER TABLE Syntax”](#).)

`NULL` is also treated in this way for partitioning expressions that use SQL functions. Suppose that we define a table using a `CREATE TABLE` statement such as this one:

```
CREATE TABLE tndate (
  id INT,
  dt DATE
)
PARTITION BY RANGE( YEAR(dt) ) (
```

```

PARTITION p0 VALUES LESS THAN (1990),
PARTITION p1 VALUES LESS THAN (2000),
PARTITION p2 VALUES LESS THAN MAXVALUE
);

```

As with other MySQL functions, `YEAR(NULL)` returns `NULL`. A row with a `dt` column value of `NULL` is treated as though the partitioning expression evaluated to a value less than any other value, and so is inserted into partition `p0`.

Handling of NULL with LIST partitioning. A table that is partitioned by `LIST` admits `NULL` values if and only if one of its partitions is defined using that value-list that contains `NULL`. The converse of this is that a table partitioned by `LIST` which does not explicitly use `NULL` in a value list rejects rows resulting in a `NULL` value for the partitioning expression, as shown in this example:

```

mysql> CREATE TABLE ts1 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY LIST(c1) (
->   PARTITION p0 VALUES IN (0, 3, 6),
->   PARTITION p1 VALUES IN (1, 4, 7),
->   PARTITION p2 VALUES IN (2, 5, 8)
-> );
Query OK, 0 rows affected (0.01 sec)

mysql> INSERT INTO ts1 VALUES (9, 'mothra');
ERROR 1504 (HY000): Table has no partition for value 9

mysql> INSERT INTO ts1 VALUES (NULL, 'mothra');
ERROR 1504 (HY000): Table has no partition for value NULL

```

Only rows having a `c1` value between 0 and 8 inclusive can be inserted into `ts1`. `NULL` falls outside this range, just like the number 9. We can create tables `ts2` and `ts3` having value lists containing `NULL`, as shown here:

```

mysql> CREATE TABLE ts2 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY LIST(c1) (
->   PARTITION p0 VALUES IN (0, 3, 6),
->   PARTITION p1 VALUES IN (1, 4, 7),
->   PARTITION p2 VALUES IN (2, 5, 8),
->   PARTITION p3 VALUES IN (NULL)
-> );
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE TABLE ts3 (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY LIST(c1) (
->   PARTITION p0 VALUES IN (0, 3, 6),
->   PARTITION p1 VALUES IN (1, 4, 7, NULL),
->   PARTITION p2 VALUES IN (2, 5, 8)
-> );
Query OK, 0 rows affected (0.01 sec)

```

When defining value lists for partitioning, you can (and should) treat `NULL` just as you would any other value. For example, both `VALUES IN (NULL)` and `VALUES IN (1, 4, 7, NULL)` are valid, as are `VALUES IN (1, NULL, 4, 7)`, `VALUES IN (NULL, 1, 4, 7)`, and so on. You can insert a row having `NULL` for column `c1` into each of the tables `ts2` and `ts3`:

```

mysql> INSERT INTO ts2 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)

```

```
mysql> INSERT INTO ts3 VALUES (NULL, 'mothra');
Query OK, 1 row affected (0.00 sec)
```

By issuing the appropriate query against `INFORMATION_SCHEMA.PARTITIONS`, you can determine which partitions were used to store the rows just inserted (we assume, as in the previous examples, that the partitioned tables were created in the `p` database):

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME LIKE 'ts_*';
```

TABLE_NAME	PARTITION_NAME	TABLE_ROWS	AVG_ROW_LENGTH	DATA_LENGTH
ts2	p0	0	0	0
ts2	p1	0	0	0
ts2	p2	0	0	0
/ ts2	/ p3	/ 1	/ 20	/ 20
ts3	p0	0	0	0
/ ts3	/ p1	/ 1	/ 20	/ 20
ts3	p2	0	0	0

```
7 rows in set (0.01 sec)
```

As shown earlier in this section, you can also verify which partitions were used for storing the rows by deleting these partitions and then performing a `SELECT`.

Handling of NULL with HASH and KEY partitioning. `NULL` is handled somewhat differently for tables partitioned by `HASH` or `KEY`. In these cases, any partition expression that yields a `NULL` value is treated as though its return value were zero. We can verify this behavior by examining the effects on the file system of creating a table partitioned by `HASH` and populating it with a record containing appropriate values. Suppose that you have a table `th` (also in the `p` database) created using the following statement:

```
mysql> CREATE TABLE th (
->   c1 INT,
->   c2 VARCHAR(20)
-> )
-> PARTITION BY HASH(c1)
-> PARTITIONS 2;
Query OK, 0 rows affected (0.00 sec)
```

The partitions belonging to this table can be viewed using the query shown here:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
```

TABLE_NAME	PARTITION_NAME	TABLE_ROWS	AVG_ROW_LENGTH	DATA_LENGTH
th	p0	0	0	0
th	p1	0	0	0

```
2 rows in set (0.00 sec)
```

`TABLE_ROWS` for each partition is 0. Now insert two rows into `th` whose `c1` column values are `NULL` and 0, and verify that these rows were inserted, as shown here:

```
mysql> INSERT INTO th VALUES (NULL, 'mothra'), (0, 'gigan');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM th;
```

c1	c2
NULL	mothra

```
| 0 | gigan |
+-----+-----+
2 rows in set (0.01 sec)
```

Recall that for any integer N , the value of `NULL MOD N` is always `NULL`. For tables that are partitioned by `HASH` or `KEY`, this result is treated for determining the correct partition as `0`. Checking the `INFORMATION_SCHEMA.PARTITIONS` table once again, we can see that both rows were inserted into partition `p0`:

```
mysql> SELECT TABLE_NAME, PARTITION_NAME, TABLE_ROWS, AVG_ROW_LENGTH, DATA_LENGTH
> FROM INFORMATION_SCHEMA.PARTITIONS
> WHERE TABLE_SCHEMA = 'p' AND TABLE_NAME = 'th';
+-----+-----+-----+-----+-----+
| TABLE_NAME | PARTITION_NAME | TABLE_ROWS | AVG_ROW_LENGTH | DATA_LENGTH |
+-----+-----+-----+-----+-----+
| th          | p0             | 2           | 20             | 20           |
| th          | p1             | 0           | 0              | 0            |
+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)
```

By repeating the last example using `PARTITION BY KEY` in place of `PARTITION BY HASH` in the definition of the table, you can verify that `NULL` is also treated like `0` for this type of partitioning.

22.3 Partition Management

There are a number of ways using SQL statements to modify partitioned tables; it is possible to add, drop, redefine, merge, or split existing partitions using the partitioning extensions to the `ALTER TABLE` statement. There are also ways to obtain information about partitioned tables and partitions. We discuss these topics in the sections that follow.

- For information about partition management in tables partitioned by `RANGE` or `LIST`, see [Section 22.3.1, “Management of RANGE and LIST Partitions”](#).
- For a discussion of managing `HASH` and `KEY` partitions, see [Section 22.3.2, “Management of HASH and KEY Partitions”](#).
- See [Section 22.3.5, “Obtaining Information About Partitions”](#), for a discussion of mechanisms provided in MySQL 8.0 for obtaining information about partitioned tables and partitions.
- For a discussion of performing maintenance operations on partitions, see [Section 22.3.4, “Maintenance of Partitions”](#).

Note

All partitions of a partitioned table must have the same number of subpartitions; it is not possible to change the subpartitioning once the table has been created.

To change a table's partitioning scheme, it is necessary only to use the `ALTER TABLE` statement with a `partition_options` option, which has the same syntax as that as used with `CREATE TABLE` for creating a partitioned table; this option (also) always begins with the keywords `PARTITION BY`. Suppose that the following `CREATE TABLE` statement was used to create a table that is partitioned by range:

```
CREATE TABLE trb3 (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE( YEAR(purchased) ) (
PARTITION p0 VALUES LESS THAN (1990),
PARTITION p1 VALUES LESS THAN (1995),
PARTITION p2 VALUES LESS THAN (2000),
PARTITION p3 VALUES LESS THAN (2005)
);
```

To repartition this table so that it is partitioned by key into two partitions using the `id` column value as the basis for the key, you can use this statement:

```
ALTER TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;
```

This has the same effect on the structure of the table as dropping the table and re-creating it using `CREATE TABLE trb3 PARTITION BY KEY(id) PARTITIONS 2;`.

`ALTER TABLE ... ENGINE = ...` changes only the storage engine used by the table, and leaves the table's partitioning scheme intact. The statement succeeds only if the target storage engine provides partitioning support. You can use `ALTER TABLE ... REMOVE PARTITIONING` to remove a table's partitioning; see [Section 13.1.7, "ALTER TABLE Syntax"](#).

Important

Only a single `PARTITION BY`, `ADD PARTITION`, `DROP PARTITION`, `REORGANIZE PARTITION`, or `COALESCE PARTITION` clause can be used in a given `ALTER TABLE` statement. If you (for example) wish to drop a partition and reorganize a table's remaining partitions, you must do so in two separate `ALTER TABLE` statements (one using `DROP PARTITION` and then a second one using `REORGANIZE PARTITION`).

You can delete all rows from one or more selected partitions using `ALTER TABLE ... TRUNCATE PARTITION`.

22.3.1 Management of RANGE and LIST Partitions

Adding and dropping of range and list partitions are handled in a similar fashion, so we discuss the management of both sorts of partitioning in this section. For information about working with tables that are partitioned by hash or key, see [Section 22.3.2, "Management of HASH and KEY Partitions"](#).

Dropping a partition from a table that is partitioned by either `RANGE` or by `LIST` can be accomplished using the `ALTER TABLE` statement with the `DROP PARTITION` option. Suppose that you have created a table that is partitioned by range and then populated with 10 records using the following `CREATE TABLE` and `INSERT` statements:

```
mysql> CREATE TABLE tr (id INT, name VARCHAR(50), purchased DATE)
->     PARTITION BY RANGE( YEAR(purchased) ) (
->         PARTITION p0 VALUES LESS THAN (1990),
->         PARTITION p1 VALUES LESS THAN (1995),
->         PARTITION p2 VALUES LESS THAN (2000),
->         PARTITION p3 VALUES LESS THAN (2005),
->         PARTITION p4 VALUES LESS THAN (2010),
->         PARTITION p5 VALUES LESS THAN (2015)
->     );
Query OK, 0 rows affected (0.28 sec)

mysql> INSERT INTO tr VALUES
->     (1, 'desk organiser', '2003-10-15'),
->     (2, 'alarm clock', '1997-11-05'),
->     (3, 'chair', '2009-03-10'),
->     (4, 'bookcase', '1989-01-10'),
->     (5, 'exercise bike', '2014-05-09'),
->     (6, 'sofa', '1987-06-05'),
->     (7, 'espresso maker', '2011-11-22'),
->     (8, 'aquarium', '1992-08-04'),
->     (9, 'study desk', '2006-09-16'),
->     (10, 'lava lamp', '1998-12-25');
Query OK, 10 rows affected (0.05 sec)
Records: 10 Duplicates: 0 Warnings: 0
```

You can see which items should have been inserted into partition `p2` as shown here:

```
mysql> SELECT * FROM tr
->     WHERE purchased BETWEEN '1995-01-01' AND '1999-12-31';
+-----+-----+-----+-----+
+-----+-----+-----+-----+
```

```

| id | name          | purchased |
+----+-----+-----+
|  2 | alarm clock  | 1997-11-05 |
| 10 | lava lamp   | 1998-12-25 |
+----+-----+-----+
2 rows in set (0.00 sec)

```

You can also get this information using partition selection, as shown here:

```

mysql> SELECT * FROM tr PARTITION (p2);
+----+-----+-----+
| id | name          | purchased |
+----+-----+-----+
|  2 | alarm clock  | 1997-11-05 |
| 10 | lava lamp   | 1998-12-25 |
+----+-----+-----+
2 rows in set (0.00 sec)

```

See [Section 22.5, “Partition Selection”](#), for more information.

To drop the partition named `p2`, execute the following command:

```

mysql> ALTER TABLE tr DROP PARTITION p2;
Query OK, 0 rows affected (0.03 sec)

```

Note

The `NDBCLUSTER` storage engine does not support `ALTER TABLE ... DROP PARTITION`. It does, however, support the other partitioning-related extensions to `ALTER TABLE` that are described in this chapter.

It is very important to remember that, *when you drop a partition, you also delete all the data that was stored in that partition*. You can see that this is the case by re-running the previous `SELECT` query:

```

mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '1999-12-31';
Empty set (0.00 sec)

```

Note

As of MySQL 8.0.2, `DROP PARTITION` is supported by native partitioning in-place APIs and may be used with `ALGORITHM={COPY|INPLACE}`. `DROP PARTITION` with `ALGORITHM=INPLACE` deletes data stored in the partition and drops the partition. However, `DROP PARTITION` with `ALGORITHM=COPY` or `old_alter_table=ON` rebuilds the partitioned table and attempts to move data from the dropped partition to another partition with a compatible `PARTITION ... VALUES` definition. Data that cannot be moved to another partition is deleted.

Because of this, you must have the `DROP` privilege for a table before you can execute `ALTER TABLE ... DROP PARTITION` on that table.

If you wish to drop all data from all partitions while preserving the table definition and its partitioning scheme, use the `TRUNCATE TABLE` statement. (See [Section 13.1.30, “TRUNCATE TABLE Syntax”](#).)

If you intend to change the partitioning of a table *without* losing data, use `ALTER TABLE ... REORGANIZE PARTITION` instead. See below or in [Section 13.1.7, “ALTER TABLE Syntax”](#), for information about `REORGANIZE PARTITION`.

If you now execute a `SHOW CREATE TABLE` statement, you can see how the partitioning makeup of the table has been changed:

```

mysql> SHOW CREATE TABLE tr\G

```

```
***** 1. row *****
Table: tr
Create Table: CREATE TABLE `tr` (
  `id` int(11) DEFAULT NULL,
  `name` varchar(50) DEFAULT NULL,
  `purchased` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY RANGE ( YEAR(purchased))
(PARTITION p0 VALUES LESS THAN (1990) ENGINE = InnoDB,
PARTITION p1 VALUES LESS THAN (1995) ENGINE = InnoDB,
PARTITION p3 VALUES LESS THAN (2005) ENGINE = InnoDB,
PARTITION p4 VALUES LESS THAN (2010) ENGINE = InnoDB,
PARTITION p5 VALUES LESS THAN (2015) ENGINE = InnoDB) */
1 row in set (0.00 sec)
```

When you insert new rows into the changed table with `purchased` column values between `'1995-01-01'` and `'2004-12-31'` inclusive, those rows will be stored in partition `p3`. You can verify this as follows:

```
mysql> INSERT INTO tr VALUES (11, 'pencil holder', '1995-07-12');
Query OK, 1 row affected (0.00 sec)

mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '2004-12-31';
+-----+-----+-----+
| id   | name           | purchased |
+-----+-----+-----+
| 1    | desk organiser | 2003-10-15 |
| 11   | pencil holder  | 1995-07-12 |
+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> ALTER TABLE tr DROP PARTITION p3;
Query OK, 0 rows affected (0.03 sec)

mysql> SELECT * FROM tr WHERE purchased
-> BETWEEN '1995-01-01' AND '2004-12-31';
Empty set (0.00 sec)
```

The number of rows dropped from the table as a result of `ALTER TABLE ... DROP PARTITION` is not reported by the server as it would be by the equivalent `DELETE` query.

Dropping `LIST` partitions uses exactly the same `ALTER TABLE ... DROP PARTITION` syntax as used for dropping `RANGE` partitions. However, there is one important difference in the effect this has on your use of the table afterward: You can no longer insert into the table any rows having any of the values that were included in the value list defining the deleted partition. (See [Section 22.2.2, “LIST Partitioning”](#), for an example.)

To add a new range or list partition to a previously partitioned table, use the `ALTER TABLE ... ADD PARTITION` statement. For tables which are partitioned by `RANGE`, this can be used to add a new range to the end of the list of existing partitions. Suppose that you have a partitioned table containing membership data for your organization, which is defined as follows:

```
CREATE TABLE members (
  id INT,
  fname VARCHAR(25),
  lname VARCHAR(25),
  dob DATE
)
PARTITION BY RANGE( YEAR(dob) ) (
  PARTITION p0 VALUES LESS THAN (1980),
  PARTITION p1 VALUES LESS THAN (1990),
  PARTITION p2 VALUES LESS THAN (2000)
);
```

Suppose further that the minimum age for members is 16. As the calendar approaches the end of 2015, you realize that you will soon be admitting members who were born in 2000 (and later). You can

modify the `members` table to accommodate new members born in the years 2000 to 2010 as shown here:

```
ALTER TABLE members ADD PARTITION (PARTITION p3 VALUES LESS THAN (2010));
```

With tables that are partitioned by range, you can use `ADD PARTITION` to add new partitions to the high end of the partitions list only. Trying to add a new partition in this manner between or before existing partitions results in an error as shown here:

```
mysql> ALTER TABLE members
> ADD PARTITION (
> PARTITION n VALUES LESS THAN (1970));
ERROR 1463 (HY000): VALUES LESS THAN value must be strictly »
increasing for each partition
```

You can work around this problem by reorganizing the first partition into two new ones that split the range between them, like this:

```
ALTER TABLE members
REORGANIZE PARTITION p0 INTO (
PARTITION n0 VALUES LESS THAN (1970),
PARTITION n1 VALUES LESS THAN (1980)
);
```

Using `SHOW CREATE TABLE` you can see that the `ALTER TABLE` statement has had the desired effect:

```
mysql> SHOW CREATE TABLE members\G
***** 1. row *****
Table: members
Create Table: CREATE TABLE `members` (
  `id` int(11) DEFAULT NULL,
  `fname` varchar(25) DEFAULT NULL,
  `lname` varchar(25) DEFAULT NULL,
  `dob` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY RANGE ( YEAR(dob))
(PARTITION n0 VALUES LESS THAN (1970) ENGINE = InnoDB,
PARTITION n1 VALUES LESS THAN (1980) ENGINE = InnoDB,
PARTITION p1 VALUES LESS THAN (1990) ENGINE = InnoDB,
PARTITION p2 VALUES LESS THAN (2000) ENGINE = InnoDB,
PARTITION p3 VALUES LESS THAN (2010) ENGINE = InnoDB) */
1 row in set (0.00 sec)
```

See also [Section 13.1.7.1, “ALTER TABLE Partition Operations”](#).

You can also use `ALTER TABLE ... ADD PARTITION` to add new partitions to a table that is partitioned by `LIST`. Suppose a table `tt` is defined using the following `CREATE TABLE` statement:

```
CREATE TABLE tt (
  id INT,
  data INT
)
PARTITION BY LIST(data) (
  PARTITION p0 VALUES IN (5, 10, 15),
  PARTITION p1 VALUES IN (6, 12, 18)
);
```

You can add a new partition in which to store rows having the `data` column values 7, 14, and 21 as shown:

```
ALTER TABLE tt ADD PARTITION (PARTITION p2 VALUES IN (7, 14, 21));
```

Keep in mind that you *cannot* add a new [LIST](#) partition encompassing any values that are already included in the value list of an existing partition. If you attempt to do so, an error will result:

```
mysql> ALTER TABLE tt ADD PARTITION
> (PARTITION np VALUES IN (4, 8, 12));
ERROR 1465 (HY000): Multiple definition of same constant »
in list partitioning
```

Because any rows with the `data` column value `12` have already been assigned to partition `p1`, you cannot create a new partition on table `tt` that includes `12` in its value list. To accomplish this, you could drop `p1`, and add `np` and then a new `p1` with a modified definition. However, as discussed earlier, this would result in the loss of all data stored in `p1`—and it is often the case that this is not what you really want to do. Another solution might appear to be to make a copy of the table with the new partitioning and to copy the data into it using `CREATE TABLE ... SELECT ...`, then drop the old table and rename the new one, but this could be very time-consuming when dealing with a large amounts of data. This also might not be feasible in situations where high availability is a requirement.

You can add multiple partitions in a single `ALTER TABLE ... ADD PARTITION` statement as shown here:

```
CREATE TABLE employees (
  id INT NOT NULL,
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  hired DATE NOT NULL
)
PARTITION BY RANGE( YEAR(hired) ) (
  PARTITION p1 VALUES LESS THAN (1991),
  PARTITION p2 VALUES LESS THAN (1996),
  PARTITION p3 VALUES LESS THAN (2001),
  PARTITION p4 VALUES LESS THAN (2005)
);

ALTER TABLE employees ADD PARTITION (
  PARTITION p5 VALUES LESS THAN (2010),
  PARTITION p6 VALUES LESS THAN MAXVALUE
);
```

Fortunately, MySQL's partitioning implementation provides ways to redefine partitions without losing data. Let us look first at a couple of simple examples involving [RANGE](#) partitioning. Recall the `members` table which is now defined as shown here:

```
mysql> SHOW CREATE TABLE members\G
***** 1. row *****
      Table: members
Create Table: CREATE TABLE `members` (
  `id` int(11) DEFAULT NULL,
  `fname` varchar(25) DEFAULT NULL,
  `lname` varchar(25) DEFAULT NULL,
  `dob` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
/*!50100 PARTITION BY RANGE ( YEAR(dob))
(PARTITION n0 VALUES LESS THAN (1970) ENGINE = InnoDB,
PARTITION n1 VALUES LESS THAN (1980) ENGINE = InnoDB,
PARTITION p1 VALUES LESS THAN (1990) ENGINE = InnoDB,
PARTITION p2 VALUES LESS THAN (2000) ENGINE = InnoDB,
PARTITION p3 VALUES LESS THAN (2010) ENGINE = InnoDB) */
1 row in set (0.00 sec)
```

Suppose that you would like to move all rows representing members born before 1960 into a separate partition. As we have already seen, this cannot be done using `ALTER TABLE ... ADD PARTITION`. However, you can use another partition-related extension to `ALTER TABLE` to accomplish this:

```
ALTER TABLE members REORGANIZE PARTITION n0 INTO (
```

```
PARTITION s0 VALUES LESS THAN (1960),
PARTITION s1 VALUES LESS THAN (1970)
);
```

In effect, this command splits partition `p0` into two new partitions `s0` and `s1`. It also moves the data that was stored in `p0` into the new partitions according to the rules embodied in the two `PARTITION ... VALUES ...` clauses, so that `s0` contains only those records for which `YEAR(dob)` is less than 1960 and `s1` contains those rows in which `YEAR(dob)` is greater than or equal to 1960 but less than 1970.

A `REORGANIZE PARTITION` clause may also be used for merging adjacent partitions. You can reverse the effect of the previous statement on the `members` table as shown here:

```
ALTER TABLE members REORGANIZE PARTITION s0,s1 INTO (
    PARTITION p0 VALUES LESS THAN (1970)
);
```

No data is lost in splitting or merging partitions using `REORGANIZE PARTITION`. In executing the above statement, MySQL moves all of the records that were stored in partitions `s0` and `s1` into partition `p0`.

The general syntax for `REORGANIZE PARTITION` is shown here:

```
ALTER TABLE tbl_name
    REORGANIZE PARTITION partition_list
    INTO (partition_definitions);
```

Here, `tbl_name` is the name of the partitioned table, and `partition_list` is a comma-separated list of names of one or more existing partitions to be changed. `partition_definitions` is a comma-separated list of new partition definitions, which follow the same rules as for the `partition_definitions` list used in `CREATE TABLE`. You are not limited to merging several partitions into one, or to splitting one partition into many, when using `REORGANIZE PARTITION`. For example, you can reorganize all four partitions of the `members` table into two, like this:

```
ALTER TABLE members REORGANIZE PARTITION p0,p1,p2,p3 INTO (
    PARTITION m0 VALUES LESS THAN (1980),
    PARTITION m1 VALUES LESS THAN (2000)
);
```

You can also use `REORGANIZE PARTITION` with tables that are partitioned by `LIST`. Let us return to the problem of adding a new partition to the list-partitioned `tt` table and failing because the new partition had a value that was already present in the value-list of one of the existing partitions. We can handle this by adding a partition that contains only nonconflicting values, and then reorganizing the new partition and the existing one so that the value which was stored in the existing one is now moved to the new one:

```
ALTER TABLE tt ADD PARTITION (PARTITION np VALUES IN (4, 8));
ALTER TABLE tt REORGANIZE PARTITION p1,np INTO (
    PARTITION p1 VALUES IN (6, 18),
    PARTITION np VALUES in (4, 8, 12)
);
```

Here are some key points to keep in mind when using `ALTER TABLE ... REORGANIZE PARTITION` to repartition tables that are partitioned by `RANGE` or `LIST`:

- The `PARTITION` options used to determine the new partitioning scheme are subject to the same rules as those used with a `CREATE TABLE` statement.

A new `RANGE` partitioning scheme cannot have any overlapping ranges; a new `LIST` partitioning scheme cannot have any overlapping sets of values.

- The combination of partitions in the `partition_definitions` list should account for the same range or set of values overall as the combined partitions named in the `partition_list`.

For example, partitions `p1` and `p2` together cover the years 1980 through 1999 in the `members` table used as an example in this section. Any reorganization of these two partitions should cover the same range of years overall.

- For tables partitioned by `RANGE`, you can reorganize only adjacent partitions; you cannot skip over range partitions.

For instance, you could not reorganize the example `members` table using a statement beginning with `ALTER TABLE members REORGANIZE PARTITION p0,p2 INTO ...` because `p0` covers the years prior to 1970 and `p2` the years from 1990 through 1999 inclusive, so these are not adjacent partitions. (You cannot skip partition `p1` in this case.)

- You cannot use `REORGANIZE PARTITION` to change the type of partitioning used by the table; for example, you cannot change `RANGE` partitions to `HASH` partitions or the reverse. You also cannot use this statement to change the partitioning expression or column. To accomplish either of these tasks without dropping and re-creating the table, you can use `ALTER TABLE ... PARTITION BY ...`, as shown here:

```
ALTER TABLE members
PARTITION BY HASH( YEAR(dob) )
PARTITIONS 8;
```

22.3.2 Management of HASH and KEY Partitions

Tables which are partitioned by hash or by key are very similar to one another with regard to making changes in a partitioning setup, and both differ in a number of ways from tables which have been partitioned by range or list. For that reason, this section addresses the modification of tables partitioned by hash or by key only. For a discussion of adding and dropping of partitions of tables that are partitioned by range or list, see [Section 22.3.1, “Management of RANGE and LIST Partitions”](#).

You cannot drop partitions from tables that are partitioned by `HASH` or `KEY` in the same way that you can from tables that are partitioned by `RANGE` or `LIST`. However, you can merge `HASH` or `KEY` partitions using `ALTER TABLE ... COALESCE PARTITION`. Suppose that a `clients` table containing data about clients is divided into 12 partitions, created as shown here:

```
CREATE TABLE clients (
  id INT,
  fname VARCHAR(30),
  lname VARCHAR(30),
  signed DATE
)
PARTITION BY HASH( MONTH(signed) )
PARTITIONS 12;
```

To reduce the number of partitions from 12 to 8, execute the following `ALTER TABLE` statement:

```
mysql> ALTER TABLE clients COALESCE PARTITION 4;
Query OK, 0 rows affected (0.02 sec)
```

`COALESCE` works equally well with tables that are partitioned by `HASH`, `KEY`, `LINEAR HASH`, or `LINEAR KEY`. Here is an example similar to the previous one, differing only in that the table is partitioned by `LINEAR KEY`:

```
mysql> CREATE TABLE clients_lk (
  id INT,
  fname VARCHAR(30),
  lname VARCHAR(30),
  signed DATE
)
PARTITION BY LINEAR KEY(signed)
```

```

PARTITIONS 12;
Query OK, 0 rows affected (0.03 sec)

mysql> ALTER TABLE clients_lk COALESCE PARTITION 4;
Query OK, 0 rows affected (0.06 sec)
Records: 0 Duplicates: 0 Warnings: 0

```

The number following `COALESCE PARTITION` is the number of partitions to merge into the remainder—in other words, it is the number of partitions to remove from the table.

Attempting to remove more partitions than are in the table results in an error like this one:

```

mysql> ALTER TABLE clients COALESCE PARTITION 18;
ERROR 1478 (HY000): Cannot remove all partitions, use DROP TABLE instead

```

To increase the number of partitions for the `clients` table from 12 to 18, use `ALTER TABLE ... ADD PARTITION` as shown here:

```
ALTER TABLE clients ADD PARTITION PARTITIONS 6;
```

22.3.3 Exchanging Partitions and Subpartitions with Tables

In MySQL 8.0, it is possible to exchange a table partition or subpartition with a table using `ALTER TABLE pt EXCHANGE PARTITION p WITH TABLE nt`, where *pt* is the partitioned table and *p* is the partition or subpartition of *pt* to be exchanged with unpartitioned table *nt*, provided that the following statements are true:

1. Table *nt* is not itself partitioned.
2. Table *nt* is not a temporary table.
3. The structures of tables *pt* and *nt* are otherwise identical.
4. Table *nt* contains no foreign key references, and no other table has any foreign keys that refer to *nt*.
5. There are no rows in *nt* that lie outside the boundaries of the partition definition for *p*. This condition does not apply if `WITHOUT VALIDATION` is used.

In addition to the `ALTER`, `INSERT`, and `CREATE` privileges usually required for `ALTER TABLE` statements, you must have the `DROP` privilege to perform `ALTER TABLE ... EXCHANGE PARTITION`.

You should also be aware of the following effects of `ALTER TABLE ... EXCHANGE PARTITION`:

- Executing `ALTER TABLE ... EXCHANGE PARTITION` does not invoke any triggers on either the partitioned table or the table to be exchanged.
- Any `AUTO_INCREMENT` columns in the exchanged table are reset.
- The `IGNORE` keyword has no effect when used with `ALTER TABLE ... EXCHANGE PARTITION`.

The syntax for `ALTER TABLE ... EXCHANGE PARTITION` is shown here, where *pt* is the partitioned table, *p* is the partition (or subpartition) to be exchanged, and *nt* is the nonpartitioned table to be exchanged with *p*:

```
ALTER TABLE pt
  EXCHANGE PARTITION p
  WITH TABLE nt;
```

Optionally, you can append `WITH VALIDATION` or `WITHOUT VALIDATION`. When `WITHOUT VALIDATION` is specified, the `ALTER TABLE ... EXCHANGE PARTITION` operation does not

perform any row-by-row validation when exchanging a partition a nonpartitioned table, allowing database administrators to assume responsibility for ensuring that rows are within the boundaries of the partition definition. `WITH VALIDATION` is the default.

One and only one partition or subpartition may be exchanged with one and only one nonpartitioned table in a single `ALTER TABLE EXCHANGE PARTITION` statement. To exchange multiple partitions or subpartitions, use multiple `ALTER TABLE EXCHANGE PARTITION` statements. `EXCHANGE PARTITION` may not be combined with other `ALTER TABLE` options. The partitioning and (if applicable) subpartitioning used by the partitioned table may be of any type or types supported in MySQL 8.0.

Exchanging a Partition with a Nonpartitioned Table

Suppose that a partitioned table `e` has been created and populated using the following SQL statements:

```
CREATE TABLE e (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30)
)
PARTITION BY RANGE (id) (
  PARTITION p0 VALUES LESS THAN (50),
  PARTITION p1 VALUES LESS THAN (100),
  PARTITION p2 VALUES LESS THAN (150),
  PARTITION p3 VALUES LESS THAN (MAXVALUE)
);

INSERT INTO e VALUES
  (1669, "Jim", "Smith"),
  (337, "Mary", "Jones"),
  (16, "Frank", "White"),
  (2005, "Linda", "Black");
```

Now we create a nonpartitioned copy of `e` named `e2`. This can be done using the `mysql` client as shown here:

```
mysql> CREATE TABLE e2 LIKE e;
Query OK, 0 rows affected (0.04 sec)

mysql> ALTER TABLE e2 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.07 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

You can see which partitions in table `e` contain rows by querying the `INFORMATION_SCHEMA.PARTITIONS` table, like this:

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS
FROM INFORMATION_SCHEMA.PARTITIONS
WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0              | 1           |
| p1              | 0           |
| p2              | 0           |
| p3              | 3           |
+-----+-----+
2 rows in set (0.00 sec)
```

Note

For partitioned `InnoDB` tables, the row count given in the `TABLE_ROWS` column of the `INFORMATION_SCHEMA.PARTITIONS` table is only an estimated value used in SQL optimization, and is not always exact.

To exchange partition `p0` in table `e` with table `e2`, you can use `ALTER TABLE`, as shown here:

```
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
Query OK, 0 rows affected (0.04 sec)
```

More precisely, the statement just issued causes any rows found in the partition to be swapped with those found in the table. You can observe how this has happened by querying the `INFORMATION_SCHEMA.PARTITIONS` table, as before. The table row that was previously found in partition `p0` is no longer present:

```
mysql> SELECT PARTITION_NAME, TABLE_ROWS
        FROM INFORMATION_SCHEMA.PARTITIONS
        WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0             |            0 |
| p1             |            0 |
| p2             |            0 |
| p3             |            3 |
+-----+-----+
4 rows in set (0.00 sec)
```

If you query table `e2`, you can see that the “missing” row can now be found there:

```
mysql> SELECT * FROM e2;
+----+-----+-----+
| id | fname | lname |
+----+-----+-----+
| 16 | Frank | White |
+----+-----+-----+
1 row in set (0.00 sec)
```

The table to be exchanged with the partition does not necessarily have to be empty. To demonstrate this, we first insert a new row into table `e`, making sure that this row is stored in partition `p0` by choosing an `id` column value that is less than 50, and verifying this afterward by querying the `PARTITIONS` table:

```
mysql> INSERT INTO e VALUES (41, "Michael", "Green");
Query OK, 1 row affected (0.05 sec)

mysql> SELECT PARTITION_NAME, TABLE_ROWS
        FROM INFORMATION_SCHEMA.PARTITIONS
        WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0             |            1 |
| p1             |            0 |
| p2             |            0 |
| p3             |            3 |
+-----+-----+
4 rows in set (0.00 sec)
```

Now we once again exchange partition `p0` with table `e2` using the same `ALTER TABLE` statement as previously:

```
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
Query OK, 0 rows affected (0.28 sec)
```

The output of the following queries shows that the table row that was stored in partition `p0` and the table row that was stored in table `e2`, prior to issuing the `ALTER TABLE` statement, have now switched places:

```
mysql> SELECT * FROM e;
+-----+-----+-----+
| id   | fname | lname |
+-----+-----+-----+
| 16   | Frank | White |
| 1669 | Jim   | Smith |
| 337  | Mary  | Jones |
| 2005 | Linda | Black |
+-----+-----+-----+
4 rows in set (0.00 sec)

mysql> SELECT PARTITION_NAME, TABLE_ROWS
       FROM INFORMATION_SCHEMA.PARTITIONS
       WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0             | 1           |
| p1             | 0           |
| p2             | 0           |
| p3             | 3           |
+-----+-----+
4 rows in set (0.00 sec)

mysql> SELECT * FROM e2;
+-----+-----+-----+
| id | fname   | lname |
+-----+-----+-----+
| 41 | Michael | Green |
+-----+-----+-----+
1 row in set (0.00 sec)
```

Nonmatching Rows

You should keep in mind that any rows found in the nonpartitioned table prior to issuing the `ALTER TABLE ... EXCHANGE PARTITION` statement must meet the conditions required for them to be stored in the target partition; otherwise, the statement fails. To see how this occurs, first insert a row into `e2` that is outside the boundaries of the partition definition for partition `p0` of table `e`. For example, insert a row with an `id` column value that is too large; then, try to exchange the table with the partition again:

```
mysql> INSERT INTO e2 VALUES (51, "Ellen", "McDonald");
Query OK, 1 row affected (0.08 sec)

mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2;
ERROR 1707 (HY000): Found row that does not match the partition
```

Only the `WITHOUT VALIDATION` option would permit this operation to succeed:

```
mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2 WITHOUT VALIDATION;
Query OK, 0 rows affected (0.02 sec)
```

When a partition is exchanged with a table that contains rows that do not match the partition definition, it is the responsibility of the database administrator to fix the non-matching rows, which can be performed using `REPAIR TABLE` or `ALTER TABLE ... REPAIR PARTITION`.

Exchanging Partitions Without Row-By-Row Validation

To avoid time consuming validation when exchanging a partition with a table that has many rows, it is possible to skip the row-by-row validation step by appending `WITHOUT VALIDATION` to the `ALTER TABLE ... EXCHANGE PARTITION` statement.

The following example compares the difference between execution times when exchanging a partition with a nonpartitioned table, with and without validation. The partitioned table (table `e`) contains two

partitions of 1 million rows each. The rows in p0 of table e are removed and p0 is exchanged with a nonpartitioned table of 1 million rows. The `WITH VALIDATION` operation takes 0.74 seconds. By comparison, the `WITHOUT VALIDATION` operation takes 0.01 seconds.

```
# Create a partitioned table with 1 million rows in each partition

CREATE TABLE e (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30)
)
PARTITION BY RANGE (id) (
  PARTITION p0 VALUES LESS THAN (1000001),
  PARTITION p1 VALUES LESS THAN (2000001),
);

mysql> SELECT COUNT(*) FROM e;
+-----+
| COUNT(*) |
+-----+
| 2000000 |
+-----+
1 row in set (0.27 sec)

# View the rows in each partition

SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0              | 1000000     |
| p1              | 1000000     |
+-----+-----+
2 rows in set (0.00 sec)

# Create a nonpartitioned table of the same structure and populate it with 1 million rows

CREATE TABLE e2 (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30)
);

mysql> SELECT COUNT(*) FROM e2;
+-----+
| COUNT(*) |
+-----+
| 1000000 |
+-----+
1 row in set (0.24 sec)

# Create another nonpartitioned table of the same structure and populate it with 1 million rows

CREATE TABLE e3 (
  id INT NOT NULL,
  fname VARCHAR(30),
  lname VARCHAR(30)
);

mysql> SELECT COUNT(*) FROM e3;
+-----+
| COUNT(*) |
+-----+
| 1000000 |
+-----+
1 row in set (0.25 sec)

# Drop the rows from p0 of table e

mysql> DELETE FROM e WHERE id < 1000001;
Query OK, 1000000 rows affected (5.55 sec)
```

```
# Confirm that there are no rows in partition p0

mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0              | 0           |
| p1              | 1000000    |
+-----+-----+
2 rows in set (0.00 sec)

# Exchange partition p0 of table e with the table e2 'WITH VALIDATION'

mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e2 WITH VALIDATION;
Query OK, 0 rows affected (0.74 sec)

# Confirm that the partition was exchanged with table e2

mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0              | 1000000    |
| p1              | 1000000    |
+-----+-----+
2 rows in set (0.00 sec)

# Once again, drop the rows from p0 of table e

mysql> DELETE FROM e WHERE id < 1000001;
Query OK, 1000000 rows affected (5.55 sec)

# Confirm that there are no rows in partition p0

mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0              | 0           |
| p1              | 1000000    |
+-----+-----+
2 rows in set (0.00 sec)

# Exchange partition p0 of table e with the table e3 'WITHOUT VALIDATION'

mysql> ALTER TABLE e EXCHANGE PARTITION p0 WITH TABLE e3 WITHOUT VALIDATION;
Query OK, 0 rows affected (0.01 sec)

# Confirm that the partition was exchanged with table e3

mysql> SELECT PARTITION_NAME, TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS WHERE TABLE_NAME = 'e';
+-----+-----+
| PARTITION_NAME | TABLE_ROWS |
+-----+-----+
| p0              | 1000000    |
| p1              | 1000000    |
+-----+-----+
2 rows in set (0.00 sec)
```

If a partition is exchanged with a table that contains rows that do not match the partition definition, it is the responsibility of the database administrator to fix the non-matching rows, which can be performed using [REPAIR TABLE](#) or [ALTER TABLE ... REPAIR PARTITION](#).

Exchanging a Subpartition with a Nonpartitioned Table

You can also exchange a subpartition of a subpartitioned table (see [Section 22.2.6, “Subpartitioning”](#)) with a nonpartitioned table using an [ALTER TABLE ... EXCHANGE PARTITION](#) statement. In the following example, we first create a table `es` that is partitioned by [RANGE](#) and subpartitioned by [KEY](#),

populate this table as we did table `e`, and then create an empty, nonpartitioned copy `es2` of the table, as shown here:

```
mysql> CREATE TABLE es (
->     id INT NOT NULL,
->     fname VARCHAR(30),
->     lname VARCHAR(30)
-> )
-> PARTITION BY RANGE (id)
-> SUBPARTITION BY KEY (lname)
-> SUBPARTITIONS 2 (
->     PARTITION p0 VALUES LESS THAN (50),
->     PARTITION p1 VALUES LESS THAN (100),
->     PARTITION p2 VALUES LESS THAN (150),
->     PARTITION p3 VALUES LESS THAN (MAXVALUE)
-> );
Query OK, 0 rows affected (2.76 sec)

mysql> INSERT INTO es VALUES
->     (1669, "Jim", "Smith"),
->     (337, "Mary", "Jones"),
->     (16, "Frank", "White"),
->     (2005, "Linda", "Black");
Query OK, 4 rows affected (0.04 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> CREATE TABLE es2 LIKE es;
Query OK, 0 rows affected (1.27 sec)

mysql> ALTER TABLE es2 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.70 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

Although we did not explicitly name any of the subpartitions when creating table `es`, we can obtain generated names for these by including the `SUBPARTITION_NAME` column of the `PARTITIONS` table from `INFORMATION_SCHEMA` when selecting from that table, as shown here:

```
mysql> SELECT PARTITION_NAME, SUBPARTITION_NAME, TABLE_ROWS
->     FROM INFORMATION_SCHEMA.PARTITIONS
->     WHERE TABLE_NAME = 'es';
+-----+-----+-----+
| PARTITION_NAME | SUBPARTITION_NAME | TABLE_ROWS |
+-----+-----+-----+
| p0              | p0sp0             | 1           |
| p0              | p0sp1             | 0           |
| p1              | p1sp0             | 0           |
| p1              | p1sp1             | 0           |
| p2              | p2sp0             | 0           |
| p2              | p2sp1             | 0           |
| p3              | p3sp0             | 3           |
| p3              | p3sp1             | 0           |
+-----+-----+-----+
8 rows in set (0.00 sec)
```

The following `ALTER TABLE` statement exchanges subpartition `p3sp0` in table `es` with the nonpartitioned table `es2`:

```
mysql> ALTER TABLE es EXCHANGE PARTITION p3sp0 WITH TABLE es2;
Query OK, 0 rows affected (0.29 sec)
```

You can verify that the rows were exchanged by issuing the following queries:

```
mysql> SELECT PARTITION_NAME, SUBPARTITION_NAME, TABLE_ROWS
->     FROM INFORMATION_SCHEMA.PARTITIONS
->     WHERE TABLE_NAME = 'es';
+-----+-----+-----+
| PARTITION_NAME | SUBPARTITION_NAME | TABLE_ROWS |
+-----+-----+-----+
```

```

+-----+-----+-----+
| PARTITION_NAME | SUBPARTITION_NAME | TABLE_ROWS |
+-----+-----+-----+
| p0              | p0sp0             | 1           |
| p0              | p0sp1             | 0           |
| p1              | p1sp0             | 0           |
| p1              | p1sp1             | 0           |
| p2              | p2sp0             | 0           |
| p2              | p2sp1             | 0           |
| p3              | p3sp0             | 0           |
| p3              | p3sp1             | 0           |
+-----+-----+-----+
8 rows in set (0.00 sec)

```

```

mysql> SELECT * FROM es2;
+-----+-----+-----+
| id   | fname | lname |
+-----+-----+-----+
| 1669 | Jim   | Smith |
| 337  | Mary  | Jones |
| 2005 | Linda | Black |
+-----+-----+-----+
3 rows in set (0.00 sec)

```

If a table is subpartitioned, you can exchange only a subpartition of the table—not an entire partition—with an unpartitioned table, as shown here:

```

mysql> ALTER TABLE es EXCHANGE PARTITION p3 WITH TABLE es2;
ERROR 1704 (HY000): Subpartitioned table, use subpartition instead of partition

```

Table structures are compared in a strict fashion; the number, order, names, and types of columns and indexes of the partitioned table and the nonpartitioned table must match exactly. In addition, both tables must use the same storage engine:

```

mysql> CREATE TABLE es3 LIKE e;
Query OK, 0 rows affected (1.31 sec)

mysql> ALTER TABLE es3 REMOVE PARTITIONING;
Query OK, 0 rows affected (0.53 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> SHOW CREATE TABLE es3\G
***** 1. row *****
      Table: es3
Create Table: CREATE TABLE `es3` (
  `id` int(11) NOT NULL,
  `fname` varchar(30) DEFAULT NULL,
  `lname` varchar(30) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4
1 row in set (0.00 sec)

mysql> ALTER TABLE es3 ENGINE = MyISAM;
Query OK, 0 rows affected (0.15 sec)
Records: 0 Duplicates: 0 Warnings: 0

mysql> ALTER TABLE es EXCHANGE PARTITION p3sp0 WITH TABLE es3;
ERROR 1497 (HY000): The mix of handlers in the partitions is not allowed in this version of MySQL

```

22.3.4 Maintenance of Partitions

A number of table and partition maintenance tasks can be carried out on partitioned tables using SQL statements intended for such purposes.

Table maintenance of partitioned tables can be accomplished using the statements [CHECK TABLE](#), [OPTIMIZE TABLE](#), [ANALYZE TABLE](#), and [REPAIR TABLE](#), which are supported for partitioned tables.

You can use a number of extensions to [ALTER TABLE](#) for performing operations of this type on one or more partitions directly, as described in the following list:

- **Rebuilding partitions.** Rebuilds the partition; this has the same effect as dropping all records stored in the partition, then reinserting them. This can be useful for purposes of defragmentation.

Example:

```
ALTER TABLE t1 REBUILD PARTITION p0, p1;
```

- **Optimizing partitions.** If you have deleted a large number of rows from a partition or if you have made many changes to a partitioned table with variable-length rows (that is, having `VARCHAR`, `BLOB`, or `TEXT` columns), you can use `ALTER TABLE ... OPTIMIZE PARTITION` to reclaim any unused space and to defragment the partition data file.

Example:

```
ALTER TABLE t1 OPTIMIZE PARTITION p0, p1;
```

Using `OPTIMIZE PARTITION` on a given partition is equivalent to running `CHECK PARTITION`, `ANALYZE PARTITION`, and `REPAIR PARTITION` on that partition.

Some MySQL storage engines, including `InnoDB`, do not support per-partition optimization; in these cases, `ALTER TABLE ... OPTIMIZE PARTITION` analyzes and rebuilds the entire table, and causes an appropriate warning to be issued. (Bug #11751825, Bug #42822) Use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION` instead, to avoid this issue.

- **Analyzing partitions.** This reads and stores the key distributions for partitions.

Example:

```
ALTER TABLE t1 ANALYZE PARTITION p3;
```

- **Repairing partitions.** This repairs corrupted partitions.

Example:

```
ALTER TABLE t1 REPAIR PARTITION p0,p1;
```

Normally, `REPAIR PARTITION` fails when the partition contains duplicate key errors. You can use `ALTER IGNORE TABLE` with this option, in which case all rows that cannot be moved due to the presence of duplicate keys are removed from the partition (Bug #16900947).

- **Checking partitions.** You can check partitions for errors in much the same way that you can use `CHECK TABLE` with nonpartitioned tables.

Example:

```
ALTER TABLE trb3 CHECK PARTITION p1;
```

This command will tell you whether the data or indexes in partition `p1` of table `t1` are corrupted. If this is the case, use `ALTER TABLE ... REPAIR PARTITION` to repair the partition.

Normally, `CHECK PARTITION` fails when the partition contains duplicate key errors. You can use `ALTER IGNORE TABLE` with this option, in which case the statement returns the contents of each row in the partition where a duplicate key violation is found. Only the values for the columns in the partitioning expression for the table are reported. (Bug #16900947)

Each of the statements in the list just shown also supports the keyword `ALL` in place of the list of partition names. Using `ALL` causes the statement to act on all partitions in the table.

You can also truncate partitions using `ALTER TABLE ... TRUNCATE PARTITION`. This statement can be used to delete all rows from one or more partitions in much the same way that `TRUNCATE TABLE` deletes all rows from a table.

`ALTER TABLE ... TRUNCATE PARTITION ALL` truncates all partitions in the table.

22.3.5 Obtaining Information About Partitions

This section discusses obtaining information about existing partitions, which can be done in a number of ways. Methods of obtaining such information include the following:

- Using the `SHOW CREATE TABLE` statement to view the partitioning clauses used in creating a partitioned table.
- Using the `SHOW TABLE STATUS` statement to determine whether a table is partitioned.
- Querying the `INFORMATION_SCHEMA.PARTITIONS` table.
- Using the statement `EXPLAIN SELECT` to see which partitions are used by a given `SELECT`.

As discussed elsewhere in this chapter, `SHOW CREATE TABLE` includes in its output the `PARTITION BY` clause used to create a partitioned table. For example:

```
mysql> SHOW CREATE TABLE trb3\G
***** 1. row *****
      Table: trb3
Create Table: CREATE TABLE `trb3` (
  `id` int(11) DEFAULT NULL,
  `name` varchar(50) DEFAULT NULL,
  `purchased` date DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4
/*!50100 PARTITION BY RANGE (YEAR(purchased))
(PARTITION p0 VALUES LESS THAN (1990) ENGINE = InnoDB,
PARTITION p1 VALUES LESS THAN (1995) ENGINE = InnoDB,
PARTITION p2 VALUES LESS THAN (2000) ENGINE = InnoDB,
PARTITION p3 VALUES LESS THAN (2005) ENGINE = InnoDB) */
0 row in set (0.00 sec)
```

The output from `SHOW TABLE STATUS` for partitioned tables is the same as that for nonpartitioned tables, except that the `Create_options` column contains the string `partitioned`. The `Engine` column contains the name of the storage engine used by all partitions of the table. (See [Section 13.7.5.36, “SHOW TABLE STATUS Syntax”](#), for more information about this statement.)

You can also obtain information about partitions from `INFORMATION_SCHEMA`, which contains a `PARTITIONS` table. See [Section 24.13, “The INFORMATION_SCHEMA PARTITIONS Table”](#).

It is possible to determine which partitions of a partitioned table are involved in a given `SELECT` query using `EXPLAIN`. The `partitions` column in the `EXPLAIN` output lists the partitions from which records would be matched by the query.

Suppose that a table `trb1` is created and populated as follows:

```
CREATE TABLE trb1 (id INT, name VARCHAR(50), purchased DATE)
PARTITION BY RANGE(id)
(
  PARTITION p0 VALUES LESS THAN (3),
  PARTITION p1 VALUES LESS THAN (7),
  PARTITION p2 VALUES LESS THAN (9),
  PARTITION p3 VALUES LESS THAN (11)
);

INSERT INTO trb1 VALUES
(1, 'desk organiser', '2003-10-15'),
(2, 'CD player', '1993-11-05'),
```

```
(3, 'TV set', '1996-03-10'),
(4, 'bookcase', '1982-01-10'),
(5, 'exercise bike', '2004-05-09'),
(6, 'sofa', '1987-06-05'),
(7, 'popcorn maker', '2001-11-22'),
(8, 'aquarium', '1992-08-04'),
(9, 'study desk', '1984-09-16'),
(10, 'lava lamp', '1998-12-25');
```

You can see which partitions are used in a query such as `SELECT * FROM trb1;`, as shown here:

```
mysql> EXPLAIN SELECT * FROM trb1\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: trb1
  partitions: p0,p1,p2,p3
         type: ALL
possible_keys: NULL
         key: NULL
      key_len: NULL
         ref: NULL
         rows: 10
      Extra: Using filesort
```

In this case, all four partitions are searched. However, when a limiting condition making use of the partitioning key is added to the query, you can see that only those partitions containing matching values are scanned, as shown here:

```
mysql> EXPLAIN SELECT * FROM trb1 WHERE id < 5\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: trb1
  partitions: p0,p1
         type: ALL
possible_keys: NULL
         key: NULL
      key_len: NULL
         ref: NULL
         rows: 10
      Extra: Using where
```

`EXPLAIN` also provides information about keys used and possible keys:

```
mysql> ALTER TABLE trb1 ADD PRIMARY KEY (id);
Query OK, 10 rows affected (0.03 sec)
Records: 10 Duplicates: 0 Warnings: 0

mysql> EXPLAIN SELECT * FROM trb1 WHERE id < 5\G
***** 1. row *****
      id: 1
  select_type: SIMPLE
        table: trb1
  partitions: p0,p1
         type: range
possible_keys: PRIMARY
         key: PRIMARY
      key_len: 4
         ref: NULL
         rows: 7
      Extra: Using where
```

If `EXPLAIN` is used to examine a query against a nonpartitioned table, no error is produced, but the value of the `partitions` column is always `NULL`.

The `rows` column of `EXPLAIN` output displays the total number of rows in the table.

See also [Section 13.8.2, “EXPLAIN Syntax”](#).

22.4 Partition Pruning

The optimization known as *partition pruning* is based on a relatively simple concept which can be described as “Do not scan partitions where there can be no matching values”. Suppose a partitioned table `t1` is created by this statement:

```
CREATE TABLE t1 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY RANGE( region_code ) (
  PARTITION p0 VALUES LESS THAN (64),
  PARTITION p1 VALUES LESS THAN (128),
  PARTITION p2 VALUES LESS THAN (192),
  PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

Suppose that you wish to obtain results from a `SELECT` statement such as this one:

```
SELECT fname, lname, region_code, dob
FROM t1
WHERE region_code > 125 AND region_code < 130;
```

It is easy to see that none of the rows which ought to be returned are in either of the partitions `p0` or `p3`; that is, we need search only in partitions `p1` and `p2` to find matching rows. By limiting the search, it is possible to expend much less time and effort in finding matching rows than by scanning all partitions in the table. This “cutting away” of unneeded partitions is known as *pruning*. When the optimizer can make use of partition pruning in performing this query, execution of the query can be an order of magnitude faster than the same query against a nonpartitioned table containing the same column definitions and data.

The optimizer can perform pruning whenever a `WHERE` condition can be reduced to either one of the following two cases:

- `partition_column = constant`
- `partition_column IN (constant1, constant2, ..., constantN)`

In the first case, the optimizer simply evaluates the partitioning expression for the value given, determines which partition contains that value, and scans only this partition. In many cases, the equal sign can be replaced with another arithmetic comparison, including `<`, `>`, `<=`, `>=`, and `<>`. Some queries using `BETWEEN` in the `WHERE` clause can also take advantage of partition pruning. See the examples later in this section.

In the second case, the optimizer evaluates the partitioning expression for each value in the list, creates a list of matching partitions, and then scans only the partitions in this partition list.

`SELECT`, `DELETE`, and `UPDATE` statements support partition pruning. `INSERT` statements currently cannot be pruned.

Pruning can also be applied to short ranges, which the optimizer can convert into equivalent lists of values. For instance, in the previous example, the `WHERE` clause can be converted to `WHERE region_code IN (126, 127, 128, 129)`. Then the optimizer can determine that the first two values in the list are found in partition `p1`, the remaining two values in partition `p2`, and that the other partitions contain no relevant values and so do not need to be searched for matching rows.

The optimizer can also perform pruning for `WHERE` conditions that involve comparisons of the preceding types on multiple columns for tables that use `RANGE COLUMNS` or `LIST COLUMNS` partitioning.

This type of optimization can be applied whenever the partitioning expression consists of an equality or a range which can be reduced to a set of equalities, or when the partitioning expression represents an increasing or decreasing relationship. Pruning can also be applied for tables partitioned on a `DATE` or `DATETIME` column when the partitioning expression uses the `YEAR()` or `TO_DAYS()` function. Pruning can also be applied for such tables when the partitioning expression uses the `TO_SECONDS()` function.

Suppose that table `t2`, partitioned on a `DATE` column, is created using the statement shown here:

```
CREATE TABLE t2 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY RANGE( YEAR(dob) ) (
  PARTITION d0 VALUES LESS THAN (1970),
  PARTITION d1 VALUES LESS THAN (1975),
  PARTITION d2 VALUES LESS THAN (1980),
  PARTITION d3 VALUES LESS THAN (1985),
  PARTITION d4 VALUES LESS THAN (1990),
  PARTITION d5 VALUES LESS THAN (2000),
  PARTITION d6 VALUES LESS THAN (2005),
  PARTITION d7 VALUES LESS THAN MAXVALUE
);
```

The following statements using `t2` can make use of partition pruning:

```
SELECT * FROM t2 WHERE dob = '1982-06-23';

UPDATE t2 SET region_code = 8 WHERE dob BETWEEN '1991-02-15' AND '1997-04-25';

DELETE FROM t2 WHERE dob >= '1984-06-21' AND dob <= '1999-06-21'
```

In the case of the last statement, the optimizer can also act as follows:

1. *Find the partition containing the low end of the range.*
`YEAR('1984-06-21')` yields the value `1984`, which is found in partition `d3`.
2. *Find the partition containing the high end of the range.*
`YEAR('1999-06-21')` evaluates to `1999`, which is found in partition `d5`.
3. *Scan only these two partitions and any partitions that may lie between them.*

In this case, this means that only partitions `d3`, `d4`, and `d5` are scanned. The remaining partitions may be safely ignored (and are ignored).

Important

Invalid `DATE` and `DATETIME` values referenced in the `WHERE` condition of a statement against a partitioned table are treated as `NULL`. This means that a query such as `SELECT * FROM partitioned_table WHERE date_column < '2008-12-00'` does not return any values (see Bug #40972).

So far, we have looked only at examples using `RANGE` partitioning, but pruning can be applied with other partitioning types as well.

Consider a table that is partitioned by `LIST`, where the partitioning expression is increasing or decreasing, such as the table `t3` shown here. (In this example, we assume for the sake of brevity that the `region_code` column is limited to values between 1 and 10 inclusive.)

```
CREATE TABLE t3 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY LIST(region_code) (
  PARTITION r0 VALUES IN (1, 3),
  PARTITION r1 VALUES IN (2, 5, 8),
  PARTITION r2 VALUES IN (4, 9),
  PARTITION r3 VALUES IN (6, 7, 10)
);
```

For a statement such as `SELECT * FROM t3 WHERE region_code BETWEEN 1 AND 3`, the optimizer determines in which partitions the values 1, 2, and 3 are found (`r0` and `r1`) and skips the remaining ones (`r2` and `r3`).

For tables that are partitioned by `HASH` or `[LINEAR] KEY`, partition pruning is also possible in cases in which the `WHERE` clause uses a simple `=` relation against a column used in the partitioning expression. Consider a table created like this:

```
CREATE TABLE t4 (
  fname VARCHAR(50) NOT NULL,
  lname VARCHAR(50) NOT NULL,
  region_code TINYINT UNSIGNED NOT NULL,
  dob DATE NOT NULL
)
PARTITION BY KEY(region_code)
PARTITIONS 8;
```

A statement that compares a column value with a constant can be pruned:

```
UPDATE t4 WHERE region_code = 7;
```

Pruning can also be employed for short ranges, because the optimizer can turn such conditions into `IN` relations. For example, using the same table `t4` as defined previously, queries such as these can be pruned:

```
SELECT * FROM t4 WHERE region_code > 2 AND region_code < 6;
SELECT * FROM t4 WHERE region_code BETWEEN 3 AND 5;
```

In both these cases, the `WHERE` clause is transformed by the optimizer into `WHERE region_code IN (3, 4, 5)`.

Important

This optimization is used only if the range size is smaller than the number of partitions. Consider this statement:

```
DELETE FROM t4 WHERE region_code BETWEEN 4 AND 12;
```

The range in the `WHERE` clause covers 9 values (4, 5, 6, 7, 8, 9, 10, 11, 12), but `t4` has only 8 partitions. This means that the `DELETE` cannot be pruned.

When a table is partitioned by `HASH` or `[LINEAR] KEY`, pruning can be used only on integer columns. For example, this statement cannot use pruning because `dob` is a `DATE` column:

```
SELECT * FROM t4 WHERE dob >= '2001-04-14' AND dob <= '2005-10-15';
```

However, if the table stores year values in an `INT` column, then a query having `WHERE year_col >= 2001 AND year_col <= 2005` can be pruned.

Tables using a storage engine that provides automatic partitioning, such as the [NDB](#) storage engine used by MySQL Cluster (not currently supported in MySQL 8.0), can be pruned if they are explicitly partitioned.

22.5 Partition Selection

Explicit selection of partitions and subpartitions for rows matching a given [WHERE](#) condition is supported. Partition selection is similar to partition pruning, in that only specific partitions are checked for matches, but differs in two key respects:

1. The partitions to be checked are specified by the issuer of the statement, unlike partition pruning, which is automatic.
2. Whereas partition pruning applies only to queries, explicit selection of partitions is supported for both queries and a number of DML statements.

SQL statements supporting explicit partition selection are listed here:

- [SELECT](#)
- [DELETE](#)
- [INSERT](#)
- [REPLACE](#)
- [UPDATE](#)
- [LOAD DATA](#).
- [LOAD XML](#).

The remainder of this section discusses explicit partition selection as it applies generally to the statements just listed, and provides some examples.

Explicit partition selection is implemented using a [PARTITION](#) option. For all supported statements, this option uses the syntax shown here:

```
PARTITION (partition_names)  
  
partition_names:  
    partition_name, ...
```

This option always follows the name of the table to which the partition or partitions belong. *partition_names* is a comma-separated list of partitions or subpartitions to be used. Each name in this list must be the name of an existing partition or subpartition of the specified table; if any of the partitions or subpartitions are not found, the statement fails with an error (`partition 'partition_name' doesn't exist`). Partitions and subpartitions named in *partition_names* may be listed in any order, and may overlap.

When the [PARTITION](#) option is used, only the partitions and subpartitions listed are checked for matching rows. This option can be used in a [SELECT](#) statement to determine which rows belong to a given partition. Consider a partitioned table named `employees`, created and populated using the statements shown here:

```
SET @@SQL_MODE = '';  
  
CREATE TABLE employees (  
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,  
    fname VARCHAR(25) NOT NULL,  
    lname VARCHAR(25) NOT NULL,  
    store_id INT NOT NULL,  
    department_id INT NOT NULL
```

```

)
PARTITION BY RANGE(id) (
PARTITION p0 VALUES LESS THAN (5),
PARTITION p1 VALUES LESS THAN (10),
PARTITION p2 VALUES LESS THAN (15),
PARTITION p3 VALUES LESS THAN MAXVALUE
);

INSERT INTO employees VALUES
(' ', 'Bob', 'Taylor', 3, 2), (' ', 'Frank', 'Williams', 1, 2),
(' ', 'Ellen', 'Johnson', 3, 4), (' ', 'Jim', 'Smith', 2, 4),
(' ', 'Mary', 'Jones', 1, 1), (' ', 'Linda', 'Black', 2, 3),
(' ', 'Ed', 'Jones', 2, 1), (' ', 'June', 'Wilson', 3, 1),
(' ', 'Andy', 'Smith', 1, 3), (' ', 'Lou', 'Waters', 2, 4),
(' ', 'Jill', 'Stone', 1, 4), (' ', 'Roger', 'White', 3, 2),
(' ', 'Howard', 'Andrews', 1, 2), (' ', 'Fred', 'Goldberg', 3, 3),
(' ', 'Barbara', 'Brown', 2, 3), (' ', 'Alice', 'Rogers', 2, 2),
(' ', 'Mark', 'Morgan', 3, 3), (' ', 'Karen', 'Cole', 3, 2);

```

You can see which rows are stored in partition `p1` like this:

```

mysql> SELECT * FROM employees PARTITION (p1);
+-----+-----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+-----+-----+-----+-----+-----+
| 5 | Mary | Jones | 1 | 1 |
| 6 | Linda | Black | 2 | 3 |
| 7 | Ed | Jones | 2 | 1 |
| 8 | June | Wilson | 3 | 1 |
| 9 | Andy | Smith | 1 | 3 |
+-----+-----+-----+-----+-----+
5 rows in set (0.00 sec)

```

The result is the same as obtained by the query `SELECT * FROM employees WHERE id BETWEEN 5 AND 9`.

To obtain rows from multiple partitions, supply their names as a comma-delimited list. For example, `SELECT * FROM employees PARTITION (p1, p2)` returns all rows from partitions `p1` and `p2` while excluding rows from the remaining partitions.

Any valid query against a partitioned table can be rewritten with a `PARTITION` option to restrict the result to one or more desired partitions. You can use `WHERE` conditions, `ORDER BY` and `LIMIT` options, and so on. You can also use aggregate functions with `HAVING` and `GROUP BY` options. Each of the following queries produces a valid result when run on the `employees` table as previously defined:

```

mysql> SELECT * FROM employees PARTITION (p0, p2)
-> WHERE lname LIKE 'S%';
+-----+-----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+-----+-----+-----+-----+-----+
| 4 | Jim | Smith | 2 | 4 |
| 11 | Jill | Stone | 1 | 4 |
+-----+-----+-----+-----+-----+
2 rows in set (0.00 sec)

mysql> SELECT id, CONCAT(fname, ' ', lname) AS name
-> FROM employees PARTITION (p0) ORDER BY lname;
+-----+-----+
| id | name |
+-----+-----+
| 3 | Ellen Johnson |
| 4 | Jim Smith |
| 1 | Bob Taylor |
| 2 | Frank Williams |
+-----+-----+
4 rows in set (0.06 sec)

mysql> SELECT store_id, COUNT(department_id) AS c

```

```

-> FROM employees PARTITION (p1,p2,p3)
-> GROUP BY store_id HAVING c > 4;
+-----+
| c | store_id |
+-----+
| 5 | 2 |
| 5 | 3 |
+-----+
2 rows in set (0.00 sec)

```

Statements using partition selection can be employed with tables using any of the supported partitioning types. When a table is created using `[LINEAR] HASH` or `[LINEAR] KEY` partitioning and the names of the partitions are not specified, MySQL automatically names the partitions `p0`, `p1`, `p2`, ..., `pN-1`, where `N` is the number of partitions. For subpartitions not explicitly named, MySQL assigns automatically to the subpartitions in each partition `pX` the names `pXsp0`, `pXsp1`, `pXsp2`, ..., `pXspM-1`, where `M` is the number of subpartitions. When executing against this table a `SELECT` (or other SQL statement for which explicit partition selection is allowed), you can use these generated names in a `PARTITION` option, as shown here:

```

mysql> CREATE TABLE employees_sub (
->   id INT NOT NULL AUTO_INCREMENT,
->   fname VARCHAR(25) NOT NULL,
->   lname VARCHAR(25) NOT NULL,
->   store_id INT NOT NULL,
->   department_id INT NOT NULL,
->   PRIMARY KEY pk (id, lname)
-> )
-> PARTITION BY RANGE(id)
-> SUBPARTITION BY KEY (lname)
-> SUBPARTITIONS 2 (
->   PARTITION p0 VALUES LESS THAN (5),
->   PARTITION p1 VALUES LESS THAN (10),
->   PARTITION p2 VALUES LESS THAN (15),
->   PARTITION p3 VALUES LESS THAN MAXVALUE
-> );
Query OK, 0 rows affected (1.14 sec)

mysql> INSERT INTO employees_sub # reuse data in employees table
->   SELECT * FROM employees;
Query OK, 18 rows affected (0.09 sec)
Records: 18 Duplicates: 0 Warnings: 0

mysql> SELECT id, CONCAT(fname, ' ', lname) AS name
->   FROM employees_sub PARTITION (p2sp1);
+-----+
| id | name          |
+-----+
| 10 | Lou Waters    |
| 14 | Fred Goldberg |
+-----+
2 rows in set (0.00 sec)

```

You may also use a `PARTITION` option in the `SELECT` portion of an `INSERT ... SELECT` statement, as shown here:

```

mysql> CREATE TABLE employees_copy LIKE employees;
Query OK, 0 rows affected (0.28 sec)

mysql> INSERT INTO employees_copy
->   SELECT * FROM employees PARTITION (p2);
Query OK, 5 rows affected (0.04 sec)
Records: 5 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM employees_copy;
+-----+-----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+-----+-----+-----+-----+-----+
| 10 | Lou   | Waters | 2        | 4             |
+-----+-----+-----+-----+-----+

```

11	Jill	Stone	1	4
12	Roger	White	3	2
13	Howard	Andrews	1	2
14	Fred	Goldberg	3	3

5 rows in set (0.00 sec)

Partition selection can also be used with joins. Suppose we create and populate two tables using the statements shown here:

```
CREATE TABLE stores (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  city VARCHAR(30) NOT NULL
)
PARTITION BY HASH(id)
PARTITIONS 2;

INSERT INTO stores VALUES
  ('', 'Nambucca'), ('', 'Uranga'),
  ('', 'Bellinghen'), ('', 'Grafton');

CREATE TABLE departments (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(30) NOT NULL
)
PARTITION BY KEY(id)
PARTITIONS 2;

INSERT INTO departments VALUES
  ('', 'Sales'), ('', 'Customer Service'),
  ('', 'Delivery'), ('', 'Accounting');
```

You can explicitly select partitions (or subpartitions, or both) from any or all of the tables in a join. (The `PARTITION` option used to select partitions from a given table immediately follows the name of the table, before all other options, including any table alias.) For example, the following query gets the name, employee ID, department, and city of all employees who work in the Sales or Delivery department (partition `p1` of the `departments` table) at the stores in either of the cities of Nambucca and Bellinghen (partition `p0` of the `stores` table):

```
mysql> SELECT
->   e.id AS 'Employee ID', CONCAT(e.fname, ' ', e.lname) AS Name,
->   s.city AS City, d.name AS department
-> FROM employees AS e
-> JOIN stores PARTITION (p1) AS s ON e.store_id=s.id
-> JOIN departments PARTITION (p0) AS d ON e.department_id=d.id
-> ORDER BY e.lname;
```

Employee ID	Name	City	department
14	Fred Goldberg	Bellinghen	Delivery
5	Mary Jones	Nambucca	Sales
17	Mark Morgan	Bellinghen	Delivery
9	Andy Smith	Nambucca	Delivery
8	June Wilson	Bellinghen	Sales

5 rows in set (0.00 sec)

For general information about joins in MySQL, see [Section 13.2.10.2, “JOIN Syntax”](#).

When the `PARTITION` option is used with `DELETE` statements, only those partitions (and subpartitions, if any) listed with the option are checked for rows to be deleted. Any other partitions are ignored, as shown here:

```
mysql> SELECT * FROM employees WHERE fname LIKE 'j%';
```

id	fname	lname	store_id	department_id
----	-------	-------	----------	---------------

```

| 4 | Jim | Smith | 2 | 4 |
| 8 | June | Wilson | 3 | 1 |
| 11 | Jill | Stone | 1 | 4 |
+-----+-----+-----+-----+
3 rows in set (0.00 sec)

mysql> DELETE FROM employees PARTITION (p0, p1)
      -> WHERE fname LIKE 'j%';
Query OK, 2 rows affected (0.09 sec)

mysql> SELECT * FROM employees WHERE fname LIKE 'j%';
+-----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+-----+-----+-----+-----+
| 11 | Jill | Stone | 1 | 4 |
+-----+-----+-----+-----+
1 row in set (0.00 sec)

```

Only the two rows in partitions `p0` and `p1` matching the `WHERE` condition were deleted. As you can see from the result when the `SELECT` is run a second time, there remains a row in the table matching the `WHERE` condition, but residing in a different partition (`p2`).

`UPDATE` statements using explicit partition selection behave in the same way; only rows in the partitions referenced by the `PARTITION` option are considered when determining the rows to be updated, as can be seen by executing the following statements:

```

mysql> UPDATE employees PARTITION (p0)
      -> SET store_id = 2 WHERE fname = 'Jill';
Query OK, 0 rows affected (0.00 sec)
Rows matched: 0 Changed: 0 Warnings: 0

mysql> SELECT * FROM employees WHERE fname = 'Jill';
+-----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+-----+-----+-----+-----+
| 11 | Jill | Stone | 1 | 4 |
+-----+-----+-----+-----+
1 row in set (0.00 sec)

mysql> UPDATE employees PARTITION (p2)
      -> SET store_id = 2 WHERE fname = 'Jill';
Query OK, 1 row affected (0.09 sec)
Rows matched: 1 Changed: 1 Warnings: 0

mysql> SELECT * FROM employees WHERE fname = 'Jill';
+-----+-----+-----+-----+
| id | fname | lname | store_id | department_id |
+-----+-----+-----+-----+
| 11 | Jill | Stone | 2 | 4 |
+-----+-----+-----+-----+
1 row in set (0.00 sec)

```

In the same way, when `PARTITION` is used with `DELETE`, only rows in the partition or partitions named in the partition list are checked for deletion.

For statements that insert rows, the behavior differs in that failure to find a suitable partition causes the statement to fail. This is true for both `INSERT` and `REPLACE` statements, as shown here:

```

mysql> INSERT INTO employees PARTITION (p2) VALUES (20, 'Jan', 'Jones', 1, 3);
ERROR 1729 (HY000): Found a row not matching the given partition set
mysql> INSERT INTO employees PARTITION (p3) VALUES (20, 'Jan', 'Jones', 1, 3);
Query OK, 1 row affected (0.07 sec)

mysql> REPLACE INTO employees PARTITION (p0) VALUES (20, 'Jan', 'Jones', 3, 2);
ERROR 1729 (HY000): Found a row not matching the given partition set

mysql> REPLACE INTO employees PARTITION (p3) VALUES (20, 'Jan', 'Jones', 3, 2);
Query OK, 2 rows affected (0.09 sec)

```

For statements that write multiple rows to a partitioned table that using the [InnoDB](#) storage engine: If any row in the list following [VALUES](#) cannot be written to one of the partitions specified in the [partition_names](#) list, the entire statement fails and no rows are written. This is shown for [INSERT](#) statements in the following example, reusing the [employees](#) table created previously:

```
mysql> ALTER TABLE employees
->     REORGANIZE PARTITION p3 INTO (
->         PARTITION p3 VALUES LESS THAN (20),
->         PARTITION p4 VALUES LESS THAN (25),
->         PARTITION p5 VALUES LESS THAN MAXVALUE
->     );
Query OK, 6 rows affected (2.09 sec)
Records: 6  Duplicates: 0  Warnings: 0

mysql> SHOW CREATE TABLE employees\G
***** 1. row *****
      Table: employees
Create Table: CREATE TABLE `employees` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `fname` varchar(25) NOT NULL,
  `lname` varchar(25) NOT NULL,
  `store_id` int(11) NOT NULL,
  `department_id` int(11) NOT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB AUTO_INCREMENT=27 DEFAULT CHARSET=utf8mb4
/*!50100 PARTITION BY RANGE (id)
(PARTITION p0 VALUES LESS THAN (5) ENGINE = InnoDB,
PARTITION p1 VALUES LESS THAN (10) ENGINE = InnoDB,
PARTITION p2 VALUES LESS THAN (15) ENGINE = InnoDB,
PARTITION p3 VALUES LESS THAN (20) ENGINE = InnoDB,
PARTITION p4 VALUES LESS THAN (25) ENGINE = InnoDB,
PARTITION p5 VALUES LESS THAN MAXVALUE ENGINE = InnoDB) */
1 row in set (0.00 sec)

mysql> INSERT INTO employees PARTITION (p3, p4) VALUES
->     (24, 'Tim', 'Greene', 3, 1), (26, 'Linda', 'Mills', 2, 1);
ERROR 1729 (HY000): Found a row not matching the given partition set

mysql> INSERT INTO employees PARTITION (p3, p4, p5) VALUES
->     (24, 'Tim', 'Greene', 3, 1), (26, 'Linda', 'Mills', 2, 1);
Query OK, 2 rows affected (0.06 sec)
Records: 2  Duplicates: 0  Warnings: 0
```

The preceding is true for both [INSERT](#) statements and [REPLACE](#) statements that write multiple rows.

Partition selection is disabled for tables employing a storage engine that supplies automatic partitioning, such as [NDB](#) (used with MySQL Cluster; not currently supported in MySQL 8.0).

22.6 Restrictions and Limitations on Partitioning

This section discusses current restrictions and limitations on MySQL partitioning support.

Prohibited constructs. The following constructs are not permitted in partitioning expressions:

- Stored procedures, stored functions, UDFs, or plugins.
- Declared variables or user variables.

For a list of SQL functions which are permitted in partitioning expressions, see [Section 22.6.3](#), “[Partitioning Limitations Relating to Functions](#)”.

Arithmetic and logical operators. Use of the arithmetic operators `+`, `-`, and `*` is permitted in partitioning expressions. However, the result must be an integer value or `NULL` (except in the case of [\[LINEAR\] KEY](#) partitioning, as discussed elsewhere in this chapter; see [Section 22.2](#), “[Partitioning Types](#)”, for more information).

The `DIV` operator is also supported; the `/` operator is not permitted.

The bit operators `|`, `&`, `^`, `<<`, `>>`, and `~` are not permitted in partitioning expressions.

Server SQL mode. Tables employing user-defined partitioning do not preserve the SQL mode in effect at the time that they were created. As discussed elsewhere in this Manual (see [Section 5.1.8, “Server SQL Modes”](#)), the results of many MySQL functions and operators may change according to the server SQL mode. Therefore, a change in the SQL mode at any time after the creation of partitioned tables may lead to major changes in the behavior of such tables, and could easily lead to corruption or loss of data. For these reasons, *it is strongly recommended that you never change the server SQL mode after creating partitioned tables.*

Examples. The following examples illustrate some changes in behavior of partitioned tables due to a change in the server SQL mode:

1. **Error handling.** As discussed elsewhere, handling of “special” values such as zero and `NULL` can differ between different server SQL modes (see [Section 5.1.8, “Server SQL Modes”](#)). For example, `ERROR_FOR_DIVISION_BY_ZERO` can affect whether or not 0 can be inserted as a value into a table whose partitioning expression uses `column DIV value` or `column MOD value`.
2. **Table accessibility.** Sometimes a change in the server SQL mode can make partitioned tables unusable. The following `CREATE TABLE` statement can be executed successfully only if the `NO_UNSIGNED_SUBTRACTION` mode is in effect:

```
mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
|             |
+-----+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
-> PARTITION BY RANGE(c1 - 10) (
-> PARTITION p0 VALUES LESS THAN (-5),
-> PARTITION p1 VALUES LESS THAN (0),
-> PARTITION p2 VALUES LESS THAN (5),
-> PARTITION p3 VALUES LESS THAN (10),
-> PARTITION p4 VALUES LESS THAN (MAXVALUE)
-> );
ERROR 1563 (HY000): Partition constant is out of partition function domain

mysql> SET sql_mode='NO_UNSIGNED_SUBTRACTION';
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@sql_mode;
+-----+
| @@sql_mode |
+-----+
| NO_UNSIGNED_SUBTRACTION |
+-----+
1 row in set (0.00 sec)

mysql> CREATE TABLE tu (c1 BIGINT UNSIGNED)
-> PARTITION BY RANGE(c1 - 10) (
-> PARTITION p0 VALUES LESS THAN (-5),
-> PARTITION p1 VALUES LESS THAN (0),
-> PARTITION p2 VALUES LESS THAN (5),
-> PARTITION p3 VALUES LESS THAN (10),
-> PARTITION p4 VALUES LESS THAN (MAXVALUE)
-> );
Query OK, 0 rows affected (0.05 sec)
```

If you remove the `NO_UNSIGNED_SUBTRACTION` server SQL mode after creating `tu`, you may no longer be able to access this table:

```
mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> SELECT * FROM tu;
ERROR 1563 (HY000): Partition constant is out of partition function domain
mysql> INSERT INTO tu VALUES (20);
ERROR 1563 (HY000): Partition constant is out of partition function domain
```

See also [Section 5.1.8, “Server SQL Modes”](#).

Server SQL modes also impact replication of partitioned tables. Disparate SQL modes on master and slave can lead to partitioning expressions being evaluated differently; this can cause the distribution of data among partitions to be different in the master's and slave's copies of a given table, and may even cause inserts into partitioned tables that succeed on the master to fail on the slave. For best results, you should always use the same server SQL mode on the master and on the slave.

Performance considerations. Some effects of partitioning operations on performance are given in the following list:

- **File system operations.** Partitioning and repartitioning operations (such as `ALTER TABLE` with `PARTITION BY ...`, `REORGANIZE PARTITION`, or `REMOVE PARTITIONING`) depend on file system operations for their implementation. This means that the speed of these operations is affected by such factors as file system type and characteristics, disk speed, swap space, file handling efficiency of the operating system, and MySQL server options and variables that relate to file handling. In particular, you should make sure that `large_files_support` is enabled and that `open_files_limit` is set properly. Partitioning and repartitioning operations involving InnoDB tables may be made more efficient by enabling `innodb_file_per_table`.

See also [Maximum number of partitions](#).

- **Table locks.** Generally, the process executing a partitioning operation on a table takes a write lock on the table. Reads from such tables are relatively unaffected; pending `INSERT` and `UPDATE` operations are performed as soon as the partitioning operation has completed. For InnoDB-specific exceptions to this limitation, see [Section 15.12.7, “Online DDL for Partitioned Tables”](#).
- **Indexes; partition pruning.** As with nonpartitioned tables, proper use of indexes can speed up queries on partitioned tables significantly. In addition, designing partitioned tables and queries on these tables to take advantage of *partition pruning* can improve performance dramatically. See [Section 22.4, “Partition Pruning”](#), for more information.

Index condition pushdown is supported for partitioned tables. See [Section 8.2.1.5, “Index Condition Pushdown Optimization”](#).

- **Performance with LOAD DATA.** In MySQL 8.0, `LOAD DATA` uses buffering to improve performance. You should be aware that the buffer uses 130 KB memory per partition to achieve this.

Maximum number of partitions.

In MySQL 8.0, the maximum possible number of partitions for a given table is 8192. This number includes subpartitions.

If, when creating tables with a large number of partitions (but less than the maximum), you encounter an error message such as `Got error ... from storage engine: Out of resources when opening file`, you may be able to address the issue by increasing the value of the `open_files_limit` system variable. However, this is dependent on the operating system, and may not be possible or advisable on all platforms; see [Section B.5.2.17, “File Not Found and Similar Errors”](#), for more information. In some cases, using large numbers (hundreds) of partitions may also not be advisable due to other concerns, so using more partitions does not automatically lead to better results.

See also [File system operations](#).

Query cache not supported.

The query cache is not supported for partitioned tables, and is automatically disabled for queries involving partitioned tables. The query cache cannot be enabled for such queries.

Foreign keys not supported for partitioned InnoDB tables.

Partitioned tables using the `InnoDB` storage engine do not support foreign keys. More specifically, this means that the following two statements are true:

1. No definition of an `InnoDB` table employing user-defined partitioning may contain foreign key references; no `InnoDB` table whose definition contains foreign key references may be partitioned.
2. No `InnoDB` table definition may contain a foreign key reference to a user-partitioned table; no `InnoDB` table with user-defined partitioning may contain columns referenced by foreign keys.

The scope of the restrictions just listed includes all tables that use the `InnoDB` storage engine. `CREATE TABLE` and `ALTER TABLE` statements that would result in tables violating these restrictions are not allowed.

ALTER TABLE ... ORDER BY. An `ALTER TABLE ... ORDER BY column` statement run against a partitioned table causes ordering of rows only within each partition.

Effects on REPLACE statements by modification of primary keys. It can be desirable in some cases (see [Section 22.6.1, “Partitioning Keys, Primary Keys, and Unique Keys”](#)) to modify a table's primary key. Be aware that, if your application uses `REPLACE` statements and you do this, the results of these statements can be drastically altered. See [Section 13.2.9, “REPLACE Syntax”](#), for more information and an example.

FULLTEXT indexes.

Partitioned tables do not support `FULLTEXT` indexes or searches.

Spatial columns. Columns with spatial data types such as `POINT` or `GEOMETRY` cannot be used in partitioned tables.

Temporary tables.

Temporary tables cannot be partitioned.

Log tables. It is not possible to partition the log tables; an `ALTER TABLE ... PARTITION BY ...` statement on such a table fails with an error.

Data type of partitioning key.

A partitioning key must be either an integer column or an expression that resolves to an integer. Expressions employing `ENUM` columns cannot be used. The column or expression value may also be `NULL`; see [Section 22.2.7, “How MySQL Partitioning Handles NULL”](#).

There are two exceptions to this restriction:

1. When partitioning by `[LINEAR] KEY`, it is possible to use columns of any valid MySQL data type other than `TEXT` or `BLOB` as partitioning keys, because the internal key-hashing functions produce the correct data type from these types. For example, the following two `CREATE TABLE` statements are valid:

```
CREATE TABLE tkc (c1 CHAR)
PARTITION BY KEY(c1)
PARTITIONS 4;

CREATE TABLE tke
  ( c1 ENUM('red', 'orange', 'yellow', 'green', 'blue', 'indigo', 'violet') )
PARTITION BY LINEAR KEY(c1)
PARTITIONS 6;
```

2. When partitioning by `RANGE COLUMNS` or `LIST COLUMNS`, it is possible to use string, `DATE`, and `DATETIME` columns. For example, each of the following `CREATE TABLE` statements is valid:

```
CREATE TABLE rc (c1 INT, c2 DATE)
PARTITION BY RANGE COLUMNS(c2) (
```

```

PARTITION p0 VALUES LESS THAN('1990-01-01'),
PARTITION p1 VALUES LESS THAN('1995-01-01'),
PARTITION p2 VALUES LESS THAN('2000-01-01'),
PARTITION p3 VALUES LESS THAN('2005-01-01'),
PARTITION p4 VALUES LESS THAN(MAXVALUE)
);

CREATE TABLE lc (c1 INT, c2 CHAR(1))
PARTITION BY LIST COLUMNS(c2) (
  PARTITION p0 VALUES IN('a', 'd', 'g', 'j', 'm', 'p', 's', 'v', 'y'),
  PARTITION p1 VALUES IN('b', 'e', 'h', 'k', 'n', 'q', 't', 'w', 'z'),
  PARTITION p2 VALUES IN('c', 'f', 'i', 'l', 'o', 'r', 'u', 'x', NULL)
);

```

Neither of the preceding exceptions applies to [BLOB](#) or [TEXT](#) column types.

Subqueries.

A partitioning key may not be a subquery, even if that subquery resolves to an integer value or [NULL](#).

Issues with subpartitions.

Subpartitions must use [HASH](#) or [KEY](#) partitioning. Only [RANGE](#) and [LIST](#) partitions may be subpartitioned; [HASH](#) and [KEY](#) partitions cannot be subpartitioned.

[SUBPARTITION BY KEY](#) requires that the subpartitioning column or columns be specified explicitly, unlike the case with [PARTITION BY KEY](#), where it can be omitted (in which case the table's primary key column is used by default). Consider the table created by this statement:

```

CREATE TABLE ts (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(30)
);

```

You can create a table having the same columns, partitioned by [KEY](#), using a statement such as this one:

```

CREATE TABLE ts (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(30)
)
PARTITION BY KEY()
PARTITIONS 4;

```

The previous statement is treated as though it had been written like this, with the table's primary key column used as the partitioning column:

```

CREATE TABLE ts (
  id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(30)
)
PARTITION BY KEY(id)
PARTITIONS 4;

```

However, the following statement that attempts to create a subpartitioned table using the default column as the subpartitioning column fails, and the column must be specified for the statement to succeed, as shown here:

```

mysql> CREATE TABLE ts (
->   id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->   name VARCHAR(30)
-> )
-> PARTITION BY RANGE(id)
-> SUBPARTITION BY KEY()
-> SUBPARTITIONS 4

```

```

-> (
->     PARTITION p0 VALUES LESS THAN (100),
->     PARTITION p1 VALUES LESS THAN (MAXVALUE)
-> );
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that
corresponds to your MySQL server version for the right syntax to use near ')'

mysql> CREATE TABLE ts (
->     id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
->     name VARCHAR(30)
-> )
-> PARTITION BY RANGE(id)
-> SUBPARTITION BY KEY(id)
-> SUBPARTITIONS 4
-> (
->     PARTITION p0 VALUES LESS THAN (100),
->     PARTITION p1 VALUES LESS THAN (MAXVALUE)
-> );
Query OK, 0 rows affected (0.07 sec)

```

This is a known issue (see Bug #51470).

DATA DIRECTORY and INDEX DIRECTORY options. Table-level `DATA DIRECTORY` and `INDEX DIRECTORY` options are ignored (see Bug #32091). You can employ these options for individual partitions or subpartitions of `InnoDB` tables.

Repairing and rebuilding partitioned tables. The statements `CHECK TABLE`, `OPTIMIZE TABLE`, `ANALYZE TABLE`, and `REPAIR TABLE` are supported for partitioned tables.

In addition, you can use `ALTER TABLE ... REBUILD PARTITION` to rebuild one or more partitions of a partitioned table; `ALTER TABLE ... REORGANIZE PARTITION` also causes partitions to be rebuilt. See [Section 13.1.7, “ALTER TABLE Syntax”](#), for more information about these two statements.

`ANALYZE`, `CHECK`, `OPTIMIZE`, `REPAIR`, and `TRUNCATE` operations are supported with subpartitions. See [Section 13.1.7.1, “ALTER TABLE Partition Operations”](#).

22.6.1 Partitioning Keys, Primary Keys, and Unique Keys

This section discusses the relationship of partitioning keys with primary keys and unique keys. The rule governing this relationship can be expressed as follows: All columns used in the partitioning expression for a partitioned table must be part of every unique key that the table may have.

In other words, *every unique key on the table must use every column in the table's partitioning expression.* (This also includes the table's primary key, since it is by definition a unique key. This particular case is discussed later in this section.) For example, each of the following table creation statements is invalid:

```

CREATE TABLE t1 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1),
  UNIQUE KEY (col3)
)
PARTITION BY HASH(col1 + col3)

```

```
PARTITIONS 4;
```

In each case, the proposed table would have at least one unique key that does not include all columns used in the partitioning expression.

Each of the following statements is valid, and represents one way in which the corresponding invalid table creation statement could be made to work:

```
CREATE TABLE t1 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col2, col3)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  UNIQUE KEY (col1, col3)
)
PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

This example shows the error produced in such cases:

```
mysql> CREATE TABLE t3 (
->   col1 INT NOT NULL,
->   col2 DATE NOT NULL,
->   col3 INT NOT NULL,
->   col4 INT NOT NULL,
->   UNIQUE KEY (col1, col2),
->   UNIQUE KEY (col3)
-> )
-> PARTITION BY HASH(col1 + col3)
-> PARTITIONS 4;
ERROR 1491 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

The `CREATE TABLE` statement fails because both `col1` and `col3` are included in the proposed partitioning key, but neither of these columns is part of both of unique keys on the table. This shows one possible fix for the invalid table definition:

```
mysql> CREATE TABLE t3 (
->   col1 INT NOT NULL,
->   col2 DATE NOT NULL,
->   col3 INT NOT NULL,
->   col4 INT NOT NULL,
->   UNIQUE KEY (col1, col2, col3),
->   UNIQUE KEY (col3)
-> )
-> PARTITION BY HASH(col3)
-> PARTITIONS 4;
Query OK, 0 rows affected (0.05 sec)
```

In this case, the proposed partitioning key `col3` is part of both unique keys, and the table creation statement succeeds.

The following table cannot be partitioned at all, because there is no way to include in a partitioning key any columns that belong to both unique keys:

```
CREATE TABLE t4 (
```

```

col1 INT NOT NULL,
col2 INT NOT NULL,
col3 INT NOT NULL,
col4 INT NOT NULL,
UNIQUE KEY (col1, col3),
UNIQUE KEY (col2, col4)
);

```

Since every primary key is by definition a unique key, this restriction also includes the table's primary key, if it has one. For example, the next two statements are invalid:

```

CREATE TABLE t5 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t6 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  PRIMARY KEY(col1, col3),
  UNIQUE KEY(col2)
)
PARTITION BY HASH( YEAR(col2) )
PARTITIONS 4;

```

In both cases, the primary key does not include all columns referenced in the partitioning expression. However, both of the next two statements are valid:

```

CREATE TABLE t7 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  PRIMARY KEY(col1, col2)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;

CREATE TABLE t8 (
  col1 INT NOT NULL,
  col2 DATE NOT NULL,
  col3 INT NOT NULL,
  col4 INT NOT NULL,
  PRIMARY KEY(col1, col2, col4),
  UNIQUE KEY(col2, col1)
)
PARTITION BY HASH(col1 + YEAR(col2))
PARTITIONS 4;

```

If a table has no unique keys—this includes having no primary key—then this restriction does not apply, and you may use any column or columns in the partitioning expression as long as the column type is compatible with the partitioning type.

For the same reason, you cannot later add a unique key to a partitioned table unless the key includes all columns used by the table's partitioning expression. Consider the partitioned table created as shown here:

```

mysql> CREATE TABLE t_no_pk (c1 INT, c2 INT)
-> PARTITION BY RANGE(c1) (
-> PARTITION p0 VALUES LESS THAN (10),

```

```

->     PARTITION p1 VALUES LESS THAN (20),
->     PARTITION p2 VALUES LESS THAN (30),
->     PARTITION p3 VALUES LESS THAN (40)
-> );
Query OK, 0 rows affected (0.12 sec)
    
```

It is possible to add a primary key to `t_no_pk` using either of these `ALTER TABLE` statements:

```

# possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1);
Query OK, 0 rows affected (0.13 sec)
Records: 0 Duplicates: 0 Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.10 sec)
Records: 0 Duplicates: 0 Warnings: 0

# use another possible PK
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c1, c2);
Query OK, 0 rows affected (0.12 sec)
Records: 0 Duplicates: 0 Warnings: 0

# drop this PK
mysql> ALTER TABLE t_no_pk DROP PRIMARY KEY;
Query OK, 0 rows affected (0.09 sec)
Records: 0 Duplicates: 0 Warnings: 0
    
```

However, the next statement fails, because `c1` is part of the partitioning key, but is not part of the proposed primary key:

```

# fails with error 1503
mysql> ALTER TABLE t_no_pk ADD PRIMARY KEY(c2);
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
    
```

Since `t_no_pk` has only `c1` in its partitioning expression, attempting to adding a unique key on `c2` alone fails. However, you can add a unique key that uses both `c1` and `c2`.

These rules also apply to existing nonpartitioned tables that you wish to partition using `ALTER TABLE ... PARTITION BY`. Consider a table `np_pk` created as shown here:

```

mysql> CREATE TABLE np_pk (
->     id INT NOT NULL AUTO_INCREMENT,
->     name VARCHAR(50),
->     added DATE,
->     PRIMARY KEY (id)
-> );
Query OK, 0 rows affected (0.08 sec)
    
```

The following `ALTER TABLE` statement fails with an error, because the `added` column is not part of any unique key in the table:

```

mysql> ALTER TABLE np_pk
->     PARTITION BY HASH( TO_DAYS(added) )
->     PARTITIONS 4;
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
    
```

However, this statement using the `id` column for the partitioning column is valid, as shown here:

```

mysql> ALTER TABLE np_pk
->     PARTITION BY HASH(id)
->     PARTITIONS 4;
Query OK, 0 rows affected (0.11 sec)
Records: 0 Duplicates: 0 Warnings: 0
    
```

In the case of `np_pk`, the only column that may be used as part of a partitioning expression is `id`; if you wish to partition this table using any other column or columns in the partitioning expression, you must first modify the table, either by adding the desired column or columns to the primary key, or by dropping the primary key altogether.

22.6.2 Partitioning Limitations Relating to Storage Engines

In MySQL 8.0, partitioning support is not actually provided by the MySQL Server, but rather by a table storage engine's own or native partitioning handler. In MySQL 8.0, only the `InnoDB` storage engine provides a native partitioning handler. This means that partitioned tables cannot be created using any other storage engine.

Note

MySQL Cluster's `NDB` storage engine also provides native partitioning support, but is not currently supported in MySQL 8.0.

`ALTER TABLE ... OPTIMIZE PARTITION` does not work correctly with partitioned tables that use `InnoDB`. Use `ALTER TABLE ... REBUILD PARTITION` and `ALTER TABLE ... ANALYZE PARTITION`, instead, for such tables. For more information, see [Section 13.1.7.1, “ALTER TABLE Partition Operations”](#).

Upgrading partitioned tables. When performing an upgrade, tables which are partitioned by `KEY` must be dumped and reloaded. Partitioned tables using storage engines other than `InnoDB` cannot be upgraded from MySQL 5.7 or earlier to MySQL 8.0 or later; you must either drop the partitioning from such tables with `ALTER TABLE ... REMOVE PARTITIONING` or convert them to `InnoDB` using `ALTER TABLE ... ENGINE=INNODB` prior to the upgrade.

For information about converting `MyISAM` tables to `InnoDB`, see [Section 15.8.1.4, “Converting Tables from MyISAM to InnoDB”](#).

22.6.3 Partitioning Limitations Relating to Functions

This section discusses limitations in MySQL Partitioning relating specifically to functions used in partitioning expressions.

Only the MySQL functions shown in the following table are allowed in partitioning expressions.

<code>ABS()</code>	<code>CEILING()</code> (see CEILING() and FLOOR())	<code>DAY()</code>
<code>DAYOFMONTH()</code>	<code>DAYOFWEEK()</code>	<code>DAYOFYEAR()</code>
<code>DATEDIFF()</code>	<code>EXTRACT()</code> (see EXTRACT() function with <code>WEEK</code> specifier)	<code>FLOOR()</code> (see CEILING() and FLOOR())
<code>HOURL()</code>	<code>MICROSECOND()</code>	<code>MINUTE()</code>
<code>MOD()</code>	<code>MONTH()</code>	<code>QUARTER()</code>
<code>SECOND()</code>	<code>TIME_TO_SEC()</code>	<code>TO_DAYS()</code>
<code>TO_SECONDS()</code>	<code>UNIX_TIMESTAMP()</code> (with <code>TIMESTAMP</code> columns)	<code>WEEKDAY()</code>
<code>YEAR()</code>		<code>YEARWEEK()</code>

In MySQL 8.0, partition pruning is supported for the `TO_DAYS()`, `TO_SECONDS()`, `YEAR()`, and `UNIX_TIMESTAMP()` functions. See [Section 22.4, “Partition Pruning”](#), for more information.

`CEILING()` and `FLOOR()`. Each of these functions returns an integer only if it is passed an argument of an exact numeric type, such as one of the `INT` types or `DECIMAL`. This means, for example, that the following `CREATE TABLE` statement fails with an error, as shown here:

```
mysql> CREATE TABLE t (c FLOAT) PARTITION BY LIST( FLOOR(c) )(
->     PARTITION p0 VALUES IN (1,3,5),
->     PARTITION p1 VALUES IN (2,4,6)
-> );
ERROR 1490 (HY000): The PARTITION function returns the wrong type
```

EXTRACT() function with WEEK specifier. The value returned by the `EXTRACT()` function, when used as `EXTRACT(WEEK FROM col)`, depends on the value of the `default_week_format` system variable. For this reason, `EXTRACT()` is not permitted as a partitioning function when it specifies the unit as `WEEK`. (Bug #54483)

See [Section 12.6.2, “Mathematical Functions”](#), for more information about the return types of these functions, as well as [Section 11.2, “Numeric Types”](#).

23.5.5 View Metadata	2835
23.6 Access Control for Stored Programs and Views	2835
23.7 Binary Logging of Stored Programs	2837

This chapter discusses stored programs and views, which are database objects defined in terms of SQL code that is stored on the server for later execution.

Stored programs include these objects:

- Stored routines, that is, stored procedures and functions. A stored procedure is invoked using the [CALL](#) statement. A procedure does not have a return value but can modify its parameters for later inspection by the caller. It can also generate result sets to be returned to the client program. A stored function is used much like a built-in function. you invoke it in an expression and it returns a value during expression evaluation.
- Triggers. A trigger is a named database object that is associated with a table and that is activated when a particular event occurs for the table, such as an insert or update.
- Events. An event is a task that the server runs according to schedule.

Views are stored queries that when referenced produce a result set. A view acts as a virtual table.

This chapter describes how to use stored programs and views. The following sections provide additional information about SQL syntax for statements related to these objects:

- For each object type, there are [CREATE](#), [ALTER](#), and [DROP](#) statements that control which objects exist and how they are defined. See [Section 13.1, “Data Definition Statements”](#).
- The [CALL](#) statement is used to invoke stored procedures. See [Section 13.2.1, “CALL Syntax”](#).
- Stored program definitions include a body that may use compound statements, loops, conditionals, and declared variables. See [Section 13.6, “Compound-Statement Syntax”](#).

In MySQL, metadata changes to objects referred to by stored programs are detected and cause automatic reparsing of the affected statements when the program is next executed. For more information, see [Section 8.10.4, “Caching of Prepared Statements and Stored Programs”](#).

23.1 Defining Stored Programs

Each stored program contains a body that consists of an SQL statement. This statement may be a compound statement made up of several statements separated by semicolon (;) characters. For example, the following stored procedure has a body made up of a `BEGIN . . . END` block that contains a `SET` statement and a `REPEAT` loop that itself contains another `SET` statement:

```
CREATE PROCEDURE dorepeat(p1 INT)
BEGIN
  SET @x = 0;
  REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
END;
```

If you use the `mysql` client program to define a stored program containing semicolon characters, a problem arises. By default, `mysql` itself recognizes the semicolon as a statement delimiter, so you must redefine the delimiter temporarily to cause `mysql` to pass the entire stored program definition to the server.

To redefine the `mysql` delimiter, use the `delimiter` command. The following example shows how to do this for the `dorepeat()` procedure just shown. The delimiter is changed to `//` to enable the entire definition to be passed to the server as a single statement, and then restored to `;` before invoking the procedure. This enables the `;` delimiter used in the procedure body to be passed through to the server rather than being interpreted by `mysql` itself.

```
mysql> delimiter //
mysql> CREATE PROCEDURE dorepeat(p1 INT)
-> BEGIN
->   SET @x = 0;
->   REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
-> END
-> //
Query OK, 0 rows affected (0.00 sec)

mysql> delimiter ;
mysql> CALL dorepeat(1000);
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @x;
+-----+
| @x    |
+-----+
| 1001  |
+-----+
1 row in set (0.00 sec)
```

You can redefine the delimiter to a string other than `//`, and the delimiter can consist of a single character or multiple characters. You should avoid the use of the backslash (\) character because that is the escape character for MySQL.

The following is an example of a function that takes a parameter, performs an operation using an SQL function, and returns the result. In this case, it is unnecessary to use `delimiter` because the function definition contains no internal `;` statement delimiters:

```
mysql> CREATE FUNCTION hello (s CHAR(20))
mysql> RETURNS CHAR(50) DETERMINISTIC
-> RETURN CONCAT('Hello, ',s,'!');
```

```
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT hello('world');
+-----+
| hello('world') |
+-----+
| Hello, world! |
+-----+
1 row in set (0.00 sec)
```

23.2 Using Stored Routines (Procedures and Functions)

MySQL supports stored routines (procedures and functions). A stored routine is a set of SQL statements that can be stored in the server. Once this has been done, clients don't need to keep reissuing the individual statements but can refer to the stored routine instead.

Stored routines can be particularly useful in certain situations:

- When multiple client applications are written in different languages or work on different platforms, but need to perform the same database operations.
- When security is paramount. Banks, for example, use stored procedures and functions for all common operations. This provides a consistent and secure environment, and routines can ensure that each operation is properly logged. In such a setup, applications and users would have no access to the database tables directly, but can only execute specific stored routines.

Stored routines can provide improved performance because less information needs to be sent between the server and the client. The tradeoff is that this does increase the load on the database server because more of the work is done on the server side and less is done on the client (application) side. Consider this if many client machines (such as Web servers) are serviced by only one or a few database servers.

Stored routines also enable you to have libraries of functions in the database server. This is a feature shared by modern application languages that enable such design internally (for example, by using classes). Using these client application language features is beneficial for the programmer even outside the scope of database use.

MySQL follows the SQL:2003 syntax for stored routines, which is also used by IBM's DB2. All syntax described here is supported and any limitations and extensions are documented where appropriate.

Additional Resources

- You may find the [Stored Procedures User Forum](#) of use when working with stored procedures and functions.
- For answers to some commonly asked questions regarding stored routines in MySQL, see [Section A.4, "MySQL 8.0 FAQ: Stored Procedures and Functions"](#).
- There are some restrictions on the use of stored routines. See [Section C.1, "Restrictions on Stored Programs"](#).
- Binary logging for stored routines takes place as described in [Section 23.7, "Binary Logging of Stored Programs"](#).

23.2.1 Stored Routine Syntax

A stored routine is either a procedure or a function. Stored routines are created with the `CREATE PROCEDURE` and `CREATE FUNCTION` statements (see [Section 13.1.13, "CREATE PROCEDURE and CREATE FUNCTION Syntax"](#)). A procedure is invoked using a `CALL` statement (see [Section 13.2.1, "CALL Syntax"](#)), and can only pass back values using output variables. A function can be called

from inside a statement just like any other function (that is, by invoking the function's name), and can return a scalar value. The body of a stored routine can use compound statements (see [Section 13.6, “Compound-Statement Syntax”](#)).

Stored routines can be dropped with the `DROP PROCEDURE` and `DROP FUNCTION` statements (see [Section 13.1.23, “DROP PROCEDURE and DROP FUNCTION Syntax”](#)), and altered with the `ALTER PROCEDURE` and `ALTER FUNCTION` statements (see [Section 13.1.5, “ALTER PROCEDURE Syntax”](#)).

A stored procedure or function is associated with a particular database. This has several implications:

- When the routine is invoked, an implicit `USE db_name` is performed (and undone when the routine terminates). `USE` statements within stored routines are not permitted.
- You can qualify routine names with the database name. This can be used to refer to a routine that is not in the current database. For example, to invoke a stored procedure `p` or function `f` that is associated with the `test` database, you can say `CALL test.p()` or `test.f()`.
- When a database is dropped, all stored routines associated with it are dropped as well.

Stored functions cannot be recursive.

Recursion in stored procedures is permitted but disabled by default. To enable recursion, set the `max_sp_recursion_depth` server system variable to a value greater than zero. Stored procedure recursion increases the demand on thread stack space. If you increase the value of `max_sp_recursion_depth`, it may be necessary to increase thread stack size by increasing the value of `thread_stack` at server startup. See [Section 5.1.5, “Server System Variables”](#), for more information.

MySQL supports a very useful extension that enables the use of regular `SELECT` statements (that is, without using cursors or local variables) inside a stored procedure. The result set of such a query is simply sent directly to the client. Multiple `SELECT` statements generate multiple result sets, so the client must use a MySQL client library that supports multiple result sets. This means the client must use a client library from a version of MySQL at least as recent as 4.1. The client should also specify the `CLIENT_MULTI_RESULTS` option when it connects. For C programs, this can be done with the `mysql_real_connect()` C API function. See [Section 27.7.7.54, “mysql_real_connect\(\)”](#), and [Section 27.7.20, “C API Support for Multiple Statement Execution”](#).

23.2.2 Stored Routines and MySQL Privileges

The MySQL grant system takes stored routines into account as follows:

- The `CREATE ROUTINE` privilege is needed to create stored routines.
- The `ALTER ROUTINE` privilege is needed to alter or drop stored routines. This privilege is granted automatically to the creator of a routine if necessary, and dropped from the creator when the routine is dropped.
- The `EXECUTE` privilege is required to execute stored routines. However, this privilege is granted automatically to the creator of a routine if necessary (and dropped from the creator when the routine is dropped). Also, the default `SQL SECURITY` characteristic for a routine is `DEFINER`, which enables users who have access to the database with which the routine is associated to execute the routine.
- If the `automatic_sp_privileges` system variable is 0, the `EXECUTE` and `ALTER ROUTINE` privileges are not automatically granted to and dropped from the routine creator.
- The creator of a routine is the account used to execute the `CREATE` statement for it. This might not be the same as the account named as the `DEFINER` in the routine definition.

23.2.3 Stored Routine Metadata

Metadata about stored routines can be obtained as follows:

- Query the `ROUTINES` table of the `INFORMATION_SCHEMA` database. See [Section 24.18, “The INFORMATION_SCHEMA ROUTINES Table”](#).
- Use the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements to see routine definitions. See [Section 13.7.5.9, “SHOW CREATE PROCEDURE Syntax”](#).
- Use the `SHOW PROCEDURE STATUS` and `SHOW FUNCTION STATUS` statements to see routine characteristics. See [Section 13.7.5.28, “SHOW PROCEDURE STATUS Syntax”](#).

23.2.4 Stored Procedures, Functions, Triggers, and LAST_INSERT_ID()

Within the body of a stored routine (procedure or function) or a trigger, the value of `LAST_INSERT_ID()` changes the same way as for statements executed outside the body of these kinds of objects (see [Section 12.14, “Information Functions”](#)). The effect of a stored routine or trigger upon the value of `LAST_INSERT_ID()` that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of `LAST_INSERT_ID()`, the changed value is seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements do not see a changed value.

23.3 Using Triggers

A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. Some uses for triggers are to perform checks of values to be inserted into a table or to perform calculations on values involved in an update.

A trigger is defined to activate when a statement inserts, updates, or deletes rows in the associated table. These row operations are trigger events. For example, rows can be inserted by `INSERT` or `LOAD DATA` statements, and an insert trigger activates for each inserted row. A trigger can be set to activate either before or after the trigger event. For example, you can have a trigger activate before each row that is inserted into a table or after each row that is updated.

Important

MySQL triggers activate only for changes made to tables by SQL statements. This includes changes to base tables that underlie updatable views. Triggers do not activate for changes to tables made by APIs that do not transmit SQL statements to the MySQL Server. This means that triggers are not activated by updates made using the `NDB` API.

Triggers are not activated by changes in `INFORMATION_SCHEMA` or `performance_schema` tables. Those tables are actually views and triggers are not permitted on views.

The following sections describe the syntax for creating and dropping triggers, show some examples of how to use them, and indicate how to obtain trigger metadata.

Additional Resources

- You may find the [Triggers User Forum](#) of use when working with triggers.
- For answers to commonly asked questions regarding triggers in MySQL, see [Section A.5, “MySQL 8.0 FAQ: Triggers”](#).

- There are some restrictions on the use of triggers; see [Section C.1, “Restrictions on Stored Programs”](#).
- Binary logging for triggers takes place as described in [Section 23.7, “Binary Logging of Stored Programs”](#).

23.3.1 Trigger Syntax and Examples

To create a trigger or drop a trigger, use the `CREATE TRIGGER` or `DROP TRIGGER` statement, described in [Section 13.1.17, “CREATE TRIGGER Syntax”](#), and [Section 13.1.27, “DROP TRIGGER Syntax”](#).

Here is a simple example that associates a trigger with a table, to activate for `INSERT` operations. The trigger acts as an accumulator, summing the values inserted into one of the columns of the table.

```
mysql> CREATE TABLE account (acct_num INT, amount DECIMAL(10,2));
Query OK, 0 rows affected (0.03 sec)

mysql> CREATE TRIGGER ins_sum BEFORE INSERT ON account
FOR EACH ROW SET @sum = @sum + NEW.amount;
Query OK, 0 rows affected (0.01 sec)
```

The `CREATE TRIGGER` statement creates a trigger named `ins_sum` that is associated with the `account` table. It also includes clauses that specify the trigger action time, the triggering event, and what to do when the trigger activates:

- The keyword `BEFORE` indicates the trigger action time. In this case, the trigger activates before each row inserted into the table. The other permitted keyword here is `AFTER`.
- The keyword `INSERT` indicates the trigger event; that is, the type of operation that activates the trigger. In the example, `INSERT` operations cause trigger activation. You can also create triggers for `DELETE` and `UPDATE` operations.
- The statement following `FOR EACH ROW` defines the trigger body; that is, the statement to execute each time the trigger activates, which occurs once for each row affected by the triggering event. In the example, the trigger body is a simple `SET` that accumulates into a user variable the values inserted into the `amount` column. The statement refers to the column as `NEW.amount` which means “the value of the `amount` column to be inserted into the new row.”

To use the trigger, set the accumulator variable to zero, execute an `INSERT` statement, and then see what value the variable has afterward:

```
mysql> SET @sum = 0;
mysql> INSERT INTO account VALUES(137,14.98),(141,1937.50),(97,-100.00);
mysql> SELECT @sum AS 'Total amount inserted';
+-----+
| Total amount inserted |
+-----+
|           1852.48    |
+-----+
```

In this case, the value of `@sum` after the `INSERT` statement has executed is `14.98 + 1937.50 - 100`, or `1852.48`.

To destroy the trigger, use a `DROP TRIGGER` statement. You must specify the schema name if the trigger is not in the default schema:

```
mysql> DROP TRIGGER test.ins_sum;
```

If you drop a table, any triggers for the table are also dropped.

Trigger names exist in the schema namespace, meaning that all triggers must have unique names within a schema. Triggers in different schemas can have the same name.

It is possible to define multiple triggers for a given table that have the same trigger event and action time. For example, you can have two `BEFORE UPDATE` triggers for a table. By default, triggers that have the same trigger event and action time activate in the order they were created. To affect trigger order, specify a clause after `FOR EACH ROW` that indicates `FOLLOWS` or `PRECEDES` and the name of an existing trigger that also has the same trigger event and action time. With `FOLLOWS`, the new trigger activates after the existing trigger. With `PRECEDES`, the new trigger activates before the existing trigger.

For example, the following trigger definition defines another `BEFORE INSERT` trigger for the `account` table:

```
mysql> CREATE TRIGGER ins_transaction BEFORE INSERT ON account
FOR EACH ROW PRECEDES ins_sum
SET
  @deposits = @deposits + IF(NEW.amount>0,NEW.amount,0),
  @withdrawals = @withdrawals + IF(NEW.amount<0,-NEW.amount,0);
Query OK, 0 rows affected (0.01 sec)
```

This trigger, `ins_transaction`, is similar to `ins_sum` but accumulates deposits and withdrawals separately. It has a `PRECEDES` clause that causes it to activate before `ins_sum`; without that clause, it would activate after `ins_sum` because it is created after `ins_sum`.

Within the trigger body, the `OLD` and `NEW` keywords enable you to access columns in the rows affected by a trigger. `OLD` and `NEW` are MySQL extensions to triggers; they are not case sensitive.

In an `INSERT` trigger, only `NEW.col_name` can be used; there is no old row. In a `DELETE` trigger, only `OLD.col_name` can be used; there is no new row. In an `UPDATE` trigger, you can use `OLD.col_name` to refer to the columns of a row before it is updated and `NEW.col_name` to refer to the columns of the row after it is updated.

A column named with `OLD` is read only. You can refer to it (if you have the `SELECT` privilege), but not modify it. You can refer to a column named with `NEW` if you have the `SELECT` privilege for it. In a `BEFORE` trigger, you can also change its value with `SET NEW.col_name = value` if you have the `UPDATE` privilege for it. This means you can use a trigger to modify the values to be inserted into a new row or used to update a row. (Such a `SET` statement has no effect in an `AFTER` trigger because the row change will have already occurred.)

In a `BEFORE` trigger, the `NEW` value for an `AUTO_INCREMENT` column is 0, not the sequence number that is generated automatically when the new row actually is inserted.

By using the `BEGIN ... END` construct, you can define a trigger that executes multiple statements. Within the `BEGIN` block, you also can use other syntax that is permitted within stored routines such as conditionals and loops. However, just as for stored routines, if you use the `mysql` program to define a trigger that executes multiple statements, it is necessary to redefine the `mysql` statement delimiter so that you can use the `;` statement delimiter within the trigger definition. The following example illustrates these points. It defines an `UPDATE` trigger that checks the new value to be used for updating each row, and modifies the value to be within the range from 0 to 100. This must be a `BEFORE` trigger because the value must be checked before it is used to update the row:

```
mysql> delimiter //
mysql> CREATE TRIGGER upd_check BEFORE UPDATE ON account
FOR EACH ROW
BEGIN
  IF NEW.amount < 0 THEN
    SET NEW.amount = 0;
  ELSEIF NEW.amount > 100 THEN
    SET NEW.amount = 100;
  END IF;
END; //
```

```
mysql> delimiter ;
```

It can be easier to define a stored procedure separately and then invoke it from the trigger using a simple `CALL` statement. This is also advantageous if you want to execute the same code from within several triggers.

There are limitations on what can appear in statements that a trigger executes when activated:

- The trigger cannot use the `CALL` statement to invoke stored procedures that return data to the client or that use dynamic SQL. (Stored procedures are permitted to return data to the trigger through `OUT` or `INOUT` parameters.)
- The trigger cannot use statements that explicitly or implicitly begin or end a transaction, such as `START TRANSACTION`, `COMMIT`, or `ROLLBACK`. (`ROLLBACK to SAVEPOINT` is permitted because it does not end a transaction.)

See also [Section C.1, “Restrictions on Stored Programs”](#).

MySQL handles errors during trigger execution as follows:

- If a `BEFORE` trigger fails, the operation on the corresponding row is not performed.
- A `BEFORE` trigger is activated by the *attempt* to insert or modify the row, regardless of whether the attempt subsequently succeeds.
- An `AFTER` trigger is executed only if any `BEFORE` triggers and the row operation execute successfully.
- An error during either a `BEFORE` or `AFTER` trigger results in failure of the entire statement that caused trigger invocation.
- For transactional tables, failure of a statement should cause rollback of all changes performed by the statement. Failure of a trigger causes the statement to fail, so trigger failure also causes rollback. For nontransactional tables, such rollback cannot be done, so although the statement fails, any changes performed prior to the point of the error remain in effect.

Triggers can contain direct references to tables by name, such as the trigger named `testref` shown in this example:

```
CREATE TABLE test1(a1 INT);
CREATE TABLE test2(a2 INT);
CREATE TABLE test3(a3 INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
CREATE TABLE test4(
  a4 INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
  b4 INT DEFAULT 0
);

delimiter |

CREATE TRIGGER testref BEFORE INSERT ON test1
FOR EACH ROW
BEGIN
  INSERT INTO test2 SET a2 = NEW.a1;
  DELETE FROM test3 WHERE a3 = NEW.a1;
  UPDATE test4 SET b4 = b4 + 1 WHERE a4 = NEW.a1;
END;
|

delimiter ;

INSERT INTO test3 (a3) VALUES
  (NULL), (NULL), (NULL), (NULL), (NULL),
  (NULL), (NULL), (NULL), (NULL), (NULL);

INSERT INTO test4 (a4) VALUES
  (0), (0), (0), (0), (0), (0), (0), (0), (0), (0);
```

Suppose that you insert the following values into table `test1` as shown here:

```
mysql> INSERT INTO test1 VALUES
      (1), (3), (1), (7), (1), (8), (4), (4);
Query OK, 8 rows affected (0.01 sec)
Records: 8 Duplicates: 0 Warnings: 0
```

As a result, the four tables contain the following data:

```
mysql> SELECT * FROM test1;
+-----+
| a1 |
+-----+
| 1 |
| 3 |
| 1 |
| 7 |
| 1 |
| 8 |
| 4 |
| 4 |
+-----+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test2;
+-----+
| a2 |
+-----+
| 1 |
| 3 |
| 1 |
| 7 |
| 1 |
| 8 |
| 4 |
| 4 |
+-----+
8 rows in set (0.00 sec)

mysql> SELECT * FROM test3;
+-----+
| a3 |
+-----+
| 2 |
| 5 |
| 6 |
| 9 |
| 10 |
+-----+
5 rows in set (0.00 sec)

mysql> SELECT * FROM test4;
+-----+
| a4 | b4 |
+-----+
| 1 | 3 |
| 2 | 0 |
| 3 | 1 |
| 4 | 2 |
| 5 | 0 |
| 6 | 0 |
| 7 | 1 |
| 8 | 1 |
| 9 | 0 |
| 10 | 0 |
+-----+
10 rows in set (0.00 sec)
```

23.3.2 Trigger Metadata

Metadata about triggers can be obtained as follows:

- Query the `TRIGGERS` table of the `INFORMATION_SCHEMA` database. See [Section 24.28, “The INFORMATION_SCHEMA TRIGGERS Table”](#).
- Use the `SHOW CREATE TRIGGER` statement. See [Section 13.7.5.11, “SHOW CREATE TRIGGER Syntax”](#).
- Use the `SHOW TRIGGERS` statement. See [Section 13.7.5.38, “SHOW TRIGGERS Syntax”](#).

23.4 Using the Event Scheduler

The *MySQL Event Scheduler* manages the scheduling and execution of events, that is, tasks that run according to a schedule. The following discussion covers the Event Scheduler and is divided into the following sections:

- [Section 23.4.1, “Event Scheduler Overview”](#), provides an introduction to and conceptual overview of MySQL Events.
- [Section 23.4.3, “Event Syntax”](#), discusses the SQL statements for creating, altering, and dropping MySQL Events.
- [Section 23.4.4, “Event Metadata”](#), shows how to obtain information about events and how this information is stored by the MySQL Server.
- [Section 23.4.6, “The Event Scheduler and MySQL Privileges”](#), discusses the privileges required to work with events and the ramifications that events have with regard to privileges when executing.

Stored routines require the `events` data dictionary table in the `mysql` system database. This table is created during the MySQL 8.0 installation procedure. If you are upgrading to MySQL 8.0 from an earlier version, be sure to run `mysql_upgrade` to make sure that your system database is up to date. See [Section 4.4.5, “mysql_upgrade — Check and Upgrade MySQL Tables”](#).

Additional Resources

- You may find the [MySQL Event Scheduler User Forum](#) of use when working with scheduled events.
- There are some restrictions on the use of events; see [Section C.1, “Restrictions on Stored Programs”](#).
- Binary logging for events takes place as described in [Section 23.7, “Binary Logging of Stored Programs”](#).

23.4.1 Event Scheduler Overview

MySQL Events are tasks that run according to a schedule. Therefore, we sometimes refer to them as *scheduled* events. When you create an event, you are creating a named database object containing one or more SQL statements to be executed at one or more regular intervals, beginning and ending at a specific date and time. Conceptually, this is similar to the idea of the Unix `crontab` (also known as a “cron job”) or the Windows Task Scheduler.

Scheduled tasks of this type are also sometimes known as “temporal triggers”, implying that these are objects that are triggered by the passage of time. While this is essentially correct, we prefer to use the term *events* to avoid confusion with triggers of the type discussed in [Section 23.3, “Using Triggers”](#). Events should more specifically not be confused with “temporary triggers”. Whereas a trigger is a database object whose statements are executed in response to a specific type of event that occurs on a given table, a (scheduled) event is an object whose statements are executed in response to the passage of a specified time interval.

While there is no provision in the SQL Standard for event scheduling, there are precedents in other database systems, and you may notice some similarities between these implementations and that found in the MySQL Server.

MySQL Events have the following major features and properties:

- In MySQL, an event is uniquely identified by its name and the schema to which it is assigned.
- An event performs a specific action according to a schedule. This action consists of an SQL statement, which can be a compound statement in a `BEGIN . . . END` block if desired (see [Section 13.6, “Compound-Statement Syntax”](#)). An event's timing can be either *one-time* or *recurrent*. A one-time event executes one time only. A recurrent event repeats its action at a regular interval, and the schedule for a recurring event can be assigned a specific start day and time, end day and time, both, or neither. (By default, a recurring event's schedule begins as soon as it is created, and continues indefinitely, until it is disabled or dropped.)

If a repeating event does not terminate within its scheduling interval, the result may be multiple instances of the event executing simultaneously. If this is undesirable, you should institute a mechanism to prevent simultaneous instances. For example, you could use the `GET_LOCK()` function, or row or table locking.

- Users can create, modify, and drop scheduled events using SQL statements intended for these purposes. Syntactically invalid event creation and modification statements fail with an appropriate error message. *A user may include statements in an event's action which require privileges that the user does not actually have.* The event creation or modification statement succeeds but the event's action fails. See [Section 23.4.6, “The Event Scheduler and MySQL Privileges”](#) for details.
- Many of the properties of an event can be set or modified using SQL statements. These properties include the event's name, timing, persistence (that is, whether it is preserved following the expiration of its schedule), status (enabled or disabled), action to be performed, and the schema to which it is assigned. See [Section 13.1.2, “ALTER EVENT Syntax”](#).

The default definer of an event is the user who created the event, unless the event has been altered, in which case the definer is the user who issued the last `ALTER EVENT` statement affecting that event. An event can be modified by any user having the `EVENT` privilege on the database for which the event is defined. See [Section 23.4.6, “The Event Scheduler and MySQL Privileges”](#).

- An event's action statement may include most SQL statements permitted within stored routines. For restrictions, see [Section C.1, “Restrictions on Stored Programs”](#).

23.4.2 Event Scheduler Configuration

Events are executed by a special *event scheduler thread*; when we refer to the Event Scheduler, we actually refer to this thread. When running, the event scheduler thread and its current state can be seen by users having the `PROCESS` privilege in the output of `SHOW PROCESSLIST`, as shown in the discussion that follows.

The global `event_scheduler` system variable determines whether the Event Scheduler is enabled and running on the server. It has one of these 3 values, which affect event scheduling as described here:

- **OFF**: The Event Scheduler is stopped. The event scheduler thread does not run, is not shown in the output of `SHOW PROCESSLIST`, and no scheduled events are executed. **OFF** is the default value for `event_scheduler`.

When the Event Scheduler is stopped (`event_scheduler` is **OFF**), it can be started by setting the value of `event_scheduler` to **ON**. (See next item.)

- **ON**: The Event Scheduler is started; the event scheduler thread runs and executes all scheduled events.

When the Event Scheduler is **ON**, the event scheduler thread is listed in the output of `SHOW PROCESSLIST` as a daemon process, and its state is represented as shown here:

```
mysql> SHOW PROCESSLIST\G
***** 1. row *****
  Id: 1
  User: root
  Host: localhost
  db: NULL
Command: Query
  Time: 0
  State: NULL
  Info: show processlist
***** 2. row *****
  Id: 2
  User: event_scheduler
  Host: localhost
  db: NULL
Command: Daemon
  Time: 3
  State: Waiting for next activation
  Info: NULL
2 rows in set (0.00 sec)
```

Event scheduling can be stopped by setting the value of `event_scheduler` to **OFF**.

- **DISABLED**: This value renders the Event Scheduler nonoperational. When the Event Scheduler is **DISABLED**, the event scheduler thread does not run (and so does not appear in the output of `SHOW PROCESSLIST`). In addition, the Event Scheduler state cannot be changed at runtime.

If the Event Scheduler status has not been set to **DISABLED**, `event_scheduler` can be toggled between **ON** and **OFF** (using `SET`). It is also possible to use `0` for **OFF**, and `1` for **ON** when setting this variable. Thus, any of the following 4 statements can be used in the `mysql` client to turn on the Event Scheduler:

```
SET GLOBAL event_scheduler = ON;
SET @@global.event_scheduler = ON;
SET GLOBAL event_scheduler = 1;
SET @@global.event_scheduler = 1;
```

Similarly, any of these 4 statements can be used to turn off the Event Scheduler:

```
SET GLOBAL event_scheduler = OFF;
SET @@global.event_scheduler = OFF;
SET GLOBAL event_scheduler = 0;
SET @@global.event_scheduler = 0;
```

Although **ON** and **OFF** have numeric equivalents, the value displayed for `event_scheduler` by `SELECT` or `SHOW VARIABLES` is always one of **OFF**, **ON**, or **DISABLED**. **DISABLED** has no numeric equivalent. For this reason, **ON** and **OFF** are usually preferred over `1` and `0` when setting this variable.

Note that attempting to set `event_scheduler` without specifying it as a global variable causes an error:

```
mysql< SET @@event_scheduler = OFF;
ERROR 1229 (HY000): Variable 'event_scheduler' is a GLOBAL
variable and should be set with SET GLOBAL
```

Important

It is possible to set the Event Scheduler to **DISABLED** only at server startup. If `event_scheduler` is **ON** or **OFF**, you cannot set it to **DISABLED** at runtime.

Also, if the Event Scheduler is set to `DISABLED` at startup, you cannot change the value of `event_scheduler` at runtime.

To disable the event scheduler, use one of the following two methods:

- As a command-line option when starting the server:

```
--event-scheduler=DISABLED
```

- In the server configuration file (`my.cnf`, or `my.ini` on Windows systems), include the line where it will be read by the server (for example, in a `[mysqld]` section):

```
event_scheduler=DISABLED
```

To enable the Event Scheduler, restart the server without the `--event-scheduler=DISABLED` command-line option, or after removing or commenting out the line containing `event_scheduler=DISABLED` in the server configuration file, as appropriate. Alternatively, you can use `ON` (or `1`) or `OFF` (or `0`) in place of the `DISABLED` value when starting the server.

Note

You can issue event-manipulation statements when `event_scheduler` is set to `DISABLED`. No warnings or errors are generated in such cases (provided that the statements are themselves valid). However, scheduled events cannot execute until this variable is set to `ON` (or `1`). Once this has been done, the event scheduler thread executes all events whose scheduling conditions are satisfied.

Starting the MySQL server with the `--skip-grant-tables` option causes `event_scheduler` to be set to `DISABLED`, overriding any other value set either on the command line or in the `my.cnf` or `my.ini` file (Bug #26807).

For SQL statements used to create, alter, and drop events, see [Section 23.4.3, “Event Syntax”](#).

MySQL provides an `EVENTS` table in the `INFORMATION_SCHEMA` database. This table can be queried to obtain information about scheduled events which have been defined on the server. See [Section 23.4.4, “Event Metadata”](#), and [Section 24.8, “The INFORMATION_SCHEMA EVENTS Table”](#), for more information.

For information regarding event scheduling and the MySQL privilege system, see [Section 23.4.6, “The Event Scheduler and MySQL Privileges”](#).

23.4.3 Event Syntax

MySQL provides several SQL statements for working with scheduled events:

- New events are defined using the `CREATE EVENT` statement. See [Section 13.1.10, “CREATE EVENT Syntax”](#).
- The definition of an existing event can be changed by means of the `ALTER EVENT` statement. See [Section 13.1.2, “ALTER EVENT Syntax”](#).
- When a scheduled event is no longer wanted or needed, it can be deleted from the server by its definer using the `DROP EVENT` statement. See [Section 13.1.20, “DROP EVENT Syntax”](#). Whether an event persists past the end of its schedule also depends on its `ON COMPLETION` clause, if it has one. See [Section 13.1.10, “CREATE EVENT Syntax”](#).

An event can be dropped by any user having the `EVENT` privilege for the database on which the event is defined. See [Section 23.4.6, “The Event Scheduler and MySQL Privileges”](#).

23.4.4 Event Metadata

Metadata about events can be obtained as follows:

- Query the `EVENTS` table of the `INFORMATION_SCHEMA` database. See [Section 24.8, “The INFORMATION_SCHEMA EVENTS Table”](#).
- Use the `SHOW CREATE EVENT` statement. See [Section 13.7.5.7, “SHOW CREATE EVENT Syntax”](#).
- Use the `SHOW EVENTS` statement. See [Section 13.7.5.18, “SHOW EVENTS Syntax”](#).

Event Scheduler Time Representation

Each session in MySQL has a session time zone (STZ). This is the session `time_zone` value that is initialized from the server's global `time_zone` value when the session begins but may be changed during the session.

The session time zone that is current when a `CREATE EVENT` or `ALTER EVENT` statement executes is used to interpret times specified in the event definition. This becomes the event time zone (ETZ); that is, the time zone that is used for event scheduling and is in effect within the event as it executes.

For representation of event information in the `mysql.event` table, the `execute_at`, `starts`, and `ends` times are converted to UTC and stored along with the event time zone. This enables event execution to proceed as defined regardless of any subsequent changes to the server time zone or daylight saving time effects. The `last_executed` time is also stored in UTC.

If you select information from `mysql.event`, the times just mentioned are retrieved as UTC values. These times can also be obtained by selecting from the `INFORMATION_SCHEMA.EVENTS` table or from `SHOW EVENTS`, but they are reported as ETZ values. Other times available from these sources indicate when an event was created or last altered; these are displayed as STZ values. The following table summarizes representation of event times.

Value	<code>mysql.event</code>	<code>INFORMATION_SCHEMA.EVENTS</code>	<code>EVENTS</code>
Execute at	UTC	ETZ	ETZ
Starts	UTC	ETZ	ETZ
Ends	UTC	ETZ	ETZ
Last executed	UTC	ETZ	n/a
Created	STZ	STZ	n/a
Last altered	STZ	STZ	n/a

23.4.5 Event Scheduler Status

The Event Scheduler writes information about event execution that terminates with an error or warning to the MySQL Server's error log. See [Section 23.4.6, “The Event Scheduler and MySQL Privileges”](#) for an example.

To obtain information about the state of the Event Scheduler for debugging and troubleshooting purposes, run `mysqladmin debug` (see [Section 4.5.2, “mysqladmin — Client for Administering a MySQL Server”](#)); after running this command, the server's error log contains output relating to the Event Scheduler, similar to what is shown here:

```
Events status:
LLA = Last Locked At  LUA = Last Unlocked At
WOC = Waiting On Condition  DL = Data Locked

Event scheduler status:
State      : INITIALIZED
Thread id  : 0
LLA       : init_scheduler:313
```

```

LUA      : init_scheduler:318
WOC      : NO
Workers  : 0
Executed  : 0
Data locked: NO

Event queue status:
Element count  : 1
Data locked    : NO
Attempting lock : NO
LLA           : init_queue:148
LUA           : init_queue:168
WOC           : NO
Next activation : 0000-00-00 00:00:00

```

In statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log. For frequently executed events, it is possible for this to result in many logged messages. For example, for `SELECT ... INTO var_list` statements, if the query returns no rows, a warning with error code 1329 occurs (`No data`), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (`Result consisted of more than one row`). For either condition, you can avoid having the warnings be logged by declaring a condition handler; see [Section 13.6.7.2, “DECLARE ... HANDLER Syntax”](#). For statements that may retrieve multiple rows, another strategy is to use `LIMIT 1` to limit the result set to a single row.

23.4.6 The Event Scheduler and MySQL Privileges

To enable or disable the execution of scheduled events, it is necessary to set the value of the global `event_scheduler` system variable. This requires the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege.

The `EVENT` privilege governs the creation, modification, and deletion of events. This privilege can be bestowed using `GRANT`. For example, this `GRANT` statement confers the `EVENT` privilege for the schema named `myschema` on the user `jon@ghidora`:

```
GRANT EVENT ON myschema.* TO jon@ghidora;
```

(We assume that this user account already exists, and that we wish for it to remain unchanged otherwise.)

To grant this same user the `EVENT` privilege on all schemas, use the following statement:

```
GRANT EVENT ON *.* TO jon@ghidora;
```

The `EVENT` privilege has global or schema-level scope. Therefore, trying to grant it on a single table results in an error as shown:

```
mysql> GRANT EVENT ON myschema.mytable TO jon@ghidora;
ERROR 1144 (42000): Illegal GRANT/REVOKE command; please
consult the manual to see which privileges can be used
```

It is important to understand that an event is executed with the privileges of its definer, and that it cannot perform any actions for which its definer does not have the requisite privileges. For example, suppose that `jon@ghidora` has the `EVENT` privilege for `myschema`. Suppose also that this user has the `SELECT` privilege for `myschema`, but no other privileges for this schema. It is possible for `jon@ghidora` to create a new event such as this one:

```
CREATE EVENT e_store_ts
ON SCHEDULE
EVERY 10 SECOND
DO
```

```
INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
```

The user waits for a minute or so, and then performs a `SELECT * FROM mytable;` query, expecting to see several new rows in the table. Instead, the table is empty. Since the user does not have the `INSERT` privilege for the table in question, the event has no effect.

If you inspect the MySQL error log (`hostname.err`), you can see that the event is executing, but the action it is attempting to perform fails:

```
2013-09-24T12:41:31.261992Z 25 [ERROR] Event Scheduler:
[jon@ghidora][cookbook.e_store_ts] INSERT command denied to user
'jon'@'ghidora' for table 'mytable'
2013-09-24T12:41:31.262022Z 25 [Note] Event Scheduler:
[jon@ghidora].[myschema.e_store_ts] event execution failed.
2013-09-24T12:41:41.271796Z 26 [ERROR] Event Scheduler:
[jon@ghidora][cookbook.e_store_ts] INSERT command denied to user
'jon'@'ghidora' for table 'mytable'
2013-09-24T12:41:41.272761Z 26 [Note] Event Scheduler:
[jon@ghidora].[myschema.e_store_ts] event execution failed.
```

Since this user very likely does not have access to the error log, it is possible to verify whether the event's action statement is valid by executing it directly:

```
mysql> INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP());
ERROR 1142 (42000): INSERT command denied to user
'jon'@'ghidora' for table 'mytable'
```

Inspection of the `INFORMATION_SCHEMA.EVENTS` table shows that `e_store_ts` exists and is enabled, but its `LAST_EXECUTED` column is `NULL`:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
> WHERE EVENT_NAME='e_store_ts'
> AND EVENT_SCHEMA='myschema'\G
***** 1. row *****
EVENT_CATALOG: NULL
EVENT_SCHEMA: myschema
EVENT_NAME: e_store_ts
DEFINER: jon@ghidora
EVENT_BODY: SQL
EVENT_DEFINITION: INSERT INTO myschema.mytable VALUES (UNIX_TIMESTAMP())
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 5
INTERVAL_FIELD: SECOND
SQL_MODE: NULL
STARTS: 0000-00-00 00:00:00
ENDS: 0000-00-00 00:00:00
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2006-02-09 22:36:06
LAST_ALTERED: 2006-02-09 22:36:06
LAST_EXECUTED: NULL
EVENT_COMMENT:
1 row in set (0.00 sec)
```

To rescind the `EVENT` privilege, use the `REVOKE` statement. In this example, the `EVENT` privilege on the schema `myschema` is removed from the `jon@ghidora` user account:

```
REVOKE EVENT ON myschema.* FROM jon@ghidora;
```

Important

Revoking the `EVENT` privilege from a user does not delete or disable any events that may have been created by that user.

An event is not migrated or dropped as a result of renaming or dropping the user who created it.

Suppose that the user `jon@ghidora` has been granted the `EVENT` and `INSERT` privileges on the `myschema` schema. This user then creates the following event:

```
CREATE EVENT e_insert
  ON SCHEDULE
    EVERY 7 SECOND
  DO
    INSERT INTO myschema.mytable;
```

After this event has been created, `root` revokes the `EVENT` privilege for `jon@ghidora`. However, `e_insert` continues to execute, inserting a new row into `mytable` each seven seconds. The same would be true if `root` had issued either of these statements:

- `DROP USER jon@ghidora;`
- `RENAME USER jon@ghidora TO someotherguy@ghidora;`

You can verify that this is true by examining the `mysql.event` table (discussed later in this section) or the `INFORMATION_SCHEMA.EVENTS` table (see [Section 24.8, “The INFORMATION_SCHEMA EVENTS Table”](#)) before and after issuing a `DROP USER` or `RENAME USER` statement.

Event definitions are stored in the `mysql.event` table. To drop an event created by another user account, the MySQL `root` user (or another user with the necessary privileges) can delete rows from this table. For example, to remove the event `e_insert` shown previously, `root` can use the following statement:

```
DELETE FROM mysql.event
  WHERE db = 'myschema'
     AND definer = 'jon@ghidora'
     AND name = 'e_insert';
```

It is very important to match the event name, database schema name, and user account when deleting rows from the `mysql.event` table. This is because the same user can create different events of the same name in different schemas.

Users' `EVENT` privileges are stored in the `Event_priv` columns of the `mysql.user` and `mysql.db` tables. In both cases, this column holds one of the values 'Y' or 'N'. 'N' is the default. `mysql.user.Event_priv` is set to 'Y' for a given user only if that user has the global `EVENT` privilege (that is, if the privilege was bestowed using `GRANT EVENT ON *.*`). For a schema-level `EVENT` privilege, `GRANT` creates a row in `mysql.db` and sets that row's `Db` column to the name of the schema, the `User` column to the name of the user, and the `Event_priv` column to 'Y'. There should never be any need to manipulate these tables directly, since the `GRANT EVENT` and `REVOKE EVENT` statements perform the required operations on them.

Five status variables provide counts of event-related operations (but *not* of statements executed by events; see [Section C.1, “Restrictions on Stored Programs”](#)). These are:

- `Com_create_event`: The number of `CREATE EVENT` statements executed since the last server restart.
- `Com_alter_event`: The number of `ALTER EVENT` statements executed since the last server restart.
- `Com_drop_event`: The number of `DROP EVENT` statements executed since the last server restart.
- `Com_show_create_event`: The number of `SHOW CREATE EVENT` statements executed since the last server restart.

- `Com_show_events`: The number of `SHOW EVENTS` statements executed since the last server restart.

You can view current values for all of these at one time by running the statement `SHOW STATUS LIKE '%event%'`;

23.5 Using Views

MySQL supports views, including updatable views. Views are stored queries that when invoked produce a result set. A view acts as a virtual table.

The following discussion describes the syntax for creating and dropping views, and shows some examples of how to use them.

Additional Resources

- You may find the [Views User Forum](#) of use when working with views.
- For answers to some commonly asked questions regarding views in MySQL, see [Section A.6, “MySQL 8.0 FAQ: Views”](#).
- There are some restrictions on the use of views; see [Section C.5, “Restrictions on Views”](#).

23.5.1 View Syntax

The `CREATE VIEW` statement creates a new view (see [Section 13.1.18, “CREATE VIEW Syntax”](#)). To alter the definition of a view or drop a view, use `ALTER VIEW` (see [Section 13.1.8, “ALTER VIEW Syntax”](#)), or `DROP VIEW` (see [Section 13.1.28, “DROP VIEW Syntax”](#)).

A view can be created from many kinds of `SELECT` statements. It can refer to base tables or other views. It can use joins, `UNION`, and subqueries. The `SELECT` need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
mysql> CREATE TABLE t (qty INT, price INT);
mysql> INSERT INTO t VALUES(3, 50), (5, 60);
mysql> CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;
mysql> SELECT * FROM v;
+-----+-----+-----+
| qty | price | value |
+-----+-----+-----+
| 3 | 50 | 150 |
| 5 | 60 | 300 |
+-----+-----+-----+
mysql> SELECT * FROM v WHERE qty = 5;
+-----+-----+-----+
| qty | price | value |
+-----+-----+-----+
| 5 | 60 | 300 |
+-----+-----+-----+
```

23.5.2 View Processing Algorithms

The optional `ALGORITHM` clause for `CREATE VIEW` or `ALTER VIEW` is a MySQL extension to standard SQL. It affects how MySQL processes the view. `ALGORITHM` takes three values: `MERGE`, `TEMPTABLE`, or `UNDEFINED`.

- For `MERGE`, the text of a statement that refers to the view and the view definition are merged such that parts of the view definition replace corresponding parts of the statement.
- For `TEMPTABLE`, the results from the view are retrieved into a temporary table, which then is used to execute the statement.

- For `UNDEFINED`, MySQL chooses which algorithm to use. It prefers `MERGE` over `TEMPTABLE` if possible, because `MERGE` is usually more efficient and because a view cannot be updatable if a temporary table is used.
- If no `ALGORITHM` clause is present, the default algorithm is determined by the value of the `derived_merge` flag of the `optimizer_switch` system variable. For additional discussion, see [Section 8.2.2.3, “Optimizing Derived Tables, View References, and Common Table Expressions”](#).

A reason to specify `TEMPTABLE` explicitly is that locks can be released on underlying tables after the temporary table has been created and before it is used to finish processing the statement. This might result in quicker lock release than the `MERGE` algorithm so that other clients that use the view are not blocked as long.

A view algorithm can be `UNDEFINED` for three reasons:

- No `ALGORITHM` clause is present in the `CREATE VIEW` statement.
- The `CREATE VIEW` statement has an explicit `ALGORITHM = UNDEFINED` clause.
- `ALGORITHM = MERGE` is specified for a view that can be processed only with a temporary table. In this case, MySQL generates a warning and sets the algorithm to `UNDEFINED`.

As mentioned earlier, `MERGE` is handled by merging corresponding parts of a view definition into the statement that refers to the view. The following examples briefly illustrate how the `MERGE` algorithm works. The examples assume that there is a view `v_merge` that has this definition:

```
CREATE ALGORITHM = MERGE VIEW v_merge (vc1, vc2) AS
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 1: Suppose that we issue this statement:

```
SELECT * FROM v_merge;
```

MySQL handles the statement as follows:

- `v_merge` becomes `t`
- `*` becomes `vc1, vc2`, which corresponds to `c1, c2`
- The view `WHERE` clause is added

The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE c3 > 100;
```

Example 2: Suppose that we issue this statement:

```
SELECT * FROM v_merge WHERE vc1 < 100;
```

This statement is handled similarly to the previous one, except that `vc1 < 100` becomes `c1 < 100` and the view `WHERE` clause is added to the statement `WHERE` clause using an `AND` connective (and parentheses are added to make sure the parts of the clause are executed with correct precedence). The resulting statement to be executed becomes:

```
SELECT c1, c2 FROM t WHERE (c3 > 100) AND (c1 < 100);
```

Effectively, the statement to be executed has a `WHERE` clause of this form:

```
WHERE (select WHERE) AND (view WHERE)
```

If the [MERGE](#) algorithm cannot be used, a temporary table must be used instead. Constructs that prevent merging are the same as those that prevent merging in derived tables. Examples are [SELECT DISTINCT](#) or [LIMIT](#) in the subquery. For details, see [Section 8.2.2.3, “Optimizing Derived Tables, View References, and Common Table Expressions”](#).

23.5.3 Updatable and Insertable Views

Some views are updatable and references to them can be used to specify tables to be updated in data change statements. That is, you can use them in statements such as [UPDATE](#), [DELETE](#), or [INSERT](#) to update the contents of the underlying table. Derived tables can also be specified in multiple-table [UPDATE](#) and [DELETE](#) statements, but can only be used for reading data to specify rows to be updated or deleted. Generally, the view references must be updatable, meaning that they may be merged and not materialized. Composite views have more complex rules.

For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view nonupdatable. To be more specific, a view is not updatable if it contains any of the following:

- Aggregate functions ([SUM\(\)](#), [MIN\(\)](#), [MAX\(\)](#), [COUNT\(\)](#), and so forth)
- [DISTINCT](#)
- [GROUP BY](#)
- [HAVING](#)
- [UNION](#) or [UNION ALL](#)
- Subquery in the select list

Nondependent subqueries in the select list fail for [INSERT](#), but are okay for [UPDATE](#), [DELETE](#). For dependent subqueries in the select list, no data change statements are permitted.

- Certain joins (see additional join discussion later in this section)
- Reference to nonupdatable view in the [FROM](#) clause
- Subquery in the [WHERE](#) clause that refers to a table in the [FROM](#) clause
- Refers only to literal values (in this case, there is no underlying table to update)
- [ALGORITHM = TEMPTABLE](#) (use of a temporary table always makes a view nonupdatable)
- Multiple references to any column of a base table (fails for [INSERT](#), okay for [UPDATE](#), [DELETE](#))

A generated column in a view is considered updatable because it is possible to assign to it. However, if such a column is updated explicitly, the only permitted value is [DEFAULT](#). For information about generated columns, see [Section 13.1.15.8, “CREATE TABLE and Generated Columns”](#).

It is sometimes possible for a multiple-table view to be updatable, assuming that it can be processed with the [MERGE](#) algorithm. For this to work, the view must use an inner join (not an outer join or a [UNION](#)). Also, only a single table in the view definition can be updated, so the [SET](#) clause must name only columns from one of the tables in the view. Views that use [UNION ALL](#) are not permitted even though they might be theoretically updatable.

With respect to insertability (being updatable with [INSERT](#) statements), an updatable view is insertable if it also satisfies these additional requirements for the view columns:

- There must be no duplicate view column names.

- The view must contain all columns in the base table that do not have a default value.
- The view columns must be simple column references. They must not be expressions, such as these:

```
3.14159
col1 + 3
UPPER(col2)
col3 / col4
(subquery)
```

MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the `INFORMATION_SCHEMA.VIEWS` table displays the status of this flag. It means that the server always knows whether a view is updatable.

If a view is not updatable, statements such `UPDATE`, `DELETE`, and `INSERT` are illegal and are rejected. (Note that even if a view is updatable, it might not be possible to insert into it, as described elsewhere in this section.)

The updatability of views may be affected by the value of the `updatable_views_with_limit` system variable. See [Section 5.1.5, “Server System Variables”](#).

For the following discussion, suppose that these tables and views exist:

```
CREATE TABLE t1 (x INTEGER);
CREATE TABLE t2 (c INTEGER);
CREATE VIEW vmat AS SELECT SUM(x) AS s FROM t1;
CREATE VIEW vup AS SELECT * FROM t2;
CREATE VIEW vjoin AS SELECT * FROM vmat JOIN vup ON vmat.s=vup.c;
```

`INSERT`, `UPDATE`, and `DELETE` statements are permitted as follows:

- `INSERT`: The insert table of an `INSERT` statement may be a view reference that is merged. If the view is a join view, all components of the view must be updatable (not materialized). For a multiple-table updatable view, `INSERT` can work if it inserts into a single table.

This statement is invalid because one component of the join view is nonupdatable:

```
INSERT INTO vjoin (c) VALUES (1);
```

This statement is valid; the view contains no materialized components:

```
INSERT INTO vup (c) VALUES (1);
```

- `UPDATE`: The table or tables to be updated in an `UPDATE` statement may be view references that are merged. If a view is a join view, at least one component of the view must be updatable (this differs from `INSERT`).

In a multiple-table `UPDATE` statement, the updated table references of the statement must be base tables or updatable view references. Nonupdated table references may be materialized views or derived tables.

This statement is valid; column `c` is from the updatable part of the join view:

```
UPDATE vjoin SET c=c+1;
```

This statement is invalid; column `x` is from the nonupdatable part:

```
UPDATE vjoin SET x=x+1;
```

This statement is valid; the updated table reference of the multiple-table `UPDATE` is an updatable view (`vup`):

```
UPDATE vup JOIN (SELECT SUM(x) AS s FROM t1) AS dt ON ...
SET c=c+1;
```

This statement is invalid; it tries to update a materialized derived table:

```
UPDATE vup JOIN (SELECT SUM(x) AS s FROM t1) AS dt ON ...
SET s=s+1;
```

- `DELETE`: The table or tables to be deleted from in a `DELETE` statement must be merged views. Join views are not allowed (this differs from `INSERT` and `UPDATE`).

This statement is invalid because the view is a join view:

```
DELETE vjoin WHERE ...;
```

This statement is valid because the view is a merged (updatable) view:

```
DELETE vup WHERE ...;
```

This statement is valid because it deletes from a merged (updatable) view:

```
DELETE vup FROM vup JOIN (SELECT SUM(x) AS s FROM t1) AS dt ON ...;
```

Additional discussion and examples follow.

Earlier discussion in this section pointed out that a view is not insertable if not all columns are simple column references (for example, if it contains columns that are expressions or composite expressions). Although such a view is not insertable, it can be updatable if you update only columns that are not expressions. Consider this view:

```
CREATE VIEW v AS SELECT col1, 1 AS col2 FROM t;
```

This view is not insertable because `col2` is an expression. But it is updatable if the update does not try to update `col2`. This update is permissible:

```
UPDATE v SET col1 = 0;
```

This update is not permissible because it attempts to update an expression column:

```
UPDATE v SET col2 = 0;
```

If a table contains an `AUTO_INCREMENT` column, inserting into an insertable view on the table that does not include the `AUTO_INCREMENT` column does not change the value of `LAST_INSERT_ID()`, because the side effects of inserting default values into columns not part of the view should not be visible.

23.5.4 The View WITH CHECK OPTION Clause

The `WITH CHECK OPTION` clause can be given for an updatable view to prevent inserts to rows for which the `WHERE` clause in the `select_statement` is not true. It also prevents updates to rows for which the `WHERE` clause is true but the update would cause it to be not true (in other words, it prevents visible rows from being updated to nonvisible rows).

In a `WITH CHECK OPTION` clause for an updatable view, the `LOCAL` and `CASCADED` keywords determine the scope of check testing when the view is defined in terms of another view. When neither keyword is given, the default is `CASCADED`.

`WITH CHECK OPTION` testing is standard-compliant:

- With `LOCAL`, the view `WHERE` clause is checked, then checking recurses to underlying views and applies the same rules.
- With `CASCADED`, the view `WHERE` clause is checked, then checking recurses to underlying views, adds `WITH CASCADED CHECK OPTION` to them (for purposes of the check; their definitions remain unchanged), and applies the same rules.
- With no check option, the view `WHERE` clause is not checked, then checking recurses to underlying views, and applies the same rules.

Consider the definitions for the following table and set of views:

```
CREATE TABLE t1 (a INT);
CREATE VIEW v1 AS SELECT * FROM t1 WHERE a < 2
WITH CHECK OPTION;
CREATE VIEW v2 AS SELECT * FROM v1 WHERE a > 0
WITH LOCAL CHECK OPTION;
CREATE VIEW v3 AS SELECT * FROM v1 WHERE a > 0
WITH CASCADED CHECK OPTION;
```

Here the `v2` and `v3` views are defined in terms of another view, `v1`.

Inserts for `v2` are checked against its `LOCAL` check option, then the check recurses to `v1` and the rules are applied again. The rules for `v1` cause a check failure. The check for `v3` also fails:

```
mysql> INSERT INTO v2 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v2'
mysql> INSERT INTO v3 VALUES (2);
ERROR 1369 (HY000): CHECK OPTION failed 'test.v3'
```

23.5.5 View Metadata

Metadata about views can be obtained as follows:

- Query the `VIEWS` table of the `INFORMATION_SCHEMA` database. See [Section 24.30, “The INFORMATION_SCHEMA VIEWS Table”](#).
- Use the `SHOW CREATE VIEW` statement. See [Section 13.7.5.13, “SHOW CREATE VIEW Syntax”](#).

23.6 Access Control for Stored Programs and Views

Stored programs and views are defined prior to use and, when referenced, execute within a security context that determines their privileges. These privileges are controlled by their `DEFINER` attribute, and, if there is one, their `SQL SECURITY` characteristic.

All stored programs (procedures, functions, triggers, and events) and views can have a `DEFINER` attribute that names a MySQL account. If the `DEFINER` attribute is omitted from a stored program or view definition, the default account is the user who creates the object.

In addition, stored routines (procedures and functions) and views can have an `SQL SECURITY` characteristic with a value of `DEFINER` or `INVOKER` to specify whether the object executes in definer or invoker context. If the `SQL SECURITY` characteristic is omitted, the default is definer context.

Triggers and events have no `SQL SECURITY` characteristic and always execute in definer context. The server invokes these objects automatically as necessary, so there is no invoking user.

Definer and invoker security contexts differ as follows:

- A stored program or view that executes in definer security context executes with the privileges of the account named by its `DEFINER` attribute. These privileges may be entirely different from those of the invoking user. The invoker must have appropriate privileges to reference the object (for example, `EXECUTE` to call a stored procedure or `SELECT` to select from a view), but when the object executes, the invoker's privileges are ignored and only the `DEFINER` account privileges matter. If this account has few privileges, the object is correspondingly limited in the operations it can perform. If the `DEFINER` account is highly privileged (such as a `root` account), the object can perform powerful operations *no matter who invokes it*.
- A stored routine or view that executes in invoker security context can perform only operations for which the invoker has privileges. The `DEFINER` attribute can be specified but has no effect for objects that execute in invoker context.

Consider the following stored procedure:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p1()
SQL SECURITY DEFINER
BEGIN
  UPDATE t1 SET counter = counter + 1;
END;
```

Any user who has the `EXECUTE` privilege for `p1` can invoke it with a `CALL` statement. However, when `p1` executes, it does so in `DEFINER` security context and thus executes with the privileges of `'admin'@'localhost'`, the account named in the `DEFINER` attribute. This account must have the `EXECUTE` privilege for `p1` as well as the `UPDATE` privilege for the table `t1`. Otherwise, the procedure fails.

Now consider this stored procedure, which is identical to `p1` except that its `SQL SECURITY` characteristic is `INVOKER`:

```
CREATE DEFINER = 'admin'@'localhost' PROCEDURE p2()
SQL SECURITY INVOKER
BEGIN
  UPDATE t1 SET counter = counter + 1;
END;
```

`p2`, unlike `p1`, executes in `INVOKER` security context. The `DEFINER` attribute is irrelevant and `p2` executes with the privileges of the invoking user. `p2` fails if the invoker lacks the `EXECUTE` privilege for `p2` or the `UPDATE` privilege for the table `t1`.

MySQL uses the following rules to control which accounts a user can specify in an object `DEFINER` attribute:

- You can specify a `DEFINER` value other than your own account only if you have the `SET_USER_ID` or `SUPER` privilege.
- If you do not have the `SET_USER_ID` or `SUPER` privilege, the only legal user value is your own account, either specified literally or by using `CURRENT_USER`. You cannot set the definer to some other account.

To minimize the risk potential for stored program and view creation and use, follow these guidelines:

- For a stored routine or view, use `SQL SECURITY INVOKER` in the object definition when possible so that it can be used only by users with permissions appropriate for the operations performed by the object.
- If you create definer-context stored programs or views while using an account that has the `SET_USER_ID` or `SUPER` privilege, specify an explicit `DEFINER` attribute that names an account

possessing only the privileges required for the operations performed by the object. Specify a highly privileged `DEFINER` account only when absolutely necessary.

- Administrators can prevent users from specifying highly privileged `DEFINER` accounts by not granting them the `SET_USER_ID` or `SUPER` privilege.
- Definer-context objects should be written keeping in mind that they may be able to access data for which the invoking user has no privileges. In some cases, you can prevent reference to these objects by not granting unauthorized users particular privileges:
 - A stored procedure or function cannot be referenced by a user who does not have the `EXECUTE` privilege for it.
 - A view cannot be referenced by a user who does not have the appropriate privilege for it (`SELECT` to select from it, `INSERT` to insert into it, and so forth).

However, no such control exists for triggers because users do not reference them directly. A trigger always executes in `DEFINER` context and is activated by access to the table with which it is associated, even ordinary table accesses by users with no special privileges. If the `DEFINER` account is highly privileged, the trigger can perform sensitive or dangerous operations. This remains true if the `SET_USER_ID` (or `SUPER`) and `TRIGGER` privileges needed to create the trigger are revoked from the account of the user who created it. Administrators should be especially careful about granting users that combination of privileges.

23.7 Binary Logging of Stored Programs

The binary log contains information about SQL statements that modify database contents. This information is stored in the form of “events” that describe the modifications. The binary log has two important purposes:

- For replication, the binary log is used on master replication servers as a record of the statements to be sent to slave servers. The master server sends the events contained in its binary log to its slaves, which execute those events to make the same data changes that were made on the master. See [Section 18.2, “Replication Implementation”](#).
- Certain data recovery operations require use of the binary log. After a backup file has been restored, the events in the binary log that were recorded after the backup was made are re-executed. These events bring databases up to date from the point of the backup. See [Section 7.3.2, “Using Backups for Recovery”](#).

However, if logging occurs at the statement level, there are certain binary logging issues with respect to stored programs (stored procedures and functions, triggers, and events):

- In some cases, a statement might affect different sets of rows on master and slave.
- Replicated statements executed on a slave are processed by the slave SQL thread, which has full privileges. It is possible for a procedure to follow different execution paths on master and slave servers, so a user can write a routine containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges.
- If a stored program that modifies data is nondeterministic, it is not repeatable. This can result in different data on master and slave, or cause restored data to differ from the original data.

This section describes how MySQL handles binary logging for stored programs. It states the current conditions that the implementation places on the use of stored programs, and what you can do to avoid logging problems. It also provides additional information about the reasons for these conditions.

In general, the issues described here result when binary logging occurs at the SQL statement level. If you use row-based binary logging, the log contains changes made to individual rows as a result of executing SQL statements. When routines or triggers execute, row changes are logged, not the

statements that make the changes. For stored procedures, this means that the `CALL` statement is not logged. For stored functions, row changes made within the function are logged, not the function invocation. For triggers, row changes made by the trigger are logged. On the slave side, only the row changes are seen, not the stored program invocation. For general information about row-based logging, see [Section 18.2.1, “Replication Formats”](#).

Unless noted otherwise, the remarks here assume that you have enabled binary logging by starting the server with the `--log-bin` option. (See [Section 5.4.4, “The Binary Log”](#).) If the binary log is not enabled, replication is not possible, nor is the binary log available for data recovery.

The conditions on the use of stored functions in MySQL can be summarized as follows. These conditions do not apply to stored procedures or Event Scheduler events and they do not apply unless binary logging is enabled.

- To create or alter a stored function, you must have the `SET_USER_ID` or `SUPER` privilege, in addition to the `CREATE ROUTINE` or `ALTER ROUTINE` privilege that is normally required. (Depending on the `DEFINER` value in the function definition, `SET_USER_ID` or `SUPER` might be required regardless of whether binary logging is enabled. See [Section 13.1.13, “CREATE PROCEDURE and CREATE FUNCTION Syntax”](#).)
- When you create a stored function, you must declare either that it is deterministic or that it does not modify data. Otherwise, it may be unsafe for data recovery or replication.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

This function is deterministic (and does not modify data), so it is safe:

```
CREATE FUNCTION f1(i INT)
RETURNS INT
DETERMINISTIC
READS SQL DATA
BEGIN
    RETURN i;
END;
```

This function uses `UUID()`, which is not deterministic, so the function also is not deterministic and is not safe:

```
CREATE FUNCTION f2()
RETURNS CHAR(36) CHARACTER SET utf8
BEGIN
    RETURN UUID();
END;
```

This function modifies data, so it may not be safe:

```
CREATE FUNCTION f3(p_id INT)
RETURNS INT
BEGIN
    UPDATE t SET modtime = NOW() WHERE id = p_id;
    RETURN ROW_COUNT();
END;
```

Assessment of the nature of a function is based on the “honesty” of the creator: MySQL does not check that a function declared `DETERMINISTIC` is free of statements that produce nondeterministic results.

- Although it is possible to create a deterministic stored function without specifying `DETERMINISTIC`, you cannot execute this function using statement-based binary logging. To execute such a function, you must use row-based or mixed binary logging. Alternatively, if you explicitly specify `DETERMINISTIC` in the function definition, you can use any kind of logging, including statement-based logging.
- To relax the preceding conditions on function creation (that you must have the `SUPER` privilege and that a function must be declared deterministic or to not modify data), set the global `log_bin_trust_function_creators` system variable to 1. By default, this variable has a value of 0, but you can change it like this:

```
mysql> SET GLOBAL log_bin_trust_function_creators = 1;
```

You can also set this variable by using the `--log-bin-trust-function-creators=1` option when starting the server.

If binary logging is not enabled, `log_bin_trust_function_creators` does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- For information about built-in functions that may be unsafe for replication (and thus cause stored functions that use them to be unsafe as well), see [Section 18.4.1, “Replication Features and Issues”](#).

Triggers are similar to stored functions, so the preceding remarks regarding functions also apply to triggers with the following exception: `CREATE TRIGGER` does not have an optional `DETERMINISTIC` characteristic, so triggers are assumed to be always deterministic. However, this assumption might be invalid in some cases. For example, the `UUID()` function is nondeterministic (and does not replicate). Be careful about using such functions in triggers.

Triggers can update tables, so error messages similar to those for stored functions occur with `CREATE TRIGGER` if you do not have the required privileges. On the slave side, the slave uses the trigger `DEFINER` attribute to determine which user is considered to be the creator of the trigger.

The rest of this section provides additional detail about the logging implementation and its implications. You need not read it unless you are interested in the background on the rationale for the current logging-related conditions on stored routine use. This discussion applies only for statement-based logging, and not for row-based logging, with the exception of the first item: `CREATE` and `DROP` statements are logged as statements regardless of the logging mode.

- The server writes `CREATE EVENT`, `CREATE PROCEDURE`, `CREATE FUNCTION`, `ALTER EVENT`, `ALTER PROCEDURE`, `ALTER FUNCTION`, `DROP EVENT`, `DROP PROCEDURE`, and `DROP FUNCTION` statements to the binary log.
- A stored function invocation is logged as a `SELECT` statement if the function changes data and occurs within a statement that would not otherwise be logged. This prevents nonreplication of data changes that result from use of stored functions in nonlogged statements. For example, `SELECT` statements are not written to the binary log, but a `SELECT` might invoke a stored function that makes changes. To handle this, a `SELECT func_name()` statement is written to the binary log when the given function makes a change. Suppose that the following statements are executed on the master:

```
CREATE FUNCTION f1(a INT) RETURNS INT
BEGIN
  IF (a < 3) THEN
    INSERT INTO t2 VALUES (a);
  END IF;
  RETURN 0;
END;

CREATE TABLE t1 (a INT);
INSERT INTO t1 VALUES (1),(2),(3);
```

```
SELECT f1(a) FROM t1;
```

When the `SELECT` statement executes, the function `f1()` is invoked three times. Two of those invocations insert a row, and MySQL logs a `SELECT` statement for each of them. That is, MySQL writes the following statements to the binary log:

```
SELECT f1(1);
SELECT f1(2);
```

The server also logs a `SELECT` statement for a stored function invocation when the function invokes a stored procedure that causes an error. In this case, the server writes the `SELECT` statement to the log along with the expected error code. On the slave, if the same error occurs, that is the expected result and replication continues. Otherwise, replication stops.

- Logging stored function invocations rather than the statements executed by a function has a security implication for replication, which arises from two factors:
 - It is possible for a function to follow different execution paths on master and slave servers.
 - Statements executed on a slave are processed by the slave SQL thread which has full privileges.

The implication is that although a user must have the `CREATE ROUTINE` privilege to create a function, the user can write a function containing a dangerous statement that will execute only on the slave where it is processed by a thread that has full privileges. For example, if the master and slave servers have server ID values of 1 and 2, respectively, a user on the master server could create and invoke an unsafe function `unsafe_func()` as follows:

```
mysql> delimiter //
mysql> CREATE FUNCTION unsafe_func () RETURNS INT
-> BEGIN
->   IF @@server_id=2 THEN dangerous_statement; END IF;
->   RETURN 1;
-> END;
-> //
mysql> delimiter ;
mysql> INSERT INTO t VALUES(unsafe_func());
```

The `CREATE FUNCTION` and `INSERT` statements are written to the binary log, so the slave will execute them. Because the slave SQL thread has full privileges, it will execute the dangerous statement. Thus, the function invocation has different effects on the master and slave and is not replication-safe.

To guard against this danger for servers that have binary logging enabled, stored function creators must have the `SUPER` privilege, in addition to the usual `CREATE ROUTINE` privilege that is required. Similarly, to use `ALTER FUNCTION`, you must have the `SUPER` privilege in addition to the `ALTER ROUTINE` privilege. Without the `SUPER` privilege, an error will occur:

```
ERROR 1419 (HY000): You do not have the SUPER privilege and
binary logging is enabled (you *might* want to use the less safe
log_bin_trust_function_creators variable)
```

If you do not want to require function creators to have the `SUPER` privilege (for example, if all users with the `CREATE ROUTINE` privilege on your system are experienced application developers), set the global `log_bin_trust_function_creators` system variable to 1. You can also set this variable by using the `--log-bin-trust-function-creators=1` option when starting the server. If binary logging is not enabled, `log_bin_trust_function_creators` does not apply. `SUPER` is not required for function creation unless, as described previously, the `DEFINER` value in the function definition requires it.

- If a function that performs updates is nondeterministic, it is not repeatable. This can have two undesirable effects:

- It will make a slave different from the master.
- Restored data will be different from the original data.

To deal with these problems, MySQL enforces the following requirement: On a master server, creation and alteration of a function is refused unless you declare the function to be deterministic or to not modify data. Two sets of function characteristics apply here:

- The `DETERMINISTIC` and `NOT DETERMINISTIC` characteristics indicate whether a function always produces the same result for given inputs. The default is `NOT DETERMINISTIC` if neither characteristic is given. To declare that a function is deterministic, you must specify `DETERMINISTIC` explicitly.
- The `CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` characteristics provide information about whether the function reads or writes data. Either `NO SQL` or `READS SQL DATA` indicates that a function does not change data, but you must specify one of these explicitly because the default is `CONTAINS SQL` if no characteristic is given.

By default, for a `CREATE FUNCTION` statement to be accepted, at least one of `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` must be specified explicitly. Otherwise an error occurs:

```
ERROR 1418 (HY000): This function has none of DETERMINISTIC, NO SQL,
or READS SQL DATA in its declaration and binary logging is enabled
(you *might* want to use the less safe log_bin_trust_function_creators
variable)
```

If you set `log_bin_trust_function_creators` to 1, the requirement that functions be deterministic or not modify data is dropped.

- Stored procedure calls are logged at the statement level rather than at the `CALL` level. That is, the server does not log the `CALL` statement, it logs those statements within the procedure that actually execute. As a result, the same changes that occur on the master will be observed on slave servers. This prevents problems that could result from a procedure having different execution paths on different machines.

In general, statements executed within a stored procedure are written to the binary log using the same rules that would apply were the statements to be executed in standalone fashion. Some special care is taken when logging procedure statements because statement execution within procedures is not quite the same as in nonprocedure context:

- A statement to be logged might contain references to local procedure variables. These variables do not exist outside of stored procedure context, so a statement that refers to such a variable cannot be logged literally. Instead, each reference to a local variable is replaced by this construct for logging purposes:

```
NAME_CONST(var_name, var_value)
```

`var_name` is the local variable name, and `var_value` is a constant indicating the value that the variable has at the time the statement is logged. `NAME_CONST()` has a value of `var_value`, and a “name” of `var_name`. Thus, if you invoke this function directly, you get a result like this:

```
mysql> SELECT NAME_CONST('myname', 14);
+-----+
| myname |
+-----+
|      14 |
+-----+
```

`NAME_CONST()` enables a logged standalone statement to be executed on a slave with the same effect as the original statement that was executed on the master within a stored procedure.

The use of `NAME_CONST()` can result in a problem for `CREATE TABLE ... SELECT` statements when the source column expressions refer to local variables. Converting these references to `NAME_CONST()` expressions can result in column names that are different on the master and slave servers, or names that are too long to be legal column identifiers. A workaround is to supply aliases for columns that refer to local variables. Consider this statement when `myvar` has a value of 1:

```
CREATE TABLE t1 SELECT myvar;
```

That will be rewritten as follows:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1);
```

To ensure that the master and slave tables have the same column names, write the statement like this:

```
CREATE TABLE t1 SELECT myvar AS myvar;
```

The rewritten statement becomes:

```
CREATE TABLE t1 SELECT NAME_CONST(myvar, 1) AS myvar;
```

- A statement to be logged might contain references to user-defined variables. To handle this, MySQL writes a `SET` statement to the binary log to make sure that the variable exists on the slave with the same value as on the master. For example, if a statement refers to a variable `@my_var`, that statement will be preceded in the binary log by the following statement, where `value` is the value of `@my_var` on the master:

```
SET @my_var = value;
```

- Procedure calls can occur within a committed or rolled-back transaction. Transactional context is accounted for so that the transactional aspects of procedure execution are replicated correctly. That is, the server logs those statements within the procedure that actually execute and modify data, and also logs `BEGIN`, `COMMIT`, and `ROLLBACK` statements as necessary. For example, if a procedure updates only transactional tables and is executed within a transaction that is rolled back, those updates are not logged. If the procedure occurs within a committed transaction, `BEGIN` and `COMMIT` statements are logged with the updates. For a procedure that executes within a rolled-back transaction, its statements are logged using the same rules that would apply if the statements were executed in standalone fashion:
 - Updates to transactional tables are not logged.
 - Updates to nontransactional tables are logged because rollback does not cancel them.
 - Updates to a mix of transactional and nontransactional tables are logged surrounded by `BEGIN` and `ROLLBACK` so that slaves will make the same changes and rollbacks as on the master.
- A stored procedure call is *not* written to the binary log at the statement level if the procedure is invoked from within a stored function. In that case, the only thing logged is the statement that invokes the function (if it occurs within a statement that is logged) or a `DO` statement (if it occurs within a statement that is not logged). For this reason, care should be exercised in the use of stored functions that invoke a procedure, even if the procedure is otherwise safe in itself.

Chapter 24 INFORMATION_SCHEMA Tables

Table of Contents

24.1	The INFORMATION_SCHEMA CHARACTER_SETS Table	2846
24.2	The INFORMATION_SCHEMA COLLATIONS Table	2847
24.3	The INFORMATION_SCHEMA COLLATION_CHARACTER_SET_APPLICABILITY Table ...	2847

[INFORMATION_SCHEMA](#) provides access to database *metadata*, information about the MySQL server such as the name of a database or table, the data type of a column, or access privileges. Other terms that are sometimes used for this information are *data dictionary* and *system catalog*.

INFORMATION_SCHEMA Usage Notes

[INFORMATION_SCHEMA](#) is a database within each MySQL instance, the place that stores information about all the other databases that the MySQL server maintains. The [INFORMATION_SCHEMA](#) database contains several read-only tables. They are actually views, not base tables, so there are no files associated with them, and you cannot set triggers on them. Also, there is no database directory with that name.

Although you can select [INFORMATION_SCHEMA](#) as the default database with a [USE](#) statement, you can only read the contents of tables, not perform [INSERT](#), [UPDATE](#), or [DELETE](#) operations on them.

Example

Here is an example of a statement that retrieves information from [INFORMATION_SCHEMA](#):

```
mysql> SELECT table_name, table_type, engine
        FROM information_schema.tables
        WHERE table_schema = 'db5'
        ORDER BY table_name;
+-----+-----+-----+
| table_name | table_type | engine |
+-----+-----+-----+
| fk         | BASE TABLE | InnoDB |
| fk2        | BASE TABLE | InnoDB |
| goto       | BASE TABLE | MyISAM |
| into       | BASE TABLE | MyISAM |
| k          | BASE TABLE | MyISAM |
| kurs       | BASE TABLE | MyISAM |
| loop       | BASE TABLE | MyISAM |
| pk         | BASE TABLE | InnoDB |
| t          | BASE TABLE | MyISAM |
| t2         | BASE TABLE | MyISAM |
| t3         | BASE TABLE | MyISAM |
| t7         | BASE TABLE | MyISAM |
| tables     | BASE TABLE | MyISAM |
| v          | VIEW        | NULL   |
| v2         | VIEW        | NULL   |
| v3         | VIEW        | NULL   |
| v56        | VIEW        | NULL   |
+-----+-----+-----+
17 rows in set (0.01 sec)
```

Explanation: The statement requests a list of all the tables in database `db5`, showing just three pieces of information: the name of the table, its type, and its storage engine.

Character Set Considerations

The definition for character columns (for example, `TABLES.TABLE_NAME`) is generally `VARCHAR(N) CHARACTER SET utf8` where `N` is at least 64. MySQL uses the default collation for this character set (`utf8_general_ci`) for all searches, sorts, comparisons, and other string operations on such columns.

Because some MySQL objects are represented as files, searches in `INFORMATION_SCHEMA` string columns can be affected by file system case sensitivity. For more information, see [Section 10.1.8.7, “Using Collation in INFORMATION_SCHEMA Searches”](#).

INFORMATION_SCHEMA as Alternative to SHOW Statements

The `SELECT ... FROM INFORMATION_SCHEMA` statement is intended as a more consistent way to provide access to the information provided by the various `SHOW` statements that MySQL supports (`SHOW DATABASES`, `SHOW TABLES`, and so forth). Using `SELECT` has these advantages, compared to `SHOW`:

- It conforms to Codd's rules, because all access is done on tables.
- You can use the familiar syntax of the `SELECT` statement, and only need to learn some table and column names.
- The implementor need not worry about adding keywords.
- You can filter, sort, concatenate, and transform the results from `INFORMATION_SCHEMA` queries into whatever format your application needs, such as a data structure or a text representation to parse.
- This technique is more interoperable with other database systems. For example, Oracle Database users are familiar with querying tables in the Oracle data dictionary.

Because `SHOW` is familiar and widely used, the `SHOW` statements remain as an alternative. In fact, along with the implementation of `INFORMATION_SCHEMA`, there are enhancements to `SHOW` as described in [Section 24.33, “Extensions to SHOW Statements”](#).

Privileges

Each MySQL user has the right to access these tables, but can see only the rows in the tables that correspond to objects for which the user has the proper access privileges. In some cases (for example, the `ROUTINE_DEFINITION` column in the `INFORMATION_SCHEMA.ROUTINES` table), users who have insufficient privileges see `NULL`. These restrictions do not apply for `InnoDB` tables; you can see them with only the `PROCESS` privilege.

The same privileges apply to selecting information from `INFORMATION_SCHEMA` and viewing the same information through `SHOW` statements. In either case, you must have some privilege on an object to see information about it.

Performance Considerations

`INFORMATION_SCHEMA` queries that search for information from more than one database might take a long time and impact performance. To check the efficiency of a query, you can use `EXPLAIN`. For information about using `EXPLAIN` output to tune `INFORMATION_SCHEMA` queries, see [Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”](#).

Standards Considerations

The implementation for the `INFORMATION_SCHEMA` table structures in MySQL follows the ANSI/ISO SQL:2003 standard Part 11 *Schemata*. Our intent is approximate compliance with SQL:2003 core feature F021 *Basic information schema*.

Users of SQL Server 2000 (which also follows the standard) may notice a strong similarity. However, MySQL has omitted many columns that are not relevant for our implementation, and added columns that are MySQL-specific. One such column is the `ENGINE` column in the `INFORMATION_SCHEMA.TABLES` table.

Although other DBMSs use a variety of names, like `syscat` or `system`, the standard name is `INFORMATION_SCHEMA`.

To avoid using any name that is reserved in the standard or in DB2, SQL Server, or Oracle, we changed the names of some columns marked “MySQL extension”. (For example, we changed `COLLATION` to `TABLE_COLLATION` in the `TABLES` table.) See the list of reserved words near the end of this article: <https://web.archive.org/web/20070428032454/http://www.dbazine.com/db2/db2-disarticles/gulutzan5>.

Conventions in the INFORMATION_SCHEMA Reference Sections

The following sections describe each of the tables and columns in `INFORMATION_SCHEMA`. For each column, there are three pieces of information:

- “`INFORMATION_SCHEMA` Name” indicates the name for the column in the `INFORMATION_SCHEMA` table. This corresponds to the standard SQL name unless the “Remarks” field says “MySQL extension.”
- “`SHOW` Name” indicates the equivalent field name in the closest `SHOW` statement, if there is one.
- “Remarks” provides additional information where applicable. If this field is `NULL`, it means that the value of the column is always `NULL`. If this field says “MySQL extension,” the column is a MySQL extension to standard SQL.

Many sections indicate what `SHOW` statement is equivalent to a `SELECT` that retrieves information from `INFORMATION_SCHEMA`. For `SHOW` statements that display information for the default database if you omit a `FROM db_name` clause, you can often select information for the default database by adding an `AND TABLE_SCHEMA = SCHEMA()` condition to the `WHERE` clause of a query that retrieves information from an `INFORMATION_SCHEMA` table.

Related Information

These sections discuss additional `INFORMATION_SCHEMA`-related topics:

- information about `INFORMATION_SCHEMA` tables specific to the `InnoDB` storage engine: [Section 24.31, “InnoDB INFORMATION_SCHEMA Tables”](#)
- Answers to questions that are often asked concerning the `INFORMATION_SCHEMA` database: [Section A.7, “MySQL 8.0 FAQ: INFORMATION_SCHEMA”](#)
- `INFORMATION_SCHEMA` queries and the optimizer: [Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”](#)
- The effect of collation on `INFORMATION_SCHEMA` comparisons: [Section 10.1.8.7, “Using Collation in INFORMATION_SCHEMA Searches”](#)

24.1 The INFORMATION_SCHEMA CHARACTER_SETS Table

The `CHARACTER_SETS` table provides information about available character sets.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>CHARACTER_SET_NAME</code>	<code>Charset</code>	
<code>DEFAULT_COLLATE_NAME</code>	<code>Default collation</code>	
<code>DESCRIPTION</code>	<code>Description</code>	MySQL extension
<code>MAXLEN</code>	<code>Maxlen</code>	MySQL extension

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.CHARACTER_SETS
  [WHERE CHARACTER_SET_NAME LIKE 'wild']

SHOW CHARACTER SET
  [LIKE 'wild']
```

24.2 The INFORMATION_SCHEMA COLLATIONS Table

The `COLLATIONS` table provides information about collations for each character set.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>COLLATION_NAME</code>	Collation	
<code>CHARACTER_SET_NAME</code>	Charset	MySQL extension
<code>ID</code>	Id	MySQL extension
<code>IS_DEFAULT</code>	Default	MySQL extension
<code>IS_COMPILED</code>	Compiled	MySQL extension
<code>SORTLEN</code>	Sortlen	MySQL extension
<code>PAD_ATTRIBUTE</code>		omit

- `COLLATION_NAME` is the collation name.
- `CHARACTER_SET_NAME` is the name of the character set with which the collation is associated.
- `ID` is the collation ID.
- `IS_DEFAULT` indicates whether the collation is the default for its character set.
- `IS_COMPILED` indicates whether the character set is compiled into the server.
- `SORTLEN` is related to the amount of memory required to sort strings expressed in the character set.
- `PAD_ATTRIBUTE` indicates the collation pad attribute.

Collation information is also available from the `SHOW COLLATION` statement. The following statements are equivalent:

```
SELECT COLLATION_NAME FROM INFORMATION_SCHEMA.COLLATIONS
  [WHERE COLLATION_NAME LIKE 'wild']

SHOW COLLATION
  [LIKE 'wild']
```

24.3 The INFORMATION_SCHEMA COLLATION_CHARACTER_SET_APPLICABILITY Table

The `COLLATION_CHARACTER_SET_APPLICABILITY` table indicates what character set is applicable for what collation. The columns are equivalent to the first two display fields that we get from `SHOW COLLATION`.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>COLLATION_NAME</code>	Collation	
<code>CHARACTER_SET_NAME</code>	Charset	

24.4 The INFORMATION_SCHEMA COLUMNS Table

The `COLUMNS` table provides information about columns in tables.

The related `ST_GEOMETRY_COLUMNS` table is a view on `COLUMNS` that provides information about table columns that store spatial data. See [Section 24.22, “The INFORMATION_SCHEMA ST_GEOMETRY_COLUMNS Table”](#).

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		def
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME	Field	
ORDINAL_POSITION		see notes
COLUMN_DEFAULT	Default	
IS_NULLABLE	Null	
DATA_TYPE	Type	
CHARACTER_MAXIMUM_LENGTH	Type	
CHARACTER_OCTET_LENGTH		
NUMERIC_PRECISION	Type	
NUMERIC_SCALE	Type	
DATETIME_PRECISION	Type	
CHARACTER_SET_NAME		
COLLATION_NAME	Collation	
COLUMN_TYPE	Type	MySQL extension
COLUMN_KEY	Key	MySQL extension
EXTRA	Extra	MySQL extension
PRIVILEGES	Privileges	MySQL extension
COLUMN_COMMENT	Comment	MySQL extension
GENERATION_EXPRESSION		MySQL extension

Notes:

- In `SHOW`, the `Type` display includes values from several different `COLUMNS` columns.
- `ORDINAL_POSITION` is necessary because you might want to say `ORDER BY ORDINAL_POSITION`. Unlike `SHOW`, `SELECT` does not have automatic ordering.
- `CHARACTER_OCTET_LENGTH` should be the same as `CHARACTER_MAXIMUM_LENGTH`, except for multibyte character sets.
- `CHARACTER_SET_NAME` can be derived from `Collation`. For example, if you say `SHOW FULL COLUMNS FROM t`, and you see in the `Collation` column a value of `utf8_swedish_ci`, the character set is what is before the first underscore: `utf8`.
- `GENERATION_EXPRESSION` is nonempty for generated columns and displays the expression used to compute column values. For information about generated columns, see [Section 13.1.15.8, “CREATE TABLE and Generated Columns”](#).
- The `EXTRA` column contains `VIRTUAL GENERATED` or `VIRTUAL STORED` for generated columns.

The following statements are nearly equivalent:

```
SELECT COLUMN_NAME, DATA_TYPE, IS_NULLABLE, COLUMN_DEFAULT
```

```
FROM INFORMATION_SCHEMA.COLUMNS
WHERE table_name = 'tbl_name'
[AND table_schema = 'db_name']
[AND column_name LIKE 'wild']

SHOW COLUMNS
FROM tbl_name
[FROM db_name]
[LIKE 'wild']
```

24.5 The INFORMATION_SCHEMA COLUMN_PRIVILEGES Table

The `COLUMN_PRIVILEGES` table provides information about column privileges. This information comes from the `mysql.columns_priv` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		'user_name'@'host_name' value
TABLE_CATALOG		def
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME		
PRIVILEGE_TYPE		
IS_GRANTABLE		

Notes:

- In the output from `SHOW FULL COLUMNS`, the privileges are all in one field and in lowercase, for example, `select,insert,update,references`. In `COLUMN_PRIVILEGES`, there is one privilege per row, in uppercase.
- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT`, `INSERT`, `UPDATE`, `REFERENCES`.
- If the user has `GRANT OPTION` privilege, `IS_GRANTABLE` should be `YES`. Otherwise, `IS_GRANTABLE` should be `NO`. The output does not list `GRANT OPTION` as a separate privilege.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.COLUMN_PRIVILEGES

SHOW GRANTS ...
```

24.6 The INFORMATION_SCHEMA COLUMN_STATISTICS Table

The `COLUMN_STATISTICS` table is a view that provides access to information in the `column_statistics` data dictionary table, which stores histogram statistics about column values. It was added in MySQL 8.0.2.

For information about histogram statistics, see [Section 8.9.6, “Optimizer Statistics”](#), and [Section 13.7.2.1, “ANALYZE TABLE Syntax”](#).

You can see information only for columns for which you have some privilege.

`COLUMN_STATISTICS` has these columns:

- `SCHEMA_NAME`

The names of the schema for which the statistics apply.

- [TABLE_NAME](#)

The names of the column for which the statistics apply.

- [COLUMN_NAME](#)

The names of the column for which the statistics apply.

- [HISTOGRAM](#)

A [JSON](#) object describing the column statistics, stored as a histogram.

24.7 The INFORMATION_SCHEMA ENGINES Table

The [ENGINES](#) table provides information about storage engines.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
ENGINE	Engine	MySQL extension
SUPPORT	Support	MySQL extension
COMMENT	Comment	MySQL extension
TRANSACTIONS	Transactions	MySQL extension
XA	XA	MySQL extension
SAVEPOINTS	Savepoints	MySQL extension

Notes:

- The [ENGINES](#) table is a nonstandard table. Its contents correspond to the columns of the [SHOW ENGINES](#) statement. For descriptions of its columns, see [Section 13.7.5.16, “SHOW ENGINES Syntax”](#).

See also [Section 13.7.5.16, “SHOW ENGINES Syntax”](#).

24.8 The INFORMATION_SCHEMA EVENTS Table

The [EVENTS](#) table provides information about scheduled events, which are discussed in [Section 23.4, “Using the Event Scheduler”](#). The [SHOW](#) Name values correspond to column names of the [SHOW EVENTS](#) statement.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
EVENT_CATALOG		def , MySQL extension
EVENT_SCHEMA	Db	MySQL extension
EVENT_NAME	Name	MySQL extension
DEFINER	Definer	MySQL extension
TIME_ZONE	Time zone	MySQL extension
EVENT_BODY		MySQL extension
EVENT_DEFINITION		MySQL extension
EVENT_TYPE	Type	MySQL extension
EXECUTE_AT	Execute at	MySQL extension
INTERVAL_VALUE	Interval value	MySQL extension
INTERVAL_FIELD	Interval field	MySQL extension
SQL_MODE		MySQL extension
STARTS	Starts	MySQL extension

INFORMATION_SCHEMA Name	SHOW Name	Remarks
ENDS	Ends	MySQL extension
STATUS	Status	MySQL extension
ON_COMPLETION		MySQL extension
CREATED		MySQL extension
LAST_ALTERED		MySQL extension
LAST_EXECUTED		MySQL extension
EVENT_COMMENT		MySQL extension
ORIGINATOR	Originator	MySQL extension
CHARACTER_SET_CLIENT	character_set_client	MySQL extension
COLLATION_CONNECTION	collation_connection	MySQL extension
DATABASE_COLLATION	Database Collation	MySQL extension

Notes:

- The `EVENTS` table is a nonstandard table.
- `EVENT_CATALOG`: The value of this column is always `def`.
- `EVENT_SCHEMA`: The name of the schema (database) to which this event belongs.
- `EVENT_NAME`: The name of the event.
- `DEFINER`: The account of the user who created the event, in '`user_name`'@'`host_name`' format.
- `TIME_ZONE`: The event time zone, which is the time zone used for scheduling the event and that is in effect within the event as it executes. The default value is `SYSTEM`.
- `EVENT_BODY`: The language used for the statements in the event's `DO` clause; in MySQL 8.0, this is always `SQL`.

This column is not to be confused with the column of the same name (now named `EVENT_DEFINITION`) that existed in earlier MySQL versions.

- `EVENT_DEFINITION`: The text of the SQL statement making up the event's `DO` clause; in other words, the statement executed by this event.
- `EVENT_TYPE`: The event repetition type, either `ONE TIME` (transient) or `RECURRING` (repeating).
- `EXECUTE_AT`: For a one-time event, this is the `DATETIME` value specified in the `AT` clause of the `CREATE EVENT` statement used to create the event, or of the last `ALTER EVENT` statement that modified the event. The value shown in this column reflects the addition or subtraction of any `INTERVAL` value included in the event's `AT` clause. For example, if an event is created using `ON SCHEDULE AT CURRENT_TIMESTAMP + '1:6' DAY_HOUR`, and the event was created at 2006-02-09 14:05:30, the value shown in this column would be '`2006-02-10 20:05:30`'.

If the event's timing is determined by an `EVERY` clause instead of an `AT` clause (that is, if the event is recurring), the value of this column is `NULL`.

- `INTERVAL_VALUE`: For recurring events, this column contains the numeric portion of the event's `EVERY` clause.

For a one-time event (that is, an event whose timing is determined by an `AT` clause), this column is `NULL`.

- `INTERVAL_FIELD`: For recurring events, this column contains the units portion of the `EVERY` clause governing the timing of the event. Thus, this column contains a value such as '`YEAR`', '`QUARTER`', '`DAY`', and so on.

For a one-time event (that is, an event whose timing is determined by an [AT](#) clause), this column is `NULL`.

- **SQL_MODE**: The SQL mode in effect when the event was created or altered, and under which the event executes. For the permitted values, see [Section 5.1.8, “Server SQL Modes”](#).
- **STARTS**: For a recurring event whose definition includes a [STARTS](#) clause, this column contains the corresponding [DATETIME](#) value. As with the [EXECUTE_AT](#) column, this value resolves any expressions used.

If there is no [STARTS](#) clause affecting the timing of the event, this column is `NULL`.

- **ENDS**: For a recurring event whose definition includes a [ENDS](#) clause, this column contains the corresponding [DATETIME](#) value. As with the [EXECUTE_AT](#) column, this value resolves any expressions used.

If there is no [ENDS](#) clause affecting the timing of the event, this column is `NULL`.

- **STATUS**: One of the three values [ENABLED](#), [DISABLED](#), or [SLAVESIDE_DISABLED](#).

[SLAVESIDE_DISABLED](#) indicates that the creation of the event occurred on another MySQL server acting as a replication master and was replicated to the current MySQL server which is acting as a slave, but the event is not presently being executed on the slave. See [Section 18.4.1.12, “Replication of Invoked Features”](#), for more information.

- **ON_COMPLETION**: One of the two values [PRESERVE](#) or [NOT PRESERVE](#).
- **CREATED**: The date and time when the event was created. This is a [TIMESTAMP](#) value.
- **LAST_ALTERED**: The date and time when the event was last modified. This is a [TIMESTAMP](#) value. If the event has not been modified since its creation, this column holds the same value as the [CREATED](#) column.
- **LAST_EXECUTED**: The date and time when the event last executed. A [DATETIME](#) value. If the event has never executed, this column is `NULL`.

[LAST_EXECUTED](#) indicates when the event started. As a result, the [ENDS](#) column is never less than [LAST_EXECUTED](#).

- **EVENT_COMMENT**: The text of a comment, if the event has one. If not, the value of this column is an empty string.
- **ORIGINATOR**: The server ID of the MySQL server on which the event was created; used in replication. The default value is 0.
- **CHARACTER_SET_CLIENT**: The session value of the [character_set_client](#) system variable when the event was created.
- **COLLATION_CONNECTION**: The session value of the [collation_connection](#) system variable when the event was created.
- **DATABASE_COLLATION**: The collation of the database with which the event is associated.

Example: Suppose that the user `jon@ghidora` creates an event named `e_daily`, and then modifies it a few minutes later using an [ALTER EVENT](#) statement, as shown here:

```
DELIMITER |
CREATE EVENT e_daily
ON SCHEDULE
EVERY 1 DAY
COMMENT 'Saves total number of sessions then clears the table each day'
```

```

DO
BEGIN
  INSERT INTO site_activity.totals (time, total)
    SELECT CURRENT_TIMESTAMP, COUNT(*)
      FROM site_activity.sessions;
  DELETE FROM site_activity.sessions;
END |

DELIMITER ;

ALTER EVENT e_daily
  ENABLE;

```

(Note that comments can span multiple lines.)

This user can then run the following `SELECT` statement, and obtain the output shown:

```

mysql> SELECT * FROM INFORMATION_SCHEMA.EVENTS
> WHERE EVENT_NAME = 'e_daily'
> AND EVENT_SCHEMA = 'myschema'\G
***** 1. row *****
EVENT_CATALOG: def
EVENT_SCHEMA: test
EVENT_NAME: e_daily
DEFINER: me@localhost
TIME_ZONE: SYSTEM
EVENT_BODY: SQL
EVENT_DEFINITION: BEGIN
  INSERT INTO site_activity.totals (time, total)
    SELECT CURRENT_TIMESTAMP, COUNT(*)
      FROM site_activity.sessions;
  DELETE FROM site_activity.sessions;
END
EVENT_TYPE: RECURRING
EXECUTE_AT: NULL
INTERVAL_VALUE: 1
INTERVAL_FIELD: DAY
SQL_MODE:
STARTS: 2008-09-03 12:13:39
ENDS: NULL
STATUS: ENABLED
ON_COMPLETION: NOT PRESERVE
CREATED: 2008-09-03 12:13:39
LAST_ALTERED: 2008-09-03 12:13:39
LAST_EXECUTED: NULL
EVENT_COMMENT: Saves total number of sessions then clears the
table each day
ORIGINATOR: 1
CHARACTER_SET_CLIENT: utf8
COLLATION_CONNECTION: utf8_swedish_ci
DATABASE_COLLATION: utf8_swedish_ci

```

Times in the `EVENTS` table are displayed using the event time zone or the current session time zone, as described in [Section 23.4.4, “Event Metadata”](#).

See also [Section 13.7.5.18, “SHOW EVENTS Syntax”](#).

24.9 The INFORMATION_SCHEMA FILES Table

The `FILES` table provides information about the files in which MySQL tablespace data is stored.

`INFORMATION_SCHEMA.FILES` reports data about `NDB` and `InnoDB` data files.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>FILE_ID</code>		MySQL extension
<code>FILE_NAME</code>		MySQL extension
<code>FILE_TYPE</code>		MySQL extension

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLESPACE_NAME		MySQL extension
TABLE_CATALOG		MySQL extension
TABLE_SCHEMA		MySQL extension
TABLE_NAME		MySQL extension
LOGFILE_GROUP_NAME		MySQL extension
LOGFILE_GROUP_NUMBER		MySQL extension
ENGINE		MySQL extension
FULLTEXT_KEYS		MySQL extension
DELETED_ROWS		MySQL extension
UPDATE_COUNT		MySQL extension
FREE_EXTENTS		MySQL extension
TOTAL_EXTENTS		MySQL extension
EXTENT_SIZE		MySQL extension
INITIAL_SIZE		MySQL extension
MAXIMUM_SIZE		MySQL extension
AUTOEXTEND_SIZE		MySQL extension
CREATION_TIME		MySQL extension
LAST_UPDATE_TIME		MySQL extension
LAST_ACCESS_TIME		MySQL extension
RECOVER_TIME		MySQL extension
TRANSACTION_COUNTER		MySQL extension
VERSION		MySQL extension
ROW_FORMAT		MySQL extension
TABLE_ROWS		MySQL extension
AVG_ROW_LENGTH		MySQL extension
DATA_LENGTH		MySQL extension
MAX_DATA_LENGTH		MySQL extension
INDEX_LENGTH		MySQL extension
DATA_FREE		MySQL extension
CREATE_TIME		MySQL extension
UPDATE_TIME		MySQL extension
CHECK_TIME		MySQL extension
CHECKSUM		MySQL extension
STATUS		MySQL extension
EXTRA		MySQL extension

InnoDB Notes:

The following notes apply to InnoDB data files. INFORMATION_SCHEMA.FILES fields that are not described below are not applicable to InnoDB and report a NULL value.

- Data reported by INFORMATION_SCHEMA.FILES is reported from the InnoDB in-memory cache for open files. By comparison, INFORMATION_SCHEMA.INNODB_SYS_DATAFILES reports data from the InnoDB SYS_DATAFILES internal data dictionary table.

- The data reported by `INFORMATION_SCHEMA.FILES` includes temporary tablespace data. This data is not available in the internal `SYS_DATAFILES` data dictionary table, and is therefore not reported by `INNODB_SYS_DATAFILES`.
- Undo tablespace data is reported by `INFORMATION_SCHEMA.FILES` when separate undo tablespaces are configured using the `innodb_undo_tablespaces` configuration option.
- `FILE_ID` is the tablespace ID, also referred to as the `space_id` or `fil_space_t::id`.
- `FILE_NAME` is the name of the data file. File-per-table and general tablespaces have a `.ibd` file name extension. Undo tablespaces are prefixed by `undo`. The system tablespace is prefixed by `ibdata`. Temporary tablespaces are prefixed by `ibtmp`. The file name includes the file path, which may be relative to the MySQL data directory (`datadir`).
- `FILE_TYPE` is the tablespace file type. There are three possible file types for InnoDB files. `TABLESPACE` is the file type for any system, general, or file-per-table tablespace file that holds tables, indexes, or other forms of user data. `TEMPORARY` is the file type for temporary tablespaces. `UNDO LOG` is the file type for undo tablespaces, which hold undo records. Separate undo tablespaces are configured using the `innodb_undo_tablespaces` option.
- `TABLESPACE_NAME` is the SQL name for the tablespace. A general tablespace name is the `SYS_TABLESPACES.NAME` value. For other tablespace files, names start with `innodb_`, such as `innodb_system`, `innodb_undo`, and `innodb_file_per_table`. The file-per-table tablespace name format is `innodb_file_per_table_##`, where `##` is the tablespace ID.
- `ENGINE` is the storage engine. For InnoDB files, the value is always `InnoDB`.
- `FREE_EXTENTS` is the number of fully free extents in the current data file.
- `TOTAL_EXTENTS` is the number of full extents used in the current data file. Any partial extent at the end of the file is not counted.
- `EXTENT_SIZE` is 1048576 (1MB) for files with a 4k, 8k, or 16k page size. Extent size is 2097152 bytes (2MB) for files with a 32k page size, and 4194304 (4MB) for files with a 64k page size. `INFORMATION_SCHEMA.FILES` does not report InnoDB page size. Page size is defined by the `innodb_page_size` option. Extent size information can also be retrieved from `INNODB_SYS_TABLESPACES` where `FILES.FILE_ID = INNODB_SYS_TABLESPACES.SPACE_ID`.
- `INITIAL_SIZE` is the initial size of the file, in bytes.
- `MAXIMUM_SIZE` is the maximum number of bytes allowed in the file. The value is `NULL` for all data files except for predefined system tablespace data files. Maximum system tablespace file size is defined by `innodb_data_file_path`. Maximum temporary tablespace file size is defined by `innodb_temp_data_file_path`. A `NULL` value for a predefined system tablespace data file indicates that a file size limit was not defined explicitly.
- `AUTOEXTEND_SIZE` is the auto-extend size defined by `innodb_data_file_path` for the system tablespace, or defined by `innodb_temp_data_file_path` for temporary tablespaces.
- `DATA_FREE` is the total amount of free space (in bytes) for the entire tablespace. Predefined system tablespaces, which include the system tablespace and temporary table tablespaces, may have one or more data files.
- `STATUS` is `NORMAL` by default. InnoDB file-per-table tablespaces may report `IMPORTING`, which indicates that the tablespace is not yet available.
- The following query returns all data pertinent to InnoDB tablespaces.

```
mysql> SELECT FILE_ID, FILE_NAME, FILE_TYPE, TABLESPACE_NAME, FREE_EXTENTS, TOTAL_EXTENTS,
EXTENT_SIZE, INITIAL_SIZE, MAXIMUM_SIZE, AUTOEXTEND_SIZE, DATA_FREE, STATUS ENGINE
FROM INFORMATION_SCHEMA.FILES \G
```

24.10 The INFORMATION_SCHEMA KEY_COLUMN_USAGE Table

The `KEY_COLUMN_USAGE` table describes which key columns have constraints.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CONSTRAINT_CATALOG		def
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
TABLE_CATALOG		def
TABLE_SCHEMA		
TABLE_NAME		
COLUMN_NAME		
ORDINAL_POSITION		
POSITION_IN_UNIQUE_CONSTRAINT		
REFERENCED_TABLE_SCHEMA		
REFERENCED_TABLE_NAME		
REFERENCED_COLUMN_NAME		

Notes:

- If the constraint is a foreign key, then this is the column of the foreign key, not the column that the foreign key references.
- The value of `ORDINAL_POSITION` is the column's position within the constraint, not the column's position within the table. Column positions are numbered beginning with 1.
- The value of `POSITION_IN_UNIQUE_CONSTRAINT` is `NULL` for unique and primary-key constraints. For foreign-key constraints, it is the ordinal position in key of the table that is being referenced.

Suppose that there are two tables name `t1` and `t3` that have the following definitions:

```
CREATE TABLE t1
(
  s1 INT,
  s2 INT,
  s3 INT,
  PRIMARY KEY(s3)
) ENGINE=InnoDB;

CREATE TABLE t3
(
  s1 INT,
  s2 INT,
  s3 INT,
  KEY(s1),
  CONSTRAINT CO FOREIGN KEY (s2) REFERENCES t1(s3)
) ENGINE=InnoDB;
```

For those two tables, the `KEY_COLUMN_USAGE` table has two rows:

- One row with `CONSTRAINT_NAME = 'PRIMARY'`, `TABLE_NAME = 't1'`, `COLUMN_NAME = 's3'`, `ORDINAL_POSITION = 1`, `POSITION_IN_UNIQUE_CONSTRAINT = NULL`.
- One row with `CONSTRAINT_NAME = 'CO'`, `TABLE_NAME = 't3'`, `COLUMN_NAME = 's2'`, `ORDINAL_POSITION = 1`, `POSITION_IN_UNIQUE_CONSTRAINT = 1`.

24.11 The INFORMATION_SCHEMA OPTIMIZER_TRACE Table

The `OPTIMIZER_TRACE` table provides information produced by the optimizer tracing capability. To enable tracking, use the `optimizer_trace` system variable. For details, see [MySQL Internals: Tracing the Optimizer](#).

24.12 The INFORMATION_SCHEMA PARAMETERS Table

The `PARAMETERS` table provides information about stored procedure and function parameters, and about return values for stored functions.

INFORMATION_SCHEMA Name	Remarks
<code>SPECIFIC_CATALOG</code>	<code>def</code>
<code>SPECIFIC_SCHEMA</code>	routine database
<code>SPECIFIC_NAME</code>	routine name
<code>ORDINAL_POSITION</code>	1, 2, 3, ... for parameters, 0 for function <code>RETURNS</code> clause
<code>PARAMETER_MODE</code>	<code>IN</code> , <code>OUT</code> , <code>INOUT</code> (<code>NULL</code> for <code>RETURNS</code>)
<code>PARAMETER_NAME</code>	parameter name (<code>NULL</code> for <code>RETURNS</code>)
<code>DATA_TYPE</code>	same as for <code>COLUMNS</code> table
<code>CHARACTER_MAXIMUM_LENGTH</code>	same as for <code>COLUMNS</code> table
<code>CHARACTER_OCTET_LENGTH</code>	same as for <code>COLUMNS</code> table
<code>NUMERIC_PRECISION</code>	same as for <code>COLUMNS</code> table
<code>NUMERIC_SCALE</code>	same as for <code>COLUMNS</code> table
<code>DATETIME_PRECISION</code>	same as for <code>COLUMNS</code> table
<code>CHARACTER_SET_NAME</code>	same as for <code>COLUMNS</code> table
<code>COLLATION_NAME</code>	same as for <code>COLUMNS</code> table
<code>DTD_IDENTIFIER</code>	same as for <code>COLUMNS</code> table
<code>ROUTINE_TYPE</code>	same as for <code>ROUTINES</code> table

Notes:

- For successive parameters of a stored procedure or function, the `ORDINAL_POSITION` values are 1, 2, 3, and so forth. For a stored function, there is also a row that describes the data type for the `RETURNS` clause. The return value is not a true parameter, so the row that describes it has these unique characteristics:
 - The `ORDINAL_POSITION` value is 0.
 - The `PARAMETER_NAME` and `PARAMETER_MODE` values are `NULL` because the return value has no name and the mode does not apply.

24.13 The INFORMATION_SCHEMA PARTITIONS Table

The `PARTITIONS` table provides information about table partitions. See [Chapter 22, Partitioning](#), for more information about partitioning tables.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
<code>TABLE_CATALOG</code>		MySQL extension
<code>TABLE_SCHEMA</code>		MySQL extension
<code>TABLE_NAME</code>		MySQL extension
<code>PARTITION_NAME</code>		MySQL extension

INFORMATION_SCHEMA Name	SHOW Name	Remarks
SUBPARTITION_NAME		MySQL extension
PARTITION_ORDINAL_POSITION		MySQL extension
SUBPARTITION_ORDINAL_POSITION		MySQL extension
PARTITION_METHOD		MySQL extension
SUBPARTITION_METHOD		MySQL extension
PARTITION_EXPRESSION		MySQL extension
SUBPARTITION_EXPRESSION		MySQL extension
PARTITION_DESCRIPTION		MySQL extension
TABLE_ROWS		MySQL extension
AVG_ROW_LENGTH		MySQL extension
DATA_LENGTH		MySQL extension
MAX_DATA_LENGTH		MySQL extension
INDEX_LENGTH		MySQL extension
DATA_FREE		MySQL extension
CREATE_TIME		MySQL extension
UPDATE_TIME		MySQL extension
CHECK_TIME		MySQL extension
CHECKSUM		MySQL extension
PARTITION_COMMENT		MySQL extension
NODEGROUP		MySQL extension
TABLESPACE_NAME		MySQL extension

Notes:

- The `PARTITIONS` table is a nonstandard table.
Each record in this table corresponds to an individual partition or subpartition of a partitioned table.
- `TABLE_CATALOG`: This column is always `def`.
- `TABLE_SCHEMA`: This column contains the name of the database to which the table belongs.
- `TABLE_NAME`: This column contains the name of the table containing the partition.
- `PARTITION_NAME`: The name of the partition.
- `SUBPARTITION_NAME`: If the `PARTITIONS` table record represents a subpartition, then this column contains the name of subpartition; otherwise it is `NULL`.
- `PARTITION_ORDINAL_POSITION`: All partitions are indexed in the same order as they are defined, with `1` being the number assigned to the first partition. The indexing can change as partitions are added, dropped, and reorganized; the number shown in this column reflects the current order, taking into account any indexing changes.
- `SUBPARTITION_ORDINAL_POSITION`: Subpartitions within a given partition are also indexed and reindexed in the same manner as partitions are indexed within a table.
- `PARTITION_METHOD`: One of the values `RANGE`, `LIST`, `HASH`, `LINEAR HASH`, `KEY`, or `LINEAR KEY`; that is, one of the available partitioning types as discussed in [Section 22.2, "Partitioning Types"](#).
- `SUBPARTITION_METHOD`: One of the values `HASH`, `LINEAR HASH`, `KEY`, or `LINEAR KEY`; that is, one of the available subpartitioning types as discussed in [Section 22.2.6, "Subpartitioning"](#).

- **PARTITION_EXPRESSION**: This is the expression for the partitioning function used in the `CREATE TABLE` or `ALTER TABLE` statement that created the table's current partitioning scheme.

For example, consider a partitioned table created in the `test` database using this statement:

```
CREATE TABLE tp (
  c1 INT,
  c2 INT,
  c3 VARCHAR(25)
)
PARTITION BY HASH(c1 + c2)
PARTITIONS 4;
```

The **PARTITION_EXPRESSION** column in a PARTITIONS table record for a partition from this table displays `c1 + c2`, as shown here:

```
mysql> SELECT DISTINCT PARTITION_EXPRESSION
>       FROM INFORMATION_SCHEMA.PARTITIONS
>       WHERE TABLE_NAME='tp' AND TABLE_SCHEMA='test';
+-----+
| PARTITION_EXPRESSION |
+-----+
| c1 + c2              |
+-----+
1 row in set (0.09 sec)
```

- **SUBPARTITION_EXPRESSION**: This works in the same fashion for the subpartitioning expression that defines the subpartitioning for a table as **PARTITION_EXPRESSION** does for the partitioning expression used to define a table's partitioning.

If the table has no subpartitions, then this column is `NULL`.

- **PARTITION_DESCRIPTION**: This column is used for `RANGE` and `LIST` partitions. For a `RANGE` partition, it contains the value set in the partition's `VALUES LESS THAN` clause, which can be either an integer or `MAXVALUE`. For a `LIST` partition, this column contains the values defined in the partition's `VALUES IN` clause, which is a comma-separated list of integer values.

For partitions whose **PARTITION_METHOD** is other than `RANGE` or `LIST`, this column is always `NULL`.

- **TABLE_ROWS**: The number of table rows in the partition.

For partitioned `InnoDB` tables, the row count given in the **TABLE_ROWS** column is only an estimated value used in SQL optimization, and may not always be exact.

- **AVG_ROW_LENGTH**: The average length of the rows stored in this partition or subpartition, in bytes.

This is the same as **DATA_LENGTH** divided by **TABLE_ROWS**.

- **DATA_LENGTH**: The total length of all rows stored in this partition or subpartition, in bytes—that is, the total number of bytes stored in the partition or subpartition.
- **MAX_DATA_LENGTH**: The maximum number of bytes that can be stored in this partition or subpartition.
- **INDEX_LENGTH**: The length of the index file for this partition or subpartition, in bytes.
- **DATA_FREE**: The number of bytes allocated to the partition or subpartition but not used.
- **CREATE_TIME**: The time of the partition's or subpartition's creation.
- **UPDATE_TIME**: The time that the partition or subpartition was last modified.
- **CHECK_TIME**: The last time that the table to which this partition or subpartition belongs was checked.

For partitioned [InnoDB](#) tables, this column is always [NULL](#).

- [CHECKSUM](#): The checksum value, if any; otherwise, this column is [NULL](#).
- [PARTITION_COMMENT](#): This column contains the text of any comment made for the partition.

In MySQL 8.0, the maximum length for a partition comment is defined as 1024 characters, and the display width of the [PARTITION_COMMENT](#) column is also 1024, characters to match this limit (Bug #11748924, Bug #37728).

The default value for this column is an empty string.

- [NODEGROUP](#): This is the nodegroup to which the partition belongs. This is relevant only to MySQL Cluster tables; otherwise the value of this column is always 0.
- [TABLESPACE_NAME](#): This column contains the name of the tablespace to which the partition belongs. The value of this column is always [DEFAULT](#).
- A nonpartitioned table has one record in [INFORMATION_SCHEMA.PARTITIONS](#); however, the values of the [PARTITION_NAME](#), [SUBPARTITION_NAME](#), [PARTITION_ORDINAL_POSITION](#), [SUBPARTITION_ORDINAL_POSITION](#), [PARTITION_METHOD](#), [SUBPARTITION_METHOD](#), [PARTITION_EXPRESSION](#), [SUBPARTITION_EXPRESSION](#), and [PARTITION_DESCRIPTION](#) columns are all [NULL](#). (The [PARTITION_COMMENT](#) column in this case is blank.)

24.14 The INFORMATION_SCHEMA PLUGINS Table

The [PLUGINS](#) table provides information about server plugins.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
PLUGIN_NAME	Name	MySQL extension
PLUGIN_VERSION		MySQL extension
PLUGIN_STATUS	Status	MySQL extension
PLUGIN_TYPE	Type	MySQL extension
PLUGIN_TYPE_VERSION		MySQL extension
PLUGIN_LIBRARY	Library	MySQL extension
PLUGIN_LIBRARY_VERSION		MySQL extension
PLUGIN_AUTHOR		MySQL extension
PLUGIN_DESCRIPTION		MySQL extension
PLUGIN_LICENSE	License	MySQL extension
LOAD_OPTION		MySQL extension

Notes:

- The [PLUGINS](#) table is a nonstandard table.
- [PLUGIN_NAME](#) is the name used to refer to the plugin in statements such as [INSTALL PLUGIN](#) and [UNINSTALL PLUGIN](#).
- [PLUGIN_VERSION](#) is the version from the plugin's general type descriptor.
- [PLUGIN_STATUS](#) indicates the plugin status, one of [ACTIVE](#), [INACTIVE](#), [DISABLED](#), or [DELETED](#).
- [PLUGIN_TYPE](#) indicates the type of plugin, such as [STORAGE ENGINE](#), [INFORMATION_SCHEMA](#), or [AUTHENTICATION](#).
- [PLUGIN_TYPE_VERSION](#) is the version from the plugin's type-specific descriptor.

- `PLUGIN_LIBRARY` is the name of the plugin shared library file. This is the name used to refer to the plugin file in statements such as `INSTALL PLUGIN` and `UNINSTALL PLUGIN`. This file is located in the directory named by the `plugin_dir` system variable. If the library name is `NULL`, the plugin is compiled in and cannot be uninstalled with `UNINSTALL PLUGIN`.
- `PLUGIN_LIBRARY_VERSION` indicates the plugin API interface version.
- `PLUGIN_AUTHOR` names the plugin author.
- `PLUGIN_DESCRIPTION` provides a short description of the plugin.
- `PLUGIN_LICENSE` indicates how the plugin is licensed; for example, `GPL`.
- `LOAD_OPTION` indicates how the plugin was loaded. The value is `OFF`, `ON`, `FORCE`, or `FORCE_PLUS_PERMANENT`. See [Section 5.6.2, “Installing and Uninstalling Plugins”](#).

For plugins installed with `INSTALL PLUGIN`, the `PLUGIN_NAME` and `PLUGIN_LIBRARY` values are also registered in the `mysql.plugin` table.

These statements are equivalent:

```
SELECT
  PLUGIN_NAME, PLUGIN_STATUS, PLUGIN_TYPE,
  PLUGIN_LIBRARY, PLUGIN_LICENSE
FROM INFORMATION_SCHEMA.PLUGINS;

SHOW PLUGINS;
```

For information about plugin data structures that form the basis of the information in the `PLUGINS` table, see [Section 28.2, “The MySQL Plugin API”](#).

Plugin information is also available using the `SHOW PLUGINS` statement. See [Section 13.7.5.25, “SHOW PLUGINS Syntax”](#).

24.15 The INFORMATION_SCHEMA PROCESSLIST Table

The `PROCESSLIST` table provides information about which threads are running.

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>ID</code>	<code>Id</code>	MySQL extension
<code>USER</code>	<code>User</code>	MySQL extension
<code>HOST</code>	<code>Host</code>	MySQL extension
<code>DB</code>	<code>db</code>	MySQL extension
<code>COMMAND</code>	<code>Command</code>	MySQL extension
<code>TIME</code>	<code>Time</code>	MySQL extension
<code>STATE</code>	<code>State</code>	MySQL extension
<code>INFO</code>	<code>Info</code>	MySQL extension

For an extensive description of the table columns, see [Section 13.7.5.29, “SHOW PROCESSLIST Syntax”](#).

Notes:

- The `PROCESSLIST` table is a nonstandard table.
- Like the output from the corresponding `SHOW` statement, the `PROCESSLIST` table will only show information about your own threads, unless you have the `PROCESS` privilege, in which case you will see information about other threads, too. As an anonymous user, you cannot see any rows at all.

- If an SQL statement refers to `INFORMATION_SCHEMA.PROCESSLIST`, MySQL populates the entire table once, when statement execution begins, so there is read consistency during the statement. There is no read consistency for a multi-statement transaction, though.
- Process information is also available from the `performance_schema.threads` table. However, access to `threads` does not require a mutex and has minimal impact on server performance. `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` have negative performance consequences because they require a mutex. `threads` also shows information about background threads, which `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` do not. This means that `threads` can be used to monitor activity the other thread information sources cannot.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST

SHOW FULL PROCESSLIST
```

24.16 The INFORMATION_SCHEMA PROFILING Table

The `PROFILING` table provides statement profiling information. Its contents correspond to the information produced by the `SHOW PROFILES` and `SHOW PROFILE` statements (see [Section 13.7.5.31](#), “`SHOW PROFILES Syntax`”). The table is empty unless the `profiling` session variable is set to 1.

Note

This table is deprecated and will be removed in a future MySQL release. Use the Performance Schema instead; see [Chapter 25, MySQL Performance Schema](#).

<code>INFORMATION_SCHEMA</code> Name	<code>SHOW</code> Name	Remarks
<code>QUERY_ID</code>	<code>Query_ID</code>	
<code>SEQ</code>		
<code>STATE</code>	<code>Status</code>	
<code>DURATION</code>	<code>Duration</code>	
<code>CPU_USER</code>	<code>CPU_user</code>	
<code>CPU_SYSTEM</code>	<code>CPU_system</code>	
<code>CONTEXT_VOLUNTARY</code>	<code>Context_voluntary</code>	
<code>CONTEXT_INVOLUNTARY</code>	<code>Context_involuntary</code>	
<code>BLOCK_OPS_IN</code>	<code>Block_ops_in</code>	
<code>BLOCK_OPS_OUT</code>	<code>Block_ops_out</code>	
<code>MESSAGES_SENT</code>	<code>Messages_sent</code>	
<code>MESSAGES_RECEIVED</code>	<code>Messages_received</code>	
<code>PAGE_FAULTS_MAJOR</code>	<code>Page_faults_major</code>	
<code>PAGE_FAULTS_MINOR</code>	<code>Page_faults_minor</code>	
<code>SWAPS</code>	<code>Swaps</code>	
<code>SOURCE_FUNCTION</code>	<code>Source_function</code>	
<code>SOURCE_FILE</code>	<code>Source_file</code>	
<code>SOURCE_LINE</code>	<code>Source_line</code>	

Notes:

- `QUERY_ID` is a numeric statement identifier.

- [SEQ](#) is a sequence number indicating the display order for rows with the same [QUERY_ID](#) value.
- [STATE](#) is the profiling state to which the row measurements apply.
- [DURATION](#) indicates how long statement execution remained in the given state, in seconds.
- [CPU_USER](#) and [CPU_SYSTEM](#) indicate user and system CPU use, in seconds.
- [CONTEXT_VOLUNTARY](#) and [CONTEXT_INVOLUNTARY](#) indicate how many voluntary and involuntary context switches occurred.
- [BLOCK_OPS_IN](#) and [BLOCK_OPS_OUT](#) indicate the number of block input and output operations.
- [MESSAGES_SENT](#) and [MESSAGES_RECEIVED](#) indicate the number of communication messages sent and received.
- [PAGE_FAULTS_MAJOR](#) and [PAGE_FAULTS_MINOR](#) indicate the number of major and minor page faults.
- [SWAPS](#) indicates how many swaps occurred.
- [SOURCE_FUNCTION](#), [SOURCE_FILE](#), and [SOURCE_LINE](#) provide information indicating where in the source code the profiled state executes.

24.17 The INFORMATION_SCHEMA REFERENTIAL_CONSTRAINTS Table

The [REFERENTIAL_CONSTRAINTS](#) table provides information about foreign keys.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CONSTRAINT_CATALOG		def
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
UNIQUE_CONSTRAINT_CATALOG		def
UNIQUE_CONSTRAINT_SCHEMA		
UNIQUE_CONSTRAINT_NAME		
MATCH_OPTION		
UPDATE_RULE		
DELETE_RULE		
TABLE_NAME		
REFERENCED_TABLE_NAME		

Notes:

- [TABLE_NAME](#) has the same value as [TABLE_NAME](#) in [INFORMATION_SCHEMA.TABLE_CONSTRAINTS](#).
- [CONSTRAINT_SCHEMA](#) and [CONSTRAINT_NAME](#) identify the foreign key.
- [UNIQUE_CONSTRAINT_SCHEMA](#), [UNIQUE_CONSTRAINT_NAME](#), and [REFERENCED_TABLE_NAME](#) identify the referenced key.
- The only valid value at this time for [MATCH_OPTION](#) is [NONE](#).
- The possible values for [UPDATE_RULE](#) or [DELETE_RULE](#) are [CASCADE](#), [SET NULL](#), [SET DEFAULT](#), [RESTRICT](#), [NO ACTION](#).

24.18 The INFORMATION_SCHEMA ROUTINES Table

The `ROUTINES` table provides information about stored routines (both procedures and functions). The `ROUTINES` table does not include user-defined functions (UDFs).

INFORMATION_SCHEMA Name	Remarks
SPECIFIC_NAME	
ROUTINE_CATALOG	def
ROUTINE_SCHEMA	
ROUTINE_NAME	
ROUTINE_TYPE	{PROCEDURE FUNCTION}
DATA_TYPE	same as for <code>COLUMNS</code> table
CHARACTER_MAXIMUM_LENGTH	same as for <code>COLUMNS</code> table
CHARACTER_OCTET_LENGTH	same as for <code>COLUMNS</code> table
NUMERIC_PRECISION	same as for <code>COLUMNS</code> table
NUMERIC_SCALE	same as for <code>COLUMNS</code> table
DATETIME_PRECISION	same as for <code>COLUMNS</code> table
CHARACTER_SET_NAME	same as for <code>COLUMNS</code> table
COLLATION_NAME	same as for <code>COLUMNS</code> table
DTD_IDENTIFIER	data type descriptor
ROUTINE_BODY	SQL
ROUTINE_DEFINITION	
EXTERNAL_NAME	NULL
EXTERNAL_LANGUAGE	NULL
PARAMETER_STYLE	SQL
IS_DETERMINISTIC	
SQL_DATA_ACCESS	
SQL_PATH	NULL
SECURITY_TYPE	
CREATED	
LAST_ALTERED	
SQL_MODE	MySQL extension
ROUTINE_COMMENT	MySQL extension
DEFINER	MySQL extension
CHARACTER_SET_CLIENT	MySQL extension
COLLATION_CONNECTION	MySQL extension
DATABASE_COLLATION	MySQL extension

Notes:

- MySQL calculates `EXTERNAL_LANGUAGE` thus:
 - If `mysql.proc.language = 'SQL'`, `EXTERNAL_LANGUAGE` is `NULL`
 - Otherwise, `EXTERNAL_LANGUAGE` is what is in `mysql.proc.language`. However, we do not have external languages yet, so it is always `NULL`.

- **CREATED**: The date and time when the routine was created. This is a [TIMESTAMP](#) value.
- **LAST_ALTERED**: The date and time when the routine was last modified. This is a [TIMESTAMP](#) value. If the routine has not been modified since its creation, this column holds the same value as the **CREATED** column.
- **SQL_MODE**: The SQL mode in effect when the routine was created or altered, and under which the routine executes. For the permitted values, see [Section 5.1.8, “Server SQL Modes”](#).
- **CHARACTER_SET_CLIENT**: The session value of the `character_set_client` system variable when the routine was created.
- **COLLATION_CONNECTION**: The session value of the `collation_connection` system variable when the routine was created.
- **DATABASE_COLLATION**: The collation of the database with which the routine is associated.
- The **DATA_TYPE**, **CHARACTER_MAXIMUM_LENGTH**, **CHARACTER_OCTET_LENGTH**, **NUMERIC_PRECISION**, **NUMERIC_SCALE**, **DATETIME_PRECISION**, **CHARACTER_SET_NAME**, and **COLLATION_NAME** columns provide information about the data type for the **RETURNS** clause of stored functions. If a stored routine is a stored procedure, these columns all are **NULL**.
- Information about stored function **RETURNS** data types is also available in the [PARAMETERS](#) table. The return value data type row for a function can be identified as the row that has an **ORDINAL_POSITION** value of 0.

24.19 The INFORMATION_SCHEMA SCHEMATA Table

A schema is a database, so the [SCHEMATA](#) table provides information about databases.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CATALOG_NAME		<code>def</code>
SCHEMA_NAME	Database	
DEFAULT_CHARACTER_SET_NAME		
DEFAULT_COLLATION_NAME		
SQL_PATH		NULL

The following statements are equivalent:

```
SELECT SCHEMA_NAME AS `Database`
FROM INFORMATION_SCHEMA.SCHEMATA
[WHERE SCHEMA_NAME LIKE 'wild']

SHOW DATABASES
[LIKE 'wild']
```

24.20 The INFORMATION_SCHEMA SCHEMA_PRIVILEGES Table

The [SCHEMA_PRIVILEGES](#) table provides information about schema (database) privileges. This information comes from the `mysql.db` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		<code>'user_name'@'host_name'</code> value, MySQL extension
TABLE_CATALOG		<code>def</code> , MySQL extension
TABLE_SCHEMA		MySQL extension

INFORMATION_SCHEMA Name	SHOW Name	Remarks
PRIVILEGE_TYPE		MySQL extension
IS_GRANTABLE		MySQL extension

Notes:

- This is a nonstandard table. It takes its values from the `mysql.db` table.

24.21 The INFORMATION_SCHEMA STATISTICS Table

The `STATISTICS` table provides information about table indexes.

Columns in `STATISTICS` that represent table statistics hold cached values. If the `information_schema_stats` system variable is `CACHED` (the default), the server retrieves the cached values for queries on the `STATISTICS` table. (To update the cached values for a given table, use `ANALYZE TABLE`.) To use the latest statistics directly from storage engines, set `information_schema_stats` to `LATEST`. For more information, see [Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”](#).

**Note**

If the `innodb_read_only` system variable is enabled, `ANALYZE TABLE` may fail because it cannot update statistics tables in the data dictionary, which use `InnoDB`. For `ANALYZE TABLE` operations that update the key distribution, failure may occur even if the operation updates the table itself (for example, if it is a `MyISAM` table). To obtain the updated distribution statistics, set `information_schema_stats=LATEST`.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		def
TABLE_SCHEMA		= Database
TABLE_NAME	Table	
NON_UNIQUE	Non_unique	
INDEX_SCHEMA		= Database
INDEX_NAME	Key_name	
SEQ_IN_INDEX	Seq_in_index	
COLUMN_NAME	Column_name	
COLLATION	Collation	
CARDINALITY	Cardinality	
SUB_PART	Sub_part	MySQL extension
PACKED	Packed	MySQL extension
NULLABLE	Null	MySQL extension
INDEX_TYPE	Index_type	MySQL extension
COMMENT	Comment	MySQL extension
INDEX_COMMENT	Index_comment	MySQL extension
IS_VISIBLE	Visible	MySQL extension

Notes:

- There is no standard table for indexes. The preceding list is similar to what SQL Server 2000 returns for `sp_statistics`, except that we replaced the name `QUALIFIER` with `CATALOG` and we replaced the name `OWNER` with `SCHEMA`.

Clearly, the preceding table and the output from `SHOW INDEX` are derived from the same parent. So the correlation is already close.

The following statements are equivalent:

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS
  WHERE table_name = 'tbl_name'
     AND table_schema = 'db_name'

SHOW INDEX
  FROM tbl_name
  FROM db_name
```

24.22 The INFORMATION_SCHEMA ST_GEOMETRY_COLUMNS Table

The `ST_GEOMETRY_COLUMNS` table provides information about table columns that store spatial data. This table is based on the SQL/MM (ISO/IEC 13249-3) standard, with extensions as noted. MySQL implements `ST_GEOMETRY_COLUMNS` as a view on the `INFORMATION_SCHEMA COLUMNS` table.

`ST_GEOMETRY_COLUMNS` has these columns:

- `TABLE_CATALOG`

The `COLUMNS.TABLE_CATALOG` value.

- `TABLE_SCHEMA`

The `COLUMNS.TABLE_SCHEMA` value.

- `TABLE_NAME`

The `COLUMNS.TABLE_NAME` value.

- `COLUMN_NAME`

The `COLUMNS.TABLE_COLUMN_NAME` value.

- `SRS_NAME`

Reserved for future use. Currently always `NULL`.

- `SRS_ID`

Reserved for future use. Currently always `NULL`.

- `GEOMETRY_TYPE_NAME`

The column data type. Permitted values are: `geometry`, `point`, `linestring`, `polygon`, `multipoint`, `multilinestring`, `multipolygon`, `geometrycollection`. This column is a MySQL extension to the standard.

24.23 The INFORMATION_SCHEMA ST_SPATIAL_REFERENCE_SYSTEMS Table

The `ST_SPATIAL_REFERENCE_SYSTEMS` table provides information about available spatial reference systems for spatial data. This table is based on the SQL/MM (ISO/IEC 13249-3) standard. MySQL implements `ST_SPATIAL_REFERENCE_SYSTEMS` as a view on the `st_spatial_reference_systems` data dictionary table.

`ST_SPATIAL_REFERENCE_SYSTEMS` has these columns:

- `SRS_NAME`

The spatial reference system name. This value is unique.

- `SRS_ID`

The spatial reference system numeric ID. This value is unique.

`SRS_ID` values represent the same kind of values passed as the SRID argument to spatial functions.

SRID 0 is special. It is always a legal spatial reference system ID and can be used in any computations on spatial data that depend on SRID values. However, SRID 0 has no entry in `ST_SPATIAL_REFERENCE_SYSTEMS` because it cannot be described by the SRS definition format. It represents an infinite flat Cartesian plane with no units assigned to its axes. Unlike projected SRSs, it is not georeferenced and it does not necessarily represent Earth. It is an abstract plane that can be used for anything.

- `ORGANIZATION`

The name of the organization that defined the coordinate system on which the spatial reference system is based.

- `ORGANIZATION_COORDSYS_ID`

The numeric ID given to the spatial reference system by the organization that defined it.

- `DEFINITION`

The spatial reference system definition, as a WKT value.

- `DESCRIPTION`

The spatial reference system description.

Notes:

- The `SRS_NAME`, `ORGANIZATION`, `ORGANIZATION_COORDSYS_ID`, and `DESCRIPTION` columns contain information that may be of interest to users, but they are not used by MySQL.

Example:

```
mysql> SELECT * FROM ST_SPATIAL_REFERENCE_SYSTEMS
      WHERE SRS_ID = 4326\G
***** 1. row *****
      SRS_NAME: WGS 84
      SRS_ID: 4326
      ORGANIZATION: EPSG
      ORGANIZATION_COORDSYS_ID: 4326
      DEFINITION: GEOGCS["WGS 84",DATUM["World Geodetic System 1984",
      SPHEROID["WGS 84",6378137,298.257223563,
      AUTHORITY["EPSG","7030"]],AUTHORITY["EPSG","6326"]],
      PRIMEM["Greenwich",0,AUTHORITY["EPSG","8901"]],
      UNIT["degree",0.017453292519943278,
      AUTHORITY["EPSG","9122"]],
      AXIS["Lat",NORTH],AXIS["Long",EAST],
      AUTHORITY["EPSG","4326"]]
      DESCRIPTION:
```

24.24 The INFORMATION_SCHEMA TABLES Table

The `TABLES` table provides information about tables in databases.

Columns in `TABLES` that represent table statistics hold cached values. If the `information_schema_stats` system variable is `CACHED` (the default), the server retrieves the cached values for queries on the `TABLES` table. (To update the cached values for a given table, use `ANALYZE TABLE`.) To use the latest statistics directly from storage engines, set `information_schema_stats` to `LATEST`. For more information, see [Section 8.2.3, “Optimizing INFORMATION_SCHEMA Queries”](#).

Note

If the `innodb_read_only` system variable is enabled, `ANALYZE TABLE` may fail because it cannot update statistics tables in the data dictionary, which use InnoDB. For `ANALYZE TABLE` operations that update the key distribution, failure may occur even if the operation updates the table itself (for example, if it is a MyISAM table). To obtain the updated distribution statistics, set `information_schema_stats=LATEST`.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		def
TABLE_SCHEMA	Table_...	
TABLE_NAME	Table_...	
TABLE_TYPE		
ENGINE	Engine	MySQL extension
VERSION	Version	The <code>.frm</code> file version. With the removal of <code>.frm</code> files in MySQL 8.0, this field now reports a hardcoded value of 10, which is the last <code>.frm</code> file version used in MySQL 5.7.
ROW_FORMAT	Row_format	MySQL extension
TABLE_ROWS	Rows	MySQL extension
AVG_ROW_LENGTH	Avg_row_length	MySQL extension
DATA_LENGTH	Data_length	MySQL extension
MAX_DATA_LENGTH	Max_data_length	MySQL extension
INDEX_LENGTH	Index_length	MySQL extension
DATA_FREE	Data_free	MySQL extension
AUTO_INCREMENT	Auto_increment	MySQL extension
CREATE_TIME	Create_time	MySQL extension
UPDATE_TIME	Update_time	MySQL extension
CHECK_TIME	Check_time	MySQL extension
TABLE_COLLATION	Collation	MySQL extension
CHECKSUM	Checksum	MySQL extension
CREATE_OPTIONS	Create_options	MySQL extension
TABLE_COMMENT	Comment	MySQL extension

Notes:

- Refer to `SHOW TABLE STATUS` for field descriptions.
- `TABLE_SCHEMA` and `TABLE_NAME` are a single field in a `SHOW` display, for example `Table_in_db1`.
- `TABLE_TYPE` should be `BASE TABLE` or `VIEW`. The `TABLES` table does not list `TEMPORARY` tables.

- For partitioned tables, the [ENGINE](#) column shows the name of the storage engine used by all partitions. (Previously, this column showed [PARTITION](#) for such tables.)
- The [TABLE_ROWS](#) column is [NULL](#) if the table is in the [INFORMATION_SCHEMA](#) database.
For [InnoDB](#) tables, the row count is only a rough estimate used in SQL optimization. (This is also true if the [InnoDB](#) table is partitioned.)
- The [DATA_FREE](#) column shows the free space in bytes for [InnoDB](#) tables.
- [UPDATE_TIME](#) displays a timestamp value for the last [UPDATE](#), [INSERT](#), or [DELETE](#) performed on [InnoDB](#) tables that are not partitioned. For MVCC, the timestamp value reflects the [COMMIT](#) time, which is considered the last update time. Timestamps are not persisted when the server is restarted or when the table is evicted from the [InnoDB](#) data dictionary cache.
- For partitioned [InnoDB](#) tables, the [CHECK_TIME](#) column is always [NULL](#).
- We have nothing for the table's default character set. [TABLE_COLLATION](#) is close, because collation names begin with a character set name.
- The [CREATE_OPTIONS](#) column shows [partitioned](#) if the table is partitioned.

The following statements are equivalent:

```
SELECT table_name FROM INFORMATION_SCHEMA.TABLES
  WHERE table_schema = 'db_name'
  [AND table_name LIKE 'wild']

SHOW TABLES
  FROM db_name
  [LIKE 'wild']
```

24.25 The INFORMATION_SCHEMA TABLESPACES Table

The [TABLESPACES](#) table provides information about active tablespaces.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLESPACE_NAME		MySQL extension
ENGINE		MySQL extension
TABLESPACE_TYPE		MySQL extension
LOGFILE_GROUP_NAME		MySQL extension
EXTENT_SIZE		MySQL extension
AUTOEXTEND_SIZE		MySQL extension
MAXIMUM_SIZE		MySQL extension
NODEGROUP_ID		MySQL extension
TABLESPACE_COMMENT		MySQL extension

Notes:

The [INFORMATION_SCHEMA.TABLESPACES](#) table does not provide information about [InnoDB](#) tablespaces. For [InnoDB](#) tablespace metadata, see [INNODB_SYS_TABLESPACES](#) and [INNODB_SYS_DATAFILES](#). The [INFORMATION_SCHEMA.FILES](#) table also provides metadata for [InnoDB](#) tablespaces.

24.26 The INFORMATION_SCHEMA TABLE_CONSTRAINTS Table

The [TABLE_CONSTRAINTS](#) table describes which tables have constraints.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
CONSTRAINT_CATALOG		def
CONSTRAINT_SCHEMA		
CONSTRAINT_NAME		
TABLE_SCHEMA		
TABLE_NAME		
CONSTRAINT_TYPE		

Notes:

- The `CONSTRAINT_TYPE` value can be `UNIQUE`, `PRIMARY KEY`, or `FOREIGN KEY`.
- The `UNIQUE` and `PRIMARY KEY` information is about the same as what you get from the `Key_name` field in the output from `SHOW INDEX` when the `Non_unique` field is 0.
- The `CONSTRAINT_TYPE` column can contain one of these values: `UNIQUE`, `PRIMARY KEY`, `FOREIGN KEY`, `CHECK`. This is a `CHAR` (not `ENUM`) column. The `CHECK` value is not available until we support `CHECK`.

24.27 The INFORMATION_SCHEMA TABLE_PRIVILEGES Table

The `TABLE_PRIVILEGES` table provides information about table privileges. This information comes from the `mysql.tables_priv` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		'user_name'@'host_name' value
TABLE_CATALOG		def
TABLE_SCHEMA		
TABLE_NAME		
PRIVILEGE_TYPE		
IS_GRANTABLE		

Notes:

- `PRIVILEGE_TYPE` can contain one (and only one) of these values: `SELECT`, `INSERT`, `UPDATE`, `REFERENCES`, `ALTER`, `INDEX`, `DROP`, `CREATE VIEW`.

The following statements are *not* equivalent:

```
SELECT ... FROM INFORMATION_SCHEMA.TABLE_PRIVILEGES
SHOW GRANTS ...
```

24.28 The INFORMATION_SCHEMA TRIGGERS Table

The `TRIGGERS` table provides information about triggers. To see information about a table's triggers, you must have the `TRIGGER` privilege for the table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TRIGGER_CATALOG		def
TRIGGER_SCHEMA		
TRIGGER_NAME	Trigger	
EVENT_MANIPULATION	Event	

INFORMATION_SCHEMA Name	SHOW Name	Remarks
EVENT_OBJECT_CATALOG		def
EVENT_OBJECT_SCHEMA		
EVENT_OBJECT_TABLE	Table	
ACTION_ORDER		
ACTION_CONDITION		NULL
ACTION_STATEMENT	Statement	
ACTION_ORIENTATION		ROW
ACTION_TIMING	Timing	
ACTION_REFERENCE_OLD_TABLE		NULL
ACTION_REFERENCE_NEW_TABLE		NULL
ACTION_REFERENCE_OLD_ROW		OLD
ACTION_REFERENCE_NEW_ROW		NEW
CREATED	Created	
SQL_MODE	sql_mode	MySQL extension
DEFINER	Definer	MySQL extension
CHARACTER_SET_CLIENT	character_set_client	MySQL extension
COLLATION_CONNECTION	collation_connection	MySQL extension
DATABASE_COLLATION	Database Collation	MySQL extension

Notes:

- The names in the “SHOW Name” column refer to the `SHOW TRIGGERS` statement, not `SHOW CREATE TRIGGER`. See [Section 13.7.5.38, “SHOW TRIGGERS Syntax”](#).
- `TRIGGER_SCHEMA` and `TRIGGER_NAME`: The name of the database in which the trigger occurs and the trigger name, respectively.
- `EVENT_MANIPULATION`: The trigger event. This is the type of operation on the associated table for which the trigger activates. The value is `'INSERT'` (a row was inserted), `'DELETE'` (a row was deleted), or `'UPDATE'` (a row was modified).
- `EVENT_OBJECT_SCHEMA` and `EVENT_OBJECT_TABLE`: As noted in [Section 23.3, “Using Triggers”](#), every trigger is associated with exactly one table. These columns indicate the database in which this table occurs, and the table name, respectively.
- `ACTION_ORDER`: The ordinal position of the trigger's action within the list of triggers on the same table with the same `EVENT_MANIPULATION` and `ACTION_TIMING` values.
- `ACTION_STATEMENT`: The trigger body; that is, the statement executed when the trigger activates. This text uses UTF-8 encoding.
- `ACTION_ORIENTATION`: Always contains the value `'ROW'`.
- `ACTION_TIMING`: Whether the trigger activates before or after the triggering event. The value is `'BEFORE'` or `'AFTER'`.
- `ACTION_REFERENCE_OLD_ROW` and `ACTION_REFERENCE_NEW_ROW`: The old and new column identifiers, respectively. This means that `ACTION_REFERENCE_OLD_ROW` always contains the value `'OLD'` and `ACTION_REFERENCE_NEW_ROW` always contains the value `'NEW'`.
- `CREATED`: The date and time when the trigger was created. This is a `TIMESTAMP(2)` value (with a fractional part in hundredths of seconds) for triggers.

- [SQL_MODE](#): The SQL mode in effect when the trigger was created, and under which the trigger executes. For the permitted values, see [Section 5.1.8, “Server SQL Modes”](#).
- [DEFINER](#): The account of the user who created the trigger, in '*user_name*'@'*host_name*' format.
- [CHARACTER_SET_CLIENT](#): The session value of the `character_set_client` system variable when the trigger was created.
- [COLLATION_CONNECTION](#): The session value of the `collation_connection` system variable when the trigger was created.
- [DATABASE_COLLATION](#): The collation of the database with which the trigger is associated.
- The following columns currently always contain `NULL`: `ACTION_CONDITION`, `ACTION_REFERENCE_OLD_TABLE`, and `ACTION_REFERENCE_NEW_TABLE`.

Example, using the `ins_sum` trigger defined in [Section 23.3, “Using Triggers”](#):

```
mysql> SELECT * FROM INFORMATION_SCHEMA.TRIGGERS
      WHERE TRIGGER_SCHEMA='test' AND TRIGGER_NAME='ins_sum'\G
***** 1. row *****
      TRIGGER_CATALOG: def
      TRIGGER_SCHEMA: test
      TRIGGER_NAME: ins_sum
      EVENT_MANIPULATION: INSERT
      EVENT_OBJECT_CATALOG: def
      EVENT_OBJECT_SCHEMA: test
      EVENT_OBJECT_TABLE: account
      ACTION_ORDER: 1
      ACTION_CONDITION: NULL
      ACTION_STATEMENT: SET @sum = @sum + NEW.amount
      ACTION_ORIENTATION: ROW
      ACTION_TIMING: BEFORE
      ACTION_REFERENCE_OLD_TABLE: NULL
      ACTION_REFERENCE_NEW_TABLE: NULL
      ACTION_REFERENCE_OLD_ROW: OLD
      ACTION_REFERENCE_NEW_ROW: NEW
      CREATED: 2017-03-30 20:29:39.06
      SQL_MODE: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,NO_ZERO_DATE,ERROR_F
      DEFINER: me@localhost
      CHARACTER_SET_CLIENT: utf8
      COLLATION_CONNECTION: utf8_general_ci
      DATABASE_COLLATION: utf8mb4_0900_ai_ci
```

24.29 The INFORMATION_SCHEMA USER_PRIVILEGES Table

The `USER_PRIVILEGES` table provides information about global privileges. This information comes from the `mysql.user` grant table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
GRANTEE		' <i>user_name</i> '@' <i>host_name</i> ' value, MySQL extension
TABLE_CATALOG		<code>def</code> , MySQL extension
PRIVILEGE_TYPE		MySQL extension
IS_GRANTABLE		MySQL extension

Notes:

- This is a nonstandard table. It takes its values from the `mysql.user` table.

24.30 The INFORMATION_SCHEMA VIEWS Table

The `VIEWS` table provides information about views in databases. You must have the `SHOW VIEW` privilege to access this table.

INFORMATION_SCHEMA Name	SHOW Name	Remarks
TABLE_CATALOG		def
TABLE_SCHEMA		
TABLE_NAME		
VIEW_DEFINITION		
CHECK_OPTION		
IS_UPDATABLE		
DEFINER		
SECURITY_TYPE		
CHARACTER_SET_CLIENT		MySQL extension
COLLATION_CONNECTION		MySQL extension

Notes:

- The `VIEW_DEFINITION` column has most of what you see in the `Create Table` field that `SHOW CREATE VIEW` produces. Skip the words before `SELECT` and skip the words `WITH CHECK OPTION`. Suppose that the original statement was:

```
CREATE VIEW v AS
  SELECT s2,s1 FROM t
  WHERE s1 > 5
  ORDER BY s1
  WITH CHECK OPTION;
```

Then the view definition looks like this:

```
SELECT s2,s1 FROM t WHERE s1 > 5 ORDER BY s1
```

- The `CHECK_OPTION` column has a value of `NONE`, `CASCADE`, or `LOCAL`.
- MySQL sets a flag, called the view updatability flag, at `CREATE VIEW` time. The flag is set to `YES` (true) if `UPDATE` and `DELETE` (and similar operations) are legal for the view. Otherwise, the flag is set to `NO` (false). The `IS_UPDATABLE` column in the `VIEWS` table displays the status of this flag. It means that the server always knows whether a view is updatable.

If a view is not updatable, statements such `UPDATE`, `DELETE`, and `INSERT` are illegal and will be rejected. (Note that even if a view is updatable, it might not be possible to insert into it; for details, refer to [Section 23.5.3, “Updatable and Insertable Views”](#).)

- `DEFINER`: The account of the user who created the view, in `'user_name'@'host_name'` format. `SECURITY_TYPE` has a value of `DEFINER` or `INVOKER`.
- `CHARACTER_SET_CLIENT`: The session value of the `character_set_client` system variable when the view was created.
- `COLLATION_CONNECTION`: The session value of the `collation_connection` system variable when the view was created.

MySQL lets you use different `sql_mode` settings to tell the server the type of SQL syntax to support. For example, you might use the `ANSI` SQL mode to ensure MySQL correctly interprets the standard SQL concatenation operator, the double bar (`||`), in your queries. If you then create a view that concatenates items, you might worry that changing the `sql_mode` setting to a value different from `ANSI` could cause the view to become invalid. But this is not the case. No matter how you write out a

view definition, MySQL always stores it the same way, in a canonical form. Here is an example that shows how the server changes a double bar concatenation operator to a `CONCAT()` function:

```
mysql> SET sql_mode = 'ANSI';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE VIEW test.v AS SELECT 'a' || 'b' as coll;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT VIEW_DEFINITION FROM INFORMATION_SCHEMA.VIEWS
       WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 'v';
+-----+
| VIEW_DEFINITION |
+-----+
| select concat('a','b') AS `coll` |
+-----+
1 row in set (0.00 sec)
```

The advantage of storing a view definition in canonical form is that changes made later to the value of `sql_mode` will not affect the results from the view. However an additional consequence is that comments prior to `SELECT` are stripped from the definition by the server.

24.31 InnoDB INFORMATION_SCHEMA Tables

This section provides table definitions for InnoDB INFORMATION_SCHEMA tables. For related information and examples, see [Section 15.14, “InnoDB INFORMATION_SCHEMA Tables”](#).

InnoDB INFORMATION_SCHEMA tables can be used to monitor ongoing InnoDB activity, to detect inefficiencies before they turn into issues, or to troubleshoot performance and capacity issues. As your database becomes bigger and busier, running up against the limits of your hardware capacity, you monitor and tune these aspects to keep the database running smoothly.

24.31.1 The INFORMATION_SCHEMA INNODB_BUFFER_PAGE Table

The `INNODB_BUFFER_PAGE` table holds information about each [page](#) in the InnoDB buffer pool.

For related usage information and examples, see [Section 15.14.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”](#).

Warning

Querying the `INNODB_BUFFER_PAGE` table can introduce significant performance overhead. Do not query this table on a production system unless you are aware of the performance impact that your query may have, and have determined it to be acceptable. To avoid impacting performance, reproduce the issue you want to investigate on a test instance and query the `INNODB_BUFFER_PAGE` table on the test instance.

Table 24.1 INNODB_BUFFER_PAGE Columns

Column name	Description
<code>POOL_ID</code>	Buffer Pool ID. An identifier to distinguish between multiple buffer pool instances.
<code>BLOCK_ID</code>	Buffer Pool Block ID.
<code>SPACE</code>	Tablespace ID. Uses the same value as in <code>INNODB_SYS_TABLES.SPACE</code> .
<code>PAGE_NUMBER</code>	Page number.
<code>PAGE_TYPE</code>	Page type. Permitted values are <code>ALLOCATED</code> (Freshly allocated page), <code>INDEX</code> (B-tree node), <code>UNDO_LOG</code> (Undo log page), <code>INODE</code> (Index

Column name	Description
	node), IBUF_FREE_LIST (Insert buffer free list), IBUF_BITMAP (Insert buffer bitmap), SYSTEM (System page), TRX_SYSTEM (Transaction system data), FILE_SPACE_HEADER (File space header), EXTENT_DESCRIPTOR (Extent descriptor page), BLOB (Uncompressed BLOB page), COMPRESSED_BLOB (First compressed BLOB page), COMPRESSED_BLOB2 (Subsequent comp BLOB page), IBUF_INDEX (Insert buffer index), RTREE_INDEX (spatial index), SDI_INDEX (SDI index), SDI_BLOB (uncompressed SDI BLOB), SDI_COMPRESSED_BLOB (compressed SDI BLOB), UNKNOWN (unknown).
FLUSH_TYPE	Flush type.
FIX_COUNT	Number of threads using this block within the buffer pool. When zero, the block is eligible to be evicted.
IS_HASHED	Whether hash index has been built on this page.
NEWEST_MODIFICATION	Log Sequence Number of the youngest modification.
OLDEST_MODIFICATION	Log Sequence Number of the oldest modification.
ACCESS_TIME	An abstract number used to judge the first access time of the page.
TABLE_NAME	Name of the table the page belongs to. This column is only applicable to pages of type INDEX .
INDEX_NAME	Name of the index the page belongs to. It can be the name of a clustered index or a secondary index. This column is only applicable to pages of type INDEX .
NUMBER_RECORDS	Number of records within the page.
DATA_SIZE	Sum of the sizes of the records. This column is only applicable to pages of type INDEX .
COMPRESSED_SIZE	Compressed page size. Null for pages that are not compressed.
PAGE_STATE	Page state. A page with valid data has one of the following states: FILE_PAGE (buffers a page of data from a file), MEMORY (buffers a page from an in-memory object), COMPRESSED . Other possible states (managed by InnoDB) are: NULL , READY_FOR_USE , NOT_USED , REMOVE_HASH .
IO_FIX	Specifies whether any I/O is pending for this page: IO_NONE = no pending I/O, IO_READ = read pending, IO_WRITE = write pending.
IS_OLD	Specifies whether or not the block is in the sublist of old blocks in the LRU list.
FREE_PAGE_CLOCK	The value of the freed_page_clock counter when the block was the last placed at the head of the LRU list. The freed_page_clock counter tracks the number of blocks removed from the end of the LRU list.

Example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE LIMIT 1\G
***** 1. row *****
      POOL_ID: 0
      BLOCK_ID: 0
      SPACE: 97
      PAGE_NUMBER: 2473
      PAGE_TYPE: INDEX
      FLUSH_TYPE: 1
      FIX_COUNT: 0
      IS_HASHED: YES
      NEWEST_MODIFICATION: 733855581
      OLDEST_MODIFICATION: 0
```

```

ACCESS_TIME: 3378385672
TABLE_NAME: `employees`.`salaries`
INDEX_NAME: PRIMARY
NUMBER_RECORDS: 468
DATA_SIZE: 14976
COMPRESSED_SIZE: 0
PAGE_STATE: FILE_PAGE
IO_FIX: IO_NONE
IS_OLD: YES
FREE_PAGE_CLOCK: 66

```

Notes:

- This table is primarily useful for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.
- When tables, table rows, partitions, or indexes are deleted, associated pages remain in the buffer pool until space is required for other data. The [INNODB_BUFFER_PAGE](#) table reports information about these pages until they are evicted from the buffer pool. For more information about how the [InnoDB](#) manages buffer pool data, see [Section 15.6.3.1, “The InnoDB Buffer Pool”](#).

24.31.2 The INFORMATION_SCHEMA INNODB_BUFFER_PAGE_LRU Table

The [INNODB_BUFFER_PAGE_LRU](#) table holds information about the pages in the [InnoDB buffer pool](#), in particular how they are ordered in the LRU list that determines which pages to [evict](#) from the buffer pool when it becomes full.

The [INNODB_BUFFER_PAGE_LRU](#) table has the same columns as the [INNODB_BUFFER_PAGE](#) table, except that the [INNODB_BUFFER_PAGE_LRU](#) table has an [LRU_POSITION](#) column instead of a [BLOCK_ID](#) column.

For related usage information and examples, see [Section 15.14.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”](#).

**Warning**

Querying the [INNODB_BUFFER_PAGE_LRU](#) table can introduce significant performance overhead. Do not query this table on a production system unless you are aware of the performance impact that your query may have, and have determined it to be acceptable. To avoid impacting performance, reproduce the issue you want to investigate on a test instance and query the [INNODB_BUFFER_PAGE_LRU](#) table on the test instance.

Table 24.2 INNODB_BUFFER_PAGE_LRU Columns

Column name	Description
POOL_ID	Buffer Pool ID. An identifier to distinguish between multiple buffer pool instances.
LRU_POSITION	The position of the page in the LRU list.
SPACE	Tablespace ID. Uses the same value as in INNODB_SYS_TABLES.SPACE .
PAGE_NUMBER	Page number.
PAGE_TYPE	Page type. Permitted values are ALLOCATED (Freshly allocated page), INDEX (B-tree node), UNDO_LOG (Undo log page), INODE (Index node), IBUF_FREE_LIST (Insert buffer free list), IBUF_BITMAP

Column name	Description
	(Insert buffer bitmap), <code>SYSTEM</code> (System page), <code>TRX_SYSTEM</code> (Transaction system data), <code>FILE_SPACE_HEADER</code> (File space header), <code>EXTENT_DESCRIPTOR</code> (Extent descriptor page), <code>BLOB</code> (Uncompressed BLOB page), <code>COMPRESSED_BLOB</code> (First compressed BLOB page), <code>COMPRESSED_BLOB2</code> (Subsequent comp BLOB page), <code>IBUF_INDEX</code> (Insert buffer index), <code>RTREE_INDEX</code> (spatial index), <code>SDI_INDEX</code> (SDI index), <code>SDI_BLOB</code> (uncompressed SDI BLOB), <code>SDI_COMPRESSED_BLOB</code> (compressed SDI BLOB), <code>UNKNOWN</code> (unknown).
<code>FLUSH_TYPE</code>	Flush type.
<code>FIX_COUNT</code>	Number of threads using this block within the buffer pool. When zero, the block is eligible to be evicted.
<code>IS_HASHED</code>	Whether hash index has been built on this page.
<code>NEWEST_MODIFICATION</code>	Log Sequence Number of the youngest modification.
<code>OLDEST_MODIFICATION</code>	Log Sequence Number of the oldest modification.
<code>ACCESS_TIME</code>	An abstract number used to judge the first access time of the page.
<code>TABLE_NAME</code>	Name of the table the page belongs to. This column is only applicable to pages of type <code>INDEX</code> .
<code>INDEX_NAME</code>	Name of the index the page belongs to. It can be the name of a clustered index or a secondary index. This column is only applicable to pages of type <code>INDEX</code> .
<code>NUMBER_RECORDS</code>	Number of records within the page.
<code>DATA_SIZE</code>	Sum of the sizes of the records. This column is only applicable to pages of type <code>INDEX</code> .
<code>COMPRESSED_SIZE</code>	Compressed page size. Null for pages that are not compressed.
<code>PAGE_STATE</code>	Page state. A page with valid data has one of the following states: <code>FILE_PAGE</code> (buffers a page of data from a file), <code>MEMORY</code> (buffers a page from an in-memory object), <code>COMPRESSED</code> . Other possible states (managed by InnoDB) are: <code>NULL</code> , <code>READY_FOR_USE</code> , <code>NOT_USED</code> , <code>REMOVE_HASH</code> .
<code>IO_FIX</code>	Specifies whether any I/O is pending for this page: <code>IO_NONE</code> = no pending I/O, <code>IO_READ</code> = read pending, <code>IO_WRITE</code> = write pending.
<code>IS_OLD</code>	Specifies whether or not the block is in the sublist of old blocks in the LRU list.
<code>FREE_PAGE_CLOCK</code>	The value of the <code>freed_page_clock</code> counter when the block was the last placed at the head of the LRU list. The <code>freed_page_clock</code> counter tracks the number of blocks removed from the end of the LRU list.

Example

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU LIMIT 1\G
***** 1. row *****
      POOL_ID: 0
     LRU_POSITION: 0
           SPACE: 97
    PAGE_NUMBER: 1984
     PAGE_TYPE: INDEX
     FLUSH_TYPE: 1
      FIX_COUNT: 0
      IS_HASHED: YES
NEWEST_MODIFICATION: 719490396
OLDEST_MODIFICATION: 0
      ACCESS_TIME: 3378383796
```

```

TABLE_NAME: `employees`.`salaries`
INDEX_NAME: PRIMARY
NUMBER_RECORDS: 468
DATA_SIZE: 14976
COMPRESSED_SIZE: 0
COMPRESSED: NO
IO_FIX: IO_NONE
IS_OLD: YES
FREE_PAGE_CLOCK: 0
    
```

Notes

- This table is primarily useful for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- You must have the [PROCESS](#) privilege to query this table.
- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- Querying this table can require MySQL to allocate a large block of contiguous memory, more than 64 bytes time the number of active pages in the buffer pool. This allocation could potentially cause an out-of-memory error, especially for systems with multi-gigabyte buffer pools.
- Querying this table requires MySQL to lock the data structure representing the buffer pool while traversing the LRU list, which can reduce concurrency, especially for systems with multi-gigabyte buffer pools.
- When tables, table rows, partitions, or indexes are deleted, associated pages remain in the buffer pool until space is required for other data. The [INNODB_BUFFER_PAGE_LRU](#) table reports information about these pages until they are evicted from the buffer pool. For more information about how the [InnoDB](#) manages buffer pool data, see [Section 15.6.3.1, “The InnoDB Buffer Pool”](#).

24.31.3 The INFORMATION_SCHEMA INNODB_BUFFER_POOL_STATS Table

The [INNODB_BUFFER_POOL_STATS](#) table provides much of the same buffer pool information provided in [SHOW ENGINE INNODB STATUS](#) output. Much of the same information may also be obtained using [InnoDB](#) buffer pool [server status variables](#).

The idea of making pages in the buffer pool “young” or “not young” refers to transferring them between the [sublists](#) at the head and tail of the buffer pool data structure. Pages made “young” take longer to age out of the buffer pool, while pages made “not young” are moved much closer to the point of [eviction](#).

For related usage information and examples, see [Section 15.14.5, “InnoDB INFORMATION_SCHEMA Buffer Pool Tables”](#).

Table 24.3 INNODB_BUFFER_POOL_STATS Columns

Column name	Description
POOL_ID	Buffer Pool ID. A unique identifier to distinguish between multiple buffer pool instances.
POOL_SIZE	The InnoDB buffer pool size in pages.
FREE_BUFFERS	The number of free pages in the InnoDB buffer pool
DATABASE_PAGES	The number of pages in the InnoDB buffer pool containing data. The number includes both dirty and clean pages.
OLD_DATABASE_PAGES	The number of pages in the old buffer pool sublist.
MODIFIED_DATABASE_PAGES	The number of modified (dirty) database pages

Column name	Description
PENDING_DECOMPRESS	The number of pages pending decompression
PENDING_READS	The number of pending reads
PENDING_FLUSH_LRU	The number of pages pending flush in the LRU
PENDING_FLUSH_LIST	The number of pages pending flush in the flush list
PAGES_MADE_YOUNG	The number of pages made young
PAGES_NOT_MADE_YOUNG	The number of pages not made young
PAGES_MADE_YOUNG_RATE	The number of pages made young per second (pages made young since the last printout / time elapsed)
PAGES_MADE_NOT_YOUNG_RATE	The number of pages not made per second (pages not made young since the last printout / time elapsed)
NUMBER_PAGES_READ	The number of pages read
NUMBER_PAGES_CREATED	The number of pages created
NUMBER_PAGES_WRITTEN	The number of pages written
PAGES_READ_RATE	The number of pages read per second (pages read since the last printout / time elapsed)
PAGES_CREATE_RATE	The number of pages created per second (pages created since the last printout / time elapsed)
PAGES_WRITTEN_RATE	The number of pages written per second (pages written since the last printout / time elapsed)
NUMBER_PAGES_GET	The number of logical read requests.
HIT_RATE	The buffer pool hit rate
YOUNG_MAKE_PER_THOUSAND_GETS	The number of pages made young per thousand gets
NOT_YOUNG_MAKE_PER_THOUSAND_GETS	The number of pages not made young per thousand gets
NUMBER_PAGES_READ_AHEAD	The number of pages read ahead
NUMBER_READ_AHEAD_EVICTED	The number of pages read into the InnoDB buffer pool by the read-ahead background thread that were subsequently evicted without having been accessed by queries.
READ_AHEAD_RATE	The read ahead rate per second (pages read ahead since the last printout / time elapsed)
READ_AHEAD_EVICTED_RATE	The number of read ahead pages evicted without access per second (read ahead pages not accessed since the last printout / time elapsed)
LRU_IO_TOTAL	LRU IO total
LRU_IO_CURRENT	LRU IO for the current interval
UNCOMPRESS_TOTAL	Total number of pages decompressed
UNCOMPRESS_CURRENT	The number of pages decompressed in the current interval

Example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_POOL_STATS\G
***** 1. row *****
      POOL_ID: 0
      POOL_SIZE: 8192
      FREE_BUFFERS: 1
      DATABASE_PAGES: 8085
      OLD_DATABASE_PAGES: 2964
      MODIFIED_DATABASE_PAGES: 0
      PENDING_DECOMPRESS: 0
      PENDING_READS: 0
      PENDING_FLUSH_LRU: 0
```

```

PENDING_FLUSH_LIST: 0
PAGES_MADE_YOUNG: 22821
PAGES_NOT_MADE_YOUNG: 3544303
PAGES_MADE_YOUNG_RATE: 357.62602199870594
PAGES_MADE_NOT_YOUNG_RATE: 0
NUMBER_PAGES_READ: 2389
NUMBER_PAGES_CREATED: 12385
NUMBER_PAGES_WRITTEN: 13111
PAGES_READ_RATE: 0
PAGES_CREATE_RATE: 0
PAGES_WRITTEN_RATE: 0
NUMBER_PAGES_GET: 33322210
HIT_RATE: 1000
YOUNG_MAKE_PER_THOUSAND_GETS: 18
NOT_YOUNG_MAKE_PER_THOUSAND_GETS: 0
NUMBER_PAGES_READ_AHEAD: 2024
NUMBER_READ_AHEAD_EVICTED: 0
READ_AHEAD_RATE: 0
READ_AHEAD_EVICTED_RATE: 0
LRU_IO_TOTAL: 0
LRU_IO_CURRENT: 0
UNCOMPRESS_TOTAL: 0
UNCOMPRESS_CURRENT: 0
    
```

Notes:

- This table is primarily useful for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.

24.31.4 The INFORMATION_SCHEMA INNODB_CACHED_INDEXES Table

The `INNODB_CACHED_INDEXES` table reports the number of index pages cached in the `InnoDB` buffer pool for each index.

Table 24.4 INNODB_CACHED_INDEXES Columns

Column name	Description
<code>SPACE_ID</code>	Tablespace Space ID.
<code>INDEX_ID</code>	An identifier for each index that is unique across all the databases in an instance.
<code>N_CACHED_PAGES</code>	The number of index pages cached in the <code>InnoDB</code> buffer pool.

Examples:

This query returns the number of index pages cached in the `InnoDB` buffer pool for a specific index:

```

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CACHED_INDEXES WHERE INDEX_ID=65\G
***** 1. row *****
INDEX_ID: 65
N_CACHED_PAGES: 45
1 row in set (0.00 sec)
    
```

This query returns the number of index pages cached in the `InnoDB` buffer pool for each index, and uses the `INNODB_SYS_INDEXES` and `INNODB_SYS_TABLES` to resolve the table name and index name for each `INDEX_ID` value.

```

SELECT
  tables.name AS table_name,
    
```

```

indexes.name AS index_name,
cached.n_cached_pages AS n_cached_pages
FROM
INFORMATION_SCHEMA.INNODB_CACHED_INDEXES AS cached,
INFORMATION_SCHEMA.INNODB_SYS_INDEXES AS indexes,
INFORMATION_SCHEMA.INNODB_SYS_TABLES AS tables
WHERE
cached.index_id = indexes.index_id
AND indexes.table_id = tables.table_id;

```

Notes:

- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.

24.31.5 The INFORMATION_SCHEMA INNODB_CMP and INNODB_CMP_RESET Tables

The [INNODB_CMP](#) and [INNODB_CMP_RESET](#) tables contain status information on operations related to [compressed](#) InnoDB tables.

Table 24.5 Columns of INNODB_CMP and INNODB_CMP_RESET

Column name	Description
PAGE_SIZE	Compressed page size in bytes.
COMPRESS_OPS	Number of times a B-tree page of the size PAGE_SIZE has been compressed. Pages are compressed whenever an empty page is created or the space for the uncompressed modification log runs out.
COMPRESS_OPS_OK	Number of times a B-tree page of the size PAGE_SIZE has been successfully compressed. This count should never exceed COMPRESS_OPS .
COMPRESS_TIME	Total time in seconds spent in attempts to compress B-tree pages of the size PAGE_SIZE .
UNCOMPRESS_OPS	Number of times a B-tree page of the size PAGE_SIZE has been uncompressed. B-tree pages are uncompressed whenever compression fails or at first access when the uncompressed page does not exist in the buffer pool.
UNCOMPRESS_TIME	Total time in seconds spent in uncompressing B-tree pages of the size PAGE_SIZE .

Example:

```

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMP\G
***** 1. row *****
  page_size: 1024
  compress_ops: 0
compress_ops_ok: 0
  compress_time: 0
  uncompress_ops: 0
  uncompress_time: 0
***** 2. row *****
  page_size: 2048
  compress_ops: 0
compress_ops_ok: 0
  compress_time: 0
  uncompress_ops: 0
  uncompress_time: 0
***** 3. row *****
  page_size: 4096

```

```

compress_ops: 0
compress_ops_ok: 0
compress_time: 0
uncompress_ops: 0
uncompress_time: 0
***** 4. row *****
page_size: 8192
compress_ops: 86955
compress_ops_ok: 81182
compress_time: 27
uncompress_ops: 26828
uncompress_time: 5
***** 5. row *****
page_size: 16384
compress_ops: 0
compress_ops_ok: 0
compress_time: 0
uncompress_ops: 0
uncompress_time: 0

```

Notes:

- Use these tables to measure the effectiveness of [InnoDB table compression](#) in your database.
- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of these tables including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.
- For usage information, see [Section 15.9.1.4, “Monitoring InnoDB Table Compression at Runtime”](#) and [Section 15.14.1.3, “Using the Compression Information Schema Tables”](#). For general information about [InnoDB table compression](#), see [Section 15.9, “InnoDB Table and Page Compression”](#).

24.31.6 The INFORMATION_SCHEMA INNODB_CMPMEM and INNODB_CMPMEM_RESET Tables

The [INNODB_CMPMEM](#) and [INNODB_CMPMEM_RESET](#) tables contain status information on compressed pages within the [InnoDB buffer pool](#).

Table 24.6 Columns of INNODB_CMPMEM and INNODB_CMPMEM_RESET

Column name	Description
PAGE_SIZE	Block size in bytes. Each record of this table describes blocks of this size.
BUFFER_POOL_INSTANCE	A unique identifier for the buffer pool instance.
PAGES_USED	Number of blocks of the size PAGE_SIZE that are currently in use.
PAGES_FREE	Number of blocks of the size PAGE_SIZE that are currently available for allocation. This column shows the external fragmentation in the memory pool. Ideally, these numbers should be at most 1.
RELOCATION_OPS	Number of times a block of the size PAGE_SIZE has been relocated. The buddy system can relocate the allocated “buddy neighbor” of a freed block when it tries to form a bigger freed block. Reading from the table INNODB_CMPMEM_RESET resets this count.
RELOCATION_TIME	Total time in microseconds spent in relocating blocks of the size PAGE_SIZE . Reading from the table INNODB_CMPMEM_RESET resets this count.

Example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMPMEM\G
```

```

***** 1. row *****
      page_size: 1024
buffer_pool_instance: 0
      pages_used: 0
      pages_free: 0
      relocation_ops: 0
      relocation_time: 0
***** 2. row *****
      page_size: 2048
buffer_pool_instance: 0
      pages_used: 0
      pages_free: 0
      relocation_ops: 0
      relocation_time: 0
***** 3. row *****
      page_size: 4096
buffer_pool_instance: 0
      pages_used: 0
      pages_free: 0
      relocation_ops: 0
      relocation_time: 0
***** 4. row *****
      page_size: 8192
buffer_pool_instance: 0
      pages_used: 7673
      pages_free: 15
      relocation_ops: 4638
      relocation_time: 0
***** 5. row *****
      page_size: 16384
buffer_pool_instance: 0
      pages_used: 0
      pages_free: 0
      relocation_ops: 0
      relocation_time: 0
    
```

Notes:

- Use these tables to measure the effectiveness of [InnoDB table compression](#) in your database.
- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of these tables including data types and default values.
- You must have the `PROCESS` privilege to query this table.
- For usage information, see [Section 15.9.1.4, “Monitoring InnoDB Table Compression at Runtime”](#) and [Section 15.14.1.3, “Using the Compression Information Schema Tables”](#). For general information about [InnoDB table compression](#), see [Section 15.9, “InnoDB Table and Page Compression”](#).

24.31.7 The INFORMATION_SCHEMA INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET Tables

The `INNODB_CMP_PER_INDEX` and `INNODB_CMP_PER_INDEX_RESET` tables contain status information on operations related to [compressed InnoDB tables and indexes](#), with separate statistics for each combination of database, table, and index, to help you evaluate the performance and usefulness of compression for specific tables.

For a compressed [InnoDB table](#), both the table data and all the [secondary indexes](#) are compressed. In this context, the table data is treated as just another index, one that happens to contain all the columns: the [clustered index](#).

Table 24.7 Columns of INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET

Column name	Description
<code>DATABASE_NAME</code>	Database containing the applicable table.

Column name	Description
TABLE_NAME	Table to monitor for compression statistics.
INDEX_NAME	Index to monitor for compression statistics.
COMPRESS_OPS	Number of compression operations attempted. Pages are compressed whenever an empty page is created or the space for the uncompressed modification log runs out.
COMPRESS_OPS_OK	Number of successful compression operations. Subtract from the COMPRESS_OPS value to get the number of compression failures. Divide by the COMPRESS_OPS value to get the percentage of compression failures.
COMPRESS_TIME	Total amount of CPU time, in seconds, used for compressing data in this index.
UNCOMPRESS_OPS	Number of uncompression operations performed. Compressed InnoDB pages are uncompressed whenever compression fails, or the first time a compressed page is accessed in the buffer pool and the uncompressed page does not exist.
UNCOMPRESS_TIME	Total amount of CPU time, in seconds, used for uncompressing data in this index.

Example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_CMP_PER_INDEX\G
***** 1. row *****
  database_name: employees
    table_name: salaries
    index_name: PRIMARY
   compress_ops: 0
compress_ops_ok: 0
   compress_time: 0
uncompress_ops: 23451
uncompress_time: 4
***** 2. row *****
  database_name: employees
    table_name: salaries
    index_name: emp_no
   compress_ops: 0
compress_ops_ok: 0
   compress_time: 0
uncompress_ops: 1597
uncompress_time: 0
```

Notes:

- Use these tables to measure the effectiveness of InnoDB table [compression](#) for specific tables, indexes, or both.
- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of these tables including data types and default values.
- You must have the [PROCESS](#) privilege to query these tables.
- Because collecting separate measurements for every index imposes substantial performance overhead, [INNODB_CMP_PER_INDEX](#) and [INNODB_CMP_PER_INDEX_RESET](#) statistics are not gathered by default. You must enable the [innodb_cmp_per_index_enabled](#) configuration option before performing the operations on compressed tables that you want to monitor.
- For usage information, see [Section 15.9.1.4, “Monitoring InnoDB Table Compression at Runtime”](#) and [Section 15.14.1.3, “Using the Compression Information Schema Tables”](#). For general information about InnoDB table compression, see [Section 15.9, “InnoDB Table and Page Compression”](#).

24.31.8 The INFORMATION_SCHEMA INNODB_FT_BEING_DELETED Table

The `INNODB_FT_BEING_DELETED` table is a snapshot of the `INNODB_FT_DELETED` table that is only used during an `OPTIMIZE TABLE` maintenance operation. When `OPTIMIZE TABLE` is run, the `INNODB_FT_BEING_DELETED` table is emptied, and `DOC_ID`s are removed from the `INNODB_FT_DELETED` table. Because the contents of `INNODB_FT_BEING_DELETED` typically have a short lifetime, this table has limited utility for monitoring or debugging. For information about running `OPTIMIZE TABLE` on tables with `FULLTEXT` indexes, see [Section 12.9.6, “Fine-Tuning MySQL Full-Text Search”](#).

This table initially appears empty, until you set the value of the configuration variable `innodb_ft_aux_table`. The output appears similar to the example provided for the `INNODB_FT_DELETED` table.

For related usage information and examples, see [Section 15.14.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”](#).

Table 24.8 INNODB_FT_BEING_DELETED Columns

Column name	Description
<code>DOC_ID</code>	The document ID of the row that is in the process of being deleted. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by InnoDB when the table does not contain a suitable column. This value is used to skip rows in the <code>innodb_ft_index_table</code> table, when you do text searches before data for deleted rows is physically removed from the <code>FULLTEXT</code> index by an <code>OPTIMIZE TABLE</code> statement. See Optimizing InnoDB Full-Text Indexes for more information.

Notes:

- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.
- For more information about InnoDB `FULLTEXT` search, see [Section 15.8.2.4, “InnoDB FULLTEXT Indexes”](#), and [Section 12.9, “Full-Text Search Functions”](#).

24.31.9 The INFORMATION_SCHEMA INNODB_FT_CONFIG Table

The `INNODB_FT_CONFIG` table displays metadata about the `FULLTEXT` index and associated processing for an InnoDB table.

Before you query this table, set the configuration variable `innodb_ft_aux_table` to the name (including the database name) of the table that contains the `FULLTEXT` index, for example `test/articles`.

For related usage information and examples, see [Section 15.14.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”](#).

Table 24.9 INNODB_FT_CONFIG Columns

Column name	Description
<code>KEY</code>	The name designating an item of metadata for an InnoDB table containing a <code>FULLTEXT</code> index.
<code>VALUE</code>	The value associated with the corresponding <code>KEY</code> column, reflecting some limit or current value for an aspect of a <code>FULLTEXT</code> index for an InnoDB table.

Example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_CONFIG;
+-----+-----+
| KEY          | VALUE          |
+-----+-----+
| optimize_checkpoint_limit | 180            |
| synced_doc_id | 0              |
| stopword_table_name | test/my_stopwords |
| use_stopword  | 1              |
+-----+-----+
```

Notes:

- This table is only intended for internal configuration. It is not intended for statistical information purposes.
- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.
- The values for the `KEY` column might evolve depending on the needs for performance tuning and debugging for `InnoDB` full-text processing. The key values include:
 - `optimize_checkpoint_limit`: The number of seconds after which an `OPTIMIZE TABLE` run will stop.
 - `synced_doc_id`: The next `DOC_ID` to be issued.
 - `stopword_table_name`: The `database/table` name for a user defined stopword table. This field appears empty if there is no user-defined stopword table.
 - `use_stopword`: Indicates whether or not a stopword table is used, which is defined when the `FULLTEXT` index is created.
- For more information about `InnoDB FULLTEXT` search, see [Section 15.8.2.4, “InnoDB FULLTEXT Indexes”](#), and [Section 12.9, “Full-Text Search Functions”](#).

24.31.10 The INFORMATION_SCHEMA INNODB_FT_DEFAULT_STOPWORD Table

The `INNODB_FT_DEFAULT_STOPWORD` table holds a list of `stopwords` that are used by default when creating a `FULLTEXT` index on an `InnoDB` table. For information about the default `InnoDB` stopword list and how to define your own stopword lists, see [Section 12.9.4, “Full-Text Stopwords”](#).

For related usage information and examples, see [Section 15.14.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”](#).

Table 24.10 INNODB_FT_DEFAULT_STOPWORD Columns

Column name	Description
<code>value</code>	A word that is used by default as a stopword for <code>FULLTEXT</code> indexes on <code>InnoDB</code> tables. Not used if you override the default stopword processing with either the <code>innodb_ft_server_stopword_table</code> or the <code>innodb_ft_user_stopword_table</code> option.

Example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DEFAULT_STOPWORD;
```

```

+-----+
| value |
+-----+
| a     |
| about |
| an    |

```

Notes:

- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.
- For more information about [InnoDB FULLTEXT](#) search, see [Section 15.8.2.4, “InnoDB FULLTEXT Indexes”](#), and [Section 12.9, “Full-Text Search Functions”](#).

24.31.11 The INFORMATION_SCHEMA INNODB_FT_DELETED Table

The [INNODB_FT_DELETED](#) table records rows that are deleted from the [FULLTEXT](#) index for an [InnoDB](#) table. To avoid expensive index reorganization during DML operations for an [InnoDB](#) [FULLTEXT](#) index, the information about newly deleted words is stored separately, filtered out of search results when you do a text search, and removed from the main search index only when you issue the [OPTIMIZE TABLE](#) statement for the [InnoDB](#) table. See [Optimizing InnoDB Full-Text Indexes](#) for more information.

This table initially appears empty, until you set the value of the configuration variable [innodb_ft_aux_table](#) to the name (including the database name) of the table that contains the [FULLTEXT](#) index, for example `test/articles`.

For related usage information and examples, see [Section 15.14.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”](#).

Table 24.11 INNODB_FT_DELETED Columns

Column name	Description
DOC_ID	The document ID of the newly deleted row. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by InnoDB when the table does not contain a suitable column. This value is used to skip rows in the <code>innodb_ft_index_table</code> table, when you do text searches before data for deleted rows is physically removed from the <code>FULLTEXT</code> index by an <code>OPTIMIZE TABLE</code> statement. See Optimizing InnoDB Full-Text Indexes for more information.

Example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
+-----+
| DOC_ID |
+-----+
|      6 |
|      7 |
|      8 |
+-----+
```

Notes:

- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.
- For more information about InnoDB `FULLTEXT` search, see [Section 15.8.2.4, “InnoDB FULLTEXT Indexes”](#), and [Section 12.9, “Full-Text Search Functions”](#).

24.31.12 The INFORMATION_SCHEMA INNODB_FT_INDEX_CACHE Table

`INNODB_FT_INDEX_CACHE`: Contains token information about newly inserted rows in a `FULLTEXT` index. To avoid expensive index reorganization during DML operations, the information about newly indexed words is stored separately, and combined with the main search index only when `OPTIMIZE TABLE` is run, when the server is shut down, or when the cache size exceeds a limit defined by `innodb_ft_cache_size` or `innodb_ft_total_cache_size`.

Before you query this table, set the configuration variable `innodb_ft_aux_table` to the name (including the database name) of the table that contains the `FULLTEXT` index, for example `test/articles`.

For related usage information and examples, see [Section 15.14.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”](#).

Table 24.12 INNODB_FT_INDEX_CACHE Columns

Column name	Description
WORD	A word extracted from the text of a newly inserted row.
FIRST_DOC_ID	The first document ID that this word appears in the <code>FULLTEXT</code> index.
LAST_DOC_ID	The last document ID that this word appears in the <code>FULLTEXT</code> index.
DOC_COUNT	The number of rows this word appears in the <code>FULLTEXT</code> index. The same word can occur several times within the cache table, once for each combination of <code>DOC_ID</code> and <code>POSITION</code> values.

Column name	Description
DOC_ID	The document ID of the newly inserted row. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by <code>InnoDB</code> when the table does not contain a suitable column.
POSITION	The position of this particular instance of the word within the relevant document identified by the <code>DOC_ID</code> value. The value does not represent an absolute position; it is an offset added to the <code>POSITION</code> of the previous instance of that word.

Notes:

- This table initially appears empty, until you set the value of the configuration variable `innodb_ft_aux_table`. The following example demonstrates how to use the `innodb_ft_aux_table` option to show information about a `FULLTEXT` index for a specified table.

```
mysql> USE test;

mysql> CREATE TABLE articles (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  title VARCHAR(200),
  body TEXT,
  FULLTEXT (title,body)
) ENGINE=InnoDB;

mysql> INSERT INTO articles (title,body) VALUES
('MySQL Tutorial','DBMS stands for DataBase ...'),
('How To Use MySQL Well','After you went through a ...'),
('Optimizing MySQL','In this tutorial we will show ...'),
('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
('MySQL vs. YourSQL','In the following database comparison ...'),
('MySQL Security','When configured properly, MySQL ...');

mysql> SET GLOBAL innodb_ft_aux_table = 'test/articles';
Query OK, 0 rows affected (0.00 sec)

mysql> USE INFORMATION_SCHEMA;

mysql> SELECT word, doc_count, doc_id, position FROM INNODB_FT_INDEX_CACHE LIMIT 5;
+-----+-----+-----+-----+
| word      | doc_count | doc_id | position |
+-----+-----+-----+-----+
| 1001      |          1 |      4 |          0 |
| after     |          1 |      2 |          22 |
| comparison |          1 |      5 |          44 |
| configured |          1 |      6 |          20 |
| database  |          2 |      1 |          31 |
+-----+-----+-----+-----+
```

- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.
- For more information about `InnoDB FULLTEXT` search, see [Section 15.8.2.4, “InnoDB FULLTEXT Indexes”](#), and [Section 12.9, “Full-Text Search Functions”](#).

24.31.13 The INFORMATION_SCHEMA INNODB_FT_INDEX_TABLE Table

The `INNODB_FT_INDEX_TABLE` table displays information about the inverted index used to process text searches against the `FULLTEXT` index of an `InnoDB` table.

For related usage information and examples, see [Section 15.14.4, “InnoDB INFORMATION_SCHEMA FULLTEXT Index Tables”](#).

Before you query this table, set the configuration variable `innodb_ft_aux_table` to the name (including the database name) of the table that contains the `FULLTEXT` index, for example `test/articles`.

Table 24.13 INNODB_FT_INDEX_TABLE Columns

Column name	Description
<code>WORD</code>	A word extracted from the text of the columns that are part of a <code>FULLTEXT</code> .
<code>FIRST_DOC_ID</code>	The first document ID that this word appears in the <code>FULLTEXT</code> index.
<code>LAST_DOC_ID</code>	The last document ID that this word appears in the <code>FULLTEXT</code> index.
<code>DOC_COUNT</code>	The number of rows this word appears in the <code>FULLTEXT</code> index. The same word can occur several times within the cache table, once for each combination of <code>DOC_ID</code> and <code>POSITION</code> values.
<code>DOC_ID</code>	The document ID of the row containing the word. This value might reflect the value of an ID column that you defined for the underlying table, or it can be a sequence value generated by <code>InnoDB</code> when the table does not contain a suitable column.
<code>POSITION</code>	The position of this particular instance of the word within the relevant document identified by the <code>DOC_ID</code> value.

Notes:

- This table initially appears empty, until you set the value of the configuration variable `innodb_ft_aux_table`. The following example demonstrates how to use the `innodb_ft_aux_table` option to show information about a `FULLTEXT` index for a specified table. Before information for newly inserted rows appears in `INNODB_FT_INDEX_TABLE`, the `FULLTEXT` index cache must be flushed to disk. This is accomplished by running an `OPTIMIZE TABLE` operation on the indexed table with `innodb_optimize_fulltext_only=ON`.

```
mysql> use test;

mysql> CREATE TABLE articles (
  id INT UNSIGNED AUTO_INCREMENT NOT NULL PRIMARY KEY,
  title VARCHAR(200),
  body TEXT,
  FULLTEXT (title,body)
) ENGINE=InnoDB;

mysql> INSERT INTO articles (title,body) VALUES
('MySQL Tutorial','DBMS stands for DataBase ...'),
('How To Use MySQL Well','After you went through a ...'),
('Optimizing MySQL','In this tutorial we will show ...'),
('1001 MySQL Tricks','1. Never run mysqld as root. 2. ...'),
('MySQL vs. YourSQL','In the following database comparison ...'),
('MySQL Security','When configured properly, MySQL ...');

mysql> SET GLOBAL innodb_optimize_fulltext_only=ON;
Query OK, 0 rows affected (0.00 sec)

mysql> OPTIMIZE TABLE articles;
+-----+-----+-----+-----+
| Table          | Op      | Msg_type | Msg_text |
+-----+-----+-----+-----+
| test.articles | optimize | status   | OK       |
+-----+-----+-----+-----+

mysql> SET GLOBAL innodb_ft_aux_table = 'test/articles';
Query OK, 0 rows affected (0.00 sec)

mysql> USE INFORMATION_SCHEMA;
```

```
mysql> SELECT word, doc_count, doc_id, position FROM INNODB_FT_INDEX_TABLE LIMIT 5;
```

word	doc_count	doc_id	position
1001	1	4	0
after	1	2	22
comparison	1	5	44
configured	1	6	20
database	2	1	31

- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.
- For more information about `InnoDB FULLTEXT` search, see [Section 15.8.2.4, “InnoDB FULLTEXT Indexes”](#), and [Section 12.9, “Full-Text Search Functions”](#).

24.31.14 The INFORMATION_SCHEMA INNODB_LOCKS Table

The `INNODB_LOCKS` table contains information about each lock that an `InnoDB` transaction has requested but not yet acquired, and each lock that a transaction holds that is blocking another transaction.

Note

This table is deprecated and is removed as of MySQL 8.0.1. Use the Performance Schema `data_locks` table instead. See [Section 25.11.12.1, “The data_locks Table”](#).

Differences between `INNODB_LOCKS` and `data_locks`:

- If a transaction holds a lock, `INNODB_LOCKS` displays the lock only if another transaction is waiting for it. `data_locks` displays the lock regardless of whether any transaction is waiting for it.
- The `data_locks` table has no columns corresponding to `LOCK_SPACE`, `LOCK_PAGE`, or `LOCK_REC`.
- The `INNODB_LOCKS` table requires the global `PROCESS` privilege. The `data_locks` table requires the usual Performance Schema privilege of `SELECT` on the table to be selected from.

The following table shows the mapping from `INNODB_LOCKS` columns to `data_locks` columns. Use this information to migrate applications from one table to the other.

Table 24.14 Mapping from INNODB_LOCKS to data_locks Columns

INNODB_LOCKS Column	data_locks Column
<code>LOCK_ID</code>	<code>ENGINE_LOCK_ID</code>
<code>LOCK_TRX_ID</code>	<code>ENGINE_TRANSACTION_ID</code>
<code>LOCK_MODE</code>	<code>LOCK_MODE</code>
<code>LOCK_TYPE</code>	<code>LOCK_TYPE</code>
<code>LOCK_TABLE</code> (combined schema/table names)	<code>OBJECT_SCHEMA</code> (schema name), <code>OBJECT_NAME</code> (table name)
<code>LOCK_INDEX</code>	<code>INDEX_NAME</code>
<code>LOCK_SPACE</code>	None
<code>LOCK_PAGE</code>	None

INNODB_LOCKS Column	data_locks Column
LOCK_REC	None
LOCK_DATA	LOCK_DATA

24.31.15 The INFORMATION_SCHEMA INNODB_LOCK_WAITS Table

The `INNODB_LOCK_WAITS` table contains one or more rows for each blocked `InnoDB` transaction, indicating the lock it has requested and any locks that are blocking that request.

Note

This table is deprecated and is removed as of MySQL 8.0.1. Use the Performance Schema `data_lock_waits` table instead. See [Section 25.11.12.2, “The data_lock_waits Table”](#).

The tables differ in the privileges required: The `INNODB_LOCK_WAITS` table requires the global `PROCESS` privilege. The `data_lock_waits` table requires the usual Performance Schema privilege of `SELECT` on the table to be selected from.

The following table shows the mapping from `INNODB_LOCK_WAITS` columns to `data_lock_waits` columns. Use this information to migrate applications from one table to the other.

Table 24.15 Mapping from INNODB_LOCK_WAITS to data_lock_waits Columns

INNODB_LOCK_WAITS Column	data_lock_waits Column
REQUESTING_TRX_ID	REQUESTING_ENGINE_TRANSACTION_ID
REQUESTED_LOCK_ID	REQUESTING_ENGINE_LOCK_ID
BLOCKING_TRX_ID	BLOCKING_ENGINE_TRANSACTION_ID
BLOCKING_LOCK_ID	BLOCKING_ENGINE_LOCK_ID

24.31.16 The INFORMATION_SCHEMA INNODB_METRICS Table

This `INFORMATION_SCHEMA` table presents a wide variety of `InnoDB` performance information, complementing the specific focus areas of the `PERFORMANCE_SCHEMA` tables for `InnoDB`. With simple queries, you can check the overall health of the system. With more detailed queries, you can diagnose issues such as performance bottlenecks, resource shortages, and application issues.

Each monitor represents a point within the `InnoDB` source code that is instrumented to gather counter information. Each counter can be started, stopped, and reset. You can also perform these actions for a group of counters using their common module name.

By default, relatively little data is collected. To start, stop, and reset counters, you set one of the configuration options `innodb_monitor_enable`, `innodb_monitor_disable`, `innodb_monitor_reset`, or `innodb_monitor_reset_all`, using the name of the counter, the name of the module, a wildcard match for such a name using the “%” character, or the special keyword `all`.

For usage information, see [Section 15.14.6, “InnoDB INFORMATION_SCHEMA Metrics Table”](#).

Table 24.16 INNODB_METRICS Columns

Column name	Description
NAME	Unique name for the counter.
SUBSYSTEM	The aspect of <code>InnoDB</code> that the metric applies to. See the list following the table for the corresponding module names to use with the <code>SET GLOBAL</code> syntax.

Column name	Description
COUNT	Value since the counter is enabled.
MAX_COUNT	Maximum value since the counter is enabled.
MIN_COUNT	Minimum value since the counter is enabled.
AVG_COUNT	Average value since the counter is enabled.
COUNT_RESET	Counter value since it was last reset. (The <code>_RESET</code> fields act like the lap counter on a stopwatch: you can measure the activity during some time interval, while the cumulative figures are still available in the <code>COUNT</code> , <code>MAX_COUNT</code> , and so on fields.)
MAX_COUNT_RESET	Maximum counter value since it was last reset.
MIN_COUNT_RESET	Minimum counter value since it was last reset.
AVG_COUNT_RESET	Average counter value since it was last reset.
TIME_ENABLED	Timestamp of last start.
TIME_DISABLED	Timestamp of last stop.
TIME_ELAPSED	Elapsed time in seconds since the counter started.
TIME_RESET	Timestamp of last stop.
STATUS	Whether the counter is still running (<code>enabled</code>) or stopped (<code>disabled</code>).
TYPE	Whether the item is a cumulative counter, or measures the current value of some resource.
COMMENT	Counter description.

Example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME="dml_inserts"\G
***** 1. row *****
      NAME: dml_inserts
     SUBSYSTEM: dml
        COUNT: 3
     MAX_COUNT: 3
     MIN_COUNT: NULL
     AVG_COUNT: 0.046153846153846156
     COUNT_RESET: 3
  MAX_COUNT_RESET: 3
  MIN_COUNT_RESET: NULL
  AVG_COUNT_RESET: NULL
    TIME_ENABLED: 2014-12-04 14:18:28
    TIME_DISABLED: NULL
    TIME_ELAPSED: 65
    TIME_RESET: NULL
      STATUS: enabled
        TYPE: status_counter
     COMMENT: Number of rows inserted
```

Notes:

- You must have the `PROCESS` privilege to query this table.
- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.

24.31.17 The INFORMATION_SCHEMA INNODB_SYS_COLUMNS Table

The `INNODB_SYS_COLUMNS` table provides metadata about InnoDB table columns.

For related usage information and examples, see [Section 15.14.3, “InnoDB INFORMATION_SCHEMA System Tables”](#).

Table 24.17 INNODB_SYS_COLUMNS Columns

Column name	Description
TABLE_ID	An identifier representing the table associated with the column; the same value from <code>INNODB_SYS_TABLES.TABLE_ID</code> .
NAME	The name of each column in each table. These names can be uppercase or lowercase depending on the <code>lower_case_table_names</code> setting. There are no special system-reserved names for columns.
POS	The ordinal position of the column within the table, starting from 0 and incrementing sequentially. When a column is dropped, the remaining columns are reordered so that the sequence has no gaps. The <code>POS</code> value for a virtual generated column encodes the column sequence number and ordinal position of the column. For more information, see the <code>POS</code> column description in Section 24.31.26, “The INFORMATION_SCHEMA INNODB_SYS_VIRTUAL Table” .
MTYPE	Stands for “main type”. A numeric identifier for the column type. 1 = <code>VARCHAR</code> , 2 = <code>CHAR</code> , 3 = <code>FIXBINARY</code> , 4 = <code>BINARY</code> , 5 = <code>BLOB</code> , 6 = <code>INT</code> , 7 = <code>SYS_CHILD</code> , 8 = <code>SYS</code> , 9 = <code>FLOAT</code> , 10 = <code>DOUBLE</code> , 11 = <code>DECIMAL</code> , 12 = <code>VARMYSQL</code> , 13 = <code>MYSQL</code> , 14 = <code>GEOMETRY</code> .
PRTYPE	The InnoDB “precise type”, a binary value with bits representing MySQL data type, character set code, and nullability.
LEN	The column length, for example 4 for <code>INT</code> and 8 for <code>BIGINT</code> . For character columns in multibyte character sets, this length value is the maximum length in bytes needed to represent a definition such as <code>VARCHAR(N)</code> ; that is, it might be $2*N$, $3*N$, and so on depending on the character encoding.

Example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_COLUMNS where TABLE_ID = 71\G
***** 1. row *****
TABLE_ID: 71
  NAME: col1
  POS: 0
  MTYPE: 6
  PRTYPE: 1027
  LEN: 4
***** 2. row *****
TABLE_ID: 71
  NAME: col2
  POS: 1
  MTYPE: 2
  PRTYPE: 524542
  LEN: 10
***** 3. row *****
TABLE_ID: 71
  NAME: col3
  POS: 2
  MTYPE: 1
  PRTYPE: 524303
  LEN: 10
```

Notes:

- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.

24.31.18 The INFORMATION_SCHEMA INNODB_SYS_DATAFILES Table

The `INNODB_SYS_DATAFILES` table provides data file path information for InnoDB file-per-table and general tablespaces.

For related usage information and examples, see [Section 15.14.3, “InnoDB INFORMATION_SCHEMA System Tables”](#).

Note

The `INFORMATION_SCHEMA.FILES` table provides data file path information and other metadata about all InnoDB tablespace types including file-per-table tablespaces, general tablespaces, the system tablespace, temporary tablespaces, and undo tablespaces (if present).

Table 24.18 INNODB_SYS_DATAFILES Columns

Column name	Description
<code>SPACE</code>	The tablespace Space ID.
<code>PATH</code>	The tablespace data file path (for example, <code>.\world\innodb\city.ibd</code>). If a file-per-table tablespace is created in a location outside the MySQL data directory using the <code>DATA DIRECTORY</code> clause of the <code>CREATE TABLE</code> statement, the tablespace <code>PATH</code> field shows the fully qualified directory path.

Example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_DATAFILES WHERE SPACE = 57\G
***** 1. row *****
SPACE: 57
PATH: ./test/t1.ibd
```

Notes:

- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.

24.31.19 The INFORMATION_SCHEMA INNODB_SYS_FIELDS Table

The `INNODB_SYS_FIELDS` table provides metadata about the key columns (fields) of InnoDB indexes.

For related usage information and examples, see [Section 15.14.3, “InnoDB INFORMATION_SCHEMA System Tables”](#).

Table 24.19 INNODB_SYS_FIELDS Columns

Column name	Description
<code>INDEX_ID</code>	An identifier for the index associated with this key field, using the same value as in <code>INNODB_SYS_INDEXES.INDEX_ID</code> .
<code>NAME</code>	The name of the original column from the table, using the same value as in <code>INNODB_SYS_COLUMNS.NAME</code> .
<code>POS</code>	The ordinal position of the key field within the index, starting from 0 and incrementing sequentially. When a column is dropped, the remaining columns are reordered so that the sequence has no gaps.

Example:

```
-----
```

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FIELDS WHERE INDEX_ID = 117\G
***** 1. row *****
INDEX_ID: 117
NAME: coll
POS: 0
```

Notes:

- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.

24.31.20 The INFORMATION_SCHEMA INNODB_SYS_FOREIGN Table

The `INNODB_SYS_FOREIGN` table provides metadata about InnoDB foreign keys.

For related usage information and examples, see [Section 15.14.3, “InnoDB INFORMATION_SCHEMA System Tables”](#).

Table 24.20 INNODB_SYS_FOREIGN Columns

Column name	Description
ID	The name (not a numeric value) of the foreign key index. Preceded by the database name, for example, <code>test/products_fk</code> .
FOR_NAME	The name of the child table in this foreign key relationship.
REF_NAME	The name of the parent table in this foreign key relationship.
N_COLS	The number of columns in the foreign key index.
TYPE	A collection of bit flags with information about the foreign key column, ORed together. 1 = <code>ON DELETE CASCADE</code> , 2 = <code>ON UPDATE SET NULL</code> , 4 = <code>ON UPDATE CASCADE</code> , 8 = <code>ON UPDATE SET NULL</code> , 16 = <code>ON DELETE NO ACTION</code> , 32 = <code>ON UPDATE NO ACTION</code> .

Example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN\G
***** 1. row *****
ID: test/fk1
FOR_NAME: test/child
REF_NAME: test/parent
N_COLS: 1
TYPE: 1
```

Notes:

- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.

24.31.21 The INFORMATION_SCHEMA INNODB_SYS_FOREIGN_COLS Table

The `INNODB_SYS_FOREIGN_COLS` table provides status information about the columns of InnoDB foreign keys.

For related usage information and examples, see [Section 15.14.3, “InnoDB INFORMATION_SCHEMA System Tables”](#).

Table 24.21 INNODB_SYS_FOREIGN_COLS Columns

Column name	Description
ID	The foreign key index associated with this index key field, using the same value as <code>INNODB_SYS_FOREIGN.ID</code> .
FOR_COL_NAME	The name of the associated column in the child table.
REF_COL_NAME	The name of the associated column in the parent table.
POS	The ordinal position of this key field within the foreign key index, starting from 0.

Example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_FOREIGN_COLS WHERE ID = 'test/fk1'\G
***** 1. row *****
      ID: test/fk1
FOR_COL_NAME: parent_id
REF_COL_NAME: id
      POS: 0
```

Notes:

- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.

24.31.22 The INFORMATION_SCHEMA INNODB_SYS_INDEXES Table

The `INNODB_SYS_INDEXES` table provides metadata about InnoDB indexes.

For related usage information and examples, see [Section 15.14.3, “InnoDB INFORMATION_SCHEMA System Tables”](#).

Table 24.22 INNODB_SYS_INDEXES Columns

Column name	Description
INDEX_ID	An identifier for each index that is unique across all the databases in an instance.
NAME	The name of the index. Most indexes created implicitly by InnoDB have consistent names but the index names are not necessarily unique. For example, <code>PRIMARY</code> for a primary key index, <code>GEN_CLUST_INDEX</code> for the index representing a primary key when one is not specified, and <code>ID_IND</code> , <code>FOR_IND</code> , and <code>REF_IND</code> for foreign key constraints.
TABLE_ID	An identifier representing the table associated with the index; the same value from <code>INNODB_SYS_TABLES.TABLE_ID</code> .
TYPE	A numeric identifier signifying the kind of index. 0 = Secondary Index, 1 = Clustered Index, 2 = Unique Index, 3 = Primary Index, 32 = Full-text Index, 64 = Spatial Index, 128 = A secondary index that includes a virtual generated column .
N_FIELDS	The number of columns in the index key. For the <code>GEN_CLUST_INDEX</code> indexes, this value is 0 because the index is created using an artificial value rather than a real table column.
PAGE_NO	The root page number of the index B-tree. For full-text indexes, the <code>PAGE_NO</code> field is unused and set to -1 (<code>FIL_NULL</code>) because the full-text index is laid out in several B-trees (auxiliary tables).

Column name	Description
SPACE	An identifier for the tablespace where the index resides. 0 means the InnoDB system tablespace . Any other number represents a table created in file-per-table mode with a separate <code>.ibd</code> file. This identifier stays the same after a <code>TRUNCATE TABLE</code> statement. Because all indexes for a table reside in the same tablespace as the table, this value is not necessarily unique.
MERGE_THRESHOLD	The merge threshold value for index pages. If the amount of data in an index page falls below the <code>MERGE_THRESHOLD</code> value when a row is deleted or when a row is shortened by an update operation, InnoDB attempts to merge the index page with the neighboring index page. The default threshold value is 50%. For more information, see Section 15.6.12, “Configuring the Merge Threshold for Index Pages” .

Example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_INDEXES WHERE TABLE_ID = 34\G
***** 1. row *****
      INDEX_ID: 39
        NAME: GEN_CLUST_INDEX
      TABLE_ID: 34
         TYPE: 1
    N_FIELDS: 0
      PAGE_NO: 3
        SPACE: 23
MERGE_THRESHOLD: 50
***** 2. row *****
      INDEX_ID: 40
        NAME: i1
      TABLE_ID: 34
         TYPE: 0
    N_FIELDS: 1
      PAGE_NO: 4
        SPACE: 23
MERGE_THRESHOLD: 50
```

Notes:

- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.

24.31.23 The INFORMATION_SCHEMA INNODB_SYS_TABLES Table

The `INNODB_SYS_TABLES` table provides metadata about [InnoDB](#) tables.

For related usage information and examples, see [Section 15.14.3, “InnoDB INFORMATION_SCHEMA System Tables”](#).

Table 24.23 INNODB_SYS_TABLES Columns

Column name	Description
TABLE_ID	An identifier for each InnoDB table that is unique across all databases in the instance.
NAME	The name of the table. Preceded by the database name where appropriate, for example <code>test/t1</code> . InnoDB system table names are in all uppercase. Names of databases and user tables are in the same case as they were originally defined, possibly influenced by the <code>lower_case_table_names</code> setting.

Column name	Description
FLAG	This value provides bit level information about table format and storage characteristics including row format, compressed page size (if applicable), and whether or not the DATA DIRECTORY clause was used with CREATE TABLE or ALTER TABLE .
N_COLS	The number of columns in the table. The number reported includes three hidden columns that are created by InnoDB (DB_ROW_ID , DB_TRX_ID , and DB_ROLL_PTR). The number reported also includes virtual generated columns , if present.
SPACE	An identifier for the tablespace where the table resides. 0 means the InnoDB system tablespace . Any other number represents either a file-per-table tablespace or a general tablespace. This identifier stays the same after a TRUNCATE TABLE statement. For file-per-table tablespaces, this identifier is unique for tables across all databases in the instance.
ROW_FORMAT	The table's row format (Compact, Redundant, Dynamic, or Compressed).
ZIP_PAGE_SIZE	The zip page size. Only applies to tables that use the Compressed row format.
SPACE_TYPE	The type of tablespace to which the table belongs. Possible values include System (for the InnoDB system tablespace), General (for InnoDB general tablespaces created using CREATE TABLESPACE , and Single (for InnoDB file-per-table tablespaces). Tables assigned to the system tablespace using the CREATE TABLE or ALTER TABLE TABLESPACE=innodb_system clause have a General SPACE_TYPE.

Example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE TABLE_ID = 214\G
***** 1. row *****
TABLE_ID: 214
NAME: test/t1
FLAG: 129
N_COLS: 4
SPACE: 233
ROW_FORMAT: Compact
ZIP_PAGE_SIZE: 0
SPACE_TYPE: General
```

Notes:

- Use [DESCRIBE](#) or [SHOW COLUMNS](#) to view additional information about the columns of this table including data types and default values.
- You must have the [PROCESS](#) privilege to query this table.

Interpreting the INNODB_SYS_TABLES.FLAG Column Value:

The [INNODB_SYS_TABLES.FLAG](#) column provides bit-level information about the table's format and storage characteristics. You can interpret the [FLAG](#) column value by adding together the applicable decimal numeric values that are provided in the following table.

Table 24.24 Bit Position Values for Interpreting INNODB_SYS_TABLES FLAG Column Data

Bit Position	Description	Decimal Numeric Value
0	This bit is set if the row format is not REDUNDANT . In other words, it is set if	<ul style="list-style-type: none"> • 0 - REDUNDANT • 1 - COMPACT, DYNAMIC or COMPRESSED

Bit Position	Description	Decimal Numeric Value
	the row format is <code>COMPACT</code> , <code>DYNAMIC</code> or <code>COMPRESSED</code> .	
1-4	These four bits contain a small number that represents the compressed page size of the table. The <code>INNODB_SYS_TABLES.ZIP_PAGE_SIZE</code> field also reports the compressed page size, if applicable.	<ul style="list-style-type: none"> • 0 - Not Compressed • 2 - 1024 Byte Compressed Page Size • 4 - 2048 Byte Compressed Page Size • 6 - 4096 Byte Compressed Page Size • 8 - 8192 Byte Compressed Page Size • 10 - 16384 Byte Compressed Page Size
5	This bit is set if the row format is <code>DYNAMIC</code> or <code>COMPRESSED</code> .	<ul style="list-style-type: none"> • 0 - <code>REDUNDANT</code> or <code>COMPACT</code> • 32 - <code>DYNAMIC</code> or <code>COMPRESSED</code>
6	This bit is set if the <code>DATA DIRECTORY</code> option is used with <code>CREATE TABLE</code> or <code>ALTER TABLE</code> . This bit is set for file-per-table tablespaces that are located in directories other than the default data directory (<code>datadir</code>).	<ul style="list-style-type: none"> • 0 - Not a remote file-per-table tablespace • 64 - A remote file-per-table tablespace
7	This bit is set if the table is assigned to a shared tablespace (either a general tablespace or a system tablespace) using the <code>CREATE TABLE</code> or <code>ALTER TABLE TABLESPACE=tablespace_name</code> option.	<ul style="list-style-type: none"> • 0 - Table is located in a default location depending on the value of the <code>innodb_file_per_table</code>. • 128 - The table is explicitly assigned to a shared tablespace.

In the following, table `t1` uses `ROW_FORMAT=DYNAMIC` and has a `FLAG` value of 33. Based on the information in the preceding table, we can see that bit position 0 would be set to 1, and bit position 5 would be set to 32 for a table with a `DYNAMIC` row format. These values add up to a `FLAG` value of 33.

```
mysql> use test;
Database changed

mysql> CREATE TABLE t1 (c1 int) ROW_FORMAT=DYNAMIC;
Query OK, 0 rows affected (0.02 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE 'test/t1'\G
***** 1. row *****
TABLE_ID: 89
NAME: test/t1
FLAG: 33
N_COLS: 4
SPACE: 75
ROW_FORMAT: Dynamic
ZIP_PAGE_SIZE: 0
1 row in set (0.00 sec)
```

24.31.24 The INFORMATION_SCHEMA INNODB_SYS_TABLESPACES Table

The `INNODB_SYS_TABLESPACES` table provides metadata about InnoDB file-per-table and general tablespaces.

For related usage information and examples, see [Section 15.14.3, “InnoDB INFORMATION_SCHEMA System Tables”](#).

**Note**

The `INFORMATION_SCHEMA.FILES` table provides metadata about all InnoDB tablespace types including file-per-table tablespaces, general tablespaces, the system tablespace, temporary tablespaces, and undo tablespaces (if present).

Table 24.25 INNODB_SYS_TABLESPACES Columns

Column name	Description
<code>SPACE</code>	Tablespace Space ID.
<code>NAME</code>	The database and table name (for example, <code>world_innodb\city</code>)
<code>FLAG</code>	This value provides bit level information about tablespace format and storage characteristics.
<code>ROW_FORMAT</code>	The tablespace row format (Compact or Redundant, Dynamic, or Compressed). The data in this field is interpreted from the tablespace flags information that resides in the <code>.ibd</code> file.
<code>PAGE_SIZE</code>	The tablespace page size. The data in this field is interpreted from the tablespace flags information that resides in the <code>.ibd</code> file.
<code>ZIP_PAGE_SIZE</code>	The tablespace zip page size. The data in this field is interpreted from the tablespace flags information that resides in the <code>.ibd</code> file.
<code>SPACE_TYPE</code>	The type of tablespace. Possible values include <code>General</code> (for InnoDB general tablespaces created using <code>CREATE TABLESPACE</code> and <code>Single</code> (for InnoDB file-per-table tablespaces).
<code>FS_BLOCK_SIZE</code>	The file system block size, which is the unit size used for hole punching. This column was added with the introduction of the InnoDB transparent page compression feature.
<code>FILE_SIZE</code>	The apparent size of the file, which represents the maximum size of the file, uncompressed. This column was added with the introduction of the InnoDB transparent page compression feature.
<code>ALLOCATED_SIZE</code>	The actual size of the file, which is the amount of space allocated on disk. This column was added with the introduction of the InnoDB transparent page compression feature.

Example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE SPACE = 26\G
***** 1. row *****
      SPACE: 26
      NAME: test/t1
      FLAG: 0
      ROW_FORMAT: Compact or Redundant
      PAGE_SIZE: 16384
      ZIP_PAGE_SIZE: 0
      SPACE_TYPE: Single
      FS_BLOCK_SIZE: 4096
      FILE_SIZE: 98304
      ALLOCATED_SIZE: 65536
```

Notes:

- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.
- There is no way to determine from this flag integer if the tablespace row format is Redundant or Compact. As a result, the possible values for the `ROW_FORMAT` field are “Compact or Redundant”, “Compressed”, or “Dynamic.”

Interpreting the INNODB_SYS_TABLESPACES.FLAG Column Value:

The `INNODB_SYS_TABLESPACES.FLAG` column provides bit-level information about tablespace format and storage characteristics.

You can interpret the tablespace `FLAG` column value by adding together the applicable decimal numeric values that are provided in the following table.

Table 24.26 Bit Position Values for Interpreting INNODB_SYS_TABLESPACES FLAG Column Data

Bit Position	Description	Decimal Numeric Value
0	This bit is set if the row format of tables in the tablespace is <code>DYNAMIC</code> or <code>COMPRESSED</code> . If the bit is not set, the row format of tables in the tablespace may be either <code>REDUNDANT</code> or <code>COMPACT</code> . If it is a file-per-table tablespace, you can query <code>INNODB_SYS_TABLES</code> to determine if the row format is <code>REDUNDANT</code> or <code>COMPACT</code> .	<ul style="list-style-type: none"> 0 - <code>REDUNDANT</code> or <code>COMPACT</code> 1 - <code>DYNAMIC</code> or <code>COMPRESSED</code>
1-4	These four bits contain a small number that represents the compressed page size (the <code>KEY_BLOCK_SIZE</code> or “physical block size”) of the tablespace.	<ul style="list-style-type: none"> 0 - Not Compressed 2 - 1024 Byte Compressed Page Size 4 - 2048 Byte Compressed Page Size 6 - 4096 Byte Compressed Page Size 8 - 8192 Byte Compressed Page Size 10 - 16384 Byte Compressed Page Size 12 - 32768 Byte Compressed Page Size 14 - 65536 Byte Compressed Page Size
5	This bit is set for file-per-table tablespaces if the row format of the table is <code>DYNAMIC</code> or <code>COMPRESSED</code> . General tablespaces that do not contain compressed tables will have the first 6 bits set to zero, including this bit, making it appear that the tablespace holds <code>REDUNDANT</code> or <code>COMPACT</code> tables. But actually, general tablespaces may contain any combination of <code>REDUNDANT</code> , <code>COMPACT</code> and <code>DYNAMIC</code> tables. For more information about general tablespaces, see <code>CREATE TABLESPACE</code> .	<ul style="list-style-type: none"> 0 - <code>REDUNDANT</code> or <code>COMPACT</code> 32 - <code>DYNAMIC</code> or <code>COMPRESSED</code>
6-9	These four bits contain a small number that represents the uncompressed page size (logical page size) of the tablespace. The setting is zero if the logical page size is the original InnoDB default page size of 16K.	<ul style="list-style-type: none"> 192 - 4096 Byte Logical/ Uncompressed Page Size 256 - 8192 Byte Logical/ Uncompressed Page Size 0 - 16384 Byte Logical/ Uncompressed Page size

Bit Position	Description	Decimal Numeric Value
		<ul style="list-style-type: none"> • 384 - 32768 Byte Logical/Uncompressed Page Size • 448 - 65536 Byte Logical/Uncompressed Page Size
10	This bit is set if the <code>DATA DIRECTORY</code> option is used with <code>CREATE TABLE</code> or <code>ALTER TABLE</code> . This bit is set for file-per-table tablespaces that are located in directories other than the default data directory (<code>datadir</code>).	<ul style="list-style-type: none"> • 0 - Not a remote file-per-table tablespace • 1024 - A remote file-per-table tablespace
11	This bit is set if the tablespace is a shared general tablespace created using <code>CREATE TABLESPACE</code> .	<ul style="list-style-type: none"> • 0 - Table is located in a default location depending on the value of the <code>innodb_file_per_table</code> setting. • 2048 - The table was explicitly assigned to a shared tablespace.
12	This bit is set if the tablespace is dedicated to temporary tables. Only the predefined <code>ibtmp1</code> tablespace uses this flag.	<ul style="list-style-type: none"> • 0 - The tablespace does not contain temporary tables, so it is not recreated upon startup. • 4096 - The tablespace contains temporary tables and is recreated on startup.

In the following example, table `t1` is created with `innodb_file_per_table=ON`, which creates table `t1` in its own tablespace. When querying `INNODB_SYS_TABLESPACES`, we see that the tablespace has a `FLAG` value of 33. To determine how this value is arrived at, review the bit values described in the preceding table. Bit 0 has a value of 1 because table `t1` uses the `DYNAMIC` row format. Bit 5 has a value of 32 because the tablespace is a file-per-table tablespace that uses a `DYNAMIC` row format. Bit position 6-9 is 0 because `innodb_page_size` is set to the default 16K value. The other bit values are not applicable and are therefore set to 0. The values for bit position 0 and bit position 5 add up to a `FLAG` value of 33.

```
mysql> use test;
Database changed

mysql> SHOW VARIABLES LIKE 'innodb_file_per_table';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| innodb_file_per_table | ON |
+-----+-----+

mysql> SHOW VARIABLES LIKE 'innodb_page_size';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| innodb_page_size | 16384 |
+-----+-----+

mysql> CREATE TABLE t1 (c1 int) ROW_FORMAT=DYNAMIC;
Query OK, 0 rows affected (0.02 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESPACES WHERE NAME LIKE 'test/t1'\G
***** 1. row *****
SPACE: 75
```

```

NAME: test/t1
FLAG: 33
ROW_FORMAT: Dynamic
PAGE_SIZE: 16384
ZIP_PAGE_SIZE: 0
1 row in set (0.00 sec)

```

24.31.25 The INFORMATION_SCHEMA INNODB_SYS_TABLESTATS View

The `INNODB_SYS_TABLESTATS` provides a view of low-level status information about `InnoDB` tables. This data is used by the MySQL optimizer to calculate which index to use when querying an `InnoDB` table. This information is derived from in-memory data structures rather than corresponding to data stored on disk. There is no corresponding internal `InnoDB` system table.

`InnoDB` tables are represented in this view if they have been opened since the last server restart, and not aged out of the table cache. Tables for which persistent stats are available are always represented in this view.

Table statistics are only updated for `DELETE` or `UPDATE` operations that modify indexed columns. Statistics are not updated by operations that only modify non-indexed columns.

For related usage information and examples, see [Section 15.14.3, “InnoDB INFORMATION_SCHEMA System Tables”](#).

Table 24.27 INNODB_SYS_TABLESTATS Columns

Column name	Description
<code>TABLE_ID</code>	An identifier representing the table for which statistics are available, using the same value as <code>INNODB_SYS_TABLES.TABLE_ID</code> .
<code>NAME</code>	The name of the table, using the same value as <code>INNODB_SYS_TABLES.NAME</code> .
<code>STATS_INITIALIZED</code>	The value is <code>Initialized</code> if the statistics are already collected, <code>Uninitialized</code> if not.
<code>NUM_ROWS</code>	The current estimated number of rows in the table. Updated after each DML operation. Could be imprecise if uncommitted transactions are inserting into or deleting from the table.
<code>CLUST_INDEX_SIZE</code>	Number of pages on disk that store the clustered index, which holds the <code>InnoDB</code> table data in primary key order. This value might be null if no statistics are collected yet for the table.
<code>OTHER_INDEX_SIZE</code>	Number of pages on disk that store all secondary indexes for the table. This value might be null if no statistics are collected yet for the table.
<code>MODIFIED_COUNTER</code>	The number of rows modified by DML operations, such as <code>INSERT</code> , <code>UPDATE</code> , <code>DELETE</code> , and also cascade operations from foreign keys. This column is reset each time table statistics are recalculated.
<code>AUTOINC</code>	The next number to be issued for any auto-increment-based operation. The rate at which the <code>AUTOINC</code> value changes depends on how many times auto-increment numbers have been requested and how many numbers are granted per request.
<code>REF_COUNT</code>	When this counter reaches zero, the table metadata can be evicted from the table cache.

Example:

```

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_TABLESTATS where TABLE_ID = 71\G
***** 1. row *****
      TABLE_ID: 71
          NAME: test/t1
STATS_INITIALIZED: Initialized

```

```

NUM_ROWS: 1
CLUST_INDEX_SIZE: 1
OTHER_INDEX_SIZE: 0
MODIFIED_COUNTER: 1
  AUTOINC: 0
REF_COUNT: 1

```

Notes:

- This table is primarily useful for expert-level performance monitoring, or when developing performance-related extensions for MySQL.
- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.

24.31.26 The INFORMATION_SCHEMA INNODB_SYS_VIRTUAL Table

The `INNODB_SYS_VIRTUAL` table provides metadata about [InnoDB virtual generated columns](#) and columns upon which virtual generated columns are based.

A row appears in the `INNODB_SYS_VIRTUAL` table for each column upon which a virtual generated column is based.

Table 24.28 INNODB_SYS_VIRTUAL Columns

Column name	Description
<code>TABLE_ID</code>	An identifier representing the table associated with the virtual column; the same value as <code>INNODB_SYS_TABLES.TABLE_ID</code> .
<code>POS</code>	The position value of the virtual generated column . The value is large because it encodes the column sequence number and ordinal position. The formula used to calculate the value uses a bitwise operation. The formula is <code>((nth virtual generated column for the InnoDB instance + 1) << 16) + the ordinal position of the virtual generated column</code> . For example, if the first virtual generated column in the <code>InnoDB</code> instance is the third column of the table, the formula is <code>(0 + 1) << 16) + 2</code> . The first virtual generated column in the <code>InnoDB</code> instance is always number 0. As the third column in the table, the ordinal position of the virtual generated column is 2. Ordinal positions are counted from 0.
<code>BASE_POS</code>	The ordinal position of the columns upon which a virtual generated column is based.

Example:

```

mysql> CREATE TABLE `t1` (
  `a` int(11) DEFAULT NULL,
  `b` int(11) DEFAULT NULL,
  `c` int(11) GENERATED ALWAYS AS (a+b) VIRTUAL,
  `h` varchar(10) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_SYS_VIRTUAL
  WHERE TABLE_ID IN (SELECT TABLE_ID FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES WHERE NAME LIKE "test/t
+-----+-----+-----+
| TABLE_ID | POS  | BASE_POS |
+-----+-----+-----+
|          98 | 65538 |          0 |
|          98 | 65538 |          1 |
+-----+-----+-----+

```

Notes:

- If a constant value is assigned to a [virtual generated column](#), as in the following example, an entry for the column does not appear in the `INNODB_SYS_VIRTUAL` table. For an entry to appear, a virtual generated column must have a base column.

```
mysql> CREATE TABLE `t1` (
  `a` int(11) DEFAULT NULL,
  `b` int(11) DEFAULT NULL,
  `c` int(11) GENERATED ALWAYS AS (5) VIRTUAL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;
```

However, metadata for such a column appears in the `INNODB_SYS_COLUMNS` table.

- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.

24.31.27 The INFORMATION_SCHEMA INNODB_TEMP_TABLE_INFO Table

`INNODB_TEMP_TABLE_INFO` contains metadata about active `InnoDB` temporary tables. With the exception of optimized internal temporary tables used by `InnoDB`, `INNODB_TEMP_TABLE_INFO` reports on all user and system-created temporary tables that are active within a given `InnoDB` instance. The table is maintained in memory and not persisted to disk.

For usage information and examples, see [Section 15.14.7, “InnoDB INFORMATION_SCHEMA Temporary Table Information Table”](#).

Table 24.29 INNODB_TEMP_TABLE_INFO Columns

Column name	Description
<code>TABLE_ID</code>	The table ID of the active temporary table.
<code>NAME</code>	The name of the active temporary table.
<code>N_COLS</code>	The number of columns in the temporary table. The number always includes three hidden columns created by <code>InnoDB</code> (<code>DB_ROW_ID</code> , <code>DB_TRX_ID</code> , and <code>DB_ROLL_PTR</code>).
<code>SPACE</code>	The tablespace identifier (a numerical value) for the tablespace in which the temporary table resides. All <code>InnoDB</code> temporary tables reside in a shared temporary tablespace, as defined by <code>innodb_temp_data_file_path</code> . By default the shared temporary tablespace is named <code>ibtmp1</code> and located in the <code>data</code> directory. Compressed temporary tables reside in separate per-table tablespaces located in the temporary file directory, as defined by <code>tmpdir</code> . The <code>SPACE</code> ID is always a non-zero value and is dynamically generated on server restart.

Example:

```
mysql> CREATE TEMPORARY TABLE t1 (c1 INT PRIMARY KEY) ENGINE=INNODB;
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO\G
***** 1. row *****
TABLE_ID: 97
  NAME: #sql8c88_43_0
 N_COLS: 4
  SPACE: 76
1 row in set (0.00 sec)
```

Notes:

- This table is primarily useful for expert level monitoring.

- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.

24.31.28 The INFORMATION_SCHEMA INNODB_TRX Table

The `INNODB_TRX` table contains information about every transaction (excluding read-only transactions) currently executing inside `InnoDB`, including whether the transaction is waiting for a lock, when the transaction started, and the SQL statement the transaction is executing, if any.

Table 24.30 INNODB_TRX Columns

Column name	Description
<code>TRX_ID</code>	Unique transaction ID number, internal to <code>InnoDB</code> . These IDs are not created for transactions that are read only and nonlocking. See Section 8.5.3, “Optimizing InnoDB Read-Only Transactions” for details.
<code>TRX_WEIGHT</code>	The weight of a transaction, reflecting (but not necessarily the exact count of) the number of rows altered and the number of rows locked by the transaction. To resolve a deadlock, <code>InnoDB</code> selects the transaction with the smallest weight as the “victim” to roll back. Transactions that have changed non-transactional tables are considered heavier than others, regardless of the number of altered and locked rows.
<code>TRX_STATE</code>	Transaction execution state. Permitted values are <code>RUNNING</code> , <code>LOCK WAIT</code> , <code>ROLLING BACK</code> , and <code>COMMITTING</code> .
<code>TRX_STARTED</code>	Transaction start time.
<code>TRX_REQUESTED_LOCK_ID</code>	ID of the lock the transaction is currently waiting for, if <code>TRX_STATE</code> is <code>LOCK WAIT</code> ; otherwise <code>NULL</code> . To obtain details about the lock, join this column with the <code>ENGINE_LOCK_ID</code> column of the Performance Schema <code>data_locks</code> table.
<code>TRX_WAIT_STARTED</code>	Time when the transaction started waiting on the lock, if <code>TRX_STATE</code> is <code>LOCK WAIT</code> ; otherwise <code>NULL</code> .
<code>TRX_MYSQL_THREAD_ID</code>	MySQL thread ID. To obtain details about the thread, join this column with the <code>ID</code> column of the <code>PROCESSLIST</code> table, but see Section 15.14.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information” .
<code>TRX_QUERY</code>	The SQL statement that is being executed by the transaction.
<code>TRX_OPERATION_STATE</code>	The transaction’s current operation, if any; otherwise <code>NULL</code> .
<code>TRX_TABLES_IN_USE</code>	The number of <code>InnoDB</code> tables used while processing the current SQL statement of this transaction.
<code>TRX_TABLES_LOCKED</code>	Number of <code>InnoDB</code> tables that the current SQL statement has row locks on. (Because these are row locks, not table locks, the tables can usually still be read from and written to by multiple transactions, despite some rows being locked.)
<code>TRX_LOCK_STRUCTS</code>	The number of locks reserved by the transaction.
<code>TRX_LOCK_MEMORY_BYTES</code>	Total size taken up by the lock structures of this transaction in memory.
<code>TRX_ROWS_LOCKED</code>	Approximate number of rows locked by this transaction. The value might include delete-marked rows that are physically present but not visible to the transaction.
<code>TRX_ROWS_MODIFIED</code>	The number of modified and inserted rows in this transaction.

Column name	Description
TRX_CONCURRENCY_TICKETS	A value indicating how much work the current transaction can do before being swapped out, as specified by the innodb_concurrency_tickets system variable.
TRX_ISOLATION_LEVEL	The isolation level of the current transaction.
TRX_UNIQUE_CHECKS	Whether unique checks are turned on or off for the current transaction. For example, they might be turned off during a bulk data load.
TRX_FOREIGN_KEY_CHECKS	Whether foreign key checks are turned on or off for the current transaction. For example, they might be turned off during a bulk data load.
TRX_LAST_FOREIGN_KEY_ERROR	Detailed error message for the last foreign key error, if any; otherwise NULL .
TRX_ADAPTIVE_HASH_LATCHED	Whether the adaptive hash index is locked by the current transaction. When the adaptive hash index search system is partitioned, a single transaction does not lock the entire adaptive hash index. Adaptive hash index partitioning is controlled by innodb_adaptive_hash_index_parts , which is set to 8 by default.
TRX_ADAPTIVE_HASH_TIMEOUT	Whether to relinquish the search latch immediately for the adaptive hash index, or reserve it across calls from MySQL. When there is no adaptive hash index contention, this value remains zero and statements reserve the latch until they finish. During times of contention, it counts down to zero, and statements release the latch immediately after each row lookup. When the adaptive hash index search system is partitioned (controlled by innodb_adaptive_hash_index_parts), the value remains 0.
TRX_IS_READ_ONLY	A value of 1 indicates the transaction is read only.
TRX_AUTOCOMMIT_NON_LOCKING	A value of 1 indicates the transaction is a SELECT statement that does not use the FOR UPDATE or LOCK IN SHARED MODE clauses, and is executing with autocommit enabled so that the transaction will only contain this one statement. When this column and TRX_IS_READ_ONLY are both 1, InnoDB optimizes the transaction to reduce the overhead associated with transactions that change table data.

Example:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.INNODB_TRX\G
***** 1. row *****
      trx_id: 1510
      trx_state: RUNNING
      trx_started: 2014-11-19 13:24:40
      trx_requested_lock_id: NULL
      trx_wait_started: NULL
      trx_weight: 586739
      trx_mysql_thread_id: 2
      trx_query: DELETE FROM employees.salaries WHERE salary > 65000
      trx_operation_state: updating or deleting
      trx_tables_in_use: 1
      trx_tables_locked: 1
      trx_lock_structs: 3003
      trx_lock_memory_bytes: 450768
      trx_rows_locked: 1407513
      trx_rows_modified: 583736
      trx_concurrency_tickets: 0
      trx_isolation_level: REPEATABLE READ
      trx_unique_checks: 1
```

```

trx_foreign_key_checks: 1
trx_last_foreign_key_error: NULL
trx_adaptive_hash_latched: 0
trx_adaptive_hash_timeout: 10000
  trx_is_read_only: 0
trx_autocommit_non_locking: 0

```

Notes:

- Use this table to help diagnose performance problems that occur during times of heavy concurrent load. Its contents are updated as described in [Section 15.14.2.3, “Persistence and Consistency of InnoDB Transaction and Locking Information”](#).
- Use `DESCRIBE` or `SHOW COLUMNS` to view additional information about the columns of this table including data types and default values.
- You must have the `PROCESS` privilege to query this table.
- For usage information, see [Section 15.14.2.1, “Using InnoDB Transaction and Locking Information”](#).

24.32 Connection-Control INFORMATION_SCHEMA Tables

The following sections describe the `INFORMATION_SCHEMA` tables associated with the `CONNECTION_CONTROL` plugin.

24.32.1 The INFORMATION_SCHEMA

CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS Table

This table provides information about the current number of consecutive failed connection attempts per client user/host combination.

`CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` has these columns:

- `USERHOST`

The user/host combination of a client that has failed connection attempts, in `'user_name'@'host_name'` format.

- `FAILED_ATTEMPTS`

The current number of consecutive failed connection attempts for the `USERHOST` value. This counts all failed attempts, regardless of whether they were delayed. The number of attempts for which the server added a delay to its response is the difference between the `FAILED_ATTEMPTS` value and the `connection_control_failed_connections_threshold` system variable value.

Notes:

- The `CONNECTION_CONTROL_FAILED_LOGIN_ATTEMPTS` plugin must be activated for this table to be available, and the `CONNECTION_CONTROL` plugin must be activated or the table contents will always be empty. See [Section 6.5.2, “The Connection-Control Plugins”](#).
- The table contains rows only for clients that have had one or more consecutive failed connection attempts without a subsequent successful attempt. When a client connects successfully, its failed-connection count is reset to zero and the server removes any row corresponding to the client.
- Assigning a value to the `connection_control_failed_connections_threshold` system variable at runtime resets all accumulated failed-connection counters to zero, which causes the table to become empty.

24.33 Extensions to SHOW Statements

Some extensions to `SHOW` statements accompany the implementation of `INFORMATION_SCHEMA`:

- `SHOW` can be used to get information about the structure of `INFORMATION_SCHEMA` itself.
- Several `SHOW` statements accept a `WHERE` clause that provides more flexibility in specifying which rows to display.

`INFORMATION_SCHEMA` is an information database, so its name is included in the output from `SHOW DATABASES`. Similarly, `SHOW TABLES` can be used with `INFORMATION_SCHEMA` to obtain a list of its tables:

```
mysql> SHOW TABLES FROM INFORMATION_SCHEMA;
+-----+
| Tables_in_INFORMATION_SCHEMA |
+-----+
| CHARACTER_SETS              |
| COLLATIONS                   |
| COLLATION_CHARACTER_SET_APPLICABILITY |
| COLUMNS                     |
| COLUMN_PRIVILEGES           |
| ENGINES                      |
| EVENTS                       |
| FILES                        |
| KEY_COLUMN_USAGE            |
| PARTITIONS                   |
| PLUGINS                      |
| PROCESSLIST                  |
| REFERENTIAL_CONSTRAINTS     |
| ROUTINES                     |
| SCHEMATA                     |
| SCHEMA_PRIVILEGES           |
| STATISTICS                   |
| TABLES                      |
| TABLE_CONSTRAINTS          |
| TABLE_PRIVILEGES           |
| TRIGGERS                     |
| USER_PRIVILEGES             |
| VIEWS                        |
+-----+
```

`SHOW COLUMNS` and `DESCRIBE` can display information about the columns in individual `INFORMATION_SCHEMA` tables.

`SHOW` statements that accept a `LIKE` clause to limit the rows displayed also permit a `WHERE` clause that specifies more general conditions that selected rows must satisfy:

```
SHOW CHARACTER SET
SHOW COLLATION
SHOW COLUMNS
SHOW DATABASES
SHOW FUNCTION STATUS
SHOW INDEX
SHOW OPEN TABLES
SHOW PROCEDURE STATUS
SHOW STATUS
SHOW TABLE STATUS
SHOW TABLES
SHOW TRIGGERS
SHOW VARIABLES
```

The `WHERE` clause, if present, is evaluated against the column names displayed by the `SHOW` statement. For example, the `SHOW CHARACTER SET` statement produces these output columns:

```
mysql> SHOW CHARACTER SET;
+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
| Charset | Collation | Cardinality | Maxlen | Bin | Comment |
```

Charset	Description	Default collation	Maxlen
big5	Big5 Traditional Chinese	big5_chinese_ci	2
dec8	DEC West European	dec8_swedish_ci	1
cp850	DOS West European	cp850_general_ci	1
hp8	HP West European	hp8_english_ci	1
koi8r	KOI8-R Relcom Russian	koi8r_general_ci	1
latin1	cp1252 West European	latin1_swedish_ci	1
latin2	ISO 8859-2 Central European	latin2_general_ci	1
...			

To use a `WHERE` clause with `SHOW CHARACTER SET`, you would refer to those column names. As an example, the following statement displays information about character sets for which the default collation contains the string `'japanese'`:

```
mysql> SHOW CHARACTER SET WHERE `Default collation` LIKE '%japanese%';
```

Charset	Description	Default collation	Maxlen
ujis	EUC-JP Japanese	ujis_japanese_ci	3
sjis	Shift-JIS Japanese	sjis_japanese_ci	2
cp932	SJIS for Windows Japanese	cp932_japanese_ci	2
eucjpms	UJIS for Windows Japanese	eucjpms_japanese_ci	3

This statement displays the multibyte character sets:

```
mysql> SHOW CHARACTER SET WHERE Maxlen > 1;
```

Charset	Description	Default collation	Maxlen
big5	Big5 Traditional Chinese	big5_chinese_ci	2
ujis	EUC-JP Japanese	ujis_japanese_ci	3
sjis	Shift-JIS Japanese	sjis_japanese_ci	2
euckr	EUC-KR Korean	euckr_korean_ci	2
gb2312	GB2312 Simplified Chinese	gb2312_chinese_ci	2
gbk	GBK Simplified Chinese	gbk_chinese_ci	2
utf8	UTF-8 Unicode	utf8_general_ci	3
ucs2	UCS-2 Unicode	ucs2_general_ci	2
cp932	SJIS for Windows Japanese	cp932_japanese_ci	2
eucjpms	UJIS for Windows Japanese	eucjpms_japanese_ci	3

Chapter 25 MySQL Performance Schema

Table of Contents

25.17 Performance Schema and Plugins	3090
25.18 Using the Performance Schema to Diagnose Problems	3090
25.18.1 Query Profiling Using Performance Schema	3091

The MySQL Performance Schema is a feature for monitoring MySQL Server execution at a low level. The Performance Schema has these characteristics:

- The Performance Schema provides a way to inspect internal execution of the server at runtime. It is implemented using the `PERFORMANCE_SCHEMA` storage engine and the `performance_schema`

database. The Performance Schema focuses primarily on performance data. This differs from [INFORMATION_SCHEMA](#), which serves for inspection of metadata.

- The Performance Schema monitors server events. An “event” is anything the server does that takes time and has been instrumented so that timing information can be collected. In general, an event could be a function call, a wait for the operating system, a stage of an SQL statement execution such as parsing or sorting, or an entire statement or group of statements. Event collection provides access to information about synchronization calls (such as for mutexes) file and table I/O, table locks, and so forth for the server and for several storage engines.
- Performance Schema events are distinct from events written to the server's binary log (which describe data modifications) and Event Scheduler events (which are a type of stored program).
- Performance Schema events are specific to a given instance of the MySQL Server. Performance Schema tables are considered local to the server, and changes to them are not replicated or written to the binary log.
- Current events are available, as well as event histories and summaries. This enables you to determine how many times instrumented activities were performed and how much time they took. Event information is available to show the activities of specific threads, or activity associated with particular objects such as a mutex or file.
- The [PERFORMANCE_SCHEMA](#) storage engine collects event data using “instrumentation points” in server source code.
- Collected events are stored in tables in the [performance_schema](#) database. These tables can be queried using [SELECT](#) statements like other tables.
- Performance Schema configuration can be modified dynamically by updating tables in the [performance_schema](#) database through SQL statements. Configuration changes affect data collection immediately.
- Tables in the Performance Schema are in-memory tables that use no persistent on-disk storage. The contents are repopulated beginning at server startup and discarded at server shutdown.
- Monitoring is available on all platforms supported by MySQL.

Some limitations might apply: The types of timers might vary per platform. Instruments that apply to storage engines might not be implemented for all storage engines. Instrumentation of each third-party engine is the responsibility of the engine maintainer. See also [Section C.8, “Restrictions on Performance Schema”](#).

- Data collection is implemented by modifying the server source code to add instrumentation. There are no separate threads associated with the Performance Schema, unlike other features such as replication or the Event Scheduler.

The Performance Schema is intended to provide access to useful information about server execution while having minimal impact on server performance. The implementation follows these design goals:

- Activating the Performance Schema causes no changes in server behavior. For example, it does not cause thread scheduling to change, and it does not cause query execution plans (as shown by [EXPLAIN](#)) to change.
- Server monitoring occurs continuously and unobtrusively with very little overhead. Activating the Performance Schema does not make the server unusable.
- The parser is unchanged. There are no new keywords or statements.
- Execution of server code proceeds normally even if the Performance Schema fails internally.
- When there is a choice between performing processing during event collection initially or during event retrieval later, priority is given to making collection faster. This is because collection is ongoing whereas retrieval is on demand and might never happen at all.

- Most Performance Schema tables have indexes, which gives the optimizer access to execution plans other than full table scans. For more information, see [Section 8.2.4, “Optimizing Performance Schema Queries”](#).
- It is easy to add new instrumentation points.
- Instrumentation is versioned. If the instrumentation implementation changes, previously instrumented code will continue to work. This benefits developers of third-party plugins because it is not necessary to upgrade each plugin to stay synchronized with the latest Performance Schema changes.

Note

The MySQL `sys` schema is a set of objects that provides convenient access to data collected by the Performance Schema. The `sys` schema is installed by default. For usage instructions, see [Chapter 26, MySQL `sys` Schema](#).

25.1 Performance Schema Quick Start

This section briefly introduces the Performance Schema with examples that show how to use it. For additional examples, see [Section 25.18, “Using the Performance Schema to Diagnose Problems”](#).

The Performance Schema is enabled by default. To enable or disable it explicitly, start the server with the `performance_schema` variable set to an appropriate value. For example, use these lines in your `my.cnf` file:

```
[mysqld]
performance_schema=ON
```

When the server starts, it sees `performance_schema` and attempts to initialize the Performance Schema. To verify successful initialization, use this statement:

```
mysql> SHOW VARIABLES LIKE 'performance_schema';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| performance_schema | ON    |
+-----+-----+
```

A value of `ON` means that the Performance Schema initialized successfully and is ready for use. A value of `OFF` means that some error occurred. Check the server error log for information about what went wrong.

The Performance Schema is implemented as a storage engine, so you will see it listed in the output from the `INFORMATION_SCHEMA.ENGINES` table or the `SHOW ENGINES` statement:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.ENGINES
      WHERE ENGINE='PERFORMANCE_SCHEMA'\G
***** 1. row *****
ENGINE: PERFORMANCE_SCHEMA
SUPPORT: YES
COMMENT: Performance Schema
TRANSACTIONS: NO
      XA: NO
      SAVEPOINTS: NO

mysql> SHOW ENGINES\G
...
Engine: PERFORMANCE_SCHEMA
Support: YES
Comment: Performance Schema
Transactions: NO
      XA: NO
      Savepoints: NO
```

...

The `PERFORMANCE_SCHEMA` storage engine operates on tables in the `performance_schema` database. You can make `performance_schema` the default database so that references to its tables need not be qualified with the database name:

```
mysql> USE performance_schema;
```

Many examples in this chapter assume `performance_schema` as the default database.

Performance Schema tables are stored in the `performance_schema` database. Information about the structure of this database and its tables can be obtained, as for any other database, by selecting from the `INFORMATION_SCHEMA` database or by using `SHOW` statements. For example, use either of these statements to see what Performance Schema tables exist:

```
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
       WHERE TABLE_SCHEMA = 'performance_schema';
```

```
+-----+
| TABLE_NAME
+-----+
| accounts
| cond_instances
...
| events_stages_current
| events_stages_history
| events_stages_history_long

| events_stages_current
| events_stages_history
| events_stages_history_long
| ...

```

The number of Performance Schema tables increases over time as implementation of additional instrumentation proceeds.

The name of the `performance_schema` database is lowercase, as are the names of tables within it. Queries should specify the names in lowercase.

To see the structure of individual tables, use `SHOW CREATE TABLE`:

```

mysql> SHOW CREATE TABLE setup_timers\G
***** 1. row *****
      Table: setup_timers
Create Table: CREATE TABLE `setup_timers` (
  `NAME` varchar(64) NOT NULL,
  `TIMER_NAME` enum('CYCLE','NANOSECOND','MICROSECOND','MILLISECOND','TICK')
  NOT NULL
) ENGINE=PERFORMANCE_SCHEMA DEFAULT CHARSET=utf8

```

Table structure is also available by selecting from tables such as `INFORMATION_SCHEMA.COLUMNS` or by using statements such as `SHOW COLUMNS`.

Tables in the `performance_schema` database can be grouped according to the type of information in them: Current events, event histories and summaries, object instances, and setup (configuration) information. The following examples illustrate a few uses for these tables. For detailed information about the tables in each group, see [Section 25.11, “Performance Schema Table Descriptions”](#).

Initially, not all instruments and consumers are enabled, so the performance schema does not collect all events. To turn all of these on and enable event timing, execute two statements (the row counts may differ depending on MySQL version):

```

mysql> UPDATE setup_instruments SET ENABLED = 'YES', TIMED = 'YES';
Query OK, 560 rows affected (0.04 sec)
mysql> UPDATE setup_consumers SET ENABLED = 'YES';
Query OK, 10 rows affected (0.00 sec)

```

To see what the server is doing at the moment, examine the `events_waits_current` table. It contains one row per thread showing each thread's most recent monitored event:

```

mysql> SELECT * FROM events_waits_current\G
***** 1. row *****
      THREAD_ID: 0
      EVENT_ID: 5523
      END_EVENT_ID: 5523
      EVENT_NAME: wait/synch/mutex/mysys/THR_LOCK::mutex
      SOURCE: thr_lock.c:525
      TIMER_START: 201660494489586
      TIMER_END: 201660494576112
      TIMER_WAIT: 86526
      SPINS: NULL

```

```

OBJECT_SCHEMA: NULL
OBJECT_NAME: NULL
INDEX_NAME: NULL
OBJECT_TYPE: NULL
OBJECT_INSTANCE_BEGIN: 142270668
NESTING_EVENT_ID: NULL
NESTING_EVENT_TYPE: NULL
OPERATION: lock
NUMBER_OF_BYTES: NULL
FLAGS: 0
...

```

This event indicates that thread 0 was waiting for 86,526 picoseconds to acquire a lock on `THR_LOCK::mutex`, a mutex in the `mysys` subsystem. The first few columns provide the following information:

- The ID columns indicate which thread the event comes from and the event number.
- `EVENT_NAME` indicates what was instrumented and `SOURCE` indicates which source file contains the instrumented code.
- The timer columns show when the event started and stopped and how long it took. If an event is still in progress, the `TIMER_END` and `TIMER_WAIT` values are `NULL`. Timer values are approximate and expressed in picoseconds. For information about timers and event time collection, see [Section 25.4.1, “Performance Schema Event Timing”](#).

The history tables contain the same kind of rows as the current-events table but have more rows and show what the server has been doing “recently” rather than “currently.” The `events_waits_history` and `events_waits_history_long` tables contain the most recent 10 events per thread and most recent 10,000 events, respectively. For example, to see information for recent events produced by thread 13, do this:

```

mysql> SELECT EVENT_ID, EVENT_NAME, TIMER_WAIT
FROM events_waits_history WHERE THREAD_ID = 13
ORDER BY EVENT_ID;
+-----+-----+-----+
| EVENT_ID | EVENT_NAME                                     | TIMER_WAIT |
+-----+-----+-----+
| 86 | wait/synch/mutex/mysys/THR_LOCK::mutex      | 686322 |
| 87 | wait/synch/mutex/mysys/THR_LOCK_malloc      | 320535 |
| 88 | wait/synch/mutex/mysys/THR_LOCK_malloc      | 339390 |
| 89 | wait/synch/mutex/mysys/THR_LOCK_malloc      | 377100 |
| 90 | wait/synch/mutex/sql/LOCK_plugin            | 614673 |
| 91 | wait/synch/mutex/sql/LOCK_open              | 659925 |
| 92 | wait/synch/mutex/sql/THD::LOCK_thd_data     | 494001 |
| 93 | wait/synch/mutex/mysys/THR_LOCK_malloc      | 222489 |
| 94 | wait/synch/mutex/mysys/THR_LOCK_malloc      | 214947 |
| 95 | wait/synch/mutex/mysys/LOCK_alarm           | 312993 |
+-----+-----+-----+

```

As new events are added to a history table, older events are discarded if the table is full.

Summary tables provide aggregated information for all events over time. The tables in this group summarize event data in different ways. To see which instruments have been executed the most times or have taken the most wait time, sort the `events_waits_summary_global_by_event_name` table on the `COUNT_STAR` or `SUM_TIMER_WAIT` column, which correspond to a `COUNT(*)` or `SUM(TIMER_WAIT)` value, respectively, calculated over all events:

```

mysql> SELECT EVENT_NAME, COUNT_STAR
FROM events_waits_summary_global_by_event_name
ORDER BY COUNT_STAR DESC LIMIT 10;
+-----+-----+
| EVENT_NAME                                     | COUNT_STAR |
+-----+-----+
| wait/synch/mutex/mysys/THR_LOCK_malloc      | 6419 |
+-----+-----+

```

```

| wait/io/file/sql/FRM | 452 |
| wait/synch/mutex/sql/LOCK_plugin | 337 |
| wait/synch/mutex/mysys/THR_LOCK_open | 187 |
| wait/synch/mutex/mysys/LOCK_alarm | 147 |
| wait/synch/mutex/sql/THD::LOCK_thd_data | 115 |
| wait/io/file/myisam/kfile | 102 |
| wait/synch/mutex/sql/LOCK_global_system_variables | 89 |
| wait/synch/mutex/mysys/THR_LOCK::mutex | 89 |
| wait/synch/mutex/sql/LOCK_open | 88 |
+-----+-----+
mysql> SELECT EVENT_NAME, SUM_TIMER_WAIT
FROM events_waits_summary_global_by_event_name
ORDER BY SUM_TIMER_WAIT DESC LIMIT 10;
+-----+-----+
| EVENT_NAME | SUM_TIMER_WAIT |
+-----+-----+
| wait/io/file/sql/MYSQL_LOG | 1599816582 |
| wait/synch/mutex/mysys/THR_LOCK_malloc | 1530083250 |
| wait/io/file/sql/binlog_index | 1385291934 |
| wait/io/file/sql/FRM | 1292823243 |
| wait/io/file/myisam/kfile | 411193611 |
| wait/io/file/myisam/dfile | 322401645 |
| wait/synch/mutex/mysys/LOCK_alarm | 145126935 |
| wait/io/file/sql/casetest | 104324715 |
| wait/synch/mutex/sql/LOCK_plugin | 86027823 |
| wait/io/file/sql/pid | 72591750 |
+-----+-----+

```

These results show that the `THR_LOCK_malloc` mutex is “hot,” both in terms of how often it is used and amount of time that threads wait attempting to acquire it.

Note

The `THR_LOCK_malloc` mutex is used only in debug builds. In production builds it is not hot because it is nonexistent.

Instance tables document what types of objects are instrumented. An instrumented object, when used by the server, produces an event. These tables provide event names and explanatory notes or status information. For example, the `file_instances` table lists instances of instruments for file I/O operations and their associated files:

```

mysql> SELECT * FROM file_instances\G
***** 1. row *****
FILE_NAME: /opt/mysql-log/60500/binlog.000007
EVENT_NAME: wait/io/file/sql/binlog
OPEN_COUNT: 0
***** 2. row *****
FILE_NAME: /opt/mysql/60500/data/mysql/tables_priv.MYI
EVENT_NAME: wait/io/file/myisam/kfile
OPEN_COUNT: 1
***** 3. row *****
FILE_NAME: /opt/mysql/60500/data/mysql/columns_priv.MYI
EVENT_NAME: wait/io/file/myisam/kfile
OPEN_COUNT: 1
...

```

Setup tables are used to configure and display monitoring characteristics. For example, to see which event timers are selected, query the `setup_timers` tables:

```

mysql> SELECT * FROM setup_timers;
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
| idle | MICROSECOND |
| wait | CYCLE |
| stage | NANOSECOND |
| statement | NANOSECOND |

```

```
| transaction | NANOSECOND |
+-----+-----+
```

`setup_instruments` lists the set of instruments for which events can be collected and shows which of them are enabled:

```
mysql> SELECT * FROM setup_instruments;
+-----+-----+-----+
| NAME                                     | ENABLED | TIMED |
+-----+-----+-----+
...
| wait/synch/mutex/sql/LOCK_global_read_lock | YES     | YES   |
| wait/synch/mutex/sql/LOCK_global_system_variables | YES     | YES   |
| wait/synch/mutex/sql/LOCK_lock_db | YES     | YES   |
| wait/synch/mutex/sql/LOCK_manager | YES     | YES   |
...
| wait/synch/rwlock/sql/LOCK_grant | YES     | YES   |
| wait/synch/rwlock/sql/LOGGER::LOCK_logger | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_connect | YES     | YES   |
| wait/synch/rwlock/sql/LOCK_sys_init_slave | YES     | YES   |
...
| wait/io/file/sql/binlog | YES     | YES   |
| wait/io/file/sql/binlog_index | YES     | YES   |
| wait/io/file/sql/casetest | YES     | YES   |
| wait/io/file/sql/dbopt | YES     | YES   |
...
```

To understand how to interpret instrument names, see [Section 25.6, “Performance Schema Instrument Naming Conventions”](#).

To control whether events are collected for an instrument, set its `ENABLED` value to `YES` or `NO`. For example:

```
mysql> UPDATE setup_instruments SET ENABLED = 'NO'
      WHERE NAME = 'wait/synch/mutex/sql/LOCK_mysql_create_db';
```

The Performance Schema uses collected events to update tables in the `performance_schema` database, which act as “consumers” of event information. The `setup_consumers` table lists the available consumers and which are enabled:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                     | ENABLED |
+-----+-----+
| events_stages_current | NO      |
| events_stages_history | NO      |
| events_stages_history_long | NO      |
| events_statements_current | YES     |
| events_statements_history | YES     |
| events_statements_history_long | NO      |
| events_transactions_current | YES     |
| events_transactions_history | YES     |
| events_transactions_history_long | NO      |
| events_waits_current | NO      |
| events_waits_history | NO      |
| events_waits_history_long | NO      |
| global_instrumentation | YES     |
| thread_instrumentation | YES     |
| statements_digest | YES     |
+-----+-----+
```

To control whether the Performance Schema maintains a consumer as a destination for event information, set its `ENABLED` value.

For more information about the setup tables and how to use them to control event collection, see [Section 25.4.2, “Performance Schema Event Filtering”](#).

There are some miscellaneous tables that do not fall into any of the previous groups. For example, `performance_timers` lists the available event timers and their characteristics. For information about timers, see [Section 25.4.1, “Performance Schema Event Timing”](#).

25.2 Performance Schema Build Configuration

The Performance Schema is mandatory and always compiled in. It is possible to exclude certain parts of the Performance Schema instrumentation. For example, to exclude stage and statement instrumentation, do this:

```
shell> cmake . \
  -DDISABLE_PSI_STAGE=1 \
  -DDISABLE_PSI_STATEMENT=1
```

For more information, see the descriptions of the `DISABLE_PSI_XXX` CMake options in [Section 2.8.4, “MySQL Source-Configuration Options”](#).

If you install MySQL over a previous installation that was configured without the Performance Schema (or with an older version of the Performance Schema that may not have all the current tables), run `mysql_upgrade` after starting the server to ensure that the `performance_schema` database exists with all current tables. Then restart the server. One indication that you need to do this is the presence of messages such as the following in the error log:

```
[ERROR] Native table 'performance_schema`.`events_waits_history'
has the wrong structure
[ERROR] Native table 'performance_schema`.`events_waits_history_long'
has the wrong structure
...
```

Because the Performance Schema is configured into the server at build time, a row for `PERFORMANCE_SCHEMA` appears in the output from `SHOW ENGINES`. This means that the Performance Schema is available, not that it is enabled. To enable it, you must do so at server startup, as described in the next section.

25.3 Performance Schema Startup Configuration

To use the MySQL Performance Schema, it must be enabled at server startup to enable event collection to occur.

The Performance Schema is enabled by default. To enable or disable it explicitly, start the server with the `performance_schema` variable set to an appropriate value. For example, use these lines in your `my.cnf` file:

```
[mysqld]
performance_schema=ON
```

If the server is unable to allocate any internal buffer during Performance Schema initialization, the Performance Schema disables itself and sets `performance_schema` to `OFF`, and the server runs without instrumentation.

The Performance Schema also permits instrument and consumer configuration at server startup.

To control an instrument at server startup, use an option of this form:

```
--performance-schema-instrument='instrument_name=value'
```

Here, `instrument_name` is an instrument name such as `wait/synch/mutex/sql/LOCK_open`, and `value` is one of these values:

- `OFF`, `FALSE`, or `0`: Disable the instrument
- `ON`, `TRUE`, or `1`: Enable and time the instrument
- `COUNTED`: Enable and count (rather than time) the instrument

Each `--performance-schema-instrument` option can specify only one instrument name, but multiple instances of the option can be given to configure multiple instruments. In addition, patterns are permitted in instrument names to configure instruments that match the pattern. To configure all condition synchronization instruments as enabled and counted, use this option:

```
--performance-schema-instrument='wait/synch/cond/%=COUNTED'
```

To disable all instruments, use this option:

```
--performance-schema-instrument='%=OFF'
```

Exception: The `memory/performance_schema/%` instruments are built in and cannot be disabled at startup.

Longer instrument name strings take precedence over shorter pattern names, regardless of order. For information about specifying patterns to select instruments, see [Section 25.4.9, “Naming Instruments or Consumers for Filtering Operations”](#).

An unrecognized instrument name is ignored. It is possible that a plugin installed later may create the instrument, at which time the name is recognized and configured.

To control a consumer at server startup, use an option of this form:

```
--performance-schema-consumer-consumer_name=value
```

Here, `consumer_name` is a consumer name such as `events_waits_history`, and `value` is one of these values:

- `OFF`, `FALSE`, or `0`: Do not collect events for the consumer
- `ON`, `TRUE`, or `1`: Collect events for the consumer

For example, to enable the `events_waits_history` consumer, use this option:

```
--performance-schema-consumer-events-waits-history=ON
```

The permitted consumer names can be found by examining the `setup_consumers` table. Patterns are not permitted. Consumer names in the `setup_consumers` table use underscores, but for consumers set at startup, dashes and underscores within the name are equivalent.

The Performance Schema includes several system variables that provide configuration information:

```
mysql> SHOW VARIABLES LIKE 'perf%';
```

Variable_name	Value
performance_schema	ON
performance_schema_accounts_size	100
performance_schema_digests_size	200
performance_schema_events_stages_history_long_size	10000
performance_schema_events_stages_history_size	10
performance_schema_events_statements_history_long_size	10000
performance_schema_events_statements_history_size	10
performance_schema_events_waits_history_long_size	10000

<code>performance_schema_events_waits_history_size</code>	10	
<code>performance_schema_hosts_size</code>	100	
<code>performance_schema_max_cond_classes</code>	80	
<code>performance_schema_max_cond_instances</code>	1000	
...		

The `performance_schema` variable is `ON` or `OFF` to indicate whether the Performance Schema is enabled or disabled. The other variables indicate table sizes (number of rows) or memory allocation values.

Note

With the Performance Schema enabled, the number of Performance Schema instances affects the server memory footprint, perhaps to a large extent. The Performance Schema autoscales many parameters to use memory only as required; see [Section 25.16, “The Performance Schema Memory-Allocation Model”](#).

To change the value of Performance Schema system variables, set them at server startup. For example, put the following lines in a `my.cnf` file to change the sizes of the history tables for wait events:

```
[mysqld]
performance_schema
performance_schema_events_waits_history_size=20
performance_schema_events_waits_history_long_size=15000
```

The Performance Schema automatically sizes the values of several of its parameters at server startup if they are not set explicitly. For example, it sizes the parameters that control the sizes of the events waits tables this way. The Performance Schema allocates memory incrementally, scaling its memory use to actual server load, instead of allocating all the memory it needs during server startup. Consequently, many sizing parameters need not be set at all. To see which parameters are autosized or autoscaled, use `mysqld --verbose --help` and examine the option descriptions, or see [Section 25.14, “Performance Schema System Variables”](#).

For each autosized parameter that is not set at server startup (or is set to `-1`), the Performance Schema determines how to set its value based on the value of the following system values, which are considered as “hints” about how you have configured your MySQL server:

```
max_connections
open_files_limit
table_definition_cache
table_open_cache
```

To override autosizing or autoscaling for a given parameter, set it to a value other than `-1` at startup. In this case, the Performance Schema assigns it the specified value.

At runtime, `SHOW VARIABLES` displays the actual values that autosized parameters were set to. Autoscaled parameters display with a value of `-1`.

If the Performance Schema is disabled, its autosized and autoscaled parameters remain set to `-1` and `SHOW VARIABLES` displays `-1`.

25.4 Performance Schema Runtime Configuration

Specific Performance Schema features can be enabled at runtime to control which types of event collection occur.

Performance Schema setup tables contain information about monitoring configuration:

```
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'performance_schema'
AND TABLE_NAME LIKE 'setup%';
+-----+
| TABLE_NAME |
+-----+
| setup_actors |
| setup_consumers |
| setup_instruments |
| setup_objects |
| setup_timers |
+-----+
```

You can examine the contents of these tables to obtain information about Performance Schema monitoring characteristics. If you have the `UPDATE` privilege, you can change Performance Schema operation by modifying setup tables to affect how monitoring occurs. For additional details about these tables, see [Section 25.11.2, “Performance Schema Setup Tables”](#).

To see which event timers are selected, query the `setup_timers` tables:

```
mysql> SELECT * FROM setup_timers;
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
| idle | MICROSECOND |
| wait | CYCLE |
| stage | NANOSECOND |
| statement | NANOSECOND |
| transaction | NANOSECOND |
+-----+-----+
```

The `NAME` value indicates the type of instrument to which the timer applies, and `TIMER_NAME` indicates which timer applies to those instruments. The timer applies to instruments where their name begins with a component matching the `NAME` value.

To change the timer, update the `NAME` value. For example, to use the `NANOSECOND` timer for the `wait` timer:

```
mysql> UPDATE setup_timers SET TIMER_NAME = 'NANOSECOND'
WHERE NAME = 'wait';
mysql> SELECT * FROM setup_timers;
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
| idle | MICROSECOND |
| wait | NANOSECOND |
| stage | NANOSECOND |
| statement | NANOSECOND |
| transaction | NANOSECOND |
+-----+-----+
```

For discussion of timers, see [Section 25.4.1, “Performance Schema Event Timing”](#).

The `setup_instruments` and `setup_consumers` tables list the instruments for which events can be collected and the types of consumers for which event information actually is collected, respectively. Other setup tables enable further modification of the monitoring configuration. [Section 25.4.2, “Performance Schema Event Filtering”](#), discusses how you can modify these tables to affect event collection.

If there are Performance Schema configuration changes that must be made at runtime using SQL statements and you would like these changes to take effect each time the server starts, put the statements in a file and start the server with the `--init-file=file_name` option. This strategy can also be useful if you have multiple monitoring configurations, each tailored to produce a different kind of monitoring, such as casual server health monitoring, incident investigation, application behavior

troubleshooting, and so forth. Put the statements for each monitoring configuration into their own file and specify the appropriate file as the `--init-file` argument when you start the server.

25.4.1 Performance Schema Event Timing

Events are collected by means of instrumentation added to the server source code. Instruments time events, which is how the Performance Schema provides an idea of how long events take. It is also possible to configure instruments not to collect timing information. This section discusses the available timers and their characteristics, and how timing values are represented in events.

Performance Schema Timers

Two Performance Schema tables provide timer information:

- `performance_timers` lists the available timers and their characteristics.
- `setup_timers` indicates which timers are used for which instruments.

Each timer row in `setup_timers` must refer to one of the timers listed in `performance_timers`.

Timers vary in precision and amount of overhead. To see what timers are available and their characteristics, check the `performance_timers` table:

```
mysql> SELECT * FROM performance_timers;
```

TIMER_NAME	TIMER_FREQUENCY	TIMER_RESOLUTION	TIMER_OVERHEAD
CYCLE	2389029850	1	72
NANOSECOND	1000000000	1	112
MICROSECOND	1000000	1	136
MILLISECOND	1036	1	168
TICK	105	1	2416

The columns have these meanings:

- The `TIMER_NAME` column shows the names of the available timers. `CYCLE` refers to the timer that is based on the CPU (processor) cycle counter. The timers in `setup_timers` that you can use are those that do not have `NULL` in the other columns. If the values associated with a given timer name are `NULL`, that timer is not supported on your platform.
- `TIMER_FREQUENCY` indicates the number of timer units per second. For a cycle timer, the frequency is generally related to the CPU speed. The value shown was obtained on a system with a 2.4GHz processor. The other timers are based on fixed fractions of seconds. For `TICK`, the frequency may vary by platform (for example, some use 100 ticks/second, others 1000 ticks/second).
- `TIMER_RESOLUTION` indicates the number of timer units by which timer values increase at a time. If a timer has a resolution of 10, its value increases by 10 each time.
- `TIMER_OVERHEAD` is the minimal number of cycles of overhead to obtain one timing with the given timer. The overhead per event is twice the value displayed because the timer is invoked at the beginning and end of the event.

To see which timers are in effect or to change timers, access the `setup_timers` table:

```
mysql> SELECT * FROM setup_timers;
```

NAME	TIMER_NAME
idle	MICROSECOND
wait	CYCLE
stage	NANOSECOND

```

| statement | NANOSECOND |
| transaction | NANOSECOND |
+-----+-----+
mysql> UPDATE setup_timers SET TIMER_NAME = 'MICROSECOND'
      WHERE NAME = 'idle';
mysql> SELECT * FROM setup_timers;
+-----+-----+
| NAME      | TIMER_NAME |
+-----+-----+
| idle      | MICROSECOND |
| wait      | CYCLE       |
| stage     | NANOSECOND  |
| statement | NANOSECOND  |
| transaction | NANOSECOND  |
+-----+-----+

```

By default, the Performance Schema uses the best timer available for each instrument type, but you can select a different one.

To time wait events, the most important criterion is to reduce overhead, at the possible expense of the timer accuracy, so using the `CYCLE` timer is the best.

The time a statement (or stage) takes to execute is in general orders of magnitude larger than the time it takes to execute a single wait. To time statements, the most important criterion is to have an accurate measure, which is not affected by changes in processor frequency, so using a timer which is not based on cycles is the best. The default timer for statements is `NANOSECOND`. The extra “overhead” compared to the `CYCLE` timer is not significant, because the overhead caused by calling a timer twice (once when the statement starts, once when it ends) is orders of magnitude less compared to the CPU time used to execute the statement itself. Using the `CYCLE` timer has no benefit here, only drawbacks.

The precision offered by the cycle counter depends on processor speed. If the processor runs at 1 GHz (one billion cycles/second) or higher, the cycle counter delivers sub-nanosecond precision. Using the cycle counter is much cheaper than getting the actual time of day. For example, the standard `gettimeofday()` function can take hundreds of cycles, which is an unacceptable overhead for data gathering that may occur thousands or millions of times per second.

Cycle counters also have disadvantages:

- End users expect to see timings in wall-clock units, such as fractions of a second. Converting from cycles to fractions of seconds can be expensive. For this reason, the conversion is a quick and fairly rough multiplication operation.
- Processor cycle rate might change, such as when a laptop goes into power-saving mode or when a CPU slows down to reduce heat generation. If a processor's cycle rate fluctuates, conversion from cycles to real-time units is subject to error.
- Cycle counters might be unreliable or unavailable depending on the processor or the operating system. For example, on Pentiums, the instruction is `RDTSC` (an assembly-language rather than a C instruction) and it is theoretically possible for the operating system to prevent user-mode programs from using it.
- Some processor details related to out-of-order execution or multiprocessor synchronization might cause the counter to seem fast or slow by up to 1000 cycles.

MySQL works with cycle counters on x386 (Windows, OS X, Linux, Solaris, and other Unix flavors), PowerPC, and IA-64.

Performance Schema Timer Representation in Events

Rows in Performance Schema tables that store current events and historical events have three columns to represent timing information: `TIMER_START` and `TIMER_END` indicate when an event started and finished, and `TIMER_WAIT` indicates event duration.

The `setup_instruments` table has an `ENABLED` column to indicate the instruments for which to collect events. The table also has a `TIMED` column to indicate which instruments are timed. If an instrument is not enabled, it produces no events. If an enabled instrument is not timed, events produced by the instrument have `NULL` for the `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` timer values. This in turn causes those values to be ignored when calculating the sum, minimum, maximum, and average time values in summary tables.

Internally, times within events are stored in units given by the timer in effect when event timing begins. For display when events are retrieved from Performance Schema tables, times are shown in picoseconds (trillionths of a second) to normalize them to a standard unit, regardless of which timer is selected.

Modifications to the `setup_timers` table affect monitoring immediately. Events already in progress may use the original timer for the begin time and the new timer for the end time. To avoid unpredictable results after you make timer changes, use `TRUNCATE TABLE` to reset Performance Schema statistics.

The timer baseline (“time zero”) occurs at Performance Schema initialization during server startup. `TIMER_START` and `TIMER_END` values in events represent picoseconds since the baseline. `TIMER_WAIT` values are durations in picoseconds.

Picosecond values in events are approximate. Their accuracy is subject to the usual forms of error associated with conversion from one unit to another. If the `CYCLE` timer is used and the processor rate varies, there might be drift. For these reasons, it is not reasonable to look at the `TIMER_START` value for an event as an accurate measure of time elapsed since server startup. On the other hand, it is reasonable to use `TIMER_START` or `TIMER_WAIT` values in `ORDER BY` clauses to order events by start time or duration.

The choice of picoseconds in events rather than a value such as microseconds has a performance basis. One implementation goal was to show results in a uniform time unit, regardless of the timer. In an ideal world this time unit would look like a wall-clock unit and be reasonably precise; in other words, microseconds. But to convert cycles or nanoseconds to microseconds, it would be necessary to perform a division for every instrumentation. Division is expensive on many platforms. Multiplication is not expensive, so that is what is used. Therefore, the time unit is an integer multiple of the highest possible `TIMER_FREQUENCY` value, using a multiplier large enough to ensure that there is no major precision loss. The result is that the time unit is “picoseconds.” This precision is spurious, but the decision enables overhead to be minimized.

While a wait, stage, statement, or transaction event is executing, the respective current-event tables display current-event timing information:

```
events_waits_current
events_stages_current
events_statements_current
events_transactions_current
```

To make it possible to determine how long a not-yet-completed event has been running, the timer columns are set as follows:

- `TIMER_START` is populated (unchanged from previous behavior)
- `TIMER_END` is populated with the current timer value
- `TIMER_WAIT` is populated with the time elapsed so far (`TIMER_END - TIMER_START`)

Events that have not yet completed have an `END_EVENT_ID` value of `NULL`. To assess time elapsed so far for an event, use the `TIMER_WAIT` column. Therefore, to identify events that have not yet completed and have taken longer than `N` picoseconds thus far, monitoring applications can use this expression in queries:

```
WHERE END_EVENT_ID IS NULL AND TIMER_WAIT > N
```

Event identification as just described assumes that the corresponding instruments have `ENABLED` and `TIMED` set to `YES` and that the relevant consumers are enabled.

25.4.2 Performance Schema Event Filtering

Events are processed in a producer/consumer fashion:

- Instrumented code is the source for events and produces events to be collected. The `setup_instruments` table lists the instruments for which events can be collected, whether they are enabled, and (for enabled instruments) whether to collect timing information:

```
mysql> SELECT * FROM setup_instruments;
+-----+-----+-----+
| NAME                                     | ENABLED | TIMED |
+-----+-----+-----+
...
| wait/synch/mutex/sql/LOCK_global_read_lock | YES     | YES   |
| wait/synch/mutex/sql/LOCK_global_system_variables | YES     | YES   |
| wait/synch/mutex/sql/LOCK_lock_db          | YES     | YES   |
| wait/synch/mutex/sql/LOCK_manager         | YES     | YES   |
...

```

The `setup_instruments` table provides the most basic form of control over event production. To further refine event production based on the type of object or thread being monitored, other tables may be used as described in [Section 25.4.3, “Event Pre-Filtering”](#).

- Performance Schema tables are the destinations for events and consume events. The `setup_consumers` table lists the types of consumers to which event information can be sent and whether they are enabled:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                     | ENABLED |
+-----+-----+
| events_stages_current                   | NO      |
| events_stages_history                   | NO      |
| events_stages_history_long              | NO      |
| events_statements_current               | YES     |
| events_statements_history               | YES     |
| events_statements_history_long          | NO      |
| events_transactions_current              | YES     |
| events_transactions_history              | YES     |
| events_transactions_history_long        | NO      |
| events_waits_current                    | NO      |
| events_waits_history                    | NO      |
| events_waits_history_long               | NO      |
| global_instrumentation                  | YES     |
| thread_instrumentation                  | YES     |
| statements_digest                       | YES     |
+-----+-----+

```

Filtering can be done at different stages of performance monitoring:

- Pre-filtering.** This is done by modifying Performance Schema configuration so that only certain types of events are collected from producers, and collected events update only certain consumers. To do this, enable or disable instruments or consumers. Pre-filtering is done by the Performance Schema and has a global effect that applies to all users.

Reasons to use pre-filtering:

- To reduce overhead. Performance Schema overhead should be minimal even with all instruments enabled, but perhaps you want to reduce it further. Or you do not care about timing events and want to disable the timing code to eliminate timing overhead.

- To avoid filling the current-events or history tables with events in which you have no interest. Pre-filtering leaves more “room” in these tables for instances of rows for enabled instrument types. If you enable only file instruments with pre-filtering, no rows are collected for nonfile instruments. With post-filtering, nonfile events are collected, leaving fewer rows for file events.
- To avoid maintaining some kinds of event tables. If you disable a consumer, the server does not spend time maintaining destinations for that consumer. For example, if you do not care about event histories, you can disable the history table consumers to improve performance.
- **Post-filtering.** This involves the use of `WHERE` clauses in queries that select information from Performance Schema tables, to specify which of the available events you want to see. Post-filtering is performed on a per-user basis because individual users select which of the available events are of interest.

Reasons to use post-filtering:

- To avoid making decisions for individual users about which event information is of interest.
- To use the Performance Schema to investigate a performance issue when the restrictions to impose using pre-filtering are not known in advance.

The following sections provide more detail about pre-filtering and provide guidelines for naming instruments or consumers in filtering operations. For information about writing queries to retrieve information (post-filtering), see [Section 25.5, “Performance Schema Queries”](#).

25.4.3 Event Pre-Filtering

Pre-filtering is done by the Performance Schema and has a global effect that applies to all users. Pre-filtering can be applied to either the producer or consumer stage of event processing:

- To configure pre-filtering at the producer stage, several tables can be used:
 - `setup_instruments` indicates which instruments are available. An instrument disabled in this table produces no events regardless of the contents of the other production-related setup tables. An instrument enabled in this table is permitted to produce events, subject to the contents of the other tables.
 - `setup_objects` controls whether the Performance Schema monitors particular table and stored program objects.
 - `threads` indicates whether monitoring is enabled for each server thread.
 - `setup_actors` determines the initial monitoring state for new foreground threads.
- To configure pre-filtering at the consumer stage, modify the `setup_consumers` table. This determines the destinations to which events are sent. `setup_consumers` also implicitly affects event production. If a given event will not be sent to any destination (that is, will not be consumed), the Performance Schema does not produce it.

Modifications to any of these tables affect monitoring immediately, with the exception that modifications to the `setup_actors` table affect only foreground threads created subsequent to the modification, not existing threads.

When you change the monitoring configuration, the Performance Schema does not flush the history tables. Events already collected remain in the current-events and history tables until displaced by newer events. If you disable instruments, you might need to wait a while before events for them are displaced by newer events of interest. Alternatively, use `TRUNCATE TABLE` to empty the history tables.

After making instrumentation changes, you might want to truncate the summary tables. Generally, the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. This enables you to clear

collected values and restart aggregation. That might be useful, for example, after you have made a runtime configuration change. Exceptions to this truncation behavior are noted in individual summary table sections.

The following sections describe how to use specific tables to control Performance Schema pre-filtering.

25.4.4 Pre-Filtering by Instrument

The `setup_instruments` table lists the available instruments:

```
mysql> SELECT * FROM setup_instruments;
```

NAME	ENABLED	TIMED
...		
wait/synch/mutex/sql/LOCK_global_read_lock	YES	YES
wait/synch/mutex/sql/LOCK_global_system_variables	YES	YES
wait/synch/mutex/sql/LOCK_lock_db	YES	YES
wait/synch/mutex/sql/LOCK_manager	YES	YES
...		
wait/synch/rwlock/sql/LOCK_grant	YES	YES
wait/synch/rwlock/sql/LOGGER::LOCK_logger	YES	YES
wait/synch/rwlock/sql/LOCK_sys_init_connect	YES	YES
wait/synch/rwlock/sql/LOCK_sys_init_slave	YES	YES
...		
wait/io/file/sql/binlog	YES	YES
wait/io/file/sql/binlog_index	YES	YES
wait/io/file/sql/casetest	YES	YES
wait/io/file/sql/dbopt	YES	YES
...		

To control whether an instrument is enabled, set its `ENABLED` column to `YES` or `NO`. To configure whether to collect timing information for an enabled instrument, set its `TIMED` value to `YES` or `NO`. Setting the `TIMED` column affects Performance Schema table contents as described in [Section 25.4.1, “Performance Schema Event Timing”](#).

Modifications to most `setup_instruments` rows affect monitoring immediately. For some instruments, modifications are effective only at server startup; changing them at runtime has no effect. This affects primarily mutexes, conditions, and rwlocks in the server, although there may be other instruments for which this is true.

The `setup_instruments` table provides the most basic form of control over event production. To further refine event production based on the type of object or thread being monitored, other tables may be used as described in [Section 25.4.3, “Event Pre-Filtering”](#).

The following examples demonstrate possible operations on the `setup_instruments` table. These changes, like other pre-filtering operations, affect all users. Some of these queries use the `LIKE` operator and a pattern match instrument names. For additional information about specifying patterns to select instruments, see [Section 25.4.9, “Naming Instruments or Consumers for Filtering Operations”](#).

- Disable all instruments:

```
mysql> UPDATE setup_instruments SET ENABLED = 'NO';
```

Now no events will be collected.

- Disable all file instruments, adding them to the current set of disabled instruments:

```
mysql> UPDATE setup_instruments SET ENABLED = 'NO'
WHERE NAME LIKE 'wait/io/file/%';
```

- Disable only file instruments, enable all other instruments:

```
mysql> UPDATE setup_instruments
      SET ENABLED = IF(NAME LIKE 'wait/io/file/%', 'NO', 'YES');
```

- Enable all but those instruments in the `mysys` library:

```
mysql> UPDATE setup_instruments
      SET ENABLED = CASE WHEN NAME LIKE '%/mysys/%' THEN 'YES' ELSE 'NO' END;
```

- Disable a specific instrument:

```
mysql> UPDATE setup_instruments SET ENABLED = 'NO'
      WHERE NAME = 'wait/synch/mutex/mysys/TMPDIR_mutex';
```

- To toggle the state of an instrument, “flip” its `ENABLED` value:

```
mysql> UPDATE setup_instruments
      SET ENABLED = IF(ENABLED = 'YES', 'NO', 'YES')
      WHERE NAME = 'wait/synch/mutex/mysys/TMPDIR_mutex';
```

- Disable timing for all events:

```
mysql> UPDATE setup_instruments SET TIMED = 'NO';
```

25.4.5 Pre-Filtering by Object

The `setup_objects` table controls whether the Performance Schema monitors particular table and stored program objects. The initial `setup_objects` contents look like this:

```
mysql> SELECT * FROM setup_objects;
```

OBJECT_TYPE	OBJECT_SCHEMA	OBJECT_NAME	ENABLED	TIMED
EVENT	mysql	%	NO	NO
EVENT	performance_schema	%	NO	NO
EVENT	information_schema	%	NO	NO
EVENT	%	%	YES	YES
FUNCTION	mysql	%	NO	NO
FUNCTION	performance_schema	%	NO	NO
FUNCTION	information_schema	%	NO	NO
FUNCTION	%	%	YES	YES
PROCEDURE	mysql	%	NO	NO
PROCEDURE	performance_schema	%	NO	NO
PROCEDURE	information_schema	%	NO	NO
PROCEDURE	%	%	YES	YES
TABLE	mysql	%	NO	NO
TABLE	performance_schema	%	NO	NO
TABLE	information_schema	%	NO	NO
TABLE	%	%	YES	YES
TRIGGER	mysql	%	NO	NO
TRIGGER	performance_schema	%	NO	NO
TRIGGER	information_schema	%	NO	NO
TRIGGER	%	%	YES	YES

Modifications to the `setup_objects` table affect object monitoring immediately.

The `OBJECT_TYPE` column indicates the type of object to which a row applies. `TABLE` filtering affects table I/O events (`wait/io/table/sql/handler` instrument) and table lock events (`wait/lock/table/sql/handler` instrument).

The `OBJECT_SCHEMA` and `OBJECT_NAME` columns should contain a literal schema or object name, or `'%'` to match any name.

The `ENABLED` column indicates whether matching objects are monitored, and `TIMED` indicates whether to collect timing information. Setting the `TIMED` column affects Performance Schema table contents as described in [Section 25.4.1, “Performance Schema Event Timing”](#).

The effect of the default object configuration is to instrument all objects except those in the `mysql`, `INFORMATION_SCHEMA`, and `performance_schema` databases. (Tables in the `INFORMATION_SCHEMA` database are not instrumented regardless of the contents of `setup_objects`; the row for `information_schema.%` simply makes this default explicit.)

When the Performance Schema checks for a match in `setup_objects`, it tries to find more specific matches first. For rows that match a given `OBJECT_TYPE`, the Performance Schema checks rows in this order:

- Rows with `OBJECT_SCHEMA='literal'` and `OBJECT_NAME='literal'`.
- Rows with `OBJECT_SCHEMA='literal'` and `OBJECT_NAME='%'`.
- Rows with `OBJECT_SCHEMA='%'` and `OBJECT_NAME='%'`.

For example, with a table `db1.t1`, the Performance Schema looks in `TABLE` rows for a match for `'db1'` and `'t1'`, then for `'db1'` and `'%'`, then for `'%'` and `'%'`. The order in which matching occurs matters because different matching `setup_objects` rows can have different `ENABLED` and `TIMED` values.

For table-related events, the Performance Schema combines the contents of `setup_objects` with `setup_instruments` to determine whether to enable instruments and whether to time enabled instruments:

- For tables that match a row in `setup_objects`, table instruments produce events only if `ENABLED` is `YES` in both `setup_instruments` and `setup_objects`.
- The `TIMED` values in the two tables are combined, so that timing information is collected only when both values are `YES`.

For stored program objects, the Performance Schema takes the `ENABLED` and `TIMED` columns directly from the `setup_objects` row. There is no combining of values with `setup_instruments`.

Suppose that `setup_objects` contains the following `TABLE` rows that apply to `db1`, `db2`, and `db3`:

OBJECT_TYPE	OBJECT_SCHEMA	OBJECT_NAME	ENABLED	TIMED
TABLE	db1	t1	YES	YES
TABLE	db1	t2	NO	NO
TABLE	db2	%	YES	YES
TABLE	db3	%	NO	NO
TABLE	%	%	YES	YES

If an object-related instrument in `setup_instruments` has an `ENABLED` value of `NO`, events for the object are not monitored. If the `ENABLED` value is `YES`, event monitoring occurs according to the `ENABLED` value in the relevant `setup_objects` row:

- `db1.t1` events are monitored
- `db1.t2` events are not monitored
- `db2.t3` events are monitored
- `db3.t4` events are not monitored
- `db4.t5` events are monitored

Similar logic applies for combining the `TIMED` columns from the `setup_instruments` and `setup_objects` tables to determine whether to collect event timing information.

If a persistent table and a temporary table have the same name, matching against `setup_objects` rows occurs the same way for both. It is not possible to enable monitoring for one table but not the other. However, each table is instrumented separately.

25.4.6 Pre-Filtering by Thread

The `threads` table contains a row for each server thread. Each row contains information about a thread and indicates whether monitoring is enabled for it. For the Performance Schema to monitor a thread, these things must be true:

- The `thread_instrumentation` consumer in the `setup_consumers` table must be `YES`.
- The `threads.INSTRUMENTED` column must be `YES`.
- Monitoring occurs only for those thread events produced from instruments that are enabled in the `setup_instruments` table.

The `threads` table also indicates for each server thread whether to perform historical event logging. This includes wait, stage, statement, and transaction events and affects logging to these tables:

```
events_waits_history
events_waits_history_long
events_stages_history
events_stages_history_long
events_statements_history
events_statements_history_long
events_transactions_history
events_transactions_history_long
```

For historical event logging to occur, these things must be true:

- The appropriate history-related consumers in the `setup_consumers` table must be enabled. For example, wait event logging in the `events_waits_history` and `events_waits_history_long` tables requires the corresponding `events_waits_history` and `events_waits_history_long` consumers to be `YES`.
- The `threads.HISTORY` column must be `YES`.
- Logging occurs only for those thread events produced from instruments that are enabled in the `setup_instruments` table.

For foreground threads (resulting from client connections), the initial values of the `INSTRUMENTED` and `HISTORY` columns in `threads` table rows are determined by whether the user account associated with a thread matches any row in the `setup_actors` table. The values come from the `ENABLED` and `HISTORY` columns of the matching `setup_actors` table row.

For background threads, there is no associated user. `INSTRUMENTED` and `HISTORY` are `YES` by default and `setup_actors` is not consulted.

The initial `setup_actors` contents look like this:

```
mysql> SELECT * FROM setup_actors;
+-----+-----+-----+-----+-----+
| HOST | USER | ROLE | ENABLED | HISTORY |
+-----+-----+-----+-----+-----+
| %    | %    | %    | YES     | YES     |
+-----+-----+-----+-----+-----+
```

The `HOST` and `USER` columns should contain a literal host or user name, or `'%'` to match any name.

The `ENABLED` and `HISTORY` columns indicate whether to enable instrumentation and historical event logging for matching threads, subject to the other conditions described previously.

When the Performance Schema checks for a match for each new foreground thread in `setup_actors`, it tries to find more specific matches first, using the `USER` and `HOST` columns (`ROLE` is unused):

- Rows with `USER='literal'` and `HOST='literal'`.
- Rows with `USER='literal'` and `HOST='%'`.
- Rows with `USER='%'` and `HOST='literal'`.
- Rows with `USER='%'` and `HOST='%'`.

The order in which matching occurs matters because different matching `setup_actors` rows can have different `USER` and `HOST` values. This enables instrumenting and historical event logging to be applied selectively per host, user, or account (user and host combination), based on the `ENABLED` and `HISTORY` column values:

- When the best match is a row with `ENABLED=YES`, the `INSTRUMENTED` value for the thread becomes `YES`. When the best match is a row with `HISTORY=YES`, the `HISTORY` value for the thread becomes `YES`.
- When the best match is a row with `ENABLED=NO`, the `INSTRUMENTED` value for the thread becomes `NO`. When the best match is a row with `HISTORY=NO`, the `HISTORY` value for the thread becomes `NO`.
- When no match is found, the `INSTRUMENTED` and `HISTORY` values for the thread become `NO`.

The `ENABLED` and `HISTORY` columns in `setup_actors` rows can be set to `YES` or `NO` independent of one another. This means you can enable instrumentation separately from whether you collect historical events.

By default, monitoring and historical event collection are enabled for all new foreground threads because the `setup_actors` table initially contains a row with `'%'` for both `HOST` and `USER`. To perform more limited matching such as to enable monitoring only for some foreground threads, you must change this row because it matches any connection, and add rows for more specific `HOST/USER` combinations.

Suppose that you modify `setup_actors` as follows:

```
UPDATE setup_actors SET ENABLED = 'NO', HISTORY = 'NO'
WHERE HOST = '%' AND USER = '%';
INSERT INTO setup_actors (HOST,USER,ROLE,ENABLED,HISTORY)
VALUES('localhost','joe','%','YES','YES');
INSERT INTO setup_actors (HOST,USER,ROLE,ENABLED,HISTORY)
VALUES('hosta.example.com','joe','%','YES','NO');
INSERT INTO setup_actors (HOST,USER,ROLE,ENABLED,HISTORY)
VALUES('%','sam','%','NO','YES');
```

The `UPDATE` statement changes the default match to disable instrumentation and historical event collection. The `INSERT` statements add rows for more specific matches.

Now the Performance Schema determines how to set the `INSTRUMENTED` and `HISTORY` values for new connection threads as follows:

- If `joe` connects from the local host, the connection matches the first inserted row. The `INSTRUMENTED` and `HISTORY` values for the thread become `YES`.
- If `joe` connects from `hosta.example.com`, the connection matches the second inserted row. The `INSTRUMENTED` value for the thread becomes `YES` and the `HISTORY` value becomes `NO`.

- If `joe` connects from any other host, there is no match. The `INSTRUMENTED` and `HISTORY` values for the thread become `NO`.
- If `sam` connects from any host, the connection matches the third inserted row. The `INSTRUMENTED` value for the thread becomes `NO` and the `HISTORY` value becomes `YES`.
- For any other connection, the row with `HOST` and `USER` set to `'%'` matches. This row now has `ENABLED` and `HISTORY` set to `NO`, so the `INSTRUMENTED` and `HISTORY` values for the thread become `NO`.

Modifications to the `setup_actors` table affect only foreground threads created subsequent to the modification, not existing threads. To affect existing threads, modify the `INSTRUMENTED` and `HISTORY` columns of `threads` table rows.

25.4.7 Pre-Filtering by Consumer

The `setup_consumers` table lists the available consumer types and which are enabled:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                | ENABLED |
+-----+-----+
| events_stages_current               | NO      |
| events_stages_history               | NO      |
| events_stages_history_long          | NO      |
| events_statements_current           | YES     |
| events_statements_history           | YES     |
| events_statements_history_long      | NO      |
| events_transactions_current         | YES     |
| events_transactions_history         | YES     |
| events_transactions_history_long    | NO      |
| events_waits_current                | NO      |
| events_waits_history                | NO      |
| events_waits_history_long           | NO      |
| global_instrumentation              | YES     |
| thread_instrumentation              | YES     |
| statements_digest                   | YES     |
+-----+-----+
```

Modify the `setup_consumers` table to affect pre-filtering at the consumer stage and determine the destinations to which events are sent. To enable or disable a consumer, set its `ENABLED` value to `YES` or `NO`.

Modifications to the `setup_consumers` table affect monitoring immediately.

If you disable a consumer, the server does not spend time maintaining destinations for that consumer. For example, if you do not care about historical event information, disable the history consumers:

```
mysql> UPDATE setup_consumers
      SET ENABLED = 'NO' WHERE NAME LIKE '%history%';
```

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. The following principles apply:

- Destinations associated with a consumer receive no events unless the Performance Schema checks the consumer and the consumer is enabled.
- A consumer is checked only if all consumers it depends on (if any) are enabled.
- If a consumer is not checked, or is checked but is disabled, other consumers that depend on it are not checked.
- Dependent consumers may have their own dependent consumers.
- If an event would not be sent to any destination, the Performance Schema does not produce it.

The following lists describe the available consumer values. For discussion of several representative consumer configurations and their effect on instrumentation, see [Section 25.4.8, “Example Consumer Configurations”](#).

- [Global and Thread Consumers](#)
- [Wait Event Consumers](#)
- [Stage Event Consumers](#)
- [Statement Event Consumers](#)
- [Transaction Event Consumers](#)
- [Statement Digest Consumer](#)

Global and Thread Consumers

- `global_instrumentation` is the highest level consumer. If `global_instrumentation` is `NO`, it disables global instrumentation. All other settings are lower level and are not checked; it does not matter what they are set to. No global or per thread information is maintained and no individual events are collected in the current-events or event-history tables. If `global_instrumentation` is `YES`, the Performance Schema maintains information for global states and also checks the `thread_instrumentation` consumer.
- `thread_instrumentation` is checked only if `global_instrumentation` is `YES`. Otherwise, if `thread_instrumentation` is `NO`, it disables thread-specific instrumentation and all lower-level settings are ignored. No information is maintained per thread and no individual events are collected in the current-events or event-history tables. If `thread_instrumentation` is `YES`, the Performance Schema maintains thread-specific information and also checks `events_xxx_current` consumers.

Wait Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be `YES` or they are not checked. If checked, they act as follows:

- `events_waits_current`, if `NO`, disables collection of individual wait events in the `events_waits_current` table. If `YES`, it enables wait event collection and the Performance Schema checks the `events_waits_history` and `events_waits_history_long` consumers.
- `events_waits_history` is not checked if `event_waits_current` is `NO`. Otherwise, an `events_waits_history` value of `NO` or `YES` disables or enables collection of wait events in the `events_waits_history` table.
- `events_waits_history_long` is not checked if `event_waits_current` is `NO`. Otherwise, an `events_waits_history_long` value of `NO` or `YES` disables or enables collection of wait events in the `events_waits_history_long` table.

Stage Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be `YES` or they are not checked. If checked, they act as follows:

- `events_stages_current`, if `NO`, disables collection of individual stage events in the `events_stages_current` table. If `YES`, it enables stage event collection and the Performance Schema checks the `events_stages_history` and `events_stages_history_long` consumers.
- `events_stages_history` is not checked if `event_stages_current` is `NO`. Otherwise, an `events_stages_history` value of `NO` or `YES` disables or enables collection of stage events in the `events_stages_history` table.

- `events_stages_history_long` is not checked if `event_stages_current` is `NO`. Otherwise, an `events_stages_history_long` value of `NO` or `YES` disables or enables collection of stage events in the `events_stages_history_long` table.

Statement Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be `YES` or they are not checked. If checked, they act as follows:

- `events_statements_current`, if `NO`, disables collection of individual statement events in the `events_statements_current` table. If `YES`, it enables statement event collection and the Performance Schema checks the `events_statements_history` and `events_statements_history_long` consumers.
- `events_statements_history` is not checked if `events_statements_current` is `NO`. Otherwise, an `events_statements_history` value of `NO` or `YES` disables or enables collection of statement events in the `events_statements_history` table.
- `events_statements_history_long` is not checked if `events_statements_current` is `NO`. Otherwise, an `events_statements_history_long` value of `NO` or `YES` disables or enables collection of statement events in the `events_statements_history_long` table.

Transaction Event Consumers

These consumers require both `global_instrumentation` and `thread_instrumentation` to be `YES` or they are not checked. If checked, they act as follows:

- `events_transactions_current`, if `NO`, disables collection of individual transaction events in the `events_transactions_current` table. If `YES`, it enables transaction event collection and the Performance Schema checks the `events_transactions_history` and `events_transactions_history_long` consumers.
- `events_transactions_history` is not checked if `events_transactions_current` is `NO`. Otherwise, an `events_transactions_history` value of `NO` or `YES` disables or enables collection of transaction events in the `events_transactions_history` table.
- `events_transactions_history_long` is not checked if `events_transactions_current` is `NO`. Otherwise, an `events_transactions_history_long` value of `NO` or `YES` disables or enables collection of transaction events in the `events_transactions_history_long` table.

Statement Digest Consumer

The `statements_digest` consumer requires `global_instrumentation` to be `YES` or it is not checked. There is no dependency on the statement event consumers, so you can obtain statistics per digest without having to collect statistics in `events_statements_current`, which is advantageous in terms of overhead. Conversely, you can get detailed statements in `events_statements_current` without digests (the `DIGEST` and `DIGEST_TEXT` columns will be `NULL`).

For more information about statement digesting, see [Section 25.9, “Performance Schema Statement Digests”](#).

25.4.8 Example Consumer Configurations

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. The following discussion describes how consumers work, showing specific configurations and their effects as consumer settings are enabled progressively from high to low. The consumer values shown are representative. The general principles described here apply to other consumer values that may be available.

The configuration descriptions occur in order of increasing functionality and overhead. If you do not need the information provided by enabling lower-level settings, disable them and the Performance Schema will execute less code on your behalf and you will have less information to sift through.

The `setup_consumers` table contains the following hierarchy of values:

```
global_instrumentation
thread_instrumentation
  events_waits_current
  events_waits_history
  events_waits_history_long
  events_stages_current
  events_stages_history
  events_stages_history_long
  events_statements_current
  events_statements_history
  events_statements_history_long
  events_transactions_current
  events_transactions_history
  events_transactions_history_long
statements_digest
```

Note

In the consumer hierarchy, the consumers for waits, stages, statements, and transactions are all at the same level. This differs from the event nesting hierarchy, for which wait events nest within stage events, which nest within statement events, which nest within transaction events.

If a given consumer setting is **NO**, the Performance Schema disables the instrumentation associated with the consumer and ignores all lower-level settings. If a given setting is **YES**, the Performance Schema enables the instrumentation associated with it and checks the settings at the next lowest level. For a description of the rules for each consumer, see [Section 25.4.7, “Pre-Filtering by Consumer”](#).

For example, if `global_instrumentation` is enabled, `thread_instrumentation` is checked. If `thread_instrumentation` is enabled, the `events_xxx_current` consumers are checked. If of these `events_waits_current` is enabled, `events_waits_history` and `events_waits_history_long` are checked.

Each of the following configuration descriptions indicates which setup elements the Performance Schema checks and which output tables it maintains (that is, for which tables it collects information).

- [No Instrumentation](#)
- [Global Instrumentation Only](#)
- [Global and Thread Instrumentation Only](#)
- [Global, Thread, and Current-Event Instrumentation](#)
- [Global, Thread, Current-Event, and Event-History instrumentation](#)

No Instrumentation

Server configuration state:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                | ENABLED |
+-----+-----+
| global_instrumentation | NO      |
| ...                  |         |
+-----+-----+
```

In this configuration, nothing is instrumented.

Setup elements checked:

- Table `setup_consumers`, consumer `global_instrumentation`

Output tables maintained:

- None

Global Instrumentation Only

Server configuration state:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                | ENABLED |
+-----+-----+
| global_instrumentation | YES     |
| thread_instrumentation | NO      |
| ...                  |         |
+-----+-----+
```

In this configuration, instrumentation is maintained only for global states. Per-thread instrumentation is disabled.

Additional setup elements checked, relative to the preceding configuration:

- Table `setup_consumers`, consumer `thread_instrumentation`
- Table `setup_instruments`
- Table `setup_objects`
- Table `setup_timers`

Additional output tables maintained, relative to the preceding configuration:

- `mutex_instances`
- `rwlock_instances`
- `cond_instances`
- `file_instances`
- `users`
- `hosts`
- `accounts`
- `socket_summary_by_event_name`
- `file_summary_by_instance`
- `file_summary_by_event_name`
- `objects_summary_global_by_type`
- `memory_summary_global_by_event_name`
- `table_lock_waits_summary_by_table`
- `table_io_waits_summary_by_index_usage`
- `table_io_waits_summary_by_table`
- `events_waits_summary_by_instance`

- `events_waits_summary_global_by_event_name`
- `events_stages_summary_global_by_event_name`
- `events_statements_summary_global_by_event_name`
- `events_transactions_summary_global_by_event_name`

Global and Thread Instrumentation Only

Server configuration state:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                | ENABLED |
+-----+-----+
| global_instrumentation              | YES     |
| thread_instrumentation              | YES     |
| events_waits_current                 | NO      |
| ...                                  |         |
| events_stages_current                | NO      |
| ...                                  |         |
| events_statements_current            | NO      |
| ...                                  |         |
| events_transactions_current          | NO      |
| ...                                  |         |
+-----+-----+
```

In this configuration, instrumentation is maintained globally and per thread. No individual events are collected in the current-events or event-history tables.

Additional setup elements checked, relative to the preceding configuration:

- Table `setup_consumers`, consumers `events_xxx_current`, where `xxx` is `waits`, `stages`, `statements`, `transactions`
- Table `setup_actors`
- Column `threads.instrumented`

Additional output tables maintained, relative to the preceding configuration:

- `events_xxx_summary_by_yyy_by_event_name`, where `xxx` is `waits`, `stages`, `statements`, `transactions`; and `yyy` is `thread`, `user`, `host`, `account`

Global, Thread, and Current-Event Instrumentation

Server configuration state:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                | ENABLED |
+-----+-----+
| global_instrumentation              | YES     |
| thread_instrumentation              | YES     |
| events_waits_current                 | YES     |
| events_waits_history                 | NO      |
| events_waits_history_long            | NO      |
| events_stages_current                | YES     |
| events_stages_history                 | NO      |
| events_stages_history_long           | NO      |
| events_statements_current            | YES     |
| events_statements_history            | YES     |
| events_statements_history_long       | NO      |
| events_transactions_current          | YES     |
| events_transactions_history          | YES     |
+-----+-----+
```

```
| events_transactions_history_long | NO |
...
+-----+-----+
```

In this configuration, instrumentation is maintained globally and per thread. Individual events are collected in the current-events table, but not in the event-history tables.

Additional setup elements checked, relative to the preceding configuration:

- Consumers `events_xxx_history`, where `xxx` is `waits`, `stages`, `statements`, `transactions`
- Consumers `events_xxx_history_long`, where `xxx` is `waits`, `stages`, `statements`, `transactions`

Additional output tables maintained, relative to the preceding configuration:

- `events_xxx_current`, where `xxx` is `waits`, `stages`, `statements`, `transactions`

Global, Thread, Current-Event, and Event-History instrumentation

The preceding configuration collects no event history because the `events_xxx_history` and `events_xxx_history_long` consumers are disabled. Those consumers can be enabled separately or together to collect event history per thread, globally, or both.

This configuration collects event history per thread, but not globally:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                | ENABLED |
+-----+-----+
| global_instrumentation              | YES     |
| thread_instrumentation              | YES     |
| events_waits_current                 | YES     |
| events_waits_history                 | YES     |
| events_waits_history_long            | NO      |
| events_stages_current                | YES     |
| events_stages_history                 | YES     |
| events_stages_history_long           | NO      |
| events_statements_current            | YES     |
| events_statements_history            | YES     |
| events_statements_history_long       | NO      |
| events_transactions_current          | YES     |
| events_transactions_history           | YES     |
| events_transactions_history_long     | NO      |
...
+-----+-----+
```

Event-history tables maintained for this configuration:

- `events_xxx_history`, where `xxx` is `waits`, `stages`, `statements`, `transactions`

This configuration collects event history globally, but not per thread:

```
mysql> SELECT * FROM setup_consumers;
+-----+-----+
| NAME                                | ENABLED |
+-----+-----+
| global_instrumentation              | YES     |
| thread_instrumentation              | YES     |
| events_waits_current                 | YES     |
| events_waits_history                 | NO      |
| events_waits_history_long            | YES     |
| events_stages_current                | YES     |
| events_stages_history                 | NO      |
| events_stages_history_long           | YES     |
| events_statements_current            | YES     |
| events_statements_history            | YES     |
+-----+-----+
```

events_statements_history_long	YES
events_transactions_current	YES
events_transactions_history	YES
events_transactions_history_long	YES
...	

Event-history tables maintained for this configuration:

- `events_xxx_history_long`, where `xxx` is `waits`, `stages`, `statements`, `transactions`

This configuration collects event history per thread and globally:

```
mysql> SELECT * FROM setup_consumers;
```

NAME	ENABLED
global_instrumentation	YES
thread_instrumentation	YES
events_waits_current	YES
events_waits_history	YES
events_waits_history_long	YES
events_stages_current	YES
events_stages_history	YES
events_stages_history_long	YES
events_statements_current	YES
events_statements_history	YES
events_statements_history_long	YES
events_transactions_current	YES
events_transactions_history	YES
events_transactions_history_long	YES
...	

Event-history tables maintained for this configuration:

- `events_xxx_history`, where `xxx` is `waits`, `stages`, `statements`, `transactions`
- `events_xxx_history_long`, where `xxx` is `waits`, `stages`, `statements`, `transactions`

25.4.9 Naming Instruments or Consumers for Filtering Operations

Names given for filtering operations can be as specific or general as required. To indicate a single instrument or consumer, specify its name in full:

```
mysql> UPDATE setup_instruments
      SET ENABLED = 'NO'
      WHERE NAME = 'wait/synch/mutex/myisammrg/MYRG_INFO::mutex';

mysql> UPDATE setup_consumers
      SET ENABLED = 'NO' WHERE NAME = 'events_waits_current';
```

To specify a group of instruments or consumers, use a pattern that matches the group members:

```
mysql> UPDATE setup_instruments
      SET ENABLED = 'NO'
      WHERE NAME LIKE 'wait/synch/mutex/%';

mysql> UPDATE setup_consumers
      SET ENABLED = 'NO' WHERE NAME LIKE '%history%';
```

If you use a pattern, it should be chosen so that it matches all the items of interest and no others. For example, to select all file I/O instruments, it is better to use a pattern that includes the entire instrument name prefix:

```
... WHERE NAME LIKE 'wait/io/file/%';
```

A pattern of `%/file/%` will match other instruments that have a component of `/file/` anywhere in the name. Even less suitable is the pattern `%file%` because it will match instruments with `file` anywhere in the name, such as `wait/synch/mutex/sql/LOCK_des_key_file`.

To check which instrument or consumer names a pattern matches, perform a simple test:

```
mysql> SELECT NAME FROM setup_instruments WHERE NAME LIKE 'pattern';
mysql> SELECT NAME FROM setup_consumers WHERE NAME LIKE 'pattern';
```

For information about the types of names that are supported, see [Section 25.6, “Performance Schema Instrument Naming Conventions”](#).

25.4.10 Determining What Is Instrumented

It is always possible to determine what instruments the Performance Schema includes by checking the `setup_instruments` table. For example, to see what file-related events are instrumented for the InnoDB storage engine, use this query:

```
mysql> SELECT * FROM setup_instruments WHERE NAME LIKE 'wait/io/file/innodb/%';
```

NAME	ENABLED	TIMED
wait/io/file/innodb/innodb_data_file	YES	YES
wait/io/file/innodb/innodb_log_file	YES	YES
wait/io/file/innodb/innodb_temp_file	YES	YES

An exhaustive description of precisely what is instrumented is not given in this documentation, for several reasons:

- What is instrumented is the server code. Changes to this code occur often, which also affects the set of instruments.
- It is not practical to list all the instruments because there are hundreds of them.
- As described earlier, it is possible to find out by querying the `setup_instruments` table. This information is always up to date for your version of MySQL, also includes instrumentation for instrumented plugins you might have installed that are not part of the core server, and can be used by automated tools.

25.5 Performance Schema Queries

Pre-filtering limits which event information is collected and is independent of any particular user. By contrast, post-filtering is performed by individual users through the use of queries with appropriate `WHERE` clauses that restrict what event information to select from the events available after pre-filtering has been applied.

In [Section 25.4.3, “Event Pre-Filtering”](#), an example showed how to pre-filter for file instruments. If the event tables contain both file and nonfile information, post-filtering is another way to see information only for file events. Add a `WHERE` clause to queries to restrict event selection appropriately:

```
mysql> SELECT THREAD_ID, NUMBER_OF_BYTES
FROM events_waits_history
WHERE EVENT_NAME LIKE 'wait/io/file/%'
AND NUMBER_OF_BYTES IS NOT NULL;
```

THREAD_ID	NUMBER_OF_BYTES
11	66

11	47
11	139
5	24
5	834

Most Performance Schema tables have indexes, which gives the optimizer access to execution plans other than full table scans. These indexes also improve performance for related objects, such as `sys` schema views that use those tables. For more information, see [Section 8.2.4, “Optimizing Performance Schema Queries”](#).

25.6 Performance Schema Instrument Naming Conventions

An instrument name consists of a sequence of components separated by `' / '` characters. Example names:

```
wait/io/file/myisam/log
wait/io/file/mysys/charset
wait/lock/table/sql/handler
wait/synch/cond/mysys/COND_alarm
wait/synch/cond/sql/BINLOG::update_cond
wait/synch/mutex/mysys/BITMAP_mutex
wait/synch/mutex/sql/LOCK_delete
wait/synch/rwlock/sql/Query_cache_query::lock
stage/sql/closing_tables
stage/sql/Sorting_result
statement/com/Execute
statement/com/Query
statement/sql/create_table
statement/sql/lock_tables
errors
```

The instrument name space has a tree-like structure. The components of an instrument name from left to right provide a progression from more general to more specific. The number of components a name has depends on the type of instrument.

The interpretation of a given component in a name depends on the components to the left of it. For example, `myisam` appears in both of the following names, but `myisam` in the first name is related to file I/O, whereas in the second it is related to a synchronization instrument:

```
wait/io/file/myisam/log
wait/synch/cond/myisam/MI_SORT_INFO::cond
```

Instrument names consist of a prefix with a structure defined by the Performance Schema implementation and a suffix defined by the developer implementing the instrument code. The top-level component of an instrument prefix indicates the type of instrument. This component also determines which event timer in the `setup_timers` table applies to the instrument. For the prefix part of instrument names, the top level indicates the type of instrument.

The suffix part of instrument names comes from the code for the instruments themselves. Suffixes may include levels such as these:

- A name for the major component (a server module such as `myisam`, `innodb`, `mysys`, or `sql`) or a plugin name.
- The name of a variable in the code, in the form `XXX` (a global variable) or `CCC::MMM` (a member `MMM` in class `CCC`). Examples: `COND_thread_cache`, `THR_LOCK_myisam`, `BINLOG::LOCK_index`.
- [Top-Level Instrument Components](#)
- [Idle Instrument Components](#)
- [Error Instrument Components](#)

- [Memory Instrument Components](#)
- [Stage Instrument Components](#)
- [Statement Instrument Components](#)
- [Wait Instrument Components](#)

Top-Level Instrument Components

- `idle`: An instrumented idle event. This instrument has no further components.
- `error`: An instrumented error event. This instrument has no further components.
- `memory`: An instrumented memory event.
- `stage`: An instrumented stage event.
- `statement`: An instrumented statement event.
- `transaction`: An instrumented transaction event. This instrument has no further components.
- `wait`: An instrumented wait event.

Idle Instrument Components

The `idle` instrument is used for idle events, which The Performance Schema generates as discussed in the description of the `socket_instances.STATE` column in [Section 25.11.3.5, “The socket_instances Table”](#).

Error Instrument Components

The `error` instrument indicates whether to collect information for server errors and warnings. This instrument is enabled by default. The `TIMED` column for the `error` row in the `setup_instruments` table is inapplicable because timing information is not collected.

Memory Instrument Components

Memory instrumentation is enabled by default. (Prior to 8.0.2, most memory instrumentation is disabled by default.) Memory instrumentation can be enabled or disabled at startup, or dynamically at runtime by updating the `ENABLED` column of the relevant instruments in the `setup_instruments` table. Memory instruments have names of the form `memory/code_area/instrument_name` where `code_area` is a value such as `sql` or `myisam`, and `instrument_name` is the instrument detail.

Instruments named with the prefix `memory/performance_schema/` expose how much memory is allocated for internal buffers in the Performance Schema. The `memory/performance_schema/` instruments are built in, always enabled, and cannot be disabled at startup or runtime. Built-in memory instruments are displayed only in the `memory_summary_global_by_event_name` table. For more information, see [Section 25.16, “The Performance Schema Memory-Allocation Model”](#).

Stage Instrument Components

Stage instruments have names of the form `stage/code_area/stage_name`, where `code_area` is a value such as `sql` or `myisam`, and `stage_name` indicates the stage of statement processing, such as `Sorting result` or `Sending data`. Stages correspond to the thread states displayed by `SHOW PROCESSLIST` or that are visible in the `INFORMATION_SCHEMA.PROCESSLIST` table.

Statement Instrument Components

- `statement/abstract/*`: An abstract instrument for statement operations. Abstract instruments are used during the early stages of statement classification before the exact statement type is

known, then changed to a more specific statement instrument when the type is known. For a description of this process, see [Section 25.11.6, “Performance Schema Statement Event Tables”](#).

- `statement/com`: An instrumented command operation. These have names corresponding to `COM_xxx` operations (see the `mysql_com.h` header file and `sql/sql_parse.cc`). For example, the `statement/com/Connect` and `statement/com/Init DB` instruments correspond to the `COM_CONNECT` and `COM_INIT_DB` commands.
- `statement/scheduler/event`: A single instrument to track all events executed by the Event Scheduler. This instrument comes into play when a scheduled event begins executing.
- `statement/sp`: An instrumented internal instruction executed by a stored program. For example, the `statement/sp/cfetch` and `statement/sp/freturn` instruments are used cursor fetch and function return instructions.
- `statement/sql`: An instrumented SQL statement operation. For example, the `statement/sql/create_db` and `statement/sql/select` instruments are used for `CREATE DATABASE` and `SELECT` statements.

Wait Instrument Components

- `wait/io`

An instrumented I/O operation.

- `wait/io/file`

An instrumented file I/O operation. For files, the wait is the time waiting for the file operation to complete (for example, a call to `fwrite()`). Due to caching, the physical file I/O on the disk might not happen within this call.

- `wait/io/socket`

An instrumented socket operation. Socket instruments have names of the form `wait/io/socket/sql/socket_type`. The server has a listening socket for each network protocol that it supports. The instruments associated with listening sockets for TCP/IP or Unix socket file connections have a `socket_type` value of `server_tcpip_socket` or `server_unix_socket`, respectively. When a listening socket detects a connection, the server transfers the connection to a new socket managed by a separate thread. The instrument for the new connection thread has a `socket_type` value of `client_connection`.

- `wait/io/table`

An instrumented table I/O operation. These include row-level accesses to persistent base tables or temporary tables. Operations that affect rows are fetch, insert, update, and delete. For a view, waits are associated with base tables referenced by the view.

Unlike most waits, a table I/O wait can include other waits. For example, table I/O might include file I/O or memory operations. Thus, `events_waits_current` for a table I/O wait usually has two rows. For more information, see [Section 25.8, “Performance Schema Atom and Molecule Events”](#).

Some row operations might cause multiple table I/O waits. For example, an insert might activate a trigger that causes an update.

- `wait/lock`

An instrumented lock operation.

- `wait/lock/table`

An instrumented table lock operation.

- `wait/lock/metadata/sql/mdl`

An instrumented metadata lock operation.

- `wait/synch`

An instrumented synchronization object. For synchronization objects, the `TIMER_WAIT` time includes the amount of time blocked while attempting to acquire a lock on the object, if any.

- `wait/synch/cond`

A condition is used by one thread to signal to other threads that something they were waiting for has happened. If a single thread was waiting for a condition, it can wake up and proceed with its execution. If several threads were waiting, they can all wake up and compete for the resource for which they were waiting.

- `wait/synch/mutex`

A mutual exclusion object used to permit access to a resource (such as a section of executable code) while preventing other threads from accessing the resource.

- `wait/synch/rwlock`

A [read/write lock](#) object used to lock a specific variable for access while preventing its use by other threads. A shared read lock can be acquired simultaneously by multiple threads. An exclusive write lock can be acquired by only one thread at a time.

- `wait/synch/sxlock`

A shared-exclusive (SX) lock is a type of [rwlock](#) lock object that provides write access to a common resource while permitting inconsistent reads by other threads. `sxlocks` optimize concurrency and improve scalability for read-write workloads.

25.7 Performance Schema Status Monitoring

There are several status variables associated with the Performance Schema:

```
mysql> SHOW STATUS LIKE 'perf%';
```

Variable_name	Value
Performance_schema_accounts_lost	0
Performance_schema_cond_classes_lost	0
Performance_schema_cond_instances_lost	0
Performance_schema_digest_lost	0
Performance_schema_file_classes_lost	0
Performance_schema_file_handles_lost	0
Performance_schema_file_instances_lost	0
Performance_schema_hosts_lost	0
Performance_schema_locker_lost	0
Performance_schema_memory_classes_lost	0
Performance_schema_metadata_lock_lost	0
Performance_schema_mutex_classes_lost	0
Performance_schema_mutex_instances_lost	0
Performance_schema_nested_statement_lost	0
Performance_schema_program_lost	0
Performance_schema_rwlock_classes_lost	0
Performance_schema_rwlock_instances_lost	0
Performance_schema_session_connect_attrs_lost	0
Performance_schema_socket_classes_lost	0
Performance_schema_socket_instances_lost	0
Performance_schema_stage_classes_lost	0
Performance_schema_statement_classes_lost	0
Performance_schema_table_handles_lost	0

Performance_schema_table_instances_lost	0
Performance_schema_thread_classes_lost	0
Performance_schema_thread_instances_lost	0
Performance_schema_users_lost	0

The Performance Schema status variables provide information about instrumentation that could not be loaded or created due to memory constraints. Names for these variables have several forms:

- `Performance_schema_XXX_classes_lost` indicates how many instruments of type `XXX` could not be loaded.
- `Performance_schema_XXX_instances_lost` indicates how many instances of object type `XXX` could not be created.
- `Performance_schema_XXX_handles_lost` indicates how many instances of object type `XXX` could not be opened.
- `Performance_schema_locker_lost` indicates how many events are “lost” or not recorded.

For example, if a mutex is instrumented in the server source but the server cannot allocate memory for the instrumentation at runtime, it increments `Performance_schema_mutex_classes_lost`. The mutex still functions as a synchronization object (that is, the server continues to function normally), but performance data for it will not be collected. If the instrument can be allocated, it can be used for initializing instrumented mutex instances. For a singleton mutex such as a global mutex, there will be only one instance. Other mutexes have an instance per connection, or per page in various caches and data buffers, so the number of instances varies over time. Increasing the maximum number of connections or the maximum size of some buffers will increase the maximum number of instances that might be allocated at once. If the server cannot create a given instrumented mutex instance, it increments `Performance_schema_mutex_instances_lost`.

Suppose that the following conditions hold:

- The server was started with the `--performance_schema_max_mutex_classes=200` option and thus has room for 200 mutex instruments.
- 150 mutex instruments have been loaded already.
- The plugin named `plugin_a` contains 40 mutex instruments.
- The plugin named `plugin_b` contains 20 mutex instruments.

The server allocates mutex instruments for the plugins depending on how many they need and how many are available, as illustrated by the following sequence of statements:

```
INSTALL PLUGIN plugin_a
```

The server now has $150+40 = 190$ mutex instruments.

```
UNINSTALL PLUGIN plugin_a;
```

The server still has 190 instruments. All the historical data generated by the plugin code is still available, but new events for the instruments are not collected.

```
INSTALL PLUGIN plugin_a;
```

The server detects that the 40 instruments are already defined, so no new instruments are created, and previously assigned internal memory buffers are reused. The server still has 190 instruments.

```
INSTALL PLUGIN plugin_b;
```

The server has room for $200 - 190 = 10$ instruments (in this case, mutex classes), and sees that the plugin contains 20 new instruments. 10 instruments are loaded, and 10 are discarded or “lost.” The `Performance_schema_mutex_classes_lost` indicates the number of instruments (mutex classes) lost:

```
mysql> SHOW STATUS LIKE "perf%mutex_classes_lost";
+-----+-----+
| Variable_name          | Value |
+-----+-----+
| Performance_schema_mutex_classes_lost | 10    |
+-----+-----+
1 row in set (0.10 sec)
```

The instrumentation still works and collects (partial) data for `plugin_b`.

When the server cannot create a mutex instrument, these results occur:

- No row for the instrument is inserted into the `setup_instruments` table.
- `Performance_schema_mutex_classes_lost` increases by 1.
- `Performance_schema_mutex_instances_lost` does not change. (When the mutex instrument is not created, it cannot be used to create instrumented mutex instances later.)

The pattern just described applies to all types of instruments, not just mutexes.

A value of `Performance_schema_mutex_classes_lost` greater than 0 can happen in two cases:

- To save a few bytes of memory, you start the server with `--performance_schema_max_mutex_classes=N`, where N is less than the default value. The default value is chosen to be sufficient to load all the plugins provided in the MySQL distribution, but this can be reduced if some plugins are never loaded. For example, you might choose not to load some of the storage engines in the distribution.
- You load a third-party plugin that is instrumented for the Performance Schema but do not allow for the plugin's instrumentation memory requirements when you start the server. Because it comes from a third party, the instrument memory consumption of this engine is not accounted for in the default value chosen for `performance_schema_max_mutex_classes`.

If the server has insufficient resources for the plugin's instruments and you do not explicitly allocate more using `--performance_schema_max_mutex_classes=N`, loading the plugin leads to starvation of instruments.

If the value chosen for `performance_schema_max_mutex_classes` is too small, no error is reported in the error log and there is no failure at runtime. However, the content of the tables in the `performance_schema` database will miss events. The `Performance_schema_mutex_classes_lost` status variable is the only visible sign to indicate that some events were dropped internally due to failure to create instruments.

If an instrument is not lost, it is known to the Performance Schema, and is used when instrumenting instances. For example, `wait/synch/mutex/sql/LOCK_delete` is the name of a mutex instrument in the `setup_instruments` table. This single instrument is used when creating a mutex in the code (in `THD::LOCK_delete`) however many instances of the mutex are needed as the server runs. In this case, `LOCK_delete` is a mutex that is per connection (`THD`), so if a server has 1000 connections, there are 1000 threads, and 1000 instrumented `LOCK_delete` mutex instances (`THD::LOCK_delete`).

If the server does not have room for all these 1000 instrumented mutexes (instances), some mutexes are created with instrumentation, and some are created without instrumentation. If the server can create only 800 instances, 200 instances are lost. The server continues to run, but increments `Performance_schema_mutex_instances_lost` by 200 to indicate that instances could not be created.

A value of `Performance_schema_mutex_instances_lost` greater than 0 can happen when the code initializes more mutexes at runtime than were allocated for `--performance_schema_max_mutex_instances=N`.

The bottom line is that if `SHOW STATUS LIKE 'perf%'` says that nothing was lost (all values are zero), the Performance Schema data is accurate and can be relied upon. If something was lost, the data is incomplete, and the Performance Schema could not record everything given the insufficient amount of memory it was given to use. In this case, the specific `Performance_schema_XXX_lost` variable indicates the problem area.

It might be appropriate in some cases to cause deliberate instrument starvation. For example, if you do not care about performance data for file I/O, you can start the server with all Performance Schema parameters related to file I/O set to 0. No memory will be allocated for file-related classes, instances, or handles, and all file events will be lost.

Use `SHOW ENGINE PERFORMANCE_SCHEMA STATUS` to inspect the internal operation of the Performance Schema code:

```
mysql> SHOW ENGINE PERFORMANCE_SCHEMA STATUS\G
...
***** 3. row *****
  Type: performance_schema
  Name: events_waits_history.size
Status: 76
***** 4. row *****
  Type: performance_schema
  Name: events_waits_history.count
Status: 10000
***** 5. row *****
  Type: performance_schema
  Name: events_waits_history.memory
Status: 760000
...
***** 57. row *****
  Type: performance_schema
  Name: performance_schema.memory
Status: 26459600
...
```

This statement is intended to help the DBA understand the effects that different Performance Schema options have on memory requirements. For a description of the field meanings, see [Section 13.7.5.15, “SHOW ENGINE Syntax”](#).

25.8 Performance Schema Atom and Molecule Events

For a table I/O event, there are usually two rows in `events_waits_current`, not one. For example, a row fetch might result in rows like this:

Row#	EVENT_NAME	TIMER_START	TIMER_END
1	wait/io/file/myisam/dfile	10001	10002
2	wait/io/table/sql/handler	10000	NULL

The row fetch causes a file read. In the example, the table I/O fetch event started before the file I/O event but has not finished (its `TIMER_END` value is `NULL`). The file I/O event is “nested” within the table I/O event.

This occurs because, unlike other “atomic” wait events such as for mutexes or file I/O, table I/O events are “molecular” and include (overlap with) other events. In `events_waits_current`, the table I/O event usually has two rows:

- One row for the most recent table I/O wait event

- One row for the most recent wait event of any kind

Usually, but not always, the “of any kind” wait event differs from the table I/O event. As each subsidiary event completes, it disappears from `events_waits_current`. At this point, and until the next subsidiary event begins, the table I/O wait is also the most recent wait of any kind.

25.9 Performance Schema Statement Digests

The MySQL server is capable of maintaining statement digest information. The digesting process converts each SQL statement to normalized form and computes a MD5 hash value from the normalized result. Normalization permits statements that are similar to be grouped and summarized to expose information about the types of statements the server is executing and how often they occur. This section describes how statement digesting occurs and how it can be useful.

Digesting occurs in the parser regardless of whether the Performance Schema is available, so that other server components such as query rewrite plugins have access to statement digests.

- [Statement Digest General Concepts](#)
- [Statement Digests in the Performance Schema](#)
- [Statement Digest Memory Use](#)

Statement Digest General Concepts

When the parser receives an SQL statement, it computes a statement digest if that digest is needed, which is true if any of the following conditions are true:

- Performance Schema digest instrumentation is enabled
- A Query Rewrite Plugin is enabled

The `max_digest_length` system variable value determines the maximum number of bytes available for computing normalized statement digests. Once that amount of space is used during digest computation, truncation occurs: no further tokens from a parsed statement are collected or figure into its digest value. Statements that differ only after that many bytes of parsed tokens produce the same normalized statement digest and are considered identical if compared or if aggregated for digest statistics.

After the normalized statement has been computed, an MD5 hash value is computed from it. In addition:

- If any Query Rewrite Plugin is enabled, it is called and the digest as computed is available to it.
- If the Performance Schema has digest instrumentation enabled, it makes a copy of the normalized statement digest, allocating a maximum of `performance_schema_max_digest_length` bytes for it. Consequently, if `performance_schema_max_digest_length` is less than `max_digest_length`, the copy is truncated relative to the original. The copy of the normalized statement is stored in the appropriate Performance Schema tables, along with the MD5 hash value computed from the original normalized statement. (If the Performance Schema truncates its copy of the normalized statement relative to the original, it does not recompute the MD5 hash value.)

Statement normalization transforms the statement text to a more standardized digest string representation that preserves the general statement structure while removing information not essential to the structure:

- Object identifiers such as database and table names are preserved.
- Literal values are converted to parameter markers. A normalized statement does not retain information such as names, passwords, dates, and so forth.
- Comments are removed and whitespace is adjusted.

Consider these statements:

```
SELECT * FROM orders WHERE customer_id=10 AND quantity>20
SELECT * FROM orders WHERE customer_id = 20 AND quantity > 100
```

To normalize these statements, the parser replaces data values by ? and adjusts whitespace. Both statements yield the same normalized form and thus are considered “the same”:

```
SELECT * FROM orders WHERE customer_id = ? AND quantity > ?
```

The normalized statement contains less information but is still representative of the original statement. Other similar statements that have different data values have the same normalized form.

Now consider these statements:

```
SELECT * FROM customers WHERE customer_id = 1000
SELECT * FROM orders WHERE customer_id = 1000
```

In this case, the normalized statements differ because the object identifiers differ:

```
SELECT * FROM customers WHERE customer_id = ?
SELECT * FROM orders WHERE customer_id = ?
```

If normalization produces a statement that exceeds the space available in the digest buffer (as determined by `max_digest_length`), truncation occurs and the text ends with “...”. Long normalized statements that differ only in the part that occurs following the “...” are considered the same. Consider these statements:

```
SELECT * FROM mytable WHERE cola = 10 AND colb = 20
SELECT * FROM mytable WHERE cola = 10 AND colc = 20
```

If the cutoff happens to be right after the `AND`, both statements have this normalized form:

```
SELECT * FROM mytable WHERE cola = ? AND ...
```

In this case, the difference in the second column name is lost and both statements are considered the same.

Statement Digests in the Performance Schema

In the Performance Schema, statement digesting involves these components:

- A `statements_digest` consumer in the `setup_consumers` table controls whether the Performance Schema maintains digest information. See [Statement Digest Consumer](#).
- The statement event tables (`events_statements_current`, `events_statements_history`, and `events_statements_history_long`) have columns for storing normalized statement digests and the corresponding digest MD5 hash values:
 - `DIGEST_TEXT` is the text of the normalized statement digest. This is a copy of the original normalized statement that was computed to a maximum of `max_digest_length` bytes, further truncated as necessary to `performance_schema_max_digest_length` bytes.
 - `DIGEST` is the digest MD5 hash value computed from the original normalized statement.

The statement event tables also have an `SQL_TEXT` column that contains the original SQL statement. The maximum space available for statement display is 1024 bytes by default. To change this value, set the `performance_schema_max_sql_text_length` system variable at server startup.

See [Section 25.11.6, “Performance Schema Statement Event Tables”](#).

- The `events_statements_summary_by_digest` summary table provides aggregated statement digest information. This table aggregates information for statements that have the same `SCHEMA_NAME` and `DIGEST` values. The Performance Schema uses MD5 hash values for aggregation because they are fast to compute and have a favorable statistical distribution that minimizes collisions. See [Section 25.11.15.3, “Statement Summary Tables”](#).

The `performance_schema_max_digest_length` system variable determines the maximum number of bytes available for digest value storage in the Performance Schema. However, the display length of statement digests may be longer than the available buffer size due to internal encoding of statement components such as keywords and literal values. Consequently, values selected from the `DIGEST_TEXT` column of statement event tables may appear to exceed the `performance_schema_max_digest_length` value.

The `events_statements_summary_by_digest` summary table provides a profile of the statements executed by the server. It shows what kinds of statements an application is executing and how often. An application developer can use this information together with other information in the table to assess the application's performance characteristics. For example, table columns that show wait times, lock times, or index use may highlight types of queries that are inefficient. This gives the developer insight into which parts of the application need attention.

The `events_statements_summary_by_digest` summary table has a fixed size. By default the Performance Schema estimates the size to use at startup. To specify the table size explicitly, set the `performance_schema_digests_size` system variable at server startup. If the table becomes full, the Performance Schema groups statements that have `SCHEMA_NAME` and `DIGEST` values not matching existing values in the table in a special row with `SCHEMA_NAME` and `DIGEST` set to `NULL`. This permits all statements to be counted. However, if the special row accounts for a significant percentage of the statements executed, it might be desirable to increase the summary table size by increasing `performance_schema_digests_size`.

Statement Digest Memory Use

For applications that generate very long statements that differ only at the end, increasing `max_digest_length` enables computation of digests that distinguish statements that would otherwise aggregate to the same digest. Conversely, decreasing `max_digest_length` causes the server to devote less memory to digest storage but increases the likelihood of longer statements aggregating to the same digest. Administrators should keep in mind that larger values result in correspondingly increased memory requirements, particularly for workloads that involve large numbers of simultaneous sessions (the server allocates `max_digest_length` bytes per session).

As described previously, normalized statement digests as computed by the parser are constrained to a maximum of `max_digest_length` bytes, whereas normalized statement digests stored in the Performance Schema use `performance_schema_max_digest_length` bytes. The following memory-use considerations apply regarding the relative values of `max_digest_length` and `performance_schema_max_digest_length`:

- If `max_digest_length` is less than `performance_schema_max_digest_length`:
 - Server components other than the Performance Schema use normalized statement digests that take up to `max_digest_length` bytes.
 - The Performance Schema does not further truncate normalized statement digests that it stores, but allocates more memory than `max_digest_length` bytes per digest, which is unnecessary.
- If `max_digest_length` equals `performance_schema_max_digest_length`:
 - Server components other than the Performance Schema use normalized statement digests that take up to `max_digest_length` bytes.

- The Performance Schema does not further truncate normalized statement digests that it stores, and allocates the same amount of memory as `max_digest_length` bytes per digest.
- If `max_digest_length` is greater than `performance_schema_max_digest_length`:
- Server components other than the Performance Schema use normalized statement digests that take up to `max_digest_length` bytes.
- The Performance Schema further truncates normalized statement digests that it stores, and allocates less memory than `max_digest_length` bytes per digest.

Because the Performance Schema statement event tables might store many digests, setting `performance_schema_max_digest_length` smaller than `max_digest_length` enables administrators to balance these factors:

- The need to have long normalized statement digests available for server components outside the Performance Schema
- Many concurrent sessions, each of which allocates digest-computation memory
- The need to limit memory consumption by the Performance Schema statement event tables when storing many statement digests

To assess the amount of memory used for SQL statement storage and digest computation, use the `SHOW ENGINE PERFORMANCE_SCHEMA STATUS` statement, or monitor these instruments:

```
mysql> SELECT NAME FROM setup_instruments
      WHERE NAME LIKE '%.sqltext';
+-----+-----+
| NAME                                     |
+-----+-----+
| memory/performance_schema/events_statements_history.sqltext |
| memory/performance_schema/events_statements_current.sqltext |
| memory/performance_schema/events_statements_history_long.sqltext |
+-----+-----+

mysql> SELECT NAME FROM setup_instruments
      WHERE NAME LIKE 'memory/performance_schema/%.tokens';
+-----+-----+
| NAME                                     |
+-----+-----+
| memory/performance_schema/events_statements_history.tokens |
| memory/performance_schema/events_statements_current.tokens |
| memory/performance_schema/events_statements_summary_by_digest.tokens |
| memory/performance_schema/events_statements_history_long.tokens |
+-----+-----+
```

25.10 Performance Schema General Table Characteristics

The name of the `performance_schema` database is lowercase, as are the names of tables within it. Queries should specify the names in lowercase.

Many tables in the `performance_schema` database are read only and cannot be modified:

```
mysql> TRUNCATE TABLE setup_instruments;
ERROR 1683 (HY000): Invalid performance_schema usage.
```

Some of the setup tables have columns that can be modified to affect Performance Schema operation; some also permit rows to be inserted or deleted. Truncation is permitted to clear collected events, so `TRUNCATE TABLE` can be used on tables containing those kinds of information, such as tables named with a prefix of `events_waits_`.

Summary tables can be truncated with `TRUNCATE TABLE`. Generally, the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. This enables you to clear collected values and restart aggregation. That might be useful, for example, after you have made a runtime configuration change. Exceptions to this truncation behavior are noted in individual summary table sections.

Privileges are as for other databases and tables:

- To retrieve from `performance_schema` tables, you must have the `SELECT` privilege.
- To change those columns that can be modified, you must have the `UPDATE` privilege.
- To truncate tables that can be truncated, you must have the `DROP` privilege.

Because only a limited set of privileges apply to Performance Schema tables, attempts to use `GRANT ALL` as shorthand for granting privileges at the database or table level fail with an error:

```
mysql> GRANT ALL ON performance_schema.*
      TO 'u1'@'localhost';
ERROR 1044 (42000): Access denied for user 'root'@'localhost'
to database 'performance_schema'
mysql> GRANT ALL ON performance_schema.setup_instruments
      TO 'u2'@'localhost';
ERROR 1044 (42000): Access denied for user 'root'@'localhost'
to database 'performance_schema'
```

Instead, grant exactly the desired privileges:

```
mysql> GRANT SELECT ON performance_schema.*
      TO 'u1'@'localhost';
Query OK, 0 rows affected (0.03 sec)

mysql> GRANT SELECT, UPDATE ON performance_schema.setup_instruments
      TO 'u2'@'localhost';
Query OK, 0 rows affected (0.02 sec)
```

25.11 Performance Schema Table Descriptions

Tables in the `performance_schema` database can be grouped as follows:

- Setup tables. These tables are used to configure and display monitoring characteristics.
- Current events tables. The `events_waits_current` table contains the most recent event for each thread. Other similar tables contain current events at different levels of the event hierarchy: `events_stages_current` for stage events, `events_statements_current` for statement events, and `events_transactions_current` for transaction events.
- History tables. These tables have the same structure as the current events tables, but contain more rows. For example, for wait events, `events_waits_history` table contains the most recent 10 events per thread. `events_waits_history_long` contains the most recent 10,000 events. Other similar tables exist for stage, statement, and transaction histories.

To change the sizes of the history tables, set the appropriate system variables at server startup. For example, to set the sizes of the wait event history tables, set `performance_schema_events_waits_history_size` and `performance_schema_events_waits_history_long_size`.

- Summary tables. These tables contain information aggregated over groups of events, including those that have been discarded from the history tables.
- Instance tables. These tables document what types of objects are instrumented. An instrumented object, when used by the server, produces an event. These tables provide event names and explanatory notes or status information.
- Miscellaneous tables. These do not fall into any of the other table groups.

25.11.1 Performance Schema Table Index

The following table lists each Performance Schema table and provides a short description of each one.

Table 25.1 Performance Schema Tables

Table Name	Description
accounts	Connection statistics per client account
cond_instances	synchronization object instances
data_lock_waits	Data lock wait relationships
data_locks	Data locks held and requested
events_errors_summary_by_account_by_error	Errors per error code and account
events_errors_summary_by_host_by_error	Errors per error code and host
events_errors_summary_by_thread_by_error	Errors per error code and host
events_errors_summary_by_user_by_error	Errors per error code and host
events_errors_summary_global_by_error	Errors per error code
events_stages_current	Current stage events
events_stages_history	Most recent stage events for each thread
events_stages_history_long	Most recent stage events overall
events_stages_summary_by_account_by_event_name	Stage events per account and event name
events_stages_summary_by_host_by_event_name	Stage events per host name and event name
events_stages_summary_by_thread_by_event_name	Stage waits per thread and event name
events_stages_summary_by_user_by_event_name	Stage events per user name and event name
events_stages_summary_global_by_event_name	Stage waits per event name
events_statements_current	Current statement events
events_statements_histogram_by_digest	Statement histograms per schema and digest value
events_statements_histogram_global	Statement histogram summarized globally
events_statements_history	Most recent statement events for each thread
events_statements_history_long	Most recent statement events overall
events_statements_summary_by_account_by_event_name	Statement events per account and event name
events_statements_summary_by_digest	Statement events per schema and digest value
events_statements_summary_by_host_by_event_name	Statement events per host name and event name
events_statements_summary_by_program	Statement events per stored program
events_statements_summary_by_thread_by_event_name	Statement events per thread and event name
events_statements_summary_by_user_by_event_name	Statement events per user name and event name
events_statements_summary_global_by_event_name	Statement events per event name
events_transactions_current	Current transaction events
events_transactions_history	Most recent transaction events for each thread
events_transactions_history_long	Most recent transaction events overall

Performance Schema Table Index

Table Name	Description
events_transactions_summary_by_account_by_event_name	Transaction events per account and event name
events_transactions_summary_by_host_by_event_name	Transaction events per host name and event name
events_transactions_summary_by_thread_by_event_name	Transaction events per thread and event name
events_transactions_summary_by_user_by_event_name	Transaction events per user name and event name
events_transactions_summary_global_by_event_name	Transaction events per event name
events_waits_current	Current wait events
events_waits_history	Most recent wait events for each thread
events_waits_history_long	Most recent wait events overall
events_waits_summary_by_account_by_event_name	Wait events per account and event name
events_waits_summary_by_host_by_event_name	Wait events per host name and event name
events_waits_summary_by_instance	Wait events per instance
events_waits_summary_by_thread_by_event_name	Wait events per thread and event name
events_waits_summary_by_user_by_event_name	Wait events per user name and event name
events_waits_summary_global_by_event_name	Wait events per event name
file_instances	File instances
file_summary_by_event_name	File events per event name
file_summary_by_instance	File events per file instance
global_status	Global status variables
global_variables	Global system variables
host_cache	Information from the internal host cache
hosts	Connection statistics per client host name
memory_summary_by_account_by_event_name	Memory operations per account and event name
memory_summary_by_host_by_event_name	Memory operations per host and event name
memory_summary_by_thread_by_event_name	Memory operations per thread and event name
memory_summary_by_user_by_event_name	Memory operations per user and event name
memory_summary_global_by_event_name	Memory operations globally per event name
metadata_locks	Metadata locks and lock requests
mutex_instances	Mutex synchronization object instances
objects_summary_global_by_type	Object summaries
performance_timers	Which event timers are available
persisted_variables	Contents of <code>mysqld-auto.cnf</code> file
prepared_statements_instances	Prepared statement instances and statistics
replication_applier_configuration	Configuration parameters for the transaction applier on the slave
replication_applier_status	Current status of the transaction applier on the slave
replication_applier_status_by_coordinator	SQL or coordinator thread applier status

Table Name	Description
<code>replication_applier_status_by_worker</code>	Worker thread applier status (empty unless slave is multi-threaded)
<code>replication_connection_configuration</code>	Configuration parameters for connecting to the master
<code>replication_connection_status</code>	Current status of the connection to the master
<code>rwlock_instances</code>	Lock synchronization object instances
<code>session_account_connect_attrs</code>	Connection attributes per for the current session
<code>session_connect_attrs</code>	Connection attributes for all sessions
<code>session_status</code>	Status variables for current session
<code>session_variables</code>	System variables for current session
<code>setup_actors</code>	How to initialize monitoring for new foreground threads
<code>setup_consumers</code>	Consumers for which event information can be stored
<code>setup_instruments</code>	Classes of instrumented objects for which events can be collected
<code>setup_objects</code>	Which objects should be monitored
<code>setup_timers</code>	Current event timer
<code>socket_instances</code>	Active connection instances
<code>socket_summary_by_event_name</code>	Socket waits and I/O per event name
<code>socket_summary_by_instance</code>	Socket waits and I/O per instance
<code>status_by_account</code>	Session status variables per account
<code>status_by_host</code>	Session status variables per host name
<code>status_by_thread</code>	Session status variables per session
<code>status_by_user</code>	Session status variables per user name
<code>table_handles</code>	Table locks and lock requests
<code>table_io_waits_summary_by_index_usage</code>	Table I/O waits per index
<code>table_io_waits_summary_by_table</code>	Table I/O waits per table
<code>table_lock_waits_summary_by_table</code>	Table lock waits per table
<code>threads</code>	Information about server threads
<code>user_defined_functions</code>	Registered user-defined functions
<code>user_variables_by_thread</code>	User-defined variables per thread
<code>users</code>	Connection statistics per client user name
<code>variables_by_thread</code>	Session system variables per session
<code>variables_info</code>	How system variables were most recently set

25.11.2 Performance Schema Setup Tables

The setup tables provide information about the current instrumentation and enable the monitoring configuration to be changed. For this reason, some columns in these tables can be changed if you have the `UPDATE` privilege.

The use of tables rather than individual variables for setup information provides a high degree of flexibility in modifying Performance Schema configuration. For example, you can use a single statement with standard SQL syntax to make multiple simultaneous configuration changes.

These setup tables are available:

- `setup_actors`: How to initialize monitoring for new foreground threads
- `setup_consumers`: The destinations to which event information can be sent and stored
- `setup_instruments`: The classes of instrumented objects for which events can be collected
- `setup_objects`: Which objects should be monitored
- `setup_timers`: The current event timer

25.11.2.1 The `setup_actors` Table

The `setup_actors` table contains information that determines whether to enable monitoring and historical event logging for new foreground server threads (threads associated with client connections). This table has a maximum size of 100 rows by default. To change the table size, modify the `performance_schema_setup_actors_size` system variable at server startup.

For each new foreground thread, the Performance Schema matches the user and host for the thread against the rows of the `setup_actors` table. If a row from that table matches, its `ENABLED` and `HISTORY` column values are used to set the `INSTRUMENTED` and `HISTORY` columns, respectively, of the `threads` table row for the thread. This enables instrumenting and historical event logging to be applied selectively per host, user, or account (user and host combination). If there is no match, the `INSTRUMENTED` and `HISTORY` columns for the thread are set to `NO`.

For background threads, there is no associated user. `INSTRUMENTED` and `HISTORY` are `YES` by default and `setup_actors` is not consulted.

The initial contents of the `setup_actors` table match any user and host combination, so monitoring and historical event collection are enabled by default for all foreground threads:

```
mysql> SELECT * FROM setup_actors;
+-----+-----+-----+-----+-----+
| HOST | USER | ROLE | ENABLED | HISTORY |
+-----+-----+-----+-----+-----+
| %    | %    | %    | YES     | YES     |
+-----+-----+-----+-----+-----+
```

For information about how to use the `setup_actors` table to affect event monitoring, see [Section 25.4.6, “Pre-Filtering by Thread”](#).

Modifications to the `setup_actors` table affect only foreground threads created subsequent to the modification, not existing threads. To affect existing threads, modify the `INSTRUMENTED` and `HISTORY` columns of `threads` table rows.

The `setup_actors` table has these columns:

- `HOST`
The host name. This should be a literal name, or `'%'` to mean “any host.”
- `USER`
The user name. This should be a literal name, or `'%'` to mean “any user.”
- `ROLE`
Unused.

- [ENABLED](#)

Whether to enable instrumentation for foreground threads matched by the row. The value is [YES](#) or [NO](#).

- [HISTORY](#)

Whether to log historical events for foreground threads matched by the row. The value is [YES](#) or [NO](#).

The `setup_actors` table has these indexes:

- Primary key on ([HOST](#), [USER](#), [ROLE](#))

`TRUNCATE TABLE` is permitted for the `setup_actors` table. It removes the rows.

25.11.2.2 The `setup_consumers` Table

The `setup_consumers` table lists the types of consumers for which event information can be stored and which are enabled:

```
mysql> SELECT * FROM setup_consumers;
```

NAME	ENABLED
events_stages_current	NO
events_stages_history	NO
events_stages_history_long	NO
events_statements_current	YES
events_statements_history	YES
events_statements_history_long	NO
events_transactions_current	YES
events_transactions_history	YES
events_transactions_history_long	NO
events_waits_current	NO
events_waits_history	NO
events_waits_history_long	NO
global_instrumentation	YES
thread_instrumentation	YES
statements_digest	YES

The consumer settings in the `setup_consumers` table form a hierarchy from higher levels to lower. For detailed information about the effect of enabling different consumers, see [Section 25.4.7, “Pre-Filtering by Consumer”](#).

Modifications to the `setup_consumers` table affect monitoring immediately.

The `setup_consumers` table has these columns:

- [NAME](#)

The consumer name.

- [ENABLED](#)

Whether the consumer is enabled. The value is [YES](#) or [NO](#). This column can be modified. If you disable a consumer, the server does not spend time adding event information to it.

The `setup_consumers` table has these indexes:

- Primary key on ([NAME](#))

`TRUNCATE TABLE` is not permitted for the `setup_consumers` table.

25.11.2.3 The `setup_instruments` Table

The `setup_instruments` table lists classes of instrumented objects for which events can be collected:

```
mysql> SELECT * FROM setup_instruments;
```

NAME	ENABLED	TIMED
...		
wait/synch/mutex/sql/LOCK_global_read_lock	YES	YES
wait/synch/mutex/sql/LOCK_global_system_variables	YES	YES
wait/synch/mutex/sql/LOCK_lock_db	YES	YES
wait/synch/mutex/sql/LOCK_manager	YES	YES
...		
wait/synch/rwlock/sql/LOCK_grant	YES	YES
wait/synch/rwlock/sql/LOGGER::LOCK_logger	YES	YES
wait/synch/rwlock/sql/LOCK_sys_init_connect	YES	YES
wait/synch/rwlock/sql/LOCK_sys_init_slave	YES	YES
...		
wait/io/file/sql/binlog	YES	YES
wait/io/file/sql/binlog_index	YES	YES
wait/io/file/sql/casetest	YES	YES
wait/io/file/sql/dbopt	YES	YES
...		

Each instrument added to the source code provides a row for this table, even when the instrumented code is not executed. When an instrument is enabled and executed, instrumented instances are created, which are visible in the `*_instances` tables.

Modifications to most `setup_instruments` rows affect monitoring immediately. For some instruments, modifications are effective only at server startup; changing them at runtime has no effect. This affects primarily mutexes, conditions, and rwlocks in the server, although there may be other instruments for which this is true.

For more information about the role of the `setup_instruments` table in event filtering, see [Section 25.4.3, “Event Pre-Filtering”](#).

The `setup_instruments` table has these columns:

- **NAME**

The instrument name. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 25.6, “Performance Schema Instrument Naming Conventions”](#). Events produced from execution of an instrument have an `EVENT_NAME` value that is taken from the instrument `NAME` value. (Events do not really have a “name,” but this provides a way to associate events with instruments.)

- **ENABLED**

Whether the instrument is enabled. The value is `YES` or `NO`. This column can be modified. A disabled instrument produces no events.

- **TIMED**

Whether the instrument is timed. This column can be modified.

For memory instruments, the `TIMED` column in `setup_instruments` is ignored because memory operations are not timed.

If an enabled instrument is not timed, the instrument code is enabled, but the timer is not. Events produced by the instrument have `NULL` for the `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` timer values. This in turn causes those values to be ignored when calculating the sum, minimum, maximum, and average time values in summary tables.

The `setup_instruments` table has these indexes:

- Primary key on (NAME)

`TRUNCATE TABLE` is not permitted for the `setup_instruments` table.

25.11.2.4 The `setup_objects` Table

The `setup_objects` table controls whether the Performance Schema monitors particular objects. This table has a maximum size of 100 rows by default. To change the table size, modify the `performance_schema_setup_objects_size` system variable at server startup.

The initial `setup_objects` contents look like this:

```
mysql> SELECT * FROM setup_objects;
```

OBJECT_TYPE	OBJECT_SCHEMA	OBJECT_NAME	ENABLED	TIMED
EVENT	mysql	%	NO	NO
EVENT	performance_schema	%	NO	NO
EVENT	information_schema	%	NO	NO
EVENT	%	%	YES	YES
FUNCTION	mysql	%	NO	NO
FUNCTION	performance_schema	%	NO	NO
FUNCTION	information_schema	%	NO	NO
FUNCTION	%	%	YES	YES
PROCEDURE	mysql	%	NO	NO
PROCEDURE	performance_schema	%	NO	NO
PROCEDURE	information_schema	%	NO	NO
PROCEDURE	%	%	YES	YES
TABLE	mysql	%	NO	NO
TABLE	performance_schema	%	NO	NO
TABLE	information_schema	%	NO	NO
TABLE	%	%	YES	YES
TRIGGER	mysql	%	NO	NO
TRIGGER	performance_schema	%	NO	NO
TRIGGER	information_schema	%	NO	NO
TRIGGER	%	%	YES	YES

Modifications to the `setup_objects` table affect object monitoring immediately.

For object types listed in `setup_objects`, the Performance Schema uses the table to how to monitor them. Object matching is based on the `OBJECT_SCHEMA` and `OBJECT_NAME` columns. Objects for which there is no match are not monitored.

The effect of the default object configuration is to instrument all tables except those in the `mysql`, `INFORMATION_SCHEMA`, and `performance_schema` databases. (Tables in the `INFORMATION_SCHEMA` database are not instrumented regardless of the contents of `setup_objects`; the row for `information_schema.%` simply makes this default explicit.)

When the Performance Schema checks for a match in `setup_objects`, it tries to find more specific matches first. For example, with a table `db1.t1`, it looks for a match for `'db1'` and `'t1'`, then for `'db1'` and `'%'`, then for `'%'` and `'%'`. The order in which matching occurs matters because different matching `setup_objects` rows can have different `ENABLED` and `TIMED` values.

Rows can be inserted into or deleted from `setup_objects` by users with the `INSERT` or `DELETE` privilege on the table. For existing rows, only the `ENABLED` and `TIMED` columns can be modified, by users with the `UPDATE` privilege on the table.

For more information about the role of the `setup_objects` table in event filtering, see [Section 25.4.3, “Event Pre-Filtering”](#).

The `setup_objects` table has these columns:

- `OBJECT_TYPE`

The type of object to instrument. The value is one of 'EVENT' (Event Scheduler event), 'FUNCTION' (stored function), 'PROCEDURE' (stored procedure), 'TABLE' (base table), or 'TRIGGER' (trigger).

`TABLE` filtering affects table I/O events (`wait/io/table/sql/handler` instrument) and table lock events (`wait/lock/table/sql/handler` instrument).

- `OBJECT_SCHEMA`

The schema that contains the object. This should be a literal name, or '%' to mean “any schema.”

- `OBJECT_NAME`

The name of the instrumented object. This should be a literal name, or '%' to mean “any object.”

- `ENABLED`

Whether events for the object are instrumented. The value is `YES` or `NO`. This column can be modified.

- `TIMED`

Whether events for the object are timed. This column can be modified.

The `setup_objects` table has these indexes:

- Index on (`OBJECT_TYPE`, `OBJECT_SCHEMA`, `OBJECT_NAME`)

`TRUNCATE TABLE` is permitted for the `setup_objects` table. It removes the rows.

25.11.2.5 The `setup_timers` Table

The `setup_timers` table shows the currently selected event timers:

```
mysql> SELECT * FROM setup_timers;
+-----+-----+
| NAME          | TIMER_NAME |
+-----+-----+
| idle          | MICROSECOND |
| wait          | CYCLE      |
| stage         | NANOSECOND |
| statement     | NANOSECOND |
| transaction   | NANOSECOND |
+-----+-----+
```

The `setup_timers.TIMER_NAME` value can be changed to select a different timer. The value can be any of the values in the `performance_timers.TIMER_NAME` column. For an explanation of how event timing occurs, see [Section 25.4.1, “Performance Schema Event Timing”](#).

Modifications to the `setup_timers` table affect monitoring immediately. Events already in progress may use the original timer for the begin time and the new timer for the end time. To avoid unpredictable results after you make timer changes, use `TRUNCATE TABLE` to reset Performance Schema statistics.

The `setup_timers` table has these columns:

- `NAME`

The type of instrument the timer is used for.

- `TIMER_NAME`

The timer that applies to the instrument type. This column can be modified.

The `setup_timers` table has these indexes:

- Primary key on ([NAME](#))

`TRUNCATE TABLE` is not permitted for the `setup_timers` table.

25.11.3 Performance Schema Instance Tables

Instance tables document what types of objects are instrumented. They provide event names and explanatory notes or status information:

- `cond_instances`: Condition synchronization object instances
- `file_instances`: File instances
- `mutex_instances`: Mutex synchronization object instances
- `rwlock_instances`: Lock synchronization object instances
- `socket_instances`: Active connection instances

These tables list instrumented synchronization objects, files, and connections. There are three types of synchronization objects: `cond`, `mutex`, and `rwlock`. Each instance table has an `EVENT_NAME` or `NAME` column to indicate the instrument associated with each row. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 25.6, “Performance Schema Instrument Naming Conventions”](#).

The `mutex_instances.LOCKED_BY_THREAD_ID` and `rwlock_instances.WRITE_LOCKED_BY_THREAD_ID` columns are extremely important for investigating performance bottlenecks or deadlocks. For examples of how to use them for this purpose, see [Section 25.18, “Using the Performance Schema to Diagnose Problems”](#)

25.11.3.1 The `cond_instances` Table

The `cond_instances` table lists all the conditions seen by the Performance Schema while the server executes. A condition is a synchronization mechanism used in the code to signal that a specific event has happened, so that a thread waiting for this condition can resume work.

When a thread is waiting for something to happen, the condition name is an indication of what the thread is waiting for, but there is no immediate way to tell which other thread, or threads, will cause the condition to happen.

The `cond_instances` table has these columns:

- `NAME`

The instrument name associated with the condition.

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the instrumented condition.

The `cond_instances` table has these indexes:

- Primary key on (`OBJECT_INSTANCE_BEGIN`)
- Index on (`NAME`)

`TRUNCATE TABLE` is not permitted for the `cond_instances` table.

25.11.3.2 The `file_instances` Table

The `file_instances` table lists all the files seen by the Performance Schema when executing file I/O instrumentation. If a file on disk has never been opened, it will not be in `file_instances`. When a file is deleted from the disk, it is also removed from the `file_instances` table.

The `file_instances` table has these columns:

- `FILE_NAME`

The file name.

- `EVENT_NAME`

The instrument name associated with the file.

- `OPEN_COUNT`

The count of open handles on the file. If a file was opened and then closed, it was opened 1 time, but `OPEN_COUNT` will be 0. To list all the files currently opened by the server, use `WHERE OPEN_COUNT > 0`.

The `file_instances` table has these indexes:

- Primary key on (`FILE_NAME`)
- Index on (`EVENT_NAME`)

`TRUNCATE TABLE` is not permitted for the `file_instances` table.

25.11.3.3 The `mutex_instances` Table

The `mutex_instances` table lists all the mutexes seen by the Performance Schema while the server executes. A mutex is a synchronization mechanism used in the code to enforce that only one thread at a given time can have access to some common resource. The resource is said to be “protected” by the mutex.

When two threads executing in the server (for example, two user sessions executing a query simultaneously) do need to access the same resource (a file, a buffer, or some piece of data), these two threads will compete against each other, so that the first query to obtain a lock on the mutex will cause the other query to wait until the first is done and unlocks the mutex.

The work performed while holding a mutex is said to be in a “critical section,” and multiple queries do execute this critical section in a serialized way (one at a time), which is a potential bottleneck.

The `mutex_instances` table has these columns:

- `NAME`

The instrument name associated with the mutex.

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the instrumented mutex.

- `LOCKED_BY_THREAD_ID`

When a thread currently has a mutex locked, `LOCKED_BY_THREAD_ID` is the `THREAD_ID` of the locking thread, otherwise it is `NULL`.

The `mutex_instances` table has these indexes:

- Primary key on (`OBJECT_INSTANCE_BEGIN`)
- Index on (`NAME`)
- Index on (`LOCKED_BY_THREAD_ID`)

`TRUNCATE TABLE` is not permitted for the `mutex_instances` table.

For every mutex instrumented in the code, the Performance Schema provides the following information.

- The `setup_instruments` table lists the name of the instrumentation point, with the prefix `wait/synch/mutex/`.
- When some code creates a mutex, a row is added to the `mutex_instances` table. The `OBJECT_INSTANCE_BEGIN` column is a property that uniquely identifies the mutex.
- When a thread attempts to lock a mutex, the `events_waits_current` table shows a row for that thread, indicating that it is waiting on a mutex (in the `EVENT_NAME` column), and indicating which mutex is waited on (in the `OBJECT_INSTANCE_BEGIN` column).
- When a thread succeeds in locking a mutex:
 - `events_waits_current` shows that the wait on the mutex is completed (in the `TIMER_END` and `TIMER_WAIT` columns)
 - The completed wait event is added to the `events_waits_history` and `events_waits_history_long` tables
 - `mutex_instances` shows that the mutex is now owned by the thread (in the `THREAD_ID` column).
- When a thread unlocks a mutex, `mutex_instances` shows that the mutex now has no owner (the `THREAD_ID` column is `NULL`).
- When a mutex object is destroyed, the corresponding row is removed from `mutex_instances`.

By performing queries on both of the following tables, a monitoring application or a DBA can detect bottlenecks or deadlocks between threads that involve mutexes:

- `events_waits_current`, to see what mutex a thread is waiting for
- `mutex_instances`, to see which other thread currently owns a mutex

25.11.3.4 The `rwlock_instances` Table

The `rwlock_instances` table lists all the `rwlock` (read write lock) instances seen by the Performance Schema while the server executes. An `rwlock` is a synchronization mechanism used in the code to enforce that threads at a given time can have access to some common resource following certain rules. The resource is said to be “protected” by the `rwlock`. The access is either shared (many threads can have a read lock at the same time), exclusive (only one thread can have a write lock at a given time), or shared-exclusive (a thread can have a write lock while permitting inconsistent reads by other threads). Shared-exclusive access is otherwise known as an `sxlock` and optimizes concurrency and improves scalability for read-write workloads.

Depending on how many threads are requesting a lock, and the nature of the locks requested, access can be either granted in shared mode, exclusive mode, shared-exclusive mode or not granted at all, waiting for other threads to finish first.

The `rwlock_instances` table has these columns:

- `NAME`
The instrument name associated with the lock.
- `OBJECT_INSTANCE_BEGIN`
The address in memory of the instrumented lock.
- `WRITE_LOCKED_BY_THREAD_ID`

When a thread currently has an `rwlock` locked in exclusive (write) mode, `WRITE_LOCKED_BY_THREAD_ID` is the `THREAD_ID` of the locking thread, otherwise it is `NULL`.

- `READ_LOCKED_BY_COUNT`

When a thread currently has an `rwlock` locked in shared (read) mode, `READ_LOCKED_BY_COUNT` is incremented by 1. This is a counter only, so it cannot be used directly to find which thread holds a read lock, but it can be used to see whether there is a read contention on an `rwlock`, and see how many readers are currently active.

The `rwlock_instances` table has these indexes:

- Primary key on (`OBJECT_INSTANCE_BEGIN`)
- Index on (`NAME`)
- Index on (`WRITE_LOCKED_BY_THREAD_ID`)

`TRUNCATE TABLE` is not permitted for the `rwlock_instances` table.

By performing queries on both of the following tables, a monitoring application or a DBA may detect some bottlenecks or deadlocks between threads that involve locks:

- `events_waits_current`, to see what `rwlock` a thread is waiting for
- `rwlock_instances`, to see which other thread currently owns an `rwlock`

There is a limitation: The `rwlock_instances` can be used only to identify the thread holding a write lock, but not the threads holding a read lock.

25.11.3.5 The `socket_instances` Table

The `socket_instances` table provides a real-time snapshot of the active connections to the MySQL server. The table contains one row per TCP/IP or Unix socket file connection. Information available in this table provides a real-time snapshot of the active connections to the server. (Additional information is available in socket summary tables, including network activity such as socket operations and number of bytes transmitted and received; see [Section 25.11.15.9, "Socket Summary Tables"](#)).

```
mysql> SELECT * FROM socket_instances\G
***** 1. row *****
      EVENT_NAME: wait/io/socket/sql/server_unix_socket
OBJECT_INSTANCE_BEGIN: 4316619408
      THREAD_ID: 1
      SOCKET_ID: 16
         IP:
      PORT: 0
      STATE: ACTIVE
***** 2. row *****
      EVENT_NAME: wait/io/socket/sql/client_connection
OBJECT_INSTANCE_BEGIN: 4316644608
      THREAD_ID: 21
      SOCKET_ID: 39
         IP: 127.0.0.1
      PORT: 55233
      STATE: ACTIVE
***** 3. row *****
      EVENT_NAME: wait/io/socket/sql/server_tcpip_socket
OBJECT_INSTANCE_BEGIN: 4316699040
      THREAD_ID: 1
      SOCKET_ID: 14
         IP: 0.0.0.0
      PORT: 50603
      STATE: ACTIVE
```

Socket instruments have names of the form `wait/io/socket/sql/socket_type` and are used like this:

1. The server has a listening socket for each network protocol that it supports. The instruments associated with listening sockets for TCP/IP or Unix socket file connections have a `socket_type` value of `server_tcpip_socket` or `server_unix_socket`, respectively.
2. When a listening socket detects a connection, the server transfers the connection to a new socket managed by a separate thread. The instrument for the new connection thread has a `socket_type` value of `client_connection`.
3. When a connection terminates, the row in `socket_instances` corresponding to it is deleted.

The `socket_instances` table has these columns:

- `EVENT_NAME`

The name of the `wait/io/socket/*` instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 25.6, “Performance Schema Instrument Naming Conventions”](#).

- `OBJECT_INSTANCE_BEGIN`

This column uniquely identifies the socket. The value is the address of an object in memory.

- `THREAD_ID`

The internal thread identifier assigned by the server. Each socket is managed by a single thread, so each socket can be mapped to a thread which can be mapped to a server process.

- `SOCKET_ID`

The internal file handle assigned to the socket.

- `IP`

The client IP address. The value may be either an IPv4 or IPv6 address, or blank to indicate a Unix socket file connection.

- `PORT`

The TCP/IP port number, in the range from 0 to 65535.

- `STATE`

The socket status, either `IDLE` or `ACTIVE`. Wait times for active sockets are tracked using the corresponding socket instrument. Wait times for idle sockets are tracked using the `idle` instrument.

A socket is idle if it is waiting for a request from the client. When a socket becomes idle, the event row in `socket_instances` that is tracking the socket switches from a status of `ACTIVE` to `IDLE`. The `EVENT_NAME` value remains `wait/io/socket/*`, but timing for the instrument is suspended. Instead, an event is generated in the `events_waits_current` table with an `EVENT_NAME` value of `idle`.

When the next request is received, the `idle` event terminates, the socket instance switches from `IDLE` to `ACTIVE`, and timing of the socket instrument resumes.

The `socket_instances` table has these indexes:

- Primary key on (`OBJECT_INSTANCE_BEGIN`)
- Index on (`THREAD_ID`)
- Index on (`SOCKET_ID`)

- Index on (IP, PORT)

TRUNCATE TABLE is not permitted for the `socket_instances` table.

The IP:PORT column combination value identifies the connection. This combination value is used in the OBJECT_NAME column of the `events_waits_XXX` tables, to identify the connection from which socket events come:

- For the Unix domain listener socket (`server_unix_socket`), the port is 0, and the IP is ''.
- For client connections via the Unix domain listener (`client_connection`), the port is 0, and the IP is ''.
- For the TCP/IP server listener socket (`server_tcpip_socket`), the port is always the master port (for example, 3306), and the IP is always 0.0.0.0.
- For client connections via the TCP/IP listener (`client_connection`), the port is whatever the server assigns, but never 0. The IP is the IP of the originating host (127.0.0.1 or ::1 for the local host)

25.11.4 Performance Schema Wait Event Tables

The Performance Schema instruments waits, which are events that take time. Within the event hierarchy, wait events nest within stage events, which nest within statement events, which nest within transaction events.

These tables store wait events:

- `events_waits_current`: Current wait events
- `events_waits_history`: The most recent wait events per thread
- `events_waits_history_long`: The most recent wait events globally (across all threads)

The following sections describe the wait event tables. There are also summary tables that aggregate information about wait events; see [Section 25.11.15.1, “Wait Event Summary Tables”](#).

Wait Event Configuration

To control collection of wait events, set the state of the relevant instruments and consumers:

- The `setup_instruments` table contains instruments with names that begin with `wait`. Use these instruments to enable or disable collection of wait events.
- The `setup_consumers` table contains consumer values with names corresponding to the current and recent wait event table names. Use these consumers to filter collection of wait events.

Some wait instruments are enabled by default; others are disabled. For example:

```
mysql> SELECT * FROM setup_instruments
      WHERE NAME LIKE 'wait/io/file/innodb%';
+-----+-----+-----+
| NAME                                     | ENABLED | TIMED |
+-----+-----+-----+
| wait/io/file/innodb/innodb_data_file    | YES     | YES   |
| wait/io/file/innodb/innodb_log_file     | YES     | YES   |
| wait/io/file/innodb/innodb_temp_file    | YES     | YES   |
+-----+-----+-----+
mysql> SELECT * FROM setup_instruments WHERE
      NAME LIKE 'wait/io/socket/%';
+-----+-----+-----+
| NAME                                     | ENABLED | TIMED |
+-----+-----+-----+
| wait/io/socket/sql/server_tcpip_socket  | NO      | NO    |
| wait/io/socket/sql/server_unix_socket   | NO      | NO    |
+-----+-----+-----+
```

wait/io/socket/sql/client_connection	NO	NO	
-----+	-----+	-----+	-----+

The wait consumers are disabled by default:

```
mysql> SELECT * FROM setup_consumers WHERE NAME LIKE '%waits%';
+-----+-----+
| NAME                | ENABLED |
+-----+-----+
| events_waits_current| NO      |
| events_waits_history| NO      |
| events_waits_history_long| NO     |
+-----+-----+
```

To control wait event collection at server startup, use lines like these in your `my.cnf` file:

- Enable:

```
[mysqld]
performance-schema-instrument='wait/%=ON'
performance-schema-consumer-events-waits-current=ON
performance-schema-consumer-events-waits-history=ON
performance-schema-consumer-events-waits-history-long=ON
```

- Disable:

```
[mysqld]
performance-schema-instrument='wait/%=OFF'
performance-schema-consumer-events-waits-current=OFF
performance-schema-consumer-events-waits-history=OFF
performance-schema-consumer-events-waits-history-long=OFF
```

To control wait event collection at runtime, update the `setup_instruments` and `setup_consumers` tables:

- Enable:

```
UPDATE setup_instruments SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME = 'wait/%';
UPDATE setup_consumers SET ENABLED = 'YES'
WHERE NAME LIKE '%waits%';
```

- Disable:

```
UPDATE setup_instruments SET ENABLED = 'NO', TIMED = 'NO'
WHERE NAME = 'wait/%';
UPDATE setup_consumers SET ENABLED = 'NO'
WHERE NAME LIKE '%waits%';
```

To collect only specific wait events, enable only the corresponding wait instruments. To collect wait events only for specific wait event tables, enable the wait instruments but only the wait consumers corresponding to the desired tables.

The `setup_timers` table contains a row with a `NAME` value of `wait` that indicates the unit for wait event timing. The default unit is `CYCLE`:

```
mysql> SELECT * FROM setup_timers WHERE NAME = 'wait';
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
| wait | CYCLE      |
+-----+-----+
```

To change the timing unit, modify the `TIMER_NAME` value:

```
UPDATE setup_timers SET TIMER_NAME = 'NANOSECOND'
WHERE NAME = 'wait';
```

For additional information about configuring event collection, see [Section 25.3, “Performance Schema Startup Configuration”](#), and [Section 25.4, “Performance Schema Runtime Configuration”](#).

25.11.4.1 The `events_waits_current` Table

The `events_waits_current` table contains current wait events, one row per thread showing the current status of the thread's most recent monitored wait event.

Of the tables that contain wait event rows, `events_waits_current` is the most fundamental. Other tables that contain wait event rows are logically derived from the current events. For example, the `events_waits_history` and `events_waits_history_long` tables are collections of the most recent wait events, up to a fixed number of rows.

For information about configuration of wait event collection, see [Section 25.11.4, “Performance Schema Wait Event Tables”](#).

The `events_waits_current` table has these columns:

- `THREAD_ID`, `EVENT_ID`

The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- `END_EVENT_ID`

This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- `EVENT_NAME`

The name of the instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 25.6, “Performance Schema Instrument Naming Conventions”](#).

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved. For example, if a mutex or lock is being blocked, you can check the context in which this occurs.

- `TIMER_START`, `TIMER_END`, `TIMER_WAIT`

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

If an event has not finished, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 25.4.1, “Performance Schema Event Timing”](#).

- `SPINS`

For a mutex, the number of spin rounds. If the value is `NULL`, the code does not use spin rounds or spinning is not instrumented.

- `OBJECT_SCHEMA`, `OBJECT_NAME`, `OBJECT_TYPE`, `OBJECT_INSTANCE_BEGIN`

These columns identify the object “being acted on.” What that means depends on the object type.

For a synchronization object (`cond`, `mutex`, `rwlock`):

- `OBJECT_SCHEMA`, `OBJECT_NAME`, and `OBJECT_TYPE` are `NULL`.
- `OBJECT_INSTANCE_BEGIN` is the address of the synchronization object in memory.

For a file I/O object:

- `OBJECT_SCHEMA` is `NULL`.
- `OBJECT_NAME` is the file name.
- `OBJECT_TYPE` is `FILE`.
- `OBJECT_INSTANCE_BEGIN` is an address in memory.

For a socket object:

- `OBJECT_NAME` is the `IP:PORT` value for the socket.
- `OBJECT_INSTANCE_BEGIN` is an address in memory.

For a table I/O object:

- `OBJECT_SCHEMA` is the name of the schema that contains the table.
- `OBJECT_NAME` is the table name.
- `OBJECT_TYPE` is `TABLE` for a persistent base table or `TEMPORARY TABLE` for a temporary table.
- `OBJECT_INSTANCE_BEGIN` is an address in memory.

An `OBJECT_INSTANCE_BEGIN` value itself has no meaning, except that different values indicate different objects. `OBJECT_INSTANCE_BEGIN` can be used for debugging. For example, it can be used with `GROUP BY OBJECT_INSTANCE_BEGIN` to see whether the load on 1,000 mutexes (that protect, say, 1,000 pages or blocks of data) is spread evenly or just hitting a few bottlenecks. This can help you correlate with other sources of information if you see the same object address in a log file or another debugging or performance tool.

- `INDEX_NAME`

The name of the index used. `PRIMARY` indicates the table primary index. `NULL` means that no index was used.

- `NESTING_EVENT_ID`

The `EVENT_ID` value of the event within which this event is nested.

- `NESTING_EVENT_TYPE`

The nesting event type. The value is `TRANSACTION`, `STATEMENT`, `STAGE`, or `WAIT`.

- `OPERATION`

The type of operation performed, such as `lock`, `read`, or `write`.

- `NUMBER_OF_BYTES`

The number of bytes read or written by the operation. For table I/O waits (events for the `wait/io/table/sql/handler` instrument), `NUMBER_OF_BYTES` indicates the number of rows. If the value is greater than 1, the event is for a batch I/O operation. The following discussion describes the difference between exclusively single-row reporting and reporting that reflects batch I/O.

MySQL executes joins using a nested-loop implementation. The job of the Performance Schema instrumentation is to provide row count and accumulated execution time per table in the join. Assume a join query of the following form that is executed using a table join order of `t1`, `t2`, `t3`:

```
SELECT ... FROM t1 JOIN t2 ON ... JOIN t3 ON ...
```

Table “fanout” is the increase or decrease in number of rows from adding a table during join processing. If the fanout for table `t3` is greater than 1, the majority of row-fetch operations are for that table. Suppose that the join accesses 10 rows from `t1`, 20 rows from `t2` per row from `t1`, and 30 rows from `t3` per row of table `t2`. With single-row reporting, the total number of instrumented operations is:

$$10 + (10 * 20) + (10 * 20 * 30) = 6210$$

A significant reduction in the number of instrumented operations is achievable by aggregating them per scan (that is, per unique combination of rows from `t1` and `t2`). With batch I/O reporting, the Performance Schema produces an event for each scan of the innermost table `t3` rather than for each row, and the number of instrumented row operations reduces to:

$$10 + (10 * 20) + (10 * 20) = 410$$

That is a reduction of 93%, illustrating how the batch-reporting strategy significantly reduces Performance Schema overhead for table I/O by reducing the number of reporting calls. The tradeoff is lesser accuracy for event timing. Rather than time for an individual row operation as in per-row reporting, timing for batch I/O includes time spent for operations such as join buffering, aggregation, and returning rows to the client.

For batch I/O reporting to occur, these conditions must be true:

- Query execution accesses the innermost table of a query block (for a single-table query, that table counts as innermost)
 - Query execution does not request a single row from the table (so, for example, `eq_ref` access prevents use of batch reporting)
 - Query execution does not evaluate a subquery containing table access for the table
- `FLAGS`

Reserved for future use.

The `events_waits_current` table has these indexes:

- Primary key on (`THREAD_ID`, `EVENT_ID`)

`TRUNCATE TABLE` is permitted for the `events_waits_current` table. It removes the rows.

25.11.4.2 The `events_waits_history` Table

The `events_waits_history` table contains the most recent `N` wait events per thread. The value of `N` is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_waits_history_size` system variable at server startup. Wait

events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full.

The `events_waits_history` table has the same structure as `events_waits_current`, including indexing. See [Section 25.11.4.1, “The events_waits_current Table”](#).

`TRUNCATE TABLE` is permitted for the `events_waits_history` table. It removes the rows.

For information about configuration of wait event collection, see [Section 25.11.4, “Performance Schema Wait Event Tables”](#).

25.11.4.3 The events_waits_history_long Table

The `events_waits_history_long` table contains the most recent N wait events. The value of N is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_waits_history_long_size` system variable at server startup. Wait events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full. When a thread ends, its rows are removed from the table.

The `events_waits_history_long` table has the same structure as `events_waits_current`, except that it has no indexes. See [Section 25.11.4.1, “The events_waits_current Table”](#).

`TRUNCATE TABLE` is permitted for the `events_waits_history_long` table. It removes the rows.

For information about configuration of wait event collection, see [Section 25.11.4, “Performance Schema Wait Event Tables”](#).

25.11.5 Performance Schema Stage Event Tables

The Performance Schema instruments stages, which are steps during the statement-execution process, such as parsing a statement, opening a table, or performing a `filesort` operation. Stages correspond to the thread states displayed by `SHOW PROCESSLIST` or that are visible in the `INFORMATION_SCHEMA.PROCESSLIST` table. Stages begin and end when state values change.

Within the event hierarchy, wait events nest within stage events, which nest within statement events, which nest within transaction events.

These tables store stage events:

- `events_stages_current`: Current stage events
- `events_stages_history`: The most recent stage events per thread
- `events_stages_history_long`: The most recent stage events globally (across all threads)

The following sections describe the stage event tables. There are also summary tables that aggregate information about stage events; see [Section 25.11.15.2, “Stage Summary Tables”](#).

Stage Event Configuration

To control collection of stage events, set the state of the relevant instruments and consumers:

- The `setup_instruments` table contains instruments with names that begin with `stage`. Use these instruments to enable or disable collection of stage events.
- The `setup_consumers` table contains consumer values with names corresponding to the current and recent stage event table names. Use these consumers to filter collection of stage events.

Other than those instruments that provide statement progress information, the stage instruments are disabled by default. For example:

```
mysql> SELECT * FROM setup_instruments WHERE NAME RLIKE 'stage/sql/[a-c]';
```

NAME	ENABLED	TIMED
stage/sql/After create	NO	NO
stage/sql/allocating local table	NO	NO
stage/sql/altering table	NO	NO
stage/sql/committing alter table to storage engine	NO	NO
stage/sql/Changing master	NO	NO
stage/sql/Checking master version	NO	NO
stage/sql/checking permissions	NO	NO
stage/sql/checking privileges on cached query	NO	NO
stage/sql/checking query cache for query	NO	NO
stage/sql/cleaning up	NO	NO
stage/sql/closing tables	NO	NO
stage/sql/Connecting to master	NO	NO
stage/sql/converting HEAP to MyISAM	NO	NO
stage/sql/Copying to group table	NO	NO
stage/sql/Copying to tmp table	NO	NO
stage/sql/copy to tmp table	NO	NO
stage/sql/Creating sort index	NO	NO
stage/sql/creating table	NO	NO
stage/sql/Creating tmp table	NO	NO

Stage event instruments that provide statement progress information are enabled and timed by default:

```
mysql> SELECT * FROM setup_instruments WHERE
ENABLED='YES' AND NAME LIKE "stage/%";
```

NAME	ENABLED	TIMED
stage/sql/copy to tmp table	YES	YES
stage/innodb/alter table (end)	YES	YES
stage/innodb/alter table (flush)	YES	YES
stage/innodb/alter table (insert)	YES	YES
stage/innodb/alter table (log apply index)	YES	YES
stage/innodb/alter table (log apply table)	YES	YES
stage/innodb/alter table (merge sort)	YES	YES
stage/innodb/alter table (read PK and internal sort)	YES	YES
stage/innodb/buffer pool load	YES	YES

The stage consumers are disabled by default:

```
mysql> SELECT * FROM setup_consumers WHERE NAME LIKE '%stages%';
```

NAME	ENABLED
events_stages_current	NO
events_stages_history	NO
events_stages_history_long	NO

To control stage event collection at server startup, use lines like these in your `my.cnf` file:

- Enable:

```
[mysqld]
performance-schema-instrument='stage/=ON'
performance-schema-consumer-events-stages-current=ON
performance-schema-consumer-events-stages-history=ON
performance-schema-consumer-events-stages-history-long=ON
```

- Disable:

```
[mysqld]
performance-schema-instrument='stage/%=OFF'
performance-schema-consumer-events-stages-current=OFF
performance-schema-consumer-events-stages-history=OFF
performance-schema-consumer-events-stages-history-long=OFF
```

To control stage event collection at runtime, update the `setup_instruments` and `setup_consumers` tables:

- Enable:

```
UPDATE setup_instruments SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME = 'stage/%';
UPDATE setup_consumers SET ENABLED = 'YES'
WHERE NAME LIKE '%stages%';
```

- Disable:

```
UPDATE setup_instruments SET ENABLED = 'NO', TIMED = 'NO'
WHERE NAME = 'stage/%';
UPDATE setup_consumers SET ENABLED = 'NO'
WHERE NAME LIKE '%stages%';
```

To collect only specific stage events, enable only the corresponding stage instruments. To collect stage events only for specific stage event tables, enable the stage instruments but only the stage consumers corresponding to the desired tables.

The `setup_timers` table contains a row with a `NAME` value of `stage` that indicates the unit for stage event timing. The default unit is `NANOSECOND`:

```
mysql> SELECT * FROM setup_timers WHERE NAME = 'stage';
+-----+-----+
| NAME | TIMER_NAME |
+-----+-----+
| stage | NANOSECOND |
+-----+-----+
```

To change the timing unit, modify the `TIMER_NAME` value:

```
UPDATE setup_timers SET TIMER_NAME = 'MICROSECOND'
WHERE NAME = 'stage';
```

For additional information about configuring event collection, see [Section 25.3, “Performance Schema Startup Configuration”](#), and [Section 25.4, “Performance Schema Runtime Configuration”](#).

Stage Event Progress Information

The Performance Schema stage event tables contain two columns that, taken together, provide a stage progress indicator for each row:

- `WORK_COMPLETED`: The number of work units completed for the stage
- `WORK_ESTIMATED`: The number of work units expected for the stage

Each column is `NULL` if no progress information is provided for an instrument. Interpretation of the information, if it is available, depends entirely on the instrument implementation. The Performance Schema tables provide a container to store progress data, but make no assumptions about the semantics of the metric itself:

- A “work unit” is an integer metric that increases over time during execution, such as the number of bytes, rows, files, or tables processed. The definition of “work unit” for a particular instrument is left to the instrumentation code providing the data.

- The `WORK_COMPLETED` value can increase one or many units at a time, depending on the instrumented code.
- The `WORK_ESTIMATED` value can change during the stage, depending on the instrumented code.

Instrumentation for a stage event progress indicator can implement any of the following behaviors:

- No progress instrumentation

This is the most typical case, where no progress data is provided. The `WORK_COMPLETED` and `WORK_ESTIMATED` columns are both `NULL`.

- Unbounded progress instrumentation

Only the `WORK_COMPLETED` column is meaningful. No data is provided for the `WORK_ESTIMATED` column, which displays 0.

By querying the `events_stages_current` table for the monitored session, a monitoring application can report how much work has been performed so far, but cannot report whether the stage is near completion. Currently, no stages are instrumented like this.

- Bounded progress instrumentation

The `WORK_COMPLETED` and `WORK_ESTIMATED` columns are both meaningful.

This type of progress indicator is appropriate for an operation with a defined completion criterion, such as the table-copy instrument described later. By querying the `events_stages_current` table for the monitored session, a monitoring application can report how much work has been performed so far, and can report the overall completion percentage for the stage, by computing the `WORK_COMPLETED / WORK_ESTIMATED` ratio.

The `stage/sql/copy to tmp table` instrument illustrates how progress indicators work. During execution of an `ALTER TABLE` statement, the `stage/sql/copy to tmp table` stage is used, and this stage can execute potentially for a long time, depending on the size of the data to copy.

The table-copy task has a defined termination (all rows copied), and the `stage/sql/copy to tmp table` stage is instrumented to provide bounded progress information: The work unit used is number of rows copied, `WORK_COMPLETED` and `WORK_ESTIMATED` are both meaningful, and their ratio indicates task percentage complete.

To enable the instrument and the relevant consumers, execute these statements:

```
UPDATE setup_instruments SET ENABLED='YES'
WHERE NAME='stage/sql/copy to tmp table';
UPDATE setup_consumers SET ENABLED='YES'
WHERE NAME LIKE 'events_stages_%';
```

To see the progress of an ongoing `ALTER TABLE` statement, select from the `events_stages_current` table.

25.11.5.1 The `events_stages_current` Table

The `events_stages_current` table contains current stage events, one row per thread showing the current status of the thread's most recent monitored stage event.

Of the tables that contain stage event rows, `events_stages_current` is the most fundamental. Other tables that contain stage event rows are logically derived from the current events. For example, the `events_stages_history` and `events_stages_history_long` tables are collections of the most recent stage events, up to a fixed number of rows.

For information about configuration of stage event collection, see [Section 25.11.5, “Performance Schema Stage Event Tables”](#).

The `events_stages_current` table has these columns:

- `THREAD_ID`, `EVENT_ID`

The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- `END_EVENT_ID`

This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- `EVENT_NAME`

The name of the instrument that produced the event. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 25.6, “Performance Schema Instrument Naming Conventions”](#).

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- `TIMER_START`, `TIMER_END`, `TIMER_WAIT`

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

If an event has not finished, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 25.4.1, “Performance Schema Event Timing”](#).

- `WORK_COMPLETED`, `WORK_ESTIMATED`

These columns provide stage progress information, for instruments that have been implemented to produce such information. `WORK_COMPLETED` indicates how many work units have been completed for the stage, and `WORK_ESTIMATED` indicates how many work units are expected for the stage. For more information, see [Stage Event Progress Information](#).

- `NESTING_EVENT_ID`

The `EVENT_ID` value of the event within which this event is nested. The nesting event for a stage event is usually a statement event.

- `NESTING_EVENT_TYPE`

The nesting event type. The value is `TRANSACTION`, `STATEMENT`, `STAGE`, or `WAIT`.

The `events_stages_current` table has these indexes:

- Primary key on (`THREAD_ID`, `EVENT_ID`)

`TRUNCATE TABLE` is permitted for the `events_stages_current` table. It removes the rows.

25.11.5.2 The `events_stages_history` Table

The `events_stages_history` table contains the most recent N stage events per thread. The value of N is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_stages_history_size` system variable at server startup. Stage events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full.

The `events_stages_history` table has the same structure as `events_stages_current`, including indexing. See [Section 25.11.5.1, “The events_stages_current Table”](#).

`TRUNCATE TABLE` is permitted for the `events_stages_history` table. It removes the rows.

For information about configuration of stage event collection, see [Section 25.11.5, “Performance Schema Stage Event Tables”](#).

25.11.5.3 The events_stages_history_long Table

The `events_stages_history_long` table contains the most recent N stage events. The value of N is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_stages_history_long_size` system variable at server startup. Stage events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full. When a thread ends, its rows are removed from the table.

The `events_stages_history_long` table has the same structure as `events_stages_current`, except that it has no indexes. See [Section 25.11.5.1, “The events_stages_current Table”](#).

`TRUNCATE TABLE` is permitted for the `events_stages_history_long` table. It removes the rows.

For information about configuration of stage event collection, see [Section 25.11.5, “Performance Schema Stage Event Tables”](#).

25.11.6 Performance Schema Statement Event Tables

The Performance Schema instruments statement execution. Statement events occur at a high level of the event hierarchy. Within the event hierarchy, wait events nest within stage events, which nest within statement events, which nest within transaction events.

These tables store statement events:

- `events_statements_current`: Current statement events
- `events_statements_history`: The most recent statement events per thread
- `events_statements_history_long`: The most recent statement events globally (across all threads)
- `prepared_statements_instances`: Prepared statement instances and statistics

The following sections describe the statement event tables. There are also summary tables that aggregate information about statement events; see [Section 25.11.15.3, “Statement Summary Tables”](#).

Statement Event Configuration

To control collection of statement events, set the state of the relevant instruments and consumers:

- The `setup_instruments` table contains instruments with names that begin with `statement`. Use these instruments to enable or disable collection of statement events.
- The `setup_consumers` table contains consumer values with names corresponding to the current and recent statement event table names, and the statement digest consumer. Use these consumers to filter collection of statement events and statement digesting.

The statement instruments are enabled by default, and the `events_statements_current`, `events_statements_history`, and `statements_digest` statement consumers are enabled by default:

```
mysql> SELECT * FROM setup_instruments WHERE NAME LIKE 'statement/%';
```

NAME	ENABLED	TIMED
statement/sql/select	YES	YES
statement/sql/create_table	YES	YES
statement/sql/create_index	YES	YES
...		
statement/sp/stmt	YES	YES
statement/sp/set	YES	YES
statement/sp/set_trigger_field	YES	YES
statement/scheduler/event	YES	YES
statement/com/Sleep	YES	YES
statement/com/Quit	YES	YES
statement/com/Init DB	YES	YES
...		
statement/abstract/Query	YES	YES
statement/abstract/new_packet	YES	YES
statement/abstract/relay_log	YES	YES

```
mysql> SELECT * FROM setup_consumers WHERE NAME LIKE '%statements%';
```

NAME	ENABLED
events_statements_current	YES
events_statements_history	YES
events_statements_history_long	NO
statements_digest	YES

To control statement event collection at server startup, use lines like these in your `my.cnf` file:

- Enable:

```
[mysqld]
performance-schema-instrument='statement/%=ON'
performance-schema-consumer-events-statements-current=ON
performance-schema-consumer-events-statements-history=ON
performance-schema-consumer-events-statements-history-long=ON
performance-schema-consumer-statements-digest=ON
```

- Disable:

```
[mysqld]
performance-schema-instrument='statement/%=OFF'
performance-schema-consumer-events-statements-current=OFF
performance-schema-consumer-events-statements-history=OFF
performance-schema-consumer-events-statements-history-long=OFF
performance-schema-consumer-statements-digest=OFF
```

To control statement event collection at runtime, update the `setup_instruments` and `setup_consumers` tables:

- Enable:

```
UPDATE setup_instruments SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME LIKE 'statement/%';
UPDATE setup_consumers SET ENABLED = 'YES'
WHERE NAME LIKE '%statements%';
```

- Disable:

```
UPDATE setup_instruments SET ENABLED = 'NO', TIMED = 'NO'
WHERE NAME LIKE 'statement/%';
UPDATE setup_consumers SET ENABLED = 'NO'
WHERE NAME LIKE '%statements%';
```

To collect only specific statement events, enable only the corresponding statement instruments. To collect statement events only for specific statement event tables, enable the statement instruments but only the statement consumers corresponding to the desired tables.

The `setup_timers` table contains a row with a `NAME` value of `statement` that indicates the unit for statement event timing. The default unit is `NANOSECOND`:

```
mysql> SELECT * FROM setup_timers WHERE NAME = 'statement';
+-----+-----+
| NAME      | TIMER_NAME |
+-----+-----+
| statement | NANOSECOND |
+-----+-----+
```

To change the timing unit, modify the `TIMER_NAME` value:

```
UPDATE setup_timers SET TIMER_NAME = 'MICROSECOND'
WHERE NAME = 'statement';
```

For additional information about configuring event collection, see [Section 25.3, “Performance Schema Startup Configuration”](#), and [Section 25.4, “Performance Schema Runtime Configuration”](#).

Statement Monitoring

Statement monitoring begins from the moment the server sees that activity is requested on a thread, to the moment when all activity has ceased. Typically, this means from the time the server gets the first packet from the client to the time the server has finished sending the response. Statements within stored programs are monitored like other statements.

When the Performance Schema instruments a request (server command or SQL statement), it uses instrument names that proceed in stages from more general (or “abstract”) to more specific until it arrives at a final instrument name.

Final instrument names correspond to server commands and SQL statements:

- Server commands correspond to the `COM_xxx` codes defined in the `mysql_com.h` header file and processed in `sql/sql_parse.cc`. Examples are `COM_PING` and `COM_QUIT`. Instruments for commands have names that begin with `statement/com`, such as `statement/com/Ping` and `statement/com/Quit`.
- SQL statements are expressed as text, such as `DELETE FROM t1` or `SELECT * FROM t2`. Instruments for SQL statements have names that begin with `statement/sql`, such as `statement/sql/delete` and `statement/sql/select`.

Some final instrument names are specific to error handling:

- `statement/com/Error` accounts for messages received by the server that are out of band. It can be used to detect commands sent by clients that the server does not understand. This may be helpful for purposes such as identifying clients that are misconfigured or using a version of MySQL more recent than that of the server, or clients that are attempting to attack the server.
- `statement/sql/error` accounts for SQL statements that fail to parse. It can be used to detect malformed queries sent by clients. A query that fails to parse differs from a query that parses but fails due to an error during execution. For example, `SELECT * FROM` is malformed, and the `statement/sql/error` instrument is used. By contrast, `SELECT *` parses but fails with a `No`

`tables used` error. In this case, `statement/sql/select` is used and the statement event contains information to indicate the nature of the error.

A request can be obtained from any of these sources:

- As a command or statement request from a client, which sends the request as packets
- As a statement string read from the relay log on a replication slave
- As an event from the Event Scheduler

The details for a request are not initially known and the Performance Schema proceeds from abstract to specific instrument names in a sequence that depends on the source of the request.

For a request received from a client:

1. When the server detects a new packet at the socket level, a new statement is started with an abstract instrument name of `statement/abstract/new_packet`.
2. When the server reads the packet number, it knows more about the type of request received, and the Performance Schema refines the instrument name. For example, if the request is a `COM_PING` packet, the instrument name becomes `statement/com/Ping` and that is the final name. If the request is a `COM_QUERY` packet, it is known to correspond to an SQL statement but not the particular type of statement. In this case, the instrument changes from one abstract name to a more specific but still abstract name, `statement/abstract/Query`, and the request requires further classification.
3. If the request is a statement, the statement text is read and given to the parser. After parsing, the exact statement type is known. If the request is, for example, an `INSERT` statement, the Performance Schema refines the instrument name from `statement/abstract/Query` to `statement/sql/insert`, which is the final name.

For a request read as a statement from the relay log on a replication slave:

1. Statements in the relay log are stored as text and are read as such. There is no network protocol, so the `statement/abstract/new_packet` instrument is not used. Instead, the initial instrument is `statement/abstract/relay_log`.
2. When the statement is parsed, the exact statement type is known. If the request is, for example, an `INSERT` statement, the Performance Schema refines the instrument name from `statement/abstract/Query` to `statement/sql/insert`, which is the final name.

The preceding description applies only for statement-based replication. For row-based replication, table I/O done on the slave as it processes row changes can be instrumented, but row events in the relay log do not appear as discrete statements.

For a request received from the Event Scheduler:

The event execution is instrumented using the name `statement/scheduler/event`. This is the final name.

Statements executed within the event body are instrumented using `statement/sql/*` names, without use of any preceding abstract instrument. An event is a stored program, and stored programs are precompiled in memory before execution. Consequently, there is no parsing at runtime and the type of each statement is known by the time it executes.

Statements executed within the event body are child statements. For example, if an event executes an `INSERT` statement, execution of the event itself is the parent, instrumented using `statement/scheduler/event`, and the `INSERT` is the child, instrumented using `statement/sql/insert`. The parent/child relationship holds *between* separate instrumented operations. This differs from the sequence of refinement that occurs *within* a single instrumented operation, from abstract to final instrument names.

For statistics to be collected for statements, it is not sufficient to enable only the final `statement/sql/*` instruments used for individual statement types. The abstract `statement/abstract/*` instruments must be enabled as well. This should not normally be an issue because all statement instruments are enabled by default. However, an application that enables or disables statement instruments selectively must take into account that disabling abstract instruments also disables statistics collection for the individual statement instruments. For example, to collect statistics for `INSERT` statements, `statement/sql/insert` must be enabled, but also `statement/abstract/new_packet` and `statement/abstract/Query`. Similarly, for replicated statements to be instrumented, `statement/abstract/relay_log` must be enabled.

No statistics are aggregated for abstract instruments such as `statement/abstract/Query` because no statement is ever classified with an abstract instrument as the final statement name.

25.11.6.1 The `events_statements_current` Table

The `events_statements_current` table contains current statement events, one row per thread showing the current status of the thread's most recent monitored statement event.

Of the tables that contain statement event rows, `events_statements_current` is the most fundamental. Other tables that contain statement event rows are logically derived from the current events. For example, the `events_statements_history` and `events_statements_history_long` tables are collections of the most recent statement events, up to a fixed number of rows.

For information about configuration of statement event collection, see [Section 25.11.6, “Performance Schema Statement Event Tables”](#).

The `events_statements_current` table has these columns:

- `THREAD_ID`, `EVENT_ID`

The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- `END_EVENT_ID`

This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- `EVENT_NAME`

The name of the instrument from which the event was collected. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 25.6, “Performance Schema Instrument Naming Conventions”](#).

For SQL statements, the `EVENT_NAME` value initially is `statement/com/Query` until the statement is parsed, then changes to a more appropriate value, as described in [Section 25.11.6, “Performance Schema Statement Event Tables”](#).

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- `TIMER_START`, `TIMER_END`, `TIMER_WAIT`

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

If an event has not finished, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 25.4.1, “Performance Schema Event Timing”](#).

- `LOCK_TIME`

The time spent waiting for table locks. This value is computed in microseconds but normalized to picoseconds for easier comparison with other Performance Schema timers.

- `SQL_TEXT`

The text of the SQL statement. For a command not associated with an SQL statement, the value is `NULL`.

The maximum space available for statement display is 1024 bytes by default. To change this value, set the `performance_schema_max_sql_text_length` system variable at server startup.

- `DIGEST`

The statement digest MD5 value as a string of 32 hexadecimal characters, or `NULL` if the `statements_digest` consumer is `no`. For more information about statement digesting, see [Section 25.9, “Performance Schema Statement Digests”](#).

- `DIGEST_TEXT`

The normalized statement digest text, or `NULL` if the `statements_digest` consumer is `no`. For more information about statement digesting, see [Section 25.9, “Performance Schema Statement Digests”](#).

The `performance_schema_max_digest_length` system variable determines the maximum number of bytes available for digest value storage. However, the display length of statement digests may be longer than the available buffer size due to encoding of statement components such as keywords and literal values in digest buffer. Consequently, values selected from the `DIGEST_TEXT` column of statement event tables may appear to exceed the `performance_schema_max_digest_length` value.

- `CURRENT_SCHEMA`

The default database for the statement, `NULL` if there is none.

- `OBJECT_SCHEMA`, `OBJECT_NAME`, `OBJECT_TYPE`

For nested statements (stored programs), these columns contain information about the parent statement. Otherwise they are `NULL`.

- `OBJECT_INSTANCE_BEGIN`

This column identifies the statement. The value is the address of an object in memory.

- `MYSQL_ERRNO`

The statement error number, from the statement diagnostics area.

- `RETURNED_SQLSTATE`

The statement SQLSTATE value, from the statement diagnostics area.

- `MESSAGE_TEXT`
The statement error message, from the statement diagnostics area.
- `ERRORS`
Whether an error occurred for the statement. The value is 0 if the `SQLSTATE` value begins with 00 (completion) or 01 (warning). The value is 1 if the `SQLSTATE` value is anything else.
- `WARNINGS`
The number of warnings, from the statement diagnostics area.
- `ROWS_AFFECTED`
The number of rows affected by the statement. For a description of the meaning of “affected,” see [Section 27.7.7.1, “mysql_affected_rows\(\)”](#).
- `ROWS_SENT`
The number of rows returned by the statement.
- `ROWS_EXAMINED`
The number of rows read from storage engines during statement execution.
- `CREATED_TMP_DISK_TABLES`
Like the `Created_tmp_disk_tables` status variable, but specific to the statement.
- `CREATED_TMP_TABLES`
Like the `Created_tmp_tables` status variable, but specific to the statement.
- `SELECT_FULL_JOIN`
Like the `Select_full_join` status variable, but specific to the statement.
- `SELECT_FULL_RANGE_JOIN`
Like the `Select_full_range_join` status variable, but specific to the statement.
- `SELECT_RANGE`
Like the `Select_range` status variable, but specific to the statement.
- `SELECT_RANGE_CHECK`
Like the `Select_range_check` status variable, but specific to the statement.
- `SELECT_SCAN`
Like the `Select_scan` status variable, but specific to the statement.
- `SORT_MERGE_PASSES`
Like the `Sort_merge_passes` status variable, but specific to the statement.
- `SORT_RANGE`
Like the `Sort_range` status variable, but specific to the statement.
- `SORT_ROWS`
Like the `Sort_rows` status variable, but specific to the statement.

- [SORT_SCAN](#)

Like the `Sort_scan` status variable, but specific to the statement.

- [NO_INDEX_USED](#)

1 if the statement performed a table scan without using an index, 0 otherwise.

- [NO_GOOD_INDEX_USED](#)

1 if the server found no good index to use for the statement, 0 otherwise. For additional information, see the description of the `Extra` column from `EXPLAIN` output for the `Range checked for each record` value in [Section 8.8.2, “EXPLAIN Output Format”](#).

- [NESTING_EVENT_ID](#), [NESTING_EVENT_TYPE](#), [NESTING_EVENT_LEVEL](#)

These three columns are used with other columns to provide information as follows for top-level (unnested) statements and nested statements (executed within a stored program).

For top level statements:

```
OBJECT_TYPE = NULL
OBJECT_SCHEMA = NULL
OBJECT_NAME = NULL
NESTING_EVENT_ID = NULL
NESTING_EVENT_TYPE = NULL
NESTING_LEVEL = 0
```

For nested statements:

```
OBJECT_TYPE = the parent statement object type
OBJECT_SCHEMA = the parent statement object schema
OBJECT_NAME = the parent statement object name
NESTING_EVENT_ID = the parent statement EVENT_ID
NESTING_EVENT_TYPE = 'STATEMENT'
NESTING_LEVEL = the parent statement NESTING_LEVEL plus one
```

The `events_statements_current` table has these indexes:

- Primary key on (`THREAD_ID`, `EVENT_ID`)

`TRUNCATE TABLE` is permitted for the `events_statements_current` table. It removes the rows.

25.11.6.2 The `events_statements_history` Table

The `events_statements_history` table contains the most recent *N* statement events per thread. The value of *N* is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_statements_history_size` system variable at server startup. Statement events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full.

The `events_statements_history` table has the same structure as `events_statements_current`, including indexing. See [Section 25.11.6.1, “The `events_statements_current` Table”](#).

`TRUNCATE TABLE` is permitted for the `events_statements_history` table. It removes the rows.

For information about configuration of statement event collection, see [Section 25.11.6, “Performance Schema Statement Event Tables”](#).

25.11.6.3 The `events_statements_history_long` Table

The `events_statements_history_long` table contains the most recent N statement events. The value of N is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_statements_history_long_size` system variable at server startup. Statement events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full. When a thread ends, its rows are removed from the table.

The `events_statements_history_long` table has the same structure as `events_statements_current`, except that it has no indexes. See [Section 25.11.6.1, “The events_statements_current Table”](#).

`TRUNCATE TABLE` is permitted for the `events_statements_history_long` table. It removes the rows.

For information about configuration of statement event collection, see [Section 25.11.6, “Performance Schema Statement Event Tables”](#).

25.11.6.4 The prepared_statements_instances Table

The Performance Schema provides instrumentation for prepared statements, for which there are two protocols:

- The binary protocol. This is accessed through the MySQL C API and maps onto underlying server commands as shown in the following table.

C API Function	Corresponding Server Command
<code>mysql_stmt_prepare()</code>	<code>COM_STMT_PREPARE</code>
<code>mysql_stmt_execute()</code>	<code>COM_STMT_EXECUTE</code>
<code>mysql_stmt_close()</code>	<code>COM_STMT_CLOSE</code>

- The text protocol. This is accessed using SQL statements and maps onto underlying server commands as shown in the following table.

SQL Statement	Corresponding Server Command
<code>PREPARE</code>	<code>SQLCOM_PREPARE</code>
<code>EXECUTE</code>	<code>SQLCOM_EXECUTE</code>
<code>DEALLOCATE PREPARE, DROP PREPARE</code>	<code>SQLCOM_DEALLOCATE PREPARE</code>

Performance Schema prepared statement instrumentation covers both protocols. The following discussion refers to the server commands rather than the C API functions or SQL statements.

Information about prepared statements is available in the `prepared_statements_instances` table. This table enables inspection of prepared statements used in the server and provides aggregated statistics about them. To control the size of this table, set the `performance_schema_max_prepared_statements_instances` system variable at server startup.

Collection of prepared statement information depends on the statement instruments shown in the following table. These instruments are enabled by default. To modify them, update the `setup_instruments` table.

Instrument	Server Command
<code>statement/com/Prepare</code>	<code>COM_STMT_PREPARE</code>
<code>statement/com/Execute</code>	<code>COM_STMT_EXECUTE</code>
<code>statement/sql/prepare_sql</code>	<code>SQLCOM_PREPARE</code>
<code>statement/sql/execute_sql</code>	<code>SQLCOM_EXECUTE</code>

The Performance Schema manages the contents of the `prepared_statements_instances` table as follows:

- Statement preparation

A `COM_STMT_PREPARE` or `SQLCOM_PREPARE` command creates a prepared statement in the server. If the statement is successfully instrumented, a new row is added to the `prepared_statements_instances` table. If the statement cannot be instrumented, `Performance_schema_prepared_statements_lost` status variable is incremented.

- Prepared statement execution

Execution of a `COM_STMT_EXECUTE` or `SQLCOM_EXECUTE` command for an instrumented prepared statement instance updates the corresponding `prepared_statements_instances` table row.

- Prepared statement deallocation

Execution of a `COM_STMT_CLOSE` or `SQLCOM_DEALLOCATE_PREPARE` command for an instrumented prepared statement instance removes the corresponding `prepared_statements_instances` table row. To avoid resource leaks, removal occurs even if the prepared statement instruments described previously are disabled.

The `prepared_statements_instances` table has these columns:

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the instrumented prepared statement.

- `STATEMENT_ID`

The internal statement ID assigned by the server. The text and binary protocols both use statement IDs.

- `STATEMENT_NAME`

For the binary protocol, this column is `NULL`. For the text protocol, this column is the external statement name assigned by the user. For example, for the following SQL statement, the name of the prepared statement is `stmt`:

```
PREPARE stmt FROM 'SELECT 1';
```

- `SQL_TEXT`

The prepared statement text, with `?` placeholder markers.

- `OWNER_THREAD_ID`, `OWNER_EVENT_ID`

These columns indicate the event that created the prepared statement.

- `OWNER_OBJECT_TYPE`, `OWNER_OBJECT_SCHEMA`, `OWNER_OBJECT_NAME`

For a prepared statement created by a client session, these columns are `NULL`. For a prepared statement created by a stored program, these columns point to the stored program. A typical user error is forgetting to deallocate prepared statements. These columns can be used to find stored programs that leak prepared statements:

```
SELECT OWNER_OBJECT_TYPE, OWNER_OBJECT_SCHEMA, OWNER_OBJECT_NAME,
STATEMENT_NAME, SQL_TEXT
FROM performance_schema.prepared_statements_instances
WHERE OWNER_OBJECT_TYPE IS NOT NULL;
```

- `TIMER_PREPARE`

The time spent executing the statement preparation itself.

- `COUNT_REPREPARE`

The number of times the statement was reprepared internally (see [Section 8.10.4, “Caching of Prepared Statements and Stored Programs”](#)). Timing statistics for reparation are not available because it is counted as part of statement execution, not as a separate operation.

- `COUNT_EXECUTE`, `SUM_TIMER_EXECUTE`, `MIN_TIMER_EXECUTE`, `AVG_TIMER_EXECUTE`, `MAX_TIMER_EXECUTE`

Aggregated statistics for executions of the prepared statement.

- `SUM_xxx`

The remaining `SUM_xxx` columns are the same as for the statement summary tables (see [Section 25.11.15.3, “Statement Summary Tables”](#)).

The `prepared_statements_instances` table has these indexes:

- Primary key on (`OBJECT_INSTANCE_BEGIN`)
- Index on (`STATEMENT_ID`)
- Index on (`STATEMENT_NAME`)
- Index on (`OWNER_THREAD_ID`, `OWNER_EVENT_ID`)
- Index on (`OWNER_OBJECT_TYPE`, `OWNER_OBJECT_SCHEMA`, `OWNER_OBJECT_NAME`)

`TRUNCATE TABLE` resets the statistics columns of the `prepared_statements_instances` table.

25.11.7 Performance Schema Transaction Tables

The Performance Schema instruments transactions. Within the event hierarchy, wait events nest within stage events, which nest within statement events, which nest within transaction events.

These tables store transaction events:

- `events_transactions_current`: Current transaction events
- `events_transactions_history`: The most recent transaction events per thread
- `events_transactions_history_long`: The most recent transaction events globally (across all threads)

The following sections describe the transaction event tables. There are also summary tables that aggregate information about transaction events; see [Section 25.11.15.5, “Transaction Summary Tables”](#).

Transaction Event Configuration

To control collection of transaction events, set the state of the relevant instruments and consumers:

- The `setup_instruments` table contains an instrument named `transaction`. Use this instrument to enable or disable collection of transaction events.
- The `setup_consumers` table contains consumer values with names corresponding to the current and recent transaction event table names. Use these consumers to filter collection of transaction events.

The `transaction` instrument and the `events_transactions_current` and `events_transactions_history` transaction consumers are enabled by default:

```
mysql> SELECT * FROM setup_instruments WHERE NAME = 'transaction';
+-----+-----+-----+
| NAME          | ENABLED | TIMED |
+-----+-----+-----+
| transaction   | YES     | YES   |
+-----+-----+-----+
mysql> SELECT * FROM setup_consumers WHERE NAME LIKE '%transactions%';
+-----+-----+
| NAME                                     | ENABLED |
+-----+-----+
| events_transactions_current             | YES     |
| events_transactions_history             | YES     |
| events_transactions_history_long       | NO      |
+-----+-----+
```

(Prior to MySQL 8.0.2, the `transaction` instrument and the transaction consumers are disabled by default.)

To control transaction event collection at server startup, use lines like these in your `my.cnf` file:

- Enable:

```
[mysqld]
performance-schema-instrument='transaction=ON'
performance-schema-consumer-events-transactions-current=ON
performance-schema-consumer-events-transactions-history=ON
performance-schema-consumer-events-transactions-history-long=ON
```

- Disable:

```
[mysqld]
performance-schema-instrument='transaction=OFF'
performance-schema-consumer-events-transactions-current=OFF
performance-schema-consumer-events-transactions-history=OFF
performance-schema-consumer-events-transactions-history-long=OFF
```

To control transaction event collection at runtime, update the `setup_instruments` and `setup_consumers` tables:

- Enable:

```
UPDATE setup_instruments SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME = 'transaction';
UPDATE setup_consumers SET ENABLED = 'YES'
WHERE NAME LIKE '%transactions%';
```

- Disable:

```
UPDATE setup_instruments SET ENABLED = 'NO', TIMED = 'NO'
WHERE NAME = 'transaction';
UPDATE setup_consumers SET ENABLED = 'NO'
WHERE NAME LIKE '%transactions%';
```

To collect transaction events only for specific transaction event tables, enable the `transaction` instrument but only the transaction consumers corresponding to the desired tables.

The `setup_timers` table contains a row with a `NAME` value of `transaction` that indicates the unit for transaction event timing. The default unit is `NANOSECOND`:

```
mysql> SELECT * FROM setup_timers WHERE NAME = 'transaction';
+-----+-----+
| NAME          | TIMER_NAME |
+-----+-----+
| transaction   | NANOSECOND |
+-----+-----+
```

To change the timing unit, modify the `TIMER_NAME` value:

```
UPDATE setup_timers SET TIMER_NAME = 'MICROSECOND'
WHERE NAME = 'transaction';
```

For additional information about configuring event collection, see [Section 25.3, “Performance Schema Startup Configuration”](#), and [Section 25.4, “Performance Schema Runtime Configuration”](#).

Transaction Boundaries

In MySQL Server, transactions start explicitly with these statements:

```
START TRANSACTION | BEGIN | XA START | XA BEGIN
```

Transactions also start implicitly. For example, when the `autocommit` system variable is enabled, the start of each statement starts a new transaction.

When `autocommit` is disabled, the first statement following a committed transaction marks the start of a new transaction. Subsequent statements are part of the transaction until it is committed.

Transactions explicitly end with these statements:

```
COMMIT | ROLLBACK | XA COMMIT | XA ROLLBACK
```

Transactions also end implicitly, by execution of DDL statements, locking statements, and server administration statements.

In the following discussion, references to `START TRANSACTION` also apply to `BEGIN`, `XA START`, and `XA BEGIN`. Similarly, references to `COMMIT` and `ROLLBACK` apply to `XA COMMIT` and `XA ROLLBACK`, respectively.

The Performance Schema defines transaction boundaries similarly to that of the server. The start and end of a transaction event closely match the corresponding state transitions in the server:

- For an explicitly started transaction, the transaction event starts during processing of the `START TRANSACTION` statement.
- For an implicitly started transaction, the transaction event starts on the first statement that uses a transactional engine after the previous transaction has ended.
- For any transaction, whether explicitly or implicitly ended, the transaction event ends when the server transitions out of the active transaction state during the processing of `COMMIT` or `ROLLBACK`.

There are subtle implications to this approach:

- Transaction events in the Performance Schema do not fully include the statement events associated with the corresponding `START TRANSACTION`, `COMMIT`, or `ROLLBACK` statements. There is a trivial amount of timing overlap between the transaction event and these statements.
- Statements that work with nontransactional engines have no effect on the transaction state of the connection. For implicit transactions, the transaction event begins with the first statement that uses a transactional engine. This means that statements operating exclusively on nontransactional tables are ignored, even following `START TRANSACTION`.

To illustrate, consider the following scenario:

```

1. SET autocommit = OFF;
2. CREATE TABLE t1 (a INT) ENGINE = InnoDB;
3. START TRANSACTION; -- Transaction 1 START
4. INSERT INTO t1 VALUES (1), (2), (3);
5. CREATE TABLE t2 (a INT) ENGINE = MyISAM; -- Transaction 1 COMMIT
-- (implicit; DDL forces commit)
6. INSERT INTO t2 VALUES (1), (2), (3); -- Update nontransactional table
7. UPDATE t2 SET a = a + 1; -- ... and again
8. INSERT INTO t1 VALUES (4), (5), (6); -- Write to transactional table
-- Transaction 2 START (implicit)
9. COMMIT; -- Transaction 2 COMMIT

```

From the perspective of the server, Transaction 1 ends when table `t2` is created. Transaction 2 does not start until a transactional table is accessed, despite the intervening updates to nontransactional tables.

From the perspective of the Performance Schema, Transaction 2 starts when the server transitions into an active transaction state. Statements 6 and 7 are not included within the boundaries of Transaction 2, which is consistent with how the server writes transactions to the binary log.

Transaction Instrumentation

Three attributes define transactions:

- Access mode (read only, read write)
- Isolation level (`SERIALIZABLE`, `REPEATABLE READ`, and so forth)
- Implicit (`autocommit` enabled) or explicit (`autocommit` disabled)

To reduce complexity of the transaction instrumentation and to ensure that the collected transaction data provides complete, meaningful results, all transactions are instrumented independently of access mode, isolation level, or autocommit mode.

To selectively examine transaction history, use the attribute columns in the transaction event tables: `ACCESS_MODE`, `ISOLATION_LEVEL`, and `AUTOCOMMIT`.

The cost of transaction instrumentation can be reduced various ways, such as enabling or disabling transaction instrumentation according to user, account, host, or thread (client connection).

Transactions and Nested Events

The parent of a transaction event is the event that initiated the transaction. For an explicitly started transaction, this includes the `START TRANSACTION` and `COMMIT AND CHAIN` statements. For an implicitly started transaction, it is the first statement that uses a transactional engine after the previous transaction ends.

In general, a transaction is the top-level parent to all events initiated during the transaction, including statements that explicitly end the transaction such as `COMMIT` and `ROLLBACK`. Exceptions are statements that implicitly end a transaction, such as DDL statements, in which case the current transaction must be committed before the new statement is executed.

Transactions and Stored Programs

Transactions and stored program events are related as follows:

- Stored Procedures

Stored procedures operate independently of transactions. A stored procedure can be started within a transaction, and a transaction can be started or ended from within a stored procedure. If called from

within a transaction, a stored procedure can execute statements that force a commit of the parent transaction and then start a new transaction.

If a stored procedure is started within a transaction, that transaction is the parent of the stored procedure event.

If a transaction is started by a stored procedure, the stored procedure is the parent of the transaction event.

- Stored Functions

Stored functions are restricted from causing an explicit or implicit commit or rollback. Stored function events can reside within a parent transaction event.

- Triggers

Triggers activate as part of a statement that accesses the table with which it is associated, so the parent of a trigger event is always the statement that activates it.

Triggers cannot issue statements that cause an explicit or implicit commit or rollback of a transaction.

- Scheduled Events

The execution of the statements in the body of a scheduled event takes place in a new connection. Nesting of a scheduled event within a parent transaction is not applicable.

Transactions and Savepoints

Savepoint statements are recorded as separate statement events. Transaction events include separate counters for `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, and `RELEASE SAVEPOINT` statements issued during the transaction.

Transactions and Errors

Errors and warnings that occur within a transaction are recorded in statement events, but not in the corresponding transaction event. This includes transaction-specific errors and warnings, such as a rollback on a nontransactional table or GTID consistency errors.

25.11.7.1 The `events_transactions_current` Table

The `events_transactions_current` table contains current transaction events, one row per thread showing the current status of the thread's most recent monitored transaction event. For example:

```
mysql> SELECT * FROM events_transactions_current LIMIT 1\G
***** 1. row *****
      THREAD_ID: 26
      EVENT_ID: 7
      END_EVENT_ID: NULL
      EVENT_NAME: transaction
      STATE: ACTIVE
      TRX_ID: NULL
      GTID: 3E11FA47-71CA-11E1-9E33-C80AA9429562:56
      XID: NULL
      XA_STATE: NULL
      SOURCE: transaction.cc:150
      TIMER_START: 420833537900000
      TIMER_END: NULL
      TIMER_WAIT: NULL
      ACCESS_MODE: READ WRITE
      ISOLATION_LEVEL: REPEATABLE READ
      AUTOCOMMIT: NO
      NUMBER_OF_SAVEPOINTS: 0
      NUMBER_OF_ROLLBACK_TO_SAVEPOINT: 0
      NUMBER_OF_RELEASE_SAVEPOINT: 0
```

```
OBJECT_INSTANCE_BEGIN: NULL
NESTING_EVENT_ID: 6
NESTING_EVENT_TYPE: STATEMENT
```

Of the tables that contain transaction event rows, `events_transactions_current` is the most fundamental. Other tables that contain transaction event rows are logically derived from the current events. For example, the `events_transactions_history` and `events_transactions_history_long` tables are collections of the most recent transaction events, up to a fixed number of rows.

For information about configuration of transaction event collection, see [Section 25.11.7, “Performance Schema Transaction Tables”](#).

The `events_transactions_current` table has these columns:

- `THREAD_ID`, `EVENT_ID`

The thread associated with the event and the thread current event number when the event starts. The `THREAD_ID` and `EVENT_ID` values taken together uniquely identify the row. No two rows have the same pair of values.

- `END_EVENT_ID`

This column is set to `NULL` when the event starts and updated to the thread current event number when the event ends.

- `EVENT_NAME`

The name of the instrument from which the event was collected. This is a `NAME` value from the `setup_instruments` table. Instrument names may have multiple parts and form a hierarchy, as discussed in [Section 25.6, “Performance Schema Instrument Naming Conventions”](#).

- `STATE`

The current transaction state. The value is `ACTIVE` (after `START TRANSACTION` or `BEGIN`), `COMMITTED` (after `COMMIT`), or `ROLLED BACK` (after `ROLLBACK`).

- `TRX_ID`

Unused.

- `GTID`

The GTID column contains the value of `gtid_next`, which can be one of `ANONYMOUS`, `AUTOMATIC`, or a GTID using the format `UUID:NUMBER`. For transactions that use `gtid_next=AUTOMATIC`, which is all normal client transactions, the GTID column changes when the transaction commits and the actual GTID is assigned. If `gtid_mode` is either `ON` or `ON_PERMISSIVE`, the GTID column changes to the transaction's GTID. If `gtid_mode` is either `OFF` or `OFF_PERMISSIVE`, the GTID column changes to `ANONYMOUS`.

- `XID_FORMAT_ID`, `XID_GTRID`, and `XID_BQUAL`

The components of the XA transaction identifier. They have the format described in [Section 13.3.7.1, “XA Transaction SQL Syntax”](#).

- `XA_STATE`

The state of the XA transaction. The value is `ACTIVE` (after `XA START`), `IDLE` (after `XA END`), `PREPARED` (after `XA PREPARE`), `ROLLED BACK` (after `XA ROLLBACK`), or `COMMITTED` (after `XA COMMIT`).

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- `TIMER_START`, `TIMER_END`, `TIMER_WAIT`

Timing information for the event. The unit for these values is picoseconds (trillionths of a second). The `TIMER_START` and `TIMER_END` values indicate when event timing started and ended. `TIMER_WAIT` is the event elapsed time (duration).

If an event has not finished, `TIMER_END` is the current timer value and `TIMER_WAIT` is the time elapsed so far (`TIMER_END - TIMER_START`).

If an event is produced from an instrument that has `TIMED = NO`, timing information is not collected, and `TIMER_START`, `TIMER_END`, and `TIMER_WAIT` are all `NULL`.

For discussion of picoseconds as the unit for event times and factors that affect time values, see [Section 25.4.1, “Performance Schema Event Timing”](#).

- `ACCESS_MODE`

The transaction access mode. The value is `READ ONLY` or `READ WRITE`.

- `ISOLATION_LEVEL`

The transaction isolation level. The value is `REPEATABLE READ`, `READ COMMITTED`, `READ UNCOMMITTED`, or `SERIALIZABLE`.

- `AUTOCOMMIT`

Whether autocommit mode was enabled when the transaction started.

- `NUMBER_OF_SAVEPOINTS`, `NUMBER_OF_ROLLBACK_TO_SAVEPOINT`,
`NUMBER_OF_RELEASE_SAVEPOINT`

The number of `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, and `RELEASE SAVEPOINT` statements issued during the transaction.

- `OBJECT_INSTANCE_BEGIN`

Unused.

- `NESTING_EVENT_ID`

The `EVENT_ID` value of the event within which this event is nested.

- `NESTING_EVENT_TYPE`

The nesting event type. The value is `TRANSACTION`, `STATEMENT`, `STAGE`, or `WAIT`. (`TRANSACTION` will not appear because transactions cannot be nested.)

The `events_transactions_current` table has these indexes:

- Primary key on (`THREAD_ID`, `EVENT_ID`)

`TRUNCATE TABLE` is permitted for the `events_transactions_current` table. It removes the rows.

25.11.7.2 The `events_transactions_history` Table

The `events_transactions_history` table contains the most recent *N* transaction events per thread. The value of *N* is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_transactions_history_size` system variable at server startup.

Transaction events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full.

The `events_transactions_history` table has the same structure as `events_transactions_current`, including indexing. See [Section 25.11.7.1, “The events_transactions_current Table”](#).

`TRUNCATE TABLE` is permitted for the `events_transactions_history` table. It removes the rows.

For information about configuration of transaction event collection, see [Section 25.11.7, “Performance Schema Transaction Tables”](#).

25.11.7.3 The events_transactions_history_long Table

The `events_transactions_history_long` table contains the most recent N transaction events. The value of N is autosized at server startup. To set the table size explicitly, set the `performance_schema_events_transactions_history_long_size` system variable at server startup. Transaction events are not added to the table until they have ended. As new events are added, older events are discarded if the table is full. When a thread ends, its rows are removed from the table.

The `events_transactions_history_long` table has the same structure as `events_transactions_current`, except that it has no indexes. See [Section 25.11.7.1, “The events_transactions_current Table”](#).

`TRUNCATE TABLE` is permitted for the `events_transactions_history_long` table. It removes the rows.

For information about configuration of transaction event collection, see [Section 25.11.7, “Performance Schema Transaction Tables”](#).

25.11.8 Performance Schema Connection Tables

When a client connects to the MySQL server, it does so under a particular user name and from a particular host. The Performance Schema provides statistics about these connections, tracking them per account (user and host combination) as well as separately per user name and host name, using these tables:

- `accounts`: Connection statistics per client account
- `hosts`: Connection statistics per client host name
- `users`: Connection statistics per client user name

The meaning of “account” in the connection tables is similar to its meaning in the MySQL grant tables in the `mysql` system database, in the sense that the term refers to a combination of user and host values. They differ in that, for grant tables, the host part of an account can be a pattern, whereas for Performance Schema tables, the host value is always a specific nonpattern host name.

Each connection table has `CURRENT_CONNECTIONS` and `TOTAL_CONNECTIONS` columns to track the current and total number of connections per “tracking value” on which its statistics are based. The tables differ in what they use for the tracking value. The `accounts` table has `USER` and `HOST` columns to track connections per user and host combination. The `users` and `hosts` tables have a `USER` and `HOST` column, respectively, to track connections per user name and host name.

The Performance Schema also counts internal threads and threads for user sessions that failed to authenticate, using rows with `USER` and `HOST` column values of `NULL`.

Suppose that clients named `user1` and `user2` each connect one time from `hosta` and `hostb`. The Performance Schema tracks the connections as follows:

- The `accounts` table has four rows, for the `user1/hosta`, `user1/hostb`, `user2/hosta`, and `user2/hostb` account values, each row counting one connection per account.

- The `hosts` table has two rows, for `hosta` and `hostb`, each row counting two connections per host name.
- The `users` table has two rows, for `user1` and `user2`, each row counting two connections per user name.

When a client connects, the Performance Schema determines which row in each connection table applies, using the tracking value appropriate to each table. If there is no such row, one is added. Then the Performance Schema increments by one the `CURRENT_CONNECTIONS` and `TOTAL_CONNECTIONS` columns in that row.

When a client disconnects, the Performance Schema decrements by one the `CURRENT_CONNECTIONS` column in the row and leaves the `TOTAL_CONNECTIONS` column unchanged.

`TRUNCATE TABLE` is permitted for connection tables. It has these effects:

- Rows are removed for accounts, hosts, or users that have no current connections (rows with `CURRENT_CONNECTIONS = 0`).
- Nonremoved rows are reset to count only current connections: For rows with `CURRENT_CONNECTIONS > 0`, `TOTAL_CONNECTIONS` is reset to `CURRENT_CONNECTIONS`.
- Summary tables that depend on the connection table are implicitly truncated, as described later in this section.

The Performance Schema maintains summary tables that aggregate connection statistics for various event types by account, host, or user. These tables have `_summary_by_account`, `_summary_by_host`, or `_summary_by_user` in the name. To identify them, use this query:

```
mysql> SELECT TABLE_NAME FROM INFORMATION_SCHEMA.TABLES
WHERE TABLE_SCHEMA = 'performance_schema'
AND TABLE_NAME REGEXP '_summary_by_(account|host|user) '
ORDER BY TABLE_NAME;
```

TABLE_NAME
events_errors_summary_by_account_by_error
events_errors_summary_by_host_by_error
events_errors_summary_by_user_by_error
events_stages_summary_by_account_by_event_name
events_stages_summary_by_host_by_event_name
events_stages_summary_by_user_by_event_name
events_statements_summary_by_account_by_event_name
events_statements_summary_by_host_by_event_name
events_statements_summary_by_user_by_event_name
events_transactions_summary_by_account_by_event_name
events_transactions_summary_by_host_by_event_name
events_transactions_summary_by_user_by_event_name
events_waits_summary_by_account_by_event_name
events_waits_summary_by_host_by_event_name
events_waits_summary_by_user_by_event_name
memory_summary_by_account_by_event_name
memory_summary_by_host_by_event_name
memory_summary_by_user_by_event_name

For details about individual connection summary tables, consult the section that describes tables for the summarized event type:

- Wait event summaries: [Section 25.11.15.1, “Wait Event Summary Tables”](#)
- Stage event summaries: [Section 25.11.15.2, “Stage Summary Tables”](#)
- Statement event summaries: [Section 25.11.15.3, “Statement Summary Tables”](#)
- Transaction event summaries: [Section 25.11.15.5, “Transaction Summary Tables”](#)

- Memory event summaries: [Section 25.11.15.10, “Memory Summary Tables”](#)
- Error event summaries: [Section 25.11.15.11, “Error Summary Tables”](#)

`TRUNCATE TABLE` is permitted for connection summary tables. It removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows. In addition, each summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends. The following table describes the relationship between connection table truncation and implicitly truncated tables.

Table 25.2 Implicit Effects of Connection Table Truncation

Truncated Connection Table	Implicitly Truncated Summary Tables
<code>accounts</code>	Tables with names containing <code>_summary_by_account</code> , <code>_summary_by_thread</code>
<code>hosts</code>	Tables with names containing <code>_summary_by_account</code> , <code>_summary_by_host</code> , <code>_summary_by_thread</code>
<code>users</code>	Tables with names containing <code>_summary_by_account</code> , <code>_summary_by_user</code> , <code>_summary_by_thread</code>

Truncating a `_summary_global` summary table also implicitly truncates its corresponding connection and thread summary tables. For example, truncating `events_waits_summary_global_by_event_name` implicitly truncates the wait event summary tables that are aggregated by account, host, user, or thread.

25.11.8.1 The `accounts` Table

The `accounts` table contains a row for each account that has connected to the MySQL server. For each account, the table counts the current and total number of connections. The table size is autosized at server startup. To set the table size explicitly, set the `performance_schema_accounts_size` system variable at server startup. To disable account statistics, set this variable to 0.

The `accounts` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of `TRUNCATE TABLE`, see [Section 25.11.8, “Performance Schema Connection Tables”](#).

- `USER`

The client user name for the connection. This is `NULL` for an internal thread, or for a user session that failed to authenticate.

- `HOST`

The host from which the client connected. This is `NULL` for an internal thread, or for a user session that failed to authenticate.

- `CURRENT_CONNECTIONS`

The current number of connections for the account.

- `TOTAL_CONNECTIONS`

The total number of connections for the account.

The `accounts` table has these indexes:

- Primary key on (`USER`, `HOST`)

25.11.8.2 The `hosts` Table

The `hosts` table contains a row for each host from which clients have connected to the MySQL server. For each host name, the table counts the current and total number of connections. The table size is autosized at server startup. To set the table size explicitly, set the `performance_schema_hosts_size` system variable at server startup. To disable host statistics, set this variable to 0.

The `hosts` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of `TRUNCATE TABLE`, see [Section 25.11.8, “Performance Schema Connection Tables”](#).

- `HOST`

The host from which the client connected. This is `NULL` for an internal thread, or for a user session that failed to authenticate.

- `CURRENT_CONNECTIONS`

The current number of connections for the host.

- `TOTAL_CONNECTIONS`

The total number of connections for the host.

The `hosts` table has these indexes:

- Primary key on (`HOST`)

25.11.8.3 The users Table

The `users` table contains a row for each user who has connected to the MySQL server. For each user name, the table counts the current and total number of connections. The table size is autosized at server startup. To set the table size explicitly, set the `performance_schema_users_size` system variable at server startup. To disable user statistics, set this variable to 0.

The `users` table has the following columns. For a description of how the Performance Schema maintains rows in this table, including the effect of `TRUNCATE TABLE`, see [Section 25.11.8, “Performance Schema Connection Tables”](#).

- `USER`

The client user name for the connection. This is `NULL` for an internal thread, or for a user session that failed to authenticate.

- `CURRENT_CONNECTIONS`

The current number of connections for the user.

- `TOTAL_CONNECTIONS`

The total number of connections for the user.

The `users` table has these indexes:

- Primary key on (`USER`)

25.11.9 Performance Schema Connection Attribute Tables

Application programs can provide key/value pairs as connection attributes to be passed to the server at connect time. For the C API, define the attribute set using the `mysql_options()` and `mysql_options4()` functions. Other MySQL Connectors may provide their own attribute-definition methods.

These tables expose attribute information:

- `session_account_connect_attrs`: Connection attributes for the current session, and other sessions associated with the session account
- `session_connect_attrs`: Connection attributes for all sessions

Attribute names that begin with an underscore (`_`) are reserved for internal use and should not be created by application programs. This convention permits new attributes to be introduced by MySQL without colliding with application attributes.

The set of connection attributes visible on a given connection varies depending on your platform and MySQL Connector used to establish the connection.

The `libmysqlclient` client library (provided in MySQL and MySQL Connector/C distributions) sets these attributes:

- `_client_name`: The client name (`libmysql` for the client library)
- `_client_version`: The client library version
- `_os`: The operating system (for example, `Linux`, `Win64`)
- `_pid`: The client process ID
- `_platform`: The machine platform (for example, `x86_64`)
- `_thread`: The client thread ID (Windows only)

Other MySQL Connectors may define their own connection attributes.

MySQL Connector/J defines these attributes:

- `_client_license`: The connector license type
- `_runtime_vendor`: The Java runtime environment (JRE) vendor
- `_runtime_version`: The Java runtime environment (JRE) version

MySQL Connector/Net defines these attributes:

- `_client_version`: The client library version
- `_os`: The operating system (for example, `Linux`, `Win64`)
- `_pid`: The client process ID
- `_platform`: The machine platform (for example, `x86_64`)
- `_program_name`: The client name
- `_thread`: The client thread ID (Windows only)

PHP defines attributes that depend on how it was compiled:

- Compiled using `libmysqlclient`: The standard `libmysqlclient` attributes, described previously
- Compiled using `mysqlnd`: Only the `_client_name` attribute, with a value of `mysqlnd`

Many MySQL client programs set a `program_name` attribute with a value equal to the client name. For example, `mysqladmin` and `mysqldump` set `program_name` to `mysqladmin` and `mysqldump`, respectively.

Some MySQL client programs define additional attributes:

- `mysqlbinlog` defines the `_client_role` attribute as `binary_log_listener`.
- Replication slave connections define `program_name` as `mysqld`, `_client_role` as `binary_log_listener`, and `_client_replication_channel_name` as the channel name.
- `FEDERATED` storage engine connections define `program_name` as `mysqld` and `_client_role` as `federated_storage`.

There are limits on the amount of connection attribute data transmitted from client to server: A fixed limit imposed by the client prior to connect time; a fixed limit imposed by the server at connect time; and a configurable limit imposed by the Performance Schema at connect time.

For connections initiated using the C API, the `libmysqlclient` library imposes a limit of 64KB on the aggregate size of connection attribute data on the client side: Calls to `mysql_options()` that cause this limit to be exceeded produce a `CR_INVALID_PARAMETER_NO` error. Other MySQL Connectors may impose their own client-side limits on how much connection attribute data can be transmitted to the server.

On the server side, these size checks on connection attribute data occur:

- The server imposes a limit of 64KB on the aggregate size of connection attribute data it will accept. If a client attempts to send more than 64KB of attribute data, the server rejects the connection. Otherwise, the server considers the attribute buffer valid and tracks the size of the longest such buffer in the `Performance_schema_session_connect_attrs_longest_seen` status variable.
- For accepted connections, the Performance Schema checks aggregate attribute size against the value of the `performance_schema_session_connect_attrs_size` system variable. If attribute size exceeds this value, these actions take place:
 - The Performance Schema truncates the attribute data and increments the `Performance_schema_session_connect_attrs_lost` status variable, which indicates the number of connections for which attribute truncation occurred.
 - The Performance Schema writes a message to the error log if the `log_warnings` system variable is greater than zero:

```
Connection attributes of length N were truncated (N bytes lost)
for connection N, user user_name@host_name (as user_name), auth: {yes|no}
```

The information in the warning message is intended to help DBAs identify clients for which attribute truncation occurred.

- A `_truncated` attribute is added to the session attributes with a value indicating how many bytes were lost, if the attribute buffer has sufficient space. This enables the Performance Schema to expose per-connection truncation information in the connection attribute tables. This information can be examined without having to check the error log.

25.11.9.1 The `session_account_connect_attrs` Table

Application programs can provide key/value connection attributes to be passed to the server at connect time, using the `mysql_options()` and `mysql_options4()` C API functions. For descriptions of common attributes, see [Section 25.11.9, “Performance Schema Connection Attribute Tables”](#).

The `session_account_connect_attrs` table contains connection attributes only for sessions for your own account. To see connection attributes for all sessions, look in the `session_connect_attrs` table.

The `session_account_connect_attrs` table contains these columns:

- `PROCESSLIST_ID`

The connection identifier for the session.

- `ATTR_NAME`

The attribute name.

- `ATTR_VALUE`

The attribute value.

- `ORDINAL_POSITION`

The order in which the attribute was added to the set of connection attributes.

The `session_account_connect_attrs` table has these indexes:

- Primary key on (`PROCESSLIST_ID`, `ATTR_NAME`)

`TRUNCATE TABLE` is not permitted for the `session_account_connect_attrs` table.

25.11.9.2 The `session_connect_attrs` Table

Application programs can provide key/value connection attributes to be passed to the server at connect time, using the `mysql_options()` and `mysql_options4()` C API functions. For descriptions of common attributes, see [Section 25.11.9, “Performance Schema Connection Attribute Tables”](#).

The `session_connect_attrs` table contains connection attributes for all sessions. To see connection attributes only for sessions for your own account, look in the `session_account_connect_attrs` table.

The `session_connect_attrs` table contains these columns:

- `PROCESSLIST_ID`

The connection identifier for the session.

- `ATTR_NAME`

The attribute name.

- `ATTR_VALUE`

The attribute value.

- `ORDINAL_POSITION`

The order in which the attribute was added to the set of connection attributes.

The `session_connect_attrs` table has these indexes:

- Primary key on (`PROCESSLIST_ID`, `ATTR_NAME`)

`TRUNCATE TABLE` is not permitted for the `session_connect_attrs` table.

25.11.10 Performance Schema User Variable Tables

The Performance Schema provides a `user_variables_by_thread` table that exposes user-defined variables. These are variables defined within a specific session and include a `@` character preceding the name; see [Section 9.4, “User-Defined Variables”](#).

The `user_variables_by_thread` table contains these columns:

- `THREAD_ID`

The thread identifier of the session in which the variable is defined.

- `VARIABLE_NAME`

The variable name, without the leading `@` character.

- `VARIABLE_VALUE`

The variable value.

The `user_variables_by_thread` table has these indexes:

- Primary key on (`THREAD_ID`, `VARIABLE_NAME`)

`TRUNCATE TABLE` is not permitted for the `user_variables_by_thread` table.

25.11.11 Performance Schema Replication Tables

The Performance Schema provides tables that expose replication information. This is similar to the information available from the `SHOW SLAVE STATUS` statement, but representation in table form is more accessible and has usability benefits:

- `SHOW SLAVE STATUS` output is useful for visual inspection, but not so much for programmatic use. By contrast, using the Performance Schema tables, information about slave status can be searched using general `SELECT` queries, including complex `WHERE` conditions, joins, and so forth.
- Query results can be saved in tables for further analysis, or assigned to variables and thus used in stored procedures.
- The replication tables provide better diagnostic information. For multi-threaded slave operation, `SHOW SLAVE STATUS` reports all coordinator and worker thread errors using the `Last_SQL_Errno` and `Last_SQL_Error` fields, so only the most recent of those errors is visible and information can be lost. The replication tables store errors on a per-thread basis without loss of information.
- The last seen transaction is visible in the replication tables on a per-worker basis. This is information not available from `SHOW SLAVE STATUS`.
- Developers familiar with the Performance Schema interface can extend the replication tables to provide additional information by adding rows to the tables.

Replication Table Descriptions

The Performance Schema provides the following replication-related tables:

- Tables that contain information about the connection of the slave server to the master server:
 - `replication_connection_configuration`: Configuration parameters for connecting to the master
 - `replication_connection_status`: Current status of the connection to the master
- Tables that contain general (not thread-specific) information about the transaction applier:
 - `replication_applier_configuration`: Configuration parameters for the transaction applier on the slave.
 - `replication_applier_status`: Current status of the transaction applier on the slave.

- Tables that contain information about specific threads responsible for applying transactions received from the master:
 - `replication_applier_status_by_coordinator`: Status of the coordinator thread (empty unless the slave is multi-threaded).
 - `replication_applier_status_by_worker`: Status of the applier thread or worker threads if the slave is multi-threaded.
- Tables that contain information about channel based replication filters:
 - `replication_applier_filters`: Provides information about the replication filters configured on specific replication channels.
 - `replication_applier_global_filters`: Provides information about global replication filters, which apply to all replication channels.
- Tables that contain information about Group Replication members:
 - `replication_group_members`: Provides network and status information for group members.
 - `replication_group_member_stats`: Provides statistical information about group members and transactions in which they participate.

For more information see [Section 21.3, “Monitoring Group Replication”](#).

The following Performance Schema replication tables continue to be populated when the Performance Schema is disabled:

- `replication_connection_configuration`
- `replication_connection_status`
- `replication_applier_configuration`
- `replication_applier_status`
- `replication_applier_status_by_coordinator`
- `replication_applier_status_by_worker`

The exception is local timing information (start and end timestamps for transactions) in the replication tables `replication_connection_status`, `replication_applier_status_by_coordinator`, and `replication_applier_status_by_worker`. This information is not collected when the Performance Schema is disabled.

The following sections describe each replication table in more detail, including the correspondence between the columns produced by `SHOW SLAVE STATUS` and the replication table columns in which the same information appears.

The remainder of this introduction to the replication tables describes how the Performance Schema populates them and which fields from `SHOW SLAVE STATUS` are not represented in the tables.

Replication Table Life Cycle

The Performance Schema populates the replication tables as follows:

- Prior to execution of `CHANGE MASTER TO`, the tables are empty.
- After `CHANGE MASTER TO`, the configuration parameters can be seen in the tables. At this time, there are no active slave threads, so the `THREAD_ID` columns are `NULL` and the `SERVICE_STATE` columns have a value of `OFF`.

- After `START SLAVE`, non-NULL `THREAD_ID` values can be seen. Threads that are idle or active have a `SERVICE_STATE` value of `ON`. The thread that connects to the master server has a value of `CONNECTING` while it establishes the connection, and `ON` thereafter as long as the connection lasts.
- After `STOP SLAVE`, the `THREAD_ID` columns become `NULL` and the `SERVICE_STATE` columns for threads that no longer exist have a value of `OFF`.
- The tables are preserved after `STOP SLAVE` or threads dying due to an error.
- The `replication_applier_status_by_worker` table is nonempty only when the slave is operating in multi-threaded mode. That is, if the `slave_parallel_workers` system variable is greater than 0, this table is populated when `START SLAVE` is executed, and the number of rows shows the number of workers.

SHOW SLAVE STATUS Information Not In the Replication Tables

The information in the Performance Schema replication tables differs somewhat from the information available from `SHOW SLAVE STATUS` because the tables are oriented toward use of global transaction identifiers (GTIDs), not file names and positions, and they represent server UUID values, not server ID values. Due to these differences, several `SHOW SLAVE STATUS` columns are not preserved in the Performance Schema replication tables, or are represented a different way:

- The following fields refer to file names and positions and are not preserved:

```
Master_Log_File
Read_Master_Log_Pos
Relay_Log_File
Relay_Log_Pos
Relay_Master_Log_File
Exec_Master_Log_Pos
Until_Condition
Until_Log_File
Until_Log_Pos
```

- The `Master_Info_File` field is not preserved. It refers to the `master.info` file, which has been superseded by crash-safe slave tables.
- The following fields are based on `server_id`, not `server_uuid`, and are not preserved:

```
Master_Server_Id
Replicate_Ignore_Server_Ids
```

- The `Skip_Counter` field is based on event counts, not GTIDs, and is not preserved.
- These error fields are aliases for `Last_SQL_Errno` and `Last_SQL_Error`, so they are not preserved:

```
Last_Errno
Last_Error
```

In the Performance Schema, this error information is available in the `LAST_ERROR_NUMBER` and `LAST_ERROR_MESSAGE` columns of the `replication_applier_status_by_coordinator` table (and `replication_applier_status_by_worker` if the slave is multi-threaded). Those tables provide more specific per-thread error information than is available from `Last_Errno` and `Last_Error`.

- Fields that provide information about command-line filtering options is not preserved:

```
Replicate_Do_DB
Replicate_Ignore_DB
Replicate_Do_Table
```

```
Replicate_Ignore_Table
Replicate_Wild_Do_Table
Replicate_Wild_Ignore_Table
```

- The `Slave_IO_State` and `Slave_SQL_Running_State` fields are not preserved. If needed, these values can be obtained from the process list by using the `THREAD_ID` column of the appropriate replication table and joining it with the `ID` column in the `INFORMATION_SCHEMA.PROCESSLIST` table to select the `STATE` column of the latter table.
- The `Executed_Gtid_Set` field can show a large set with a great deal of text. Instead, the Performance Schema tables show GTIDs of transactions that are currently being applied by the slave. Alternatively, the set of executed GTIDs can be obtained from the value of the `gtid_executed` system variable.
- The `Seconds_Behind_Master` and `Relay_Log_Space` fields are in to-be-decided status and are not preserved.

Status Variables Moved to Replication Tables

As of MySQL version 5.7.5, the following status variables (previously monitored using `SHOW STATUS`) were moved to the Performance Schema replication tables:

- `Slave_retried_transactions`
- `Slave_last_heartbeat`
- `Slave_received_heartbeats`
- `Slave_heartbeat_period`
- `Slave_running`

These status variables are now only relevant when a single replication channel is being used because they *only* report the status of the default replication channel. When multiple replication channels exist, use the Performance Schema replication tables described in this section, which report these variables for each existing replication channel.

Replication Channels

The first column of the replication Performance Schema tables is `CHANNEL_NAME`. This enables the tables to be viewed per replication channel. In a non-multisource replication setup there is a single default replication channel. When you are using multiple replication channels on a slave, you can filter the tables per replication channel to monitor a specific replication channel. See [Section 18.2.3, “Replication Channels”](#) and [Section 18.1.4.3, “Multi-Source Replication Monitoring”](#) for more information.

25.11.11.1 The replication_connection_configuration Table

This table shows the configuration parameters used by the slave server for connecting to the master server. Parameters stored in the table can be changed at runtime with the `CHANGE MASTER TO` statement, as indicated in the column descriptions.

Compared to the `replication_connection_status` table, `replication_connection_configuration` changes less frequently. It contains values that define how the slave connects to the master and that remain constant during the connection, whereas `replication_connection_status` contains values that change during the connection.

The `replication_connection_configuration` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 18.2.3, “Replication Channels”](#) for more information.

- [HOST](#)

The master host that the slave is connected to. ([CHANGE MASTER TO](#) option: [MASTER_HOST](#))

- [PORT](#)

The port used to connect to the master. ([CHANGE MASTER TO](#) option: [MASTER_PORT](#))

- [USER](#)

The user name of the account used to connect to the master. ([CHANGE MASTER TO](#) option: [MASTER_USER](#))

- [NETWORK_INTERFACE](#)

The network interface that the slave is bound to, if any. ([CHANGE MASTER TO](#) option: [MASTER_BIND](#))

- [AUTO_POSITION](#)

1 if autopositioning is in use; otherwise 0. ([CHANGE MASTER TO](#) option: [MASTER_AUTO_POSITION](#))

- [SSL_ALLOWED](#), [SSL_CA_FILE](#), [SSL_CA_PATH](#), [SSL_CERTIFICATE](#), [SSL_CIPHER](#), [SSL_KEY](#), [SSL_VERIFY_SERVER_CERTIFICATE](#), [SSL_CRL_FILE](#), [SSL_CRL_PATH](#)

These columns show the SSL parameters used by the slave to connect to the master, if any.

[SSL_ALLOWED](#) has these values:

- [Yes](#) if an SSL connection to the master is permitted
- [No](#) if an SSL connection to the master is not permitted
- [Ignored](#) if an SSL connection is permitted but the slave server does not have SSL support enabled

[CHANGE MASTER TO](#) options for the other SSL columns: [MASTER_SSL_CA](#), [MASTER_SSL_CAPATH](#), [MASTER_SSL_CERT](#), [MASTER_SSL_CIPHER](#), [MASTER_SSL_CRL](#), [MASTER_SSL_CRLPATH](#), [MASTER_SSL_KEY](#), [MASTER_SSL_VERIFY_SERVER_CERT](#).

- [CONNECTION_RETRY_INTERVAL](#)

The number of seconds between connect retries. ([CHANGE MASTER TO](#) option: [MASTER_CONNECT_RETRY](#))

- [CONNECTION_RETRY_COUNT](#)

The number of times the slave can attempt to reconnect to the master in the event of a lost connection. ([CHANGE MASTER TO](#) option: [MASTER_RETRY_COUNT](#))

- [HEARTBEAT_INTERVAL](#)

The replication heartbeat interval on a slave, measured in seconds.

The [replication_connection_configuration](#) table has these indexes:

- Primary key on ([CHANNEL_NAME](#))

[TRUNCATE TABLE](#) is not permitted for the [replication_connection_configuration](#) table.

The following table shows the correspondence between `replication_connection_configuration` columns and `SHOW SLAVE STATUS` columns.

<code>replication_connection_configuration</code> Column	<code>SHOW SLAVE STATUS</code> Column
HOST	Master_Host
PORT	Master_Port
USER	Master_User
NETWORK_INTERFACE	Master_Bind
AUTO_POSITION	Auto_Position
SSL_ALLOWED	Master_SSL_Allowed
SSL_CA_FILE	Master_SSL_CA_File
SSL_CA_PATH	Master_SSL_CA_Path
SSL_CERTIFICATE	Master_SSL_Cert
SSL_CIPHER	Master_SSL_Cipher
SSL_KEY	Master_SSL_Key
SSL_VERIFY_SERVER_CERTIFICATE	Master_SSL_Verify_Server_Cert
SSL_CRL_FILE	Master_SSL_Crl
SSL_CRL_PATH	Master_SSL_Crlpath
CONNECTION_RETRY_INTERVAL	Connect_Retry
CONNECTION_RETRY_COUNT	Master_Retry_Count

25.11.11.2 The `replication_connection_status` Table

This table shows the current status of the I/O thread that handles the slave server connection to the master server, information on the last transaction queued in the relay log, and information on the transaction currently being queued in the relay log.

Compared to the `replication_connection_configuration` table, `replication_connection_status` changes more frequently. It contains values that change during the connection, whereas `replication_connection_configuration` contains values which define how the slave connects to the master and that remain constant during the connection.

The `replication_connection_status` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 18.2.3, “Replication Channels”](#) for more information.

- `GROUP_NAME`

If this server is a member of a group, shows the name of the group the server belongs to.

- `SOURCE_UUID`

The `server_uuid` value from the master.

- `THREAD_ID`

The I/O thread ID.

- `SERVICE_STATE`

`ON` (thread exists and is active or idle), `OFF` (thread no longer exists), or `CONNECTING` (thread exists and is connecting to the master).

- `RECEIVED_TRANSACTION_SET`

The set of global transaction IDs (GTIDs) corresponding to all transactions received by this slave. Empty if GTIDs are not in use. See [GTID Sets](#) for more information.

- `LAST_ERROR_NUMBER`, `LAST_ERROR_MESSAGE`

The error number and error message of the most recent error that caused the I/O thread to stop. An error number of 0 and message of the empty string mean “no error.” If the `LAST_ERROR_MESSAGE` value is not empty, the error values also appear in the slave's error log.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

- `LAST_ERROR_TIMESTAMP`

A timestamp in 'YYYY-MM-DD HH:MM:SS[.fraction]' format that shows when the most recent I/O error took place.

- `LAST_HEARTBEAT_TIMESTAMP`

A timestamp in 'YYYY-MM-DD HH:MM:SS[.fraction]' format that shows when the most recent heartbeat signal was received by a replication slave.

- `COUNT_RECEIVED_HEARTBEATS`

The total number of heartbeat signals that a replication slave received since the last time it was restarted or reset, or a `CHANGE MASTER TO` statement was issued.

- `LAST_QUEUED_TRANSACTION`

The global transaction ID (GTID) of the last transaction that was queued to the relay log.

- `LAST_QUEUED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`

A timestamp in 'YYYY-MM-DD HH:MM:SS[.fraction]' format that shows when the last transaction queued in the relay log was committed on the original master.

- `LAST_QUEUED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP`

A timestamp in 'YYYY-MM-DD HH:MM:SS[.fraction]' format that shows when the last transaction queued in the relay log was committed on the immediate master.

- `LAST_QUEUED_TRANSACTION_START_QUEUE_TIMESTAMP`

A timestamp in 'YYYY-MM-DD HH:MM:SS[.fraction]' format that shows when the last transaction was placed in the relay log queue by this I/O thread.

- `LAST_QUEUED_TRANSACTION_END_QUEUE_TIMESTAMP`

A timestamp in 'YYYY-MM-DD HH:MM:SS[.fraction]' format that shows when the last transaction was queued to the relay log files.

- `QUEUEING_TRANSACTION`

The global transaction ID (GTID) of the currently queueing transaction in the relay log.

- `QUEUEING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`

A timestamp in 'YYYY-MM-DD HH:MM:SS[.fraction]' format that shows when the currently queueing transaction was committed on the original master.

- `QUEUEING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP`

A timestamp in 'YYYY-MM-DD HH:MM:SS[.fraction]' format that shows when the currently queueing transaction was committed on the immediate master.

- `QUEUEING_TRANSACTION_START_QUEUE_TIMESTAMP`

A timestamp in 'YYYY-MM-DD HH:MM:SS[.fraction]' format that shows when the first event of the currently queueing transaction was written to the relay log by this I/O thread.

When the Performance Schema is disabled, local timing information is not collected, so the fields showing the start and end timestamps for queued transactions are zero.

The `replication_connection_status` table has these indexes:

- Primary key on (`CHANNEL_NAME`)
- Index on (`THREAD_ID`)

The following table shows the correspondence between `replication_connection_status` columns and `SHOW SLAVE STATUS` columns.

<code>replication_connection_status</code> Column	<code>SHOW SLAVE STATUS</code> Column
<code>SOURCE_UUID</code>	<code>Master_UUID</code>
<code>THREAD_ID</code>	None
<code>SERVICE_STATE</code>	<code>Slave_IO_Running</code>
<code>RECEIVED_TRANSACTION_SET</code>	<code>Retrieved_Gtid_Set</code>
<code>LAST_ERROR_NUMBER</code>	<code>Last_IO_Errno</code>
<code>LAST_ERROR_MESSAGE</code>	<code>Last_IO_Error</code>
<code>LAST_ERROR_TIMESTAMP</code>	<code>Last_IO_Error_Timestamp</code>

25.11.11.3 The `replication_applier_configuration` Table

This table shows the configuration parameters that affect transactions applied by the slave server. Parameters stored in the table can be changed at runtime with the `CHANGE MASTER TO` statement, as indicated in the column descriptions.

The `replication_applier_configuration` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 18.2.3, “Replication Channels”](#) for more information.

- `DESIRED_DELAY`

The number of seconds that the slave must lag the master. (`CHANGE MASTER TO` option: `MASTER_DELAY`) See [Section 18.3.11, “Delayed Replication”](#) for more information.

The `replication_applier_configuration` table has these indexes:

- Primary key on (`CHANNEL_NAME`)

`TRUNCATE TABLE` is not permitted for the `replication_applier_configuration` table.

The following table shows the correspondence between `replication_applier_configuration` columns and `SHOW SLAVE STATUS` columns.

<code>replication_applier_configuration</code> Column	<code>SHOW SLAVE STATUS</code> Column
<code>DESIRED_DELAY</code>	<code>SQL_Delay</code>

25.11.11.4 The `replication_applier_status` Table

This table shows the current general transaction execution status on the slave server. The table provides information about general aspects of transaction applier status that are not specific to any thread involved. Thread-specific status information is available in the `replication_applier_status_by_coordinator` table (and `replication_applier_status_by_worker` if the slave is multi-threaded).

The `replication_applier_status` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 18.2.3, “Replication Channels”](#) for more information.

- `SERVICE_STATE`

Shows `ON` when the replication channel's applier threads are active or idle, `OFF` means that the applier threads are not active.

- `REMAINING_DELAY`

If the slave is waiting for `DESIRED_DELAY` seconds to pass since the master applied an transaction, this field contains the number of delay seconds remaining. At other times, this field is `NULL`. (The `DESIRED_DELAY` value is stored in the `replication_applier_configuration` table.) See [Section 18.3.11, “Delayed Replication”](#) for more information.

- `COUNT_TRANSACTIONS_RETRIES`

Shows the number of retries that were made because the slave SQL thread failed to apply a transaction.

The `replication_applier_status` table has these indexes:

- Primary key on (`CHANNEL_NAME`)

`TRUNCATE TABLE` is not permitted for the `replication_applier_status` table.

The following table shows the correspondence between `replication_applier_status` columns and `SHOW SLAVE STATUS` columns.

<code>replication_applier_status</code> Column	<code>SHOW SLAVE STATUS</code> Column
<code>SERVICE_STATE</code>	None
<code>REMAINING_DELAY</code>	<code>SQL_Remaining_Delay</code>

25.11.11.5 The `replication_applier_status_by_coordinator` Table

For a multi-threaded slave, the slave uses multiple worker threads and a coordinator thread to manage them, and this table shows the status of the coordinator thread. For a single-threaded slave, this table is empty. For a multi-threaded slave, the `replication_applier_status_by_worker` table shows the status of the worker threads. This table provides information about the last transaction which was buffered by the coordinator thread to a worker's queue, as well as the transaction it is currently buffering. The start timestamp refers to when this thread read the first event of the transaction from the

relay log to buffer it to a worker's queue, while the end timestamp refers to when the last event finished buffering to the worker's queue.

The `replication_applier_status_by_coordinator` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 18.2.3, "Replication Channels"](#) for more information.

- `THREAD_ID`

The SQL/coordinator thread ID.

- `SERVICE_STATE`

`ON` (thread exists and is active or idle) or `OFF` (thread no longer exists).

- `LAST_ERROR_NUMBER`, `LAST_ERROR_MESSAGE`

The error number and error message of the most recent error that caused the SQL/coordinator thread to stop. An error number of 0 and message which is an empty string means "no error". If the `LAST_ERROR_MESSAGE` value is not empty, the error values also appear in the slave's error log.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

All error codes and messages displayed in the `LAST_ERROR_NUMBER` and `LAST_ERROR_MESSAGE` columns correspond to error values listed in [Section B.3, "Server Error Codes and Messages"](#).

- `LAST_ERROR_TIMESTAMP`

A timestamp in `'YYYY-MM-DD HH:MM:SS[.fraction]'` format that shows when the most recent SQL/coordinator error occurred.

- `LAST_PROCESSED_TRANSACTION`

The global transaction ID (GTID) of the last transaction processed by this coordinator.

- `LAST_PROCESSED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`

A timestamp in `'YYYY-MM-DD HH:MM:SS[.fraction]'` format that shows when the last transaction processed by this coordinator was committed on the original master.

- `LAST_PROCESSED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP`

A timestamp in `'YYYY-MM-DD HH:MM:SS[.fraction]'` format that shows when the last transaction processed by this coordinator was committed on the immediate master.

- `LAST_PROCESSED_TRANSACTION_START_BUFFER_TIMESTAMP`

A timestamp in `'YYYY-MM-DD HH:MM:SS[.fraction]'` format that shows when this coordinator thread started writing the last transaction to the buffer of a worker thread.

- `LAST_PROCESSED_TRANSACTION_END_BUFFER_TIMESTAMP`

A timestamp in `'YYYY-MM-DD HH:MM:SS[.fraction]'` format that shows when the last transaction was written to the buffer of a worker thread by this coordinator thread.

- `PROCESSING_TRANSACTION`

The global transaction ID (GTID) of the transaction that this coordinator thread is currently processing.

- `PROCESSING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`

A timestamp in 'YYYY-MM-DD HH:MM:SS[.fraction]' format that shows when the currently processing transaction was committed on the original master.

- `PROCESSING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP`

A timestamp in 'YYYY-MM-DD HH:MM:SS[.fraction]' format that shows when the currently processing transaction was committed on the immediate master.

- `PROCESSING_TRANSACTION_START_BUFFER_TIMESTAMP`

A timestamp in 'YYYY-MM-DD HH:MM:SS[.fraction]' format that shows when this coordinator thread started writing the currently processing transaction to the buffer of a worker thread.

When the Performance Schema is disabled, local timing information is not collected, so the fields showing the start and end timestamps for buffered transactions are zero.

The `replication_applier_status_by_coordinator` table has these indexes:

- Primary key on (`CHANNEL_NAME`)
- Index on (`THREAD_ID`)

The following table shows the correspondence between `replication_applier_status_by_coordinator` columns and `SHOW SLAVE STATUS` columns.

<code>replication_applier_status_by_coordinator</code> Column	<code>SHOW SLAVE STATUS</code> Column
<code>THREAD_ID</code>	None
<code>SERVICE_STATE</code>	<code>Slave_SQL_Running</code>
<code>LAST_ERROR_NUMBER</code>	<code>Last_SQL_Errno</code>
<code>LAST_ERROR_MESSAGE</code>	<code>Last_SQL_Error</code>
<code>LAST_ERROR_TIMESTAMP</code>	<code>Last_SQL_Error_Timestamp</code>

25.11.11.6 The `replication_applier_status_by_worker` Table

If the slave is not multi-threaded, this table shows the status of the applier thread. Otherwise, the slave uses multiple worker threads and a coordinator thread to manage them, and this table shows the status of the worker threads. For a multi-threaded slave, the `replication_applier_status_by_coordinator` table shows the status of the coordinator thread. This table provides details about the transactions applied, where the start timestamp refers to when the worker started applying the first event, and the end timestamp refers to when the last event of the transaction was applied.

The `replication_applier_status_by_worker` table has these columns:

- `CHANNEL_NAME`

The replication channel which this row is displaying. There is always a default replication channel, and more replication channels can be added. See [Section 18.2.3, “Replication Channels”](#) for more information.

- `WORKER_ID`

The worker identifier (same value as the `id` column in the `mysql.slave_worker_info` table). After `STOP SLAVE`, the `THREAD_ID` column becomes `NULL`, but the `WORKER_ID` value is preserved.

- `THREAD_ID`

The worker thread ID.

- `SERVICE_STATE`

`ON` (thread exists and is active or idle) or `OFF` (thread no longer exists).

- `LAST_ERROR_NUMBER`, `LAST_ERROR_MESSAGE`

The error number and error message of the most recent error that caused the worker thread to stop. An error number of 0 and message of the empty string mean “no error”. If the `LAST_ERROR_MESSAGE` value is not empty, the error values also appear in the slave’s error log.

Issuing `RESET MASTER` or `RESET SLAVE` resets the values shown in these columns.

All error codes and messages displayed in the `LAST_ERROR_NUMBER` and `LAST_ERROR_MESSAGE` columns correspond to error values listed in [Section B.3, “Server Error Codes and Messages”](#).

- `LAST_ERROR_TIMESTAMP`

A timestamp in `'YYYY-MM-DD HH:MM:SS[.fraction]'` format that shows when the most recent worker error occurred.

- `LAST_APPLIED_TRANSACTION`

The global transaction ID (GTID) of the last transaction applied by this worker.

- `LAST_APPLIED_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`

A timestamp in `'YYYY-MM-DD HH:MM:SS[.fraction]'` format that shows when the last transaction applied by this worker was committed on the original master.

- `LAST_APPLIED_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP`

A timestamp in `'YYYY-MM-DD HH:MM:SS[.fraction]'` format that shows when the last transaction applied by this worker was committed on the immediate master.

- `LAST_APPLIED_TRANSACTION_START_APPLY_TIMESTAMP`

A timestamp in `'YYYY-MM-DD HH:MM:SS[.fraction]'` format that shows when this worker started applying the last applied transaction.

- `LAST_APPLIED_TRANSACTION_END_APPLY_TIMESTAMP`

A timestamp in `'YYYY-MM-DD HH:MM:SS[.fraction]'` format that shows when this worker finished applying the last applied transaction.

- `APPLYING_TRANSACTION`

The global transaction ID (GTID) of the transaction this worker is currently applying.

- `APPLYING_TRANSACTION_ORIGINAL_COMMIT_TIMESTAMP`

A timestamp in `'YYYY-MM-DD HH:MM:SS[.fraction]'` format that shows when the transaction this worker is currently applying was committed on the original master.

- `APPLYING_TRANSACTION_IMMEDIATE_COMMIT_TIMESTAMP`

A timestamp in `'YYYY-MM-DD HH:MM:SS[.fraction]'` format that shows when the transaction this worker is currently applying was committed on the immediate master.

- `APPLYING_TRANSACTION_START_APPLY_TIMESTAMP`

A timestamp in 'YYYY-MM-DD HH:MM:SS[.fraction]' format that shows when this worker started applying the transaction that is currently being applied.

When the Performance Schema is disabled, local timing information is not collected, so the fields showing the start and end timestamps for applied transactions are zero.

The `replication_applier_status_by_worker` table has these indexes:

- Primary key on (`CHANNEL_NAME`, `WORKER_ID`)
- Index on (`THREAD_ID`)

The following table shows the correspondence between `replication_applier_status_by_worker` columns and `SHOW SLAVE STATUS` columns.

<code>replication_applier_status_by_worker</code> Column	<code>SHOW SLAVE STATUS</code> Column
<code>WORKER_ID</code>	None
<code>THREAD_ID</code>	None
<code>SERVICE_STATE</code>	None
<code>LAST_SEEN_TRANSACTION</code>	None
<code>LAST_ERROR_NUMBER</code>	<code>Last_SQL_Errno</code>
<code>LAST_ERROR_MESSAGE</code>	<code>Last_SQL_Error</code>
<code>LAST_ERROR_TIMESTAMP</code>	<code>Last_SQL_Error_Timestamp</code>

25.11.11.7 The `replication_applier_global_filters` Table

This table shows the global replication filters configured on this slave. The `replication_applier_global_filters` table has the following columns:

- `FILTER_NAME`

The type of replication filter that has been configured.

- `FILTER_RULE`

The rules configured for the replication filter type using either `--replicate-*` command options or `CHANGE REPLICATION FILTER`.

- `CONFIGURED_BY`

The method used to configure the replication filter, can be one of:

- `CHANGE_REPLICATION_FILTER` configured by a global replication filter using a `CHANGE REPLICATION FILTER` statement.
- `STARTUP_OPTIONS` configured by a global replication filter using a `--replicate-*` option.
- `ACTIVE_SINCE`

Timestamp of when the replication filter was configured.

25.11.11.8 The `replication_applier_filters` Table

This table shows the replication channel specific filters configured on this slave. Each row provides information on a replication channel's configured type of filter. The `replication_applier_filters` table has the following columns:

- `CHANNEL_NAME`

The name of replication channel with a replication filter configured.

- `FILTER_NAME`

The type of replication filter that has been configured for this replication channel.

- `FILTER_RULE`

The rules configured for the replication filter type using either `--replicate-*` command options or `CHANGE REPLICATION FILTER`.

- `CONFIGURED_BY`

The method used to configure the replication filter, can be one of:

- `CHANGE_REPLICATION_FILTER` configured by a global replication filter using a `CHANGE REPLICATION FILTER` statement.
- `STARTUP_OPTIONS` configured by a global replication filter using a `--replicate-*` option.
- `CHANGE_REPLICATION_FILTER_FOR_CHANNEL` configured by a channel specific replication filter using a `CHANGE REPLICATION FILTER FOR CHANNEL` statement.
- `STARTUP_OPTIONS_FOR_CHANNEL` configured by a channel specific replication filter using a `--replicate-*` option.

- `ACTIVE_SINCE`

Timestamp of when the replication filter was configured.

25.11.11.9 The `replication_group_members` Table

This table shows network and status information for replication group members.

The `replication_group_members` table has the following columns:

- `CHANNEL_NAME`

Name of the group replication channel.

- `MEMBER_ID`

Identifier for this member; same as the server UUID.

- `MEMBER_HOST`

Network address of this member (host name or IP address).

- `MEMBER_PORT`

Port on which the server is listening.

- `MEMBER_STATE`

Current state of this member; can be any one of the following:

- `OFFLINE`: The group replication plugin is installed but has not been started.
 - `RECOVERING`: The server has joined a group from which it is retrieving data.
 - `ONLINE`: The member is in a fully functioning state.
- `MEMBER_ROLE`

Role of the member in the group, either `PRIMARY` or `SECONDARY`.

- `MEMBER_VERSION`

MySQL version of the member.

The `replication_group_members` table has these indexes:

- None

`TRUNCATE TABLE` is not permitted for the `replication_group_members` table.

25.11.11.10 The `replication_group_member_stats` Table

This table shows statistical information for replication group members.

The `replication_group_member_stats` table has the following columns:

- `CHANNEL_NAME`

Name of the group replication channel

- `VIEW_ID`

Current view identifier for this group.

- `MEMBER_ID`

Identifier for this member; same as the server UUID.

- `COUNT_TRANSACTIONS_IN_QUEUE`

Number of transactions pending certification

- `COUNT_TRANSACTIONS_CHECKED`

Number of transactions already certified by this member.

- `COUNT_CONFLICTS_DETECTED`

Number of transactions that were negatively certified.

- `COUNT_TRANSACTIONS_VALIDATING`

Number of transactions with which one can execute certification with them, but have not been garbage collected.

- `TRANSACTIONS_COMMITTED_ALL_MEMBERS`

Set of stable group transactions.

- `LAST_CONFLICT_FREE_TRANSACTION`

Latest transaction certified without conflicts.

- `COUNT_TRANSACTIONS_REMOTE_IN_APPLIER_QUEUE`

Number of waiting transactions this member has received from the group.

- `COUNT_TRANSACTIONS_REMOTE_APPLIED`

Number of transactions this member has received from the group and applied.

- [COUNT_TRANSACTIONS_LOCAL_PROPOSED](#)

Number of transactions this member originated and sent to the group.

- [COUNT_TRANSACTIONS_LOCAL_ROLLBACK](#)

Number of transactions this member originated that were rolled back by the group.

The [replication_group_member_stats](#) table has these indexes:

- None

`TRUNCATE TABLE` is not permitted for the [replication_group_member_stats](#) table.

25.11.12 Performance Schema Lock Tables

The Performance Schema exposes lock information through these tables:

- [data_locks](#): Data locks held and requested
- [data_lock_waits](#): Relationships between data lock owners and data lock requestors blocked by those owners
- [metadata_locks](#): Metadata locks held and requested
- [table_handles](#): Table locks held and requested

The following sections describe these tables in more detail.

25.11.12.1 The [data_locks](#) Table

The [data_locks](#) table shows data locks held and requested. For information about which lock requests are blocked by which held locks, see [Section 25.11.12.2, “The data_lock_waits Table”](#).

Example data lock information:

```
mysql> SELECT * FROM data_locks\G
***** 1. row *****
      ENGINE: INNODB
ENGINE_LOCK_ID: 4140:74
ENGINE_TRANSACTION_ID: 4140
      THREAD_ID: 37
      EVENT_ID: 9
      OBJECT_SCHEMA: test
      OBJECT_NAME: t1
      PARTITION_NAME: NULL
      SUBPARTITION_NAME: NULL
      INDEX_NAME: NULL
OBJECT_INSTANCE_BEGIN: 140489308280888
      LOCK_TYPE: TABLE
      LOCK_MODE: IX
      LOCK_STATUS: GRANTED
      LOCK_DATA: NULL
***** 2. row *****
      ENGINE: INNODB
ENGINE_LOCK_ID: 4140:66:5:1
ENGINE_TRANSACTION_ID: 4140
      THREAD_ID: 37
      EVENT_ID: 9
      OBJECT_SCHEMA: test
      OBJECT_NAME: t1
      PARTITION_NAME: NULL
      SUBPARTITION_NAME: NULL
      INDEX_NAME: GEN_CLUST_INDEX
OBJECT_INSTANCE_BEGIN: 140489320307736
      LOCK_TYPE: RECORD
      LOCK_MODE: X
```

```
LOCK_STATUS: GRANTED
LOCK_DATA: supremum pseudo-record
```

Unlike most Performance Schema data collection, there are no instruments for controlling whether data lock information is collected or system variables for controlling data lock table sizes. The Performance Schema collects information that is already available in the server, so there is no memory or CPU overhead to generate this information or need for parameters that control its collection.

Use the `data_locks` table to help diagnose performance problems that occur during times of heavy concurrent load. For `InnoDB`, see the discussion of this topic at [Section 15.14.2, “InnoDB INFORMATION_SCHEMA Transaction and Locking Information”](#).

The `data_locks` table has these columns:

- `ENGINE`:

The storage engine that holds or requested the lock.

- `ENGINE_LOCK_ID`:

The ID of the lock held or requested by the storage engine. Tuples of (`ENGINE_LOCK_ID`, `ENGINE`) values are unique.

Lock ID formats are internal and subject to change at any time. Applications should not rely on lock IDs having a particular format.

- `ENGINE_TRANSACTION_ID`:

The storage engine internal ID of the transaction that requested the lock.

For `InnoDB`, to obtain details about the transaction, join this column with the `TRX_ID` column of the `INFORMATION_SCHEMA INNODB_TRX` table.

- `THREAD_ID`:

The thread ID of the that owns the lock. To obtain details about the thread, join this column with the `THREAD_ID` column of the Performance Schema `threads` table.

- `EVENT_ID`:

The Performance Schema event that caused the lock. Tuples of (`THREAD_ID`, `EVENT_ID`) values implicitly identify a parent event in other Performance Schema tables:

- The parent wait event in `events_waits_xxx` tables
- The parent stage event in `events_stages_xxx` tables
- The parent statement event in `events_statements_xxx` tables
- The parent transaction event in `events_transactions_xxx` tables

To obtain details about the parent event, join the `THREAD_ID` and `EVENT_ID` columns with the columns of like name in the appropriate parent event table.

- `OBJECT_SCHEMA`:

The schema that contains the locked table.

- `OBJECT_NAME`:

The name of the locked table.

- `PARTITION_NAME`:

The name of the locked partition, if any; `NULL` otherwise.

- `SUBPARTITION_NAME`:

The name of the locked subpartition, if any; `NULL` otherwise.

- `INDEX_NAME`:

The name of the locked index, if any; `NULL` otherwise.

In practice, `InnoDB` always creates an index (`GEN_CLUST_INDEX`), so `INDEX_NAME` is non-`NULL` for `InnoDB` tables.

- `OBJECT_INSTANCE_BEGIN`:

The address in memory of the lock.

- `LOCK_TYPE`:

The type of lock.

The value is storage engine dependent. For `InnoDB`, permitted values are `RECORD` for a row-level lock, `TABLE` for a table-level lock.

- `LOCK_MODE`:

How the lock is requested.

The value is storage engine dependent. For `InnoDB`, permitted values are `S[,GAP]`, `X[,GAP]`, `IS[,GAP]`, `IX[,GAP]`, `AUTO_INC`, and `UNKNOWN`. Lock modes other than `AUTO_INC` and `UNKNOWN` indicate gap locks, if present. For information about `S`, `X`, `IS`, `IX`, and gap locks, refer to [Section 15.5.1, “InnoDB Locking”](#).

- `LOCK_STATUS`:

The status of the lock request.

The value is storage engine dependent. For `InnoDB`, permitted values are `GRANTED` (lock is held) and `PENDING` (lock is being waited for).

- `LOCK_DATA`:

The data associated with the lock, if any.

The value is storage engine dependent. For `InnoDB`, values are primary key values of the locked record if `LOCK_TYPE` is `RECORD`, otherwise `NULL`. This column contains the values of the primary key columns in the locked row, formatted as a valid SQL string (ready to be copied to SQL statements). If there is no primary key, `LOCK_DATA` is the unique `InnoDB` internal row ID number. If a gap lock is taken for key values or ranges above the largest value in the index, `LOCK_DATA` reports `supremum pseudo-record`. When the page containing the locked record is not in the buffer pool (in the case that it was paged out to disk while the lock was held), `InnoDB` does not fetch the page from disk, to avoid unnecessary disk operations. Instead, `LOCK_DATA` is set to `NULL`.

The `data_locks` table has these indexes:

- Primary key on (`ENGINE_LOCK_ID`, `ENGINE`)
- Index on (`ENGINE_TRANSACTION_ID`, `ENGINE`)
- Index on (`THREAD_ID`, `EVENT_ID`)
- Index on (`OBJECT_SCHEMA`, `OBJECT_NAME`, `PARTITION_NAME`, `SUBPARTITION_NAME`)

`TRUNCATE TABLE` is not permitted for the `data_locks` table.

25.11.12.2 The `data_lock_waits` Table

The `data_lock_waits` table implements a many-to-many relationship showing which data lock requests in the `data_locks` table are blocked by which held data locks in the `data_locks` table. Held locks in `data_locks` appear in `data_lock_waits` only if they block some lock request.

This information enables you to understand data lock dependencies between sessions. The table exposes not only which lock a session or transaction is waiting for, but which session or transaction currently holds that lock.

Example data lock wait information:

```
mysql> SELECT * FROM data_lock_waits\G
***** 1. row *****
ENGINE: INNODB
REQUESTING_ENGINE_LOCK_ID: 4141:66:5:2
REQUESTING_ENGINE_TRANSACTION_ID: 4141
REQUESTING_THREAD_ID: 38
REQUESTING_EVENT_ID: 11
REQUESTING_OBJECT_INSTANCE_BEGIN: 140489320441368
BLOCKING_ENGINE_LOCK_ID: 4140:66:5:2
BLOCKING_ENGINE_TRANSACTION_ID: 4140
BLOCKING_THREAD_ID: 37
BLOCKING_EVENT_ID: 9
BLOCKING_OBJECT_INSTANCE_BEGIN: 140489320307736
```

Unlike most Performance Schema data collection, there are no instruments for controlling whether data lock information is collected or system variables for controlling data lock table sizes. The Performance Schema collects information that is already available in the server, so there is no memory or CPU overhead to generate this information or need for parameters that control its collection.

Use the `data_lock_waits` table to help diagnose performance problems that occur during times of heavy concurrent load. For `InnoDB`, see the discussion of this topic at [Section 15.14.2, “InnoDB INFORMATION_SCHEMA Transaction and Locking Information”](#).

Because the columns in the `data_lock_waits` table are similar to those in the `data_locks` table, the column descriptions here are abbreviated. For more detailed column descriptions, see [Section 25.11.12.1, “The `data_locks` Table”](#).

The `data_lock_waits` table has these columns:

- `ENGINE`
The storage engine that requested the lock.
- `REQUESTING_ENGINE_LOCK_ID`
The ID of the lock requested by the storage engine. To obtain details about the lock, join this column with the `ENGINE_LOCK_ID` column of the `data_locks` table.
- `REQUESTING_ENGINE_TRANSACTION_ID`
The storage engine internal ID of the transaction that requested the lock.
- `REQUESTING_THREAD_ID`
The thread ID of the session that requested the lock.
- `REQUESTING_EVENT_ID`
The Performance Schema event that caused the lock request in the session that requested the lock.

- `REQUESTING_OBJECT_INSTANCE_BEGIN`

The address in memory of the requested lock.

- `BLOCKING_ENGINE_LOCK_ID`

The ID of the blocking lock. To obtain details about the lock, join this column with the `ENGINE_LOCK_ID` column of the `data_locks` table.

- `BLOCKING_ENGINE_TRANSACTION_ID`

The storage engine internal ID of the transaction that holds the blocking lock.

- `BLOCKING_THREAD_ID`

The thread ID of the session that holds the blocking lock.

- `BLOCKING_EVENT_ID`

The Performance Schema event that caused the blocking lock in the session that holds it.

- `BLOCKING_OBJECT_INSTANCE_BEGIN`

The address in memory of the blocking lock.

The `data_lock_waits` table has these indexes:

- Index on (`REQUESTING_ENGINE_LOCK_ID`, `ENGINE`)
- Index on (`BLOCKING_ENGINE_LOCK_ID`, `ENGINE`)
- Index on (`REQUESTING_ENGINE_TRANSACTION_ID`, `ENGINE`)
- Index on (`BLOCKING_ENGINE_TRANSACTION_ID`, `ENGINE`)
- Index on (`REQUESTING_THREAD_ID`, `REQUESTING_EVENT_ID`)
- Index on (`BLOCKING_THREAD_ID`, `BLOCKING_EVENT_ID`)

`TRUNCATE TABLE` is not permitted for the `data_lock_waits` table.

25.11.12.3 The `metadata_locks` Table

The Performance Schema exposes metadata lock information through the `metadata_locks` table:

- Locks that have been granted (shows which sessions own which current metadata locks)
- Locks that have been requested but not yet granted (shows which sessions are waiting for which metadata locks).
- Lock requests that have been killed by the deadlock detector or timed out and are waiting for the requesting session's lock request to be discarded

This information enables you to understand metadata lock dependencies between sessions. You can see not only which lock a session is waiting for, but which session currently holds that lock.

The `metadata_locks` table is read only and cannot be updated. It is autosized by default; to configure the table size, set the `performance_schema_max_metadata_locks` system variable at server startup.

Metadata lock instrumentation uses the `wait/lock/metadata/sql/mdl` instrument, which is enabled by default. (Prior to MySQL 8.0.2, the instrument is disabled by default.)

To control metadata lock instrumentation state at server startup, use lines like these in your `my.cnf` file:

- Enable:

```
[mysqld]
performance-schema-instrument='wait/lock/metadata/sql/mdl=ON'
```

- Disable:

```
[mysqld]
performance-schema-instrument='wait/lock/metadata/sql/mdl=OFF'
```

To control metadata lock instrumentation state at runtime, update the `setup_instruments` table:

- Enable:

```
UPDATE setup_instruments SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME = 'wait/lock/metadata/sql/mdl';
```

- Disable:

```
UPDATE setup_instruments SET ENABLED = 'NO', TIMED = 'NO'
WHERE NAME = 'wait/lock/metadata/sql/mdl';
```

The Performance Schema maintains `metadata_locks` table content as follows, using the `LOCK_STATUS` column to indicate the status of each lock:

- When a metadata lock is requested and obtained immediately, a row with a status of `GRANTED` is inserted.
- When a metadata lock is requested and not obtained immediately, a row with a status of `PENDING` is inserted.
- When a metadata lock previously requested is granted, its row status is updated to `GRANTED`.
- When a metadata lock is released, its row is deleted.
- When a pending lock request is canceled by the deadlock detector to break a deadlock (`ER_LOCK_DEADLOCK`), its row status is updated from `PENDING` to `VICTIM`.
- When a pending lock request times out (`ER_LOCK_WAIT_TIMEOUT`), its row status is updated from `PENDING` to `TIMEOUT`.
- When granted lock or pending lock request is killed, its row status is updated from `GRANTED` or `PENDING` to `KILLED`.
- The `VICTIM`, `TIMEOUT`, and `KILLED` status values are brief and signify that the lock row is about to be deleted.
- The `PRE_ACQUIRE_NOTIFY` and `POST_RELEASE_NOTIFY` status values are brief and signify that the metadata locking subsystem is notifying interested storage engines while entering lock acquisition or leaving lock release operations.

The `metadata_locks` table has these columns:

- `OBJECT_TYPE`

The type of lock used in the metadata lock subsystem: The value is one of `GLOBAL`, `SCHEMA`, `TABLE`, `FUNCTION`, `PROCEDURE`, `TRIGGER` (currently unused), `EVENT`, `COMMIT`, `USER LEVEL LOCK`, `TABLESPACE`, or `LOCKING SERVICE`.

A value of `USER LEVEL LOCK` indicates a lock acquired with `GET_LOCK()`. A value of `LOCKING SERVICE` indicates a lock acquired using the locking service described in [Section 28.3.1, “The Locking Service”](#).

- `OBJECT_SCHEMA`

The schema that contains the object.

- `OBJECT_NAME`

The name of the instrumented object.

- `OBJECT_INSTANCE_BEGIN`

The address in memory of the instrumented object.

- `LOCK_TYPE`

The lock type from the metadata lock subsystem. The value is one of `INTENTION_EXCLUSIVE`, `SHARED`, `SHARED_HIGH_PRIO`, `SHARED_READ`, `SHARED_WRITE`, `SHARED_UPGRADABLE`, `SHARED_NO_WRITE`, `SHARED_NO_READ_WRITE`, or `EXCLUSIVE`.

- `LOCK_DURATION`

The lock duration from the metadata lock subsystem. The value is one of `STATEMENT`, `TRANSACTION`, or `EXPLICIT`. The `STATEMENT` and `TRANSACTION` values signify locks that are released at statement or transaction end, respectively. The `EXPLICIT` value signifies locks that survive statement or transaction end and are released explicitly, such as global locks acquired with `FLUSH TABLES WITH READ LOCK`.

- `LOCK_STATUS`

The lock status from the metadata lock subsystem. The value is one of `PENDING`, `GRANTED`, `VICTIM`, `TIMEOUT`, `KILLED`, `PRE_ACQUIRE_NOTIFY`, or `POST_RELEASE_NOTIFY`. The Performance Schema assigns these values as described previously.

- `SOURCE`

The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs. This enables you to check the source to determine exactly what code is involved.

- `OWNER_THREAD_ID`

The thread requesting a metadata lock.

- `OWNER_EVENT_ID`

The event requesting a metadata lock.

The `metadata_locks` table has these indexes:

- Primary key on (`OBJECT_INSTANCE_BEGIN`)
- Index on (`OBJECT_TYPE`, `OBJECT_SCHEMA`, `OBJECT_NAME`)
- Index on (`OWNER_THREAD_ID`, `OWNER_EVENT_ID`)

`TRUNCATE TABLE` is not permitted for the `metadata_locks` table.

25.11.12.4 The `table_handles` Table

The Performance Schema exposes table lock information through the `table_handles` table to show the table locks currently in effect for each opened table handle. `table_handles` reports what is recorded by the table lock instrumentation. This information shows which table handles the server has open, how they are locked, and by which sessions.

The `table_handles` table is read only and cannot be updated. It is autosized by default; to configure the table size, set the `performance_schema_max_table_handles` system variable at server startup.

The `table_handles` table has these columns:

- `OBJECT_TYPE`

The table opened by a table handle.

- `OBJECT_SCHEMA`

The schema that contains the object.

- `OBJECT_NAME`

The name of the instrumented object.

- `OBJECT_INSTANCE_BEGIN`

The table handle address in memory.

- `OWNER_THREAD_ID`

The thread owning the table handle.

- `OWNER_EVENT_ID`

The event which caused the table handle to be opened.

- `INTERNAL_LOCK`

The table lock used at the SQL level. The value is one of `READ`, `READ WITH SHARED LOCKS`, `READ HIGH PRIORITY`, `READ NO INSERT`, `WRITE ALLOW WRITE`, `WRITE CONCURRENT INSERT`, `WRITE LOW PRIORITY`, or `WRITE`. For information about these lock types, see the `include/thr_lock.h` source file.

- `EXTERNAL_LOCK`

The table lock used at the storage engine level. The value is one of `READ EXTERNAL` or `WRITE EXTERNAL`.

The `table_handles` table has these indexes:

- Primary key on (`OBJECT_INSTANCE_BEGIN`)
- Index on (`OBJECT_TYPE`, `OBJECT_SCHEMA`, `OBJECT_NAME`)
- Index on (`OWNER_THREAD_ID`, `OWNER_EVENT_ID`)

`TRUNCATE TABLE` is not permitted for the `table_handles` table.

25.11.13 Performance Schema System Variable Tables

The MySQL server maintains many system variables that indicate how it is configured (see [Section 5.1.5, “Server System Variables”](#)). System variable information is available in these Performance Schema tables:

- `global_variables`: Global system variables. An application that wants only global values should use this table.
- `session_variables`: System variables for the current session. An application that wants all system variable values for its own session should use this table. It includes the session variables for its session, as well as the values of global variables that have no session counterpart.

- `variables_by_thread`: Session system variables for each active session. An application that wants to know the session variable values for specific sessions should use this table. It includes session variables only, identified by thread ID.
- `persisted_variables`: Provides a SQL interface to the `mysqld-auto.cnf` file that stores persisted global system variable settings. See [Section 25.11.13.1, “Performance Schema persisted_variables Table”](#).
- `variables_info`: Shows, for each system variable, the source from which it was most recently set, and its range of values. See [Section 25.11.13.2, “Performance Schema variables_info Table”](#).

The session variable tables (`session_variables`, `variables_by_thread`) contain information only for active sessions, not terminated sessions.

`TRUNCATE TABLE` is not supported for Performance Schema system variable tables.

The `global_variables` and `session_variables` tables have these columns:

- `VARIABLE_NAME`

The system variable name.

- `VARIABLE_VALUE`

The system variable value. For `global_variables`, this column contains the global value. For `session_variables`, this column contains the variable value in effect for the current session.

The `global_variables` and `session_variables` tables have these indexes:

- Primary key on (`VARIABLE_NAME`)

The `variables_by_thread` table has these columns:

- `THREAD_ID`

The thread identifier of the session in which the system variable is defined.

- `VARIABLE_NAME`

The system variable name.

- `VARIABLE_VALUE`

The session variable value for the session named by the `THREAD_ID` column.

The `variables_by_thread` table has these indexes:

- Primary key on (`THREAD_ID`, `VARIABLE_NAME`)

The `variables_by_thread` table contains system variable information only about foreground threads. If not all threads are instrumented by the Performance Schema, this table will miss some rows. In this case, the `Performance_schema_thread_instances_lost` status variable will be greater than zero.

25.11.13.1 Performance Schema persisted_variables Table

The `persisted_variables` table provides an SQL interface to the `mysqld-auto.cnf` file that stores persisted global system variable settings, enabling the file contents to be inspected at runtime using `SELECT` statements. Variables are persisted using `SET PERSIST` or `PERSIST_ONLY` statements; see [Section 13.7.4.1, “SET Syntax for Variable Assignment”](#). The table contains a row for each persisted system variable in the file. Variables not persisted do not appear in the table.

For information about persisted system variables, see [Section 5.1.6, “Using System Variables”](#).

Suppose that `mysqld-auto.cnf` looks like this:

```
{ "mysql_server": { "autocommit": "ON" , "max_connections": "1000" } }
```

Then `persisted_variables` has these contents:

```
mysql> SELECT * FROM persisted_variables;
+-----+-----+
| VARIABLE_NAME | VARIABLE_VALUE |
+-----+-----+
| autocommit   | ON              |
| max_connections | 1000           |
+-----+-----+
```

`persisted_variables` has these columns:

- `VARIABLE_NAME`

The variable name listed in `mysqld-auto.cnf`.

- `VARIABLE_VALUE`

The value listed for the variable in `mysqld-auto.cnf`.

`persisted_variables` has these indexes:

- Primary key on (`VARIABLE_NAME`)

`TRUNCATE TABLE` is not permitted for the `persisted_variables` table.

25.11.13.2 Performance Schema variables_info Table

The `variables_info` table shows, for each system variable, the source from which it was most recently set, and its range of values.

`variables_info` has these columns:

- `VARIABLE_NAME`

The variable name.

- `VARIABLE_SOURCE`

The source from which the variable was most recently set:

- `COMMAND_LINE`

The variable was set on the command line.

- `COMPILED`

The variable has its compiled-in default value. `COMPILED` is the value used for variables not set any other way.

- `DYNAMIC`

The variable was set at runtime. This includes variables set within files specified using the `--init-file` option.

- `EXPLICIT`

The variable was set from an option file named with the `--defaults-file` option.

- `EXTRA`

The variable was set from an option file named with the `--defaults-extra-file` option.

- `GLOBAL`

The variable was set from a global option file. This includes option files not covered by `EXPLICIT`, `EXTRA`, `LOGIN`, `PERSISTED`, `SERVER`, or `USER`.

- `LOGIN`

The variable was set from a user-specific login path file (`~/mylogin.cnf`).

- `PERSISTED`

The variable was set from a server-specific `mysqld-auto.cnf` option file. No row has this value if the server was started with `persisted_globals_load` disabled.

- `SERVER`

The variable was set from a server-specific `$MYSQL_HOME/my.cnf` option file. For details about how `MYSQL_HOME` is set, see [Section 4.2.6, “Using Option Files”](#).

- `USER`

The variable was set from a user-specific `~/my.cnf` option file.

- `VARIABLE_PATH`

If the variable was set from an option file, `VARIABLE_PATH` is the path name of that file. Otherwise, the value is the empty string.

- `MIN_VALUE`, `MAX_VALUE`

The minimum and maximum permitted values for the variable. Both are 0 for variables that have no such values (that is, variables that are not numeric).

- `SET_TIME`

The time at which the variable was most recently set. The default is the time at which the server initialized global system variables during startup.

- `SET_USER`, `SET_HOST`

The user name and host name of the client user that most recently set the variable. If a client connects as `user17` from host `host34.example.com` using the account `'user17'@'%example.com`, `SET_USER` and `SET_HOST` will be `user17` and `host34.example.com`, respectively. For proxy user connections, these values correspond to the external (proxy) user, not the proxied user against which privilege checking is performed. The default for each column is the empty string, indicating that the variable has not been set since server startup.

The `variables_info` table has these indexes:

- None

`TRUNCATE TABLE` is not permitted for the `variables_info` table.

If a variable with a `VARIABLE_SOURCE` value other than `DYNAMIC` is set at runtime, `VARIABLE_SOURCE` becomes `DYNAMIC` and `VARIABLE_PATH` becomes the empty string.

A system variable that has only a session value (such as `debug_sync`) cannot be set at startup or persisted. For session-only system variables, `VARIABLE_SOURCE` can be only `COMPILED` or `DYNAMIC`.

If a system variable has an unexpected `VARIABLE_SOURCE` value, consider your server startup method. For example, `mysqld_safe` reads option files and passes certain options it finds there as part of the command line that it uses to start `mysqld`. Consequently, some system variables that you set in option files might display in `variables_info` as `COMMAND_LINE`, rather than as `GLOBAL` or `SERVER` as you might otherwise expect.

Some sample queries that use the `variables_info` table, with representative output:

- Display variables set on the command line:

```
mysql> SELECT VARIABLE_NAME FROM variables_info
       WHERE VARIABLE_SOURCE = 'COMMAND_LINE'
       ORDER BY VARIABLE_NAME;
+-----+
| VARIABLE_NAME |
+-----+
| basedir       |
| datadir       |
| log_error     |
| pid_file      |
| plugin_dir    |
| port          |
+-----+
```

- Display variables set from persistent storage:

```
mysql> SELECT VARIABLE_NAME FROM variables_info
       WHERE VARIABLE_SOURCE = 'PERSISTED'
       ORDER BY VARIABLE_NAME;
+-----+
| VARIABLE_NAME |
+-----+
| event_scheduler |
| expire_logs_days |
| max_connections |
| validate_password_policy |
+-----+
```

- Join `variables_info` with the `global_variables` table to display the current values of persisted variables, together with their range of values:

```
mysql> SELECT
       VI.VARIABLE_NAME, GV.VARIABLE_VALUE,
       VI.MIN_VALUE,VI.MAX_VALUE
FROM variables_info AS VI
     INNER JOIN global_variables AS GV
     USING(VARIABLE_NAME)
WHERE VI.VARIABLE_SOURCE = 'PERSISTED'
ORDER BY VARIABLE_NAME;
+-----+-----+-----+-----+
| VARIABLE_NAME | VARIABLE_VALUE | MIN_VALUE | MAX_VALUE |
+-----+-----+-----+-----+
| event_scheduler | ON             | 0         | 0         |
| expire_logs_days | 7             | 0         | 99        |
| max_connections | 200           | 1         | 100000    |
| validate_password_policy | STRONG       | 0         | 0         |
+-----+-----+-----+-----+
```

25.11.14 Performance Schema Status Variable Tables

The MySQL server maintains many status variables that provide information about its operation (see [Section 5.1.7, “Server Status Variables”](#)). Status variable information is available in these Performance Schema tables:

- `global_status`: Global status variables. An application that wants only global values should use this table.
- `session_status`: Status variables for the current session. An application that wants all status variable values for its own session should use this table. It includes the session variables for its session, as well as the values of global variables that have no session counterpart.
- `status_by_thread`: Session status variables for each active session. An application that wants to know the session variable values for specific sessions should use this table. It includes session variables only, identified by thread ID.

There are also summary tables that provide status variable information aggregated by account, host name, and user name. See [Section 25.11.15.12, “Status Variable Summary Tables”](#).

The session variable tables (`session_status`, `status_by_thread`) contain information only for active sessions, not terminated sessions.

The Performance Schema collects statistics for global status variables only for threads for which the `INSTRUMENTED` value is `YES` in the `threads` table. Statistics for session status variables are always collected, regardless of the `INSTRUMENTED` value.

The Performance Schema does not collect statistics for `Com_xxx` status variables in the status variable tables. To obtain global and per-session statement execution counts, use the `events_statements_summary_global_by_event_name` and `events_statements_summary_by_thread_by_event_name` tables, respectively. For example:

```
SELECT EVENT_NAME, COUNT_STAR
FROM events_statements_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'statement/sql/%';
```

The `global_status` and `session_status` tables have these columns:

- `VARIABLE_NAME`
The status variable name.
- `VARIABLE_VALUE`
The status variable value. For `global_status`, this column contains the global value. For `session_status`, this column contains the variable value for the current session.

The `global_status` and `session_status` tables have these indexes:

- Primary key on (`VARIABLE_NAME`)

The `status_by_thread` table contains the status of each active thread. It has these columns:

- `THREAD_ID`
The thread identifier of the session in which the status variable is defined.
- `VARIABLE_NAME`
The status variable name.
- `VARIABLE_VALUE`
The session variable value for the session named by the `THREAD_ID` column.

The `status_by_thread` table has these indexes:

- Primary key on (`THREAD_ID`, `VARIABLE_NAME`)

The `status_by_thread` table contains status variable information only about foreground threads. If the `performance_schema_max_thread_instances` system variable is not autoscaled (set to -1) and the maximum permitted number of instrumented thread objects is not greater than the number of background threads, the table will be empty.

The Performance Schema supports `TRUNCATE TABLE` for status variable tables as follows:

- `global_status`: Resets thread, account, host, and user status. Resets global status variables except those that the server never resets.
- `session_status`: Not supported.
- `status_by_thread`: Aggregates status for all threads to the global status and account status, then resets thread status. If account statistics are not collected, the session status is added to host and user status, if host and user status are collected.

Account, host, and user statistics are not collected if the `performance_schema_accounts_size`, `performance_schema_hosts_size`, and `performance_schema_users_size` system variables, respectively, are set to 0.

`FLUSH STATUS` adds the session status from all active sessions to the global status variables, resets the status of all active sessions, and resets account, host, and user status values aggregated from disconnected sessions.

25.11.15 Performance Schema Summary Tables

Summary tables provide aggregated information for terminated events over time. The tables in this group summarize event data in different ways.

Wait Event Summaries

- `events_waits_summary_by_account_by_event_name`: Wait events per account and event name
- `events_waits_summary_by_host_by_event_name`: Wait events per host name and event name
- `events_waits_summary_by_instance`: Wait events per instance
- `events_waits_summary_by_thread_by_event_name`: Wait events per thread and event name
- `events_waits_summary_by_user_by_event_name`: Wait events per user name and event name
- `events_waits_summary_global_by_event_name`: Wait events per event name

Stage Summaries

- `events_stages_summary_by_account_by_event_name`: Stage events per account and event name
- `events_stages_summary_by_host_by_event_name`: Stage events per host name and event name
- `events_stages_summary_by_thread_by_event_name`: Stage waits per thread and event name
- `events_stages_summary_by_user_by_event_name`: Stage events per user name and event name
- `events_stages_summary_global_by_event_name`: Stage waits per event name

Statement Summaries

- [events_statements_histogram_by_digest](#): Statement histograms per schema and digest value.
- [events_statements_histogram_global](#): Statement histogram summarized globally.
- [events_statements_summary_by_account_by_event_name](#): Statement events per account and event name
- [events_statements_summary_by_digest](#): Statement events per schema and digest value
- [events_statements_summary_by_host_by_event_name](#): Statement events per host name and event name
- [events_statements_summary_by_program](#): Statement events per stored program (stored procedures and functions, triggers, and events)
- [events_statements_summary_by_thread_by_event_name](#): Statement events per thread and event name
- [events_statements_summary_by_user_by_event_name](#): Statement events per user name and event name
- [events_statements_summary_global_by_event_name](#): Statement events per event name
- [prepared_statements_instances](#): Prepared statement instances and statistics

Transaction Summaries

- [events_transactions_summary_by_account_by_event_name](#): Transaction events per account and event name
- [events_transactions_summary_by_host_by_event_name](#): Transaction events per host name and event name
- [events_transactions_summary_by_thread_by_event_name](#): Transaction events per thread and event name
- [events_transactions_summary_by_user_by_event_name](#): Transaction events per user name and event name
- [events_transactions_summary_global_by_event_name](#): Transaction events per event name

Object Wait Summaries

- [objects_summary_global_by_type](#): Object summaries

File I/O Summaries

- [file_summary_by_event_name](#): File events per event name
- [file_summary_by_instance](#): File events per file instance

Table I/O and Lock Wait Summaries

- [table_io_waits_summary_by_index_usage](#): Table I/O waits per index
- [table_io_waits_summary_by_table](#): Table I/O waits per table
- [table_lock_waits_summary_by_table](#): Table lock waits per table

Socket Summaries

- [socket_summary_by_instance](#): Socket waits and I/O per instance
- [socket_summary_by_event_name](#): Socket waits and I/O per event name

Memory Summaries

- [memory_summary_by_account_by_event_name](#): Memory operations per account and event name
- [memory_summary_by_host_by_event_name](#): Memory operations per host and event name
- [memory_summary_by_thread_by_event_name](#): Memory operations per thread and event name
- [memory_summary_by_user_by_event_name](#): Memory operations per user and event name
- [memory_summary_global_by_event_name](#): Memory operations globally per event name

Error Summaries

- [events_errors_summary_by_account_by_error](#): Errors per error code and account
- [events_errors_summary_by_host_by_error](#): Errors per error code and host
- [events_errors_summary_by_thread_by_error](#): Errors per error code and thread
- [events_errors_summary_by_user_by_error](#): Errors per error code and user
- [events_errors_summary_global_by_error](#): Errors per error code

Status Variable Summaries

- [status_by_account](#): Status variables per account
- [status_by_host](#): Status variables per host name
- [status_by_user](#): Status variables per user name

Each summary table has grouping columns that determine how to group the data to be aggregated, and summary columns that contain the aggregated values. Tables that summarize events in similar ways often have similar sets of summary columns and differ only in the grouping columns used to determine how events are aggregated.

Summary tables can be truncated with `TRUNCATE TABLE`. Generally, the effect is to reset the summary columns to 0 or `NULL`, not to remove rows. This enables you to clear collected values and restart aggregation. That might be useful, for example, after you have made a runtime configuration change. Exceptions to this truncation behavior are noted in individual summary table sections.

25.11.15.1 Wait Event Summary Tables

The Performance Schema maintains tables for collecting current and recent wait events, and aggregates that information in summary tables. [Section 25.11.4, “Performance Schema Wait Event Tables”](#) describes the events on which wait summaries are based. See that discussion for information about the content of wait events, the current and recent wait event tables, and how to control wait event collection, which is disabled by default.

Example wait event summary information:

```
mysql> SELECT * FROM events_waits_summary_global_by_event_name\G
...
***** 6. row *****
EVENT_NAME: wait/synch/mutex/sql/BINARY_LOG::LOCK_index
```

```

COUNT_STAR: 8
SUM_TIMER_WAIT: 2119302
MIN_TIMER_WAIT: 196092
AVG_TIMER_WAIT: 264912
MAX_TIMER_WAIT: 569421
...
***** 9. row *****
EVENT_NAME: wait/synch/mutex/sql/hash_filo::lock
COUNT_STAR: 69
SUM_TIMER_WAIT: 16848828
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 244185
MAX_TIMER_WAIT: 735345
...

```

Each wait event summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the [setup_instruments](#) table:

- [events_waits_summary_by_account_by_event_name](#) has [EVENT_NAME](#), [USER](#), and [HOST](#) columns. Each row summarizes events for a given account (user and host combination) and event name.
- [events_waits_summary_by_host_by_event_name](#) has [EVENT_NAME](#) and [HOST](#) columns. Each row summarizes events for a given host and event name.
- [events_waits_summary_by_instance](#) has [EVENT_NAME](#) and [OBJECT_INSTANCE_BEGIN](#) columns. Each row summarizes events for a given event name and object. If an instrument is used to create multiple instances, each instance has a unique [OBJECT_INSTANCE_BEGIN](#) value and is summarized separately in this table.
- [events_waits_summary_by_thread_by_event_name](#) has [THREAD_ID](#) and [EVENT_NAME](#) columns. Each row summarizes events for a given thread and event name.
- [events_waits_summary_by_user_by_event_name](#) has [EVENT_NAME](#) and [USER](#) columns. Each row summarizes events for a given user and event name.
- [events_waits_summary_global_by_event_name](#) has an [EVENT_NAME](#) column. Each row summarizes events for a given event name. An instrument might be used to create multiple instances of the instrumented object. For example, if there is an instrument for a mutex that is created for each connection, there are as many instances as there are connections. The summary row for the instrument summarizes over all these instances.

Each wait event summary table has these summary columns containing aggregated values:

- [COUNT_STAR](#)
The number of summarized events. This value includes all events, whether timed or nontimed.
- [SUM_TIMER_WAIT](#)
The total wait time of the summarized timed events. This value is calculated only for timed events because nontimed events have a wait time of [NULL](#). The same is true for the other [xxx_TIMER_WAIT](#) values.
- [MIN_TIMER_WAIT](#)
The minimum wait time of the summarized timed events.
- [AVG_TIMER_WAIT](#)
The average wait time of the summarized timed events.
- [MAX_TIMER_WAIT](#)

The maximum wait time of the summarized timed events.

The wait event summary tables have these indexes:

- `events_waits_summary_by_account_by_event_name`:
 - Primary key on (`USER`, `HOST`, `EVENT_NAME`)
- `events_waits_summary_by_host_by_event_name`:
 - Primary key on (`HOST`, `EVENT_NAME`)
- `events_waits_summary_by_instance`:
 - Primary key on (`OBJECT_INSTANCE_BEGIN`)
 - Index on (`EVENT_NAME`)
- `events_waits_summary_by_thread_by_event_name`:
 - Primary key on (`THREAD_ID`, `EVENT_NAME`)
- `events_waits_summary_by_user_by_event_name`:
 - Primary key on (`USER`, `EVENT_NAME`)
- `events_waits_summary_global_by_event_name`:
 - Primary key on (`EVENT_NAME`)

`TRUNCATE TABLE` is permitted for wait summary tables. It has these effects:

- For summary tables not aggregated by account, host, or user, truncation resets the summary columns to zero rather than removing rows.
- For summary tables aggregated by account, host, or user, truncation removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows.

In addition, each wait summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of `events_waits_summary_global_by_event_name`. For details, see [Section 25.11.8, “Performance Schema Connection Tables”](#).

25.11.15.2 Stage Summary Tables

The Performance Schema maintains tables for collecting current and recent stage events, and aggregates that information in summary tables. [Section 25.11.5, “Performance Schema Stage Event Tables”](#) describes the events on which stage summaries are based. See that discussion for information about the content of stage events, the current and recent stage event tables, and how to control stage event collection, which is disabled by default.

Example stage event summary information:

```
mysql> SELECT * FROM events_stages_summary_global_by_event_name\G
...
***** 5. row *****
EVENT_NAME: stage/sql/checking permissions
COUNT_STAR: 57
SUM_TIMER_WAIT: 26501888880
MIN_TIMER_WAIT: 7317456
AVG_TIMER_WAIT: 464945295
MAX_TIMER_WAIT: 12858936792
```

```

...
***** 9. row *****
EVENT_NAME: stage/sql/closing tables
COUNT_STAR: 37
SUM_TIMER_WAIT: 662606568
MIN_TIMER_WAIT: 1593864
AVG_TIMER_WAIT: 17907891
MAX_TIMER_WAIT: 437977248
...

```

Each stage summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- `events_stages_summary_by_account_by_event_name` has `EVENT_NAME`, `USER`, and `HOST` columns. Each row summarizes events for a given account (user and host combination) and event name.
- `events_stages_summary_by_host_by_event_name` has `EVENT_NAME` and `HOST` columns. Each row summarizes events for a given host and event name.
- `events_stages_summary_by_thread_by_event_name` has `THREAD_ID` and `EVENT_NAME` columns. Each row summarizes events for a given thread and event name.
- `events_stages_summary_by_user_by_event_name` has `EVENT_NAME` and `USER` columns. Each row summarizes events for a given user and event name.
- `events_stages_summary_global_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.

Each stage summary table has these summary columns containing aggregated values: `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, and `MAX_TIMER_WAIT`. These columns are analogous to the columns of the same names in the wait event summary tables (see [Section 25.11.15.1, “Wait Event Summary Tables”](#)), except that the stage summary tables aggregate events from `events_stages_current` rather than `events_waits_current`.

The stage summary tables have these indexes:

- `events_stages_summary_by_account_by_event_name`:
 - Primary key on (`USER`, `HOST`, `EVENT_NAME`)
- `events_stages_summary_by_host_by_event_name`:
 - Primary key on (`HOST`, `EVENT_NAME`)
- `events_stages_summary_by_thread_by_event_name`:
 - Primary key on (`THREAD_ID`, `EVENT_NAME`)
- `events_stages_summary_by_user_by_event_name`:
 - Primary key on (`USER`, `EVENT_NAME`)
- `events_stages_summary_global_by_event_name`:
 - Primary key on (`EVENT_NAME`)

`TRUNCATE TABLE` is permitted for stage summary tables. It has these effects:

- For summary tables not aggregated by account, host, or user, truncation resets the summary columns to zero rather than removing rows.
- For summary tables aggregated by account, host, or user, truncation removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows.

In addition, each stage summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of `events_stages_summary_global_by_event_name`. For details, see [Section 25.11.8, “Performance Schema Connection Tables”](#).

25.11.15.3 Statement Summary Tables

The Performance Schema maintains tables for collecting current and recent statement events, and aggregates that information in summary tables. [Section 25.11.6, “Performance Schema Statement Event Tables”](#) describes the events on which statement summaries are based. See that discussion for information about the content of statement events, the current and recent statement event tables, and how to control statement event collection, which is partially disabled by default.

Example statement event summary information:

```
mysql> SELECT * FROM events_statements_summary_global_by_event_name\G
***** 1. row *****
          EVENT_NAME: statement/sql/select
          COUNT_STAR: 25
          SUM_TIMER_WAIT: 1535983999000
          MIN_TIMER_WAIT: 209823000
          AVG_TIMER_WAIT: 61439359000
          MAX_TIMER_WAIT: 1363397650000
          SUM_LOCK_TIME: 20186000000
          SUM_ERRORS: 0
          SUM_WARNINGS: 0
          SUM_ROWS_AFFECTED: 0
          SUM_ROWS_SENT: 388
          SUM_ROWS_EXAMINED: 370
SUM_CREATED_TMP_DISK_TABLES: 0
  SUM_CREATED_TMP_TABLES: 0
    SUM_SELECT_FULL_JOIN: 0
SUM_SELECT_FULL_RANGE_JOIN: 0
  SUM_SELECT_RANGE: 0
    SUM_SELECT_RANGE_CHECK: 0
      SUM_SELECT_SCAN: 6
    SUM_SORT_MERGE_PASSES: 0
      SUM_SORT_RANGE: 0
        SUM_SORT_ROWS: 0
          SUM_SORT_SCAN: 0
        SUM_NO_INDEX_USED: 6
      SUM_NO_GOOD_INDEX_USED: 0
...

```

Each statement summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- `events_statements_summary_by_account_by_event_name` has `EVENT_NAME`, `USER`, and `HOST` columns. Each row summarizes events for a given account (user and host combination) and event name.
- `events_statements_summary_by_digest` has `SCHEMA_NAME` and `DIGEST` columns. Each row summarizes events per schema and digest value. (The `DIGEST_TEXT` column contains the corresponding normalized statement digest text, but is neither a grouping nor summary column.)

The maximum number of rows in the table is autosized at server startup. To set this maximum explicitly, set the `performance_schema_digests_size` system variable at server startup.

- `events_statements_summary_by_host_by_event_name` has `EVENT_NAME` and `HOST` columns. Each row summarizes events for a given host and event name.
- `events_statements_summary_by_program` has `OBJECT_TYPE`, `OBJECT_SCHEMA`, and `OBJECT_NAME` columns. Each row summarizes events for a given stored program (stored procedure or function, trigger, or event).

- `events_statements_summary_by_thread_by_event_name` has `THREAD_ID` and `EVENT_NAME` columns. Each row summarizes events for a given thread and event name.
- `events_statements_summary_by_user_by_event_name` has `EVENT_NAME` and `USER` columns. Each row summarizes events for a given user and event name.
- `events_statements_summary_global_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.
- `prepared_statements_instances` has an `OBJECT_INSTANCE_BEGIN` column. Each row summarizes events for a given prepared statement.

Each statement summary table has these summary columns containing aggregated values (with exceptions as noted):

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`

These columns are analogous to the columns of the same names in the wait event summary tables (see [Section 25.11.15.1, “Wait Event Summary Tables”](#)), except that the statement summary tables aggregate events from `events_statements_current` rather than `events_waits_current`.

The `prepared_statements_instances` table does not have these columns.

- `SUM_xxx`

The aggregate of the corresponding `xxx` column in the `events_statements_current` table. For example, the `SUM_LOCK_TIME` and `SUM_ERRORS` columns in statement summary tables are the aggregates of the `LOCK_TIME` and `ERRORS` columns in `events_statements_current` table.

The `events_statements_summary_by_digest` table has these additional summary columns:

- `FIRST_SEEN_TIMESTAMP`, `LAST_SEEN_TIMESTAMP`

The times at which a statement with the given digest value were first seen and most recently seen.

- `QUANTILE_95`: The 95th percentile of the statement latency, in picoseconds. This percentile is a high estimate, computed from the histogram data collected. In other words, for a given digest, 95% of the statements measured have a latency lower than `QUANTILE_95`.

For access to the histogram data, use the tables described in [Section 25.11.15.4, “Statement Histogram Summary Tables”](#).

- `QUANTILE_99`: Similar to `QUANTILE_95`, but for the 99th percentile.
- `QUANTILE_999`: Similar to `QUANTILE_95`, but for the 99.9th percentile.

The `events_statements_summary_by_program` table has these additional summary columns:

- `COUNT_STATEMENTS`, `SUM_STATEMENTS_WAIT`, `MIN_STATEMENTS_WAIT`, `AVG_STATEMENTS_WAIT`, `MAX_STATEMENTS_WAIT`

Statistics about nested statements invoked during stored program execution.

The `prepared_statements_instances` table has these additional summary columns:

- `COUNT_EXECUTE`, `SUM_TIMER_EXECUTE`, `MIN_TIMER_EXECUTE`, `AVG_TIMER_EXECUTE`, `MAX_TIMER_EXECUTE`

Aggregated statistics for executions of the prepared statement.

The statement summary tables have these indexes:

- `events_transactions_summary_by_account_by_event_name`:

- Primary key on (`USER`, `HOST`, `EVENT_NAME`)
- `events_statements_summary_by_digest`:
 - Primary key on (`SCHEMA_NAME`, `DIGEST`)
- `events_transactions_summary_by_host_by_event_name`:
 - Primary key on (`HOST`, `EVENT_NAME`)
- `events_statements_summary_by_program`:
 - Primary key on (`OBJECT_TYPE`, `OBJECT_SCHEMA`, `OBJECT_NAME`)
- `events_statements_summary_by_thread_by_event_name`:
 - Primary key on (`THREAD_ID`, `EVENT_NAME`)
- `events_transactions_summary_by_user_by_event_name`:
 - Primary key on (`USER`, `EVENT_NAME`)
- `events_statements_summary_global_by_event_name`:
 - Primary key on (`EVENT_NAME`)

`TRUNCATE TABLE` is permitted for statement summary tables. It has these effects:

- For `events_statements_summary_by_digest`, it removes the rows.
- For other summary tables not aggregated by account, host, or user, truncation resets the summary columns to zero rather than removing rows.
- For other summary tables aggregated by account, host, or user, truncation removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows.

In addition, each statement summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of `events_statements_summary_global_by_event_name`. For details, see [Section 25.11.8, “Performance Schema Connection Tables”](#).

In addition, truncating `events_statements_summary_by_digest` implicitly truncates `events_statements_histogram_by_digest`, and truncating `events_statements_summary_global_by_event_name` implicitly truncates `events_statements_histogram_global`.

Statement Digest Aggregation Rules

If the `statements_digest` consumer is enabled, aggregation into `events_statements_summary_by_digest` occurs as follows when a statement completes. Aggregation is based on the `DIGEST` value computed for the statement.

- If a `events_statements_summary_by_digest` row already exists with the digest value for the statement that just completed, statistics for the statement are aggregated to that row. The `LAST_SEEN` column is updated to the current time.
- If no row has the digest value for the statement that just completed, and the table is not full, a new row is created for the statement. The `FIRST_SEEN` and `LAST_SEEN` columns are initialized with the current time.
- If no row has the statement digest value for the statement that just completed, and the table is full, the statistics for the statement that just completed are added to a special “catch-all” row with `DIGEST`

= `NULL`, which is created if necessary. If the row is created, the `FIRST_SEEN` and `LAST_SEEN` columns are initialized with the current time. Otherwise, the `LAST_SEEN` column is updated with the current time.

The row with `DIGEST = NULL` is maintained because Performance Schema tables have a maximum size due to memory constraints. The `DIGEST = NULL` row permits digests that do not match other rows to be counted even if the summary table is full, using a common “other” bucket. This row helps you estimate whether the digest summary is representative:

- A `DIGEST = NULL` row that has a `COUNT_STAR` value that represents 5% of all digests shows that the digest summary table is very representative; the other rows cover 95% of the statements seen.
- A `DIGEST = NULL` row that has a `COUNT_STAR` value that represents 50% of all digests shows that the digest summary table is not very representative; the other rows cover only half the statements seen. Most likely the DBA should increase the maximum table size so that more of the rows counted in the `DIGEST = NULL` row would be counted using more specific rows instead. To do this, set the `performance_schema_digests_size` system variable to a larger value at server startup. The default size is 200.

Stored Program Instrumentation Behavior

For stored program types for which instrumentation is enabled in the `setup_objects` table, `events_statements_summary_by_program` maintains statistics for stored programs as follows:

- A row is added for an object when it is first used in the server.
- The row for an object is removed when the object is dropped.
- Statistics are aggregated in the row for an object as it executes.

See also [Section 25.4.3, “Event Pre-Filtering”](#).

25.11.15.4 Statement Histogram Summary Tables

The Performance Schema maintains statement event summary tables that contain information about minimum, maximum, and average statement latency (see [Section 25.11.15.3, “Statement Summary Tables”](#)). Those tables permit high-level assessment of system performance. To permit assessment at a more fine-grained level, the Performance Schema also collects histogram data for statement latencies. These histograms provide additional insight into latency distributions.

[Section 25.11.6, “Performance Schema Statement Event Tables”](#) describes the events on which statement summaries are based. See that discussion for information about the content of statement events, the current and recent statement event tables, and how to control statement event collection, which is partially disabled by default.

Example statement histogram information:

```
mysql> SELECT * FROM events_statements_histogram_by_digest
      WHERE SCHEMA_NAME = 'mydb' AND DIGEST = 'bb3f69453119b2d7b3ae40673a9d4c7c'
      AND COUNT_BUCKET > 0 ORDER BY BUCKET_NUMBER\G
***** 1. row *****
      SCHEMA_NAME: mydb
      DIGEST: bb3f69453119b2d7b3ae40673a9d4c7c
      BUCKET_NUMBER: 42
      BUCKET_TIMER_LOW: 66069344
      BUCKET_TIMER_HIGH: 69183097
      COUNT_BUCKET: 1
      COUNT_BUCKET_AND_LOWER: 1
      BUCKET_QUANTILE: 0.058824
***** 2. row *****
      SCHEMA_NAME: mydb
      DIGEST: bb3f69453119b2d7b3ae40673a9d4c7c
```

```

    BUCKET_NUMBER: 43
    BUCKET_TIMER_LOW: 69183097
    BUCKET_TIMER_HIGH: 72443596
    COUNT_BUCKET: 1
COUNT_BUCKET_AND_LOWER: 2
    BUCKET_QUANTILE: 0.117647
***** 3. row *****
    SCHEMA_NAME: mydb
    DIGEST: bb3f69453119b2d7b3ae40673a9d4c7c
    BUCKET_NUMBER: 44
    BUCKET_TIMER_LOW: 72443596
    BUCKET_TIMER_HIGH: 75857757
    COUNT_BUCKET: 2
COUNT_BUCKET_AND_LOWER: 4
    BUCKET_QUANTILE: 0.235294
***** 4. row *****
    SCHEMA_NAME: mydb
    DIGEST: bb3f69453119b2d7b3ae40673a9d4c7c
    BUCKET_NUMBER: 45
    BUCKET_TIMER_LOW: 75857757
    BUCKET_TIMER_HIGH: 79432823
    COUNT_BUCKET: 6
COUNT_BUCKET_AND_LOWER: 10
    BUCKET_QUANTILE: 0.625000
...

```

For example, in row 3, these values indicate that 23.52% of queries run in under 75.86 microseconds:

```

BUCKET_TIMER_HIGH: 75857757
BUCKET_QUANTILE: 0.235294

```

In row 4, these values indicate that 62.50% of queries run in under 79.44 microseconds:

```

BUCKET_TIMER_HIGH: 79432823
BUCKET_QUANTILE: 0.625000

```

Each statement histogram summary table has one or more grouping columns to indicate how the table aggregates events:

- `events_statements_histogram_by_digest` has `SCHEMA_NAME`, `DIGEST`, and `BUCKET_NUMBER` columns:
 - The `SCHEMA_NAME` and `DIGEST` columns identify a statement digest row in the `events_statements_summary_by_digest` table.
 - The `events_statements_histogram_by_digest` rows with the same `SCHEMA_NAME` and `DIGEST` values comprise the histogram for that schema/digest combination.
 - Within a given histogram, the `BUCKET_NUMBER` column indicates the bucket number.
- `events_statements_histogram_global` has a `BUCKET_NUMBER` column. This table summarizes latencies globally across schema name and digest values, using a single histogram. The `BUCKET_NUMBER` column indicates the bucket number within this global histogram.

A histogram consists of *N* buckets, where each row represents one bucket, with the bucket number indicated by the `BUCKET_NUMBER` column. Bucket numbers begin with 0.

Each statement histogram summary table has these summary columns containing aggregated values:

- `BUCKET_TIMER_LOW`, `BUCKET_TIMER_HIGH`

A bucket counts statements that have a latency, in picoseconds, measured between `BUCKET_TIMER_LOW` and `BUCKET_TIMER_HIGH`:

- The value of `BUCKET_TIMER_LOW` for the first bucket (`BUCKET_NUMBER = 0`) is 0.

- The value of `BUCKET_TIMER_LOW` for a bucket (`BUCKET_NUMBER = k`) is the same as `BUCKET_TIMER_HIGH` for the previous bucket (`BUCKET_NUMBER = k-1`)
- The last bucket is a catchall for statements that have a latency exceeding previous buckets in the histogram.

- `COUNT_BUCKET`

The number of statements measured with a latency in the interval from `BUCKET_TIMER_LOW` up to but not including `BUCKET_TIMER_HIGH`.

- `COUNT_BUCKET_AND_LOWER`

The number of statements measured with a latency in the interval from 0 up to but not including `BUCKET_TIMER_HIGH`.

- `BUCKET_QUANTILE`

The proportion of statements that fall into this or a lower bucket. This proportion corresponds by definition to `COUNT_BUCKET_AND_LOWER / SUM(COUNT_BUCKET)` and is displayed as a convenience column.

The statement histogram summary tables have these indexes:

- `events_statements_histogram_by_digest`:
 - Unique index on (`SCHEMA_NAME`, `DIGEST`, `BUCKET_NUMBER`)
- `events_statements_histogram_global`:
 - Primary key on (`BUCKET_NUMBER`)

`TRUNCATE TABLE` is permitted for statement histogram summary tables. Truncation sets the `COUNT_BUCKET` and `COUNT_BUCKET_AND_LOWER` columns to 0.

In addition, truncating `events_statements_summary_by_digest` implicitly truncates `events_statements_histogram_by_digest`, and truncating `events_statements_summary_global_by_event_name` implicitly truncates `events_statements_histogram_global`.

25.11.15.5 Transaction Summary Tables

The Performance Schema maintains tables for collecting current and recent transaction events, and aggregates that information in summary tables. [Section 25.11.7, “Performance Schema Transaction Tables”](#) describes the events on which transaction summaries are based. See that discussion for information about the content of transaction events, the current and recent transaction event tables, and how to control transaction event collection, which is disabled by default.

Example transaction event summary information:

```
mysql> SELECT * FROM events_transactions_summary_global_by_event_name LIMIT 1\G
***** 1. row *****
      EVENT_NAME: transaction
      COUNT_STAR: 5
      SUM_TIMER_WAIT: 19550092000
      MIN_TIMER_WAIT: 2954148000
      AVG_TIMER_WAIT: 3910018000
      MAX_TIMER_WAIT: 5486275000
      COUNT_READ_WRITE: 5
      SUM_TIMER_READ_WRITE: 19550092000
      MIN_TIMER_READ_WRITE: 2954148000
      AVG_TIMER_READ_WRITE: 3910018000
```

```

MAX_TIMER_READ_WRITE: 5486275000
COUNT_READ_ONLY: 0
SUM_TIMER_READ_ONLY: 0
MIN_TIMER_READ_ONLY: 0
AVG_TIMER_READ_ONLY: 0
MAX_TIMER_READ_ONLY: 0

```

Each transaction summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- `events_transactions_summary_by_account_by_event_name` has `USER`, `HOST`, and `EVENT_NAME` columns. Each row summarizes events for a given account (user and host combination) and event name.
- `events_transactions_summary_by_host_by_event_name` has `HOST` and `EVENT_NAME` columns. Each row summarizes events for a given host and event name.
- `events_transactions_summary_by_thread_by_event_name` has `THREAD_ID` and `EVENT_NAME` columns. Each row summarizes events for a given thread and event name.
- `events_transactions_summary_by_user_by_event_name` has `USER` and `EVENT_NAME` columns. Each row summarizes events for a given user and event name.
- `events_transactions_summary_global_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.

Each transaction summary table has these summary columns containing aggregated values:

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`

These columns are analogous to the columns of the same names in the wait event summary tables (see [Section 25.11.15.1, "Wait Event Summary Tables"](#)), except that the transaction summary tables aggregate events from `events_transactions_current` rather than `events_waits_current`. These columns summarize read-write and read-only transactions.

- `COUNT_READ_WRITE`, `SUM_TIMER_READ_WRITE`, `MIN_TIMER_READ_WRITE`, `AVG_TIMER_READ_WRITE`, `MAX_TIMER_READ_WRITE`

These are similar to the `COUNT_STAR` and `xxx_TIMER_WAIT` columns, but summarize read-write transactions only.

- `COUNT_READ_ONLY`, `SUM_TIMER_READ_ONLY`, `MIN_TIMER_READ_ONLY`, `AVG_TIMER_READ_ONLY`, `MAX_TIMER_READ_ONLY`

These are similar to the `COUNT_STAR` and `xxx_TIMER_WAIT` columns, but summarize read-only transactions only.

The transaction summary tables have these indexes:

- `events_transactions_summary_by_account_by_event_name`:
 - Primary key on (`USER`, `HOST`, `EVENT_NAME`)
- `events_transactions_summary_by_host_by_event_name`:
 - Primary key on (`HOST`, `EVENT_NAME`)
- `events_transactions_summary_by_thread_by_event_name`:
 - Primary key on (`THREAD_ID`, `EVENT_NAME`)
- `events_transactions_summary_by_user_by_event_name`:

- Primary key on ([USER](#), [EVENT_NAME](#))
- [events_transactions_summary_global_by_event_name](#):
 - Primary key on ([EVENT_NAME](#))

`TRUNCATE TABLE` is permitted for transaction summary tables. It has these effects:

- For summary tables not aggregated by account, host, or user, truncation resets the summary columns to zero rather than removing rows.
- For summary tables aggregated by account, host, or user, truncation removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero for the remaining rows.

In addition, each transaction summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of [events_transactions_summary_global_by_event_name](#). For details, see [Section 25.11.8](#), “Performance Schema Connection Tables”.

Transaction Aggregation Rules

Transaction event collection occurs without regard to isolation level, access mode, or autocommit mode.

Read-write transactions are generally more resource intensive than read-only transactions, therefore transaction summary tables include separate aggregate columns for read-write and read-only transactions.

Resource requirements may also vary with transaction isolation level. However, presuming that only one isolation level would be used per server, aggregation by isolation level is not provided.

25.11.15.6 Object Wait Summary Table

The Performance Schema maintains the [objects_summary_global_by_type](#) table for aggregating object wait events.

Example object wait event summary information:

```
mysql> SELECT * FROM objects_summary_global_by_type\G
...
***** 3. row *****
  OBJECT_TYPE: TABLE
  OBJECT_SCHEMA: test
  OBJECT_NAME: t
  COUNT_STAR: 3
  SUM_TIMER_WAIT: 263126976
  MIN_TIMER_WAIT: 1522272
  AVG_TIMER_WAIT: 87708678
  MAX_TIMER_WAIT: 258428280
...
***** 10. row *****
  OBJECT_TYPE: TABLE
  OBJECT_SCHEMA: mysql
  OBJECT_NAME: user
  COUNT_STAR: 14
  SUM_TIMER_WAIT: 365567592
  MIN_TIMER_WAIT: 1141704
  AVG_TIMER_WAIT: 26111769
  MAX_TIMER_WAIT: 334783032
...
```

The [objects_summary_global_by_type](#) table has these grouping columns to indicate how the table aggregates events: [OBJECT_TYPE](#), [OBJECT_SCHEMA](#), and [OBJECT_NAME](#). Each row summarizes events for the given object.

`objects_summary_global_by_type` has the same summary columns as the `events_waits_summary_by_xxx` tables. See [Section 25.11.15.1, “Wait Event Summary Tables”](#).

The `objects_summary_global_by_type` table has these indexes:

- Primary key on (`OBJECT_TYPE`, `OBJECT_SCHEMA`, `OBJECT_NAME`)

`TRUNCATE TABLE` is permitted for the object summary table. It resets the summary columns to zero rather than removing rows.

25.11.15.7 File I/O Summary Tables

The Performance Schema maintains file I/O summary tables that aggregate information about I/O operations.

Example file I/O event summary information:

```
mysql> SELECT * FROM file_summary_by_event_name\G
...
***** 2. row *****
          EVENT_NAME: wait/io/file/sql/binlog
          COUNT_STAR: 31
          SUM_TIMER_WAIT: 8243784888
          MIN_TIMER_WAIT: 0
          AVG_TIMER_WAIT: 265928484
          MAX_TIMER_WAIT: 6490658832
...
mysql> SELECT * FROM file_summary_by_instance\G
...
***** 2. row *****
          FILE_NAME: /var/mysql/share/english/errmsg.sys
          EVENT_NAME: wait/io/file/sql/ERRMSG
          EVENT_NAME: wait/io/file/sql/ERRMSG
          OBJECT_INSTANCE_BEGIN: 4686193384
          COUNT_STAR: 5
          SUM_TIMER_WAIT: 13990154448
          MIN_TIMER_WAIT: 26349624
          AVG_TIMER_WAIT: 2798030607
          MAX_TIMER_WAIT: 8150662536
...

```

Each file I/O summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- `file_summary_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.
- `file_summary_by_instance` has `FILE_NAME`, `EVENT_NAME`, and `OBJECT_INSTANCE_BEGIN` columns. Each row summarizes events for a given file and event name.

Each file I/O summary table has the following summary columns containing aggregated values. Some columns are more general and have values that are the same as the sum of the values of more fine-grained columns. In this way, aggregations at higher levels are available directly without the need for user-defined views that sum lower-level columns.

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`

These columns aggregate all I/O operations.

- `COUNT_READ`, `SUM_TIMER_READ`, `MIN_TIMER_READ`, `AVG_TIMER_READ`, `MAX_TIMER_READ`, `SUM_NUMBER_OF_BYTES_READ`

These columns aggregate all read operations, including `FGETS`, `FGETC`, `FREAD`, and `READ`.

- `COUNT_WRITE`, `SUM_TIMER_WRITE`, `MIN_TIMER_WRITE`, `AVG_TIMER_WRITE`, `MAX_TIMER_WRITE`, `SUM_NUMBER_OF_BYTES_WRITE`

These columns aggregate all write operations, including `FPUTS`, `FPUTC`, `FPRINTF`, `VPRINTF`, `FWRITE`, and `PWRITE`.

- `COUNT_MISC`, `SUM_TIMER_MISC`, `MIN_TIMER_MISC`, `AVG_TIMER_MISC`, `MAX_TIMER_MISC`

These columns aggregate all other I/O operations, including `CREATE`, `DELETE`, `OPEN`, `CLOSE`, `STREAM_OPEN`, `STREAM_CLOSE`, `SEEK`, `TELL`, `FLUSH`, `STAT`, `FSTAT`, `CHSIZE`, `RENAME`, and `SYNC`. There are no byte counts for these operations.

The file I/O summary tables have these indexes:

- `file_summary_by_event_name`:
 - Primary key on (`EVENT_NAME`)
- `file_summary_by_instance`:
 - Primary key on (`OBJECT_INSTANCE_BEGIN`)
 - Index on (`FILE_NAME`)
 - Index on (`EVENT_NAME`)

`TRUNCATE TABLE` is permitted for file I/O summary tables. It resets the summary columns to zero rather than removing rows.

The MySQL server uses several techniques to avoid I/O operations by caching information read from files, so it is possible that statements you might expect to result in I/O events will not. You may be able to ensure that I/O does occur by flushing caches or restarting the server to reset its state.

25.11.15.8 Table I/O and Lock Wait Summary Tables

The following sections describe the table I/O and lock wait summary tables:

- `table_io_waits_summary_by_index_usage`: Table I/O waits per index
- `table_io_waits_summary_by_table`: Table I/O waits per table
- `table_lock_waits_summary_by_table`: Table lock waits per table

The `table_io_waits_summary_by_table` Table

The `table_io_waits_summary_by_table` table aggregates all table I/O wait events, as generated by the `wait/io/table/sql/handler` instrument. The grouping is by table.

The `table_io_waits_summary_by_table` table has these grouping columns to indicate how the table aggregates events: `OBJECT_TYPE`, `OBJECT_SCHEMA`, and `OBJECT_NAME`. These columns have the same meaning as in the `events_waits_current` table. They identify the table to which the row applies.

`table_io_waits_summary_by_table` has the following summary columns containing aggregated values. As indicated in the column descriptions, some columns are more general and have values that are the same as the sum of the values of more fine-grained columns. For example, columns that aggregate all writes hold the sum of the corresponding columns that aggregate inserts, updates, and deletes. In this way, aggregations at higher levels are available directly without the need for user-defined views that sum lower-level columns.

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`

These columns aggregate all I/O operations. They are the same as the sum of the corresponding `xxx_READ` and `xxx_WRITE` columns.

- [COUNT_READ](#), [SUM_TIMER_READ](#), [MIN_TIMER_READ](#), [AVG_TIMER_READ](#), [MAX_TIMER_READ](#)

These columns aggregate all read operations. They are the same as the sum of the corresponding [xxx_FETCH](#) columns.

- [COUNT_WRITE](#), [SUM_TIMER_WRITE](#), [MIN_TIMER_WRITE](#), [AVG_TIMER_WRITE](#), [MAX_TIMER_WRITE](#)

These columns aggregate all write operations. They are the same as the sum of the corresponding [xxx_INSERT](#), [xxx_UPDATE](#), and [xxx_DELETE](#) columns.

- [COUNT_FETCH](#), [SUM_TIMER_FETCH](#), [MIN_TIMER_FETCH](#), [AVG_TIMER_FETCH](#), [MAX_TIMER_FETCH](#)

These columns aggregate all fetch operations.

- [COUNT_INSERT](#), [SUM_TIMER_INSERT](#), [MIN_TIMER_INSERT](#), [AVG_TIMER_INSERT](#), [MAX_TIMER_INSERT](#)

These columns aggregate all insert operations.

- [COUNT_UPDATE](#), [SUM_TIMER_UPDATE](#), [MIN_TIMER_UPDATE](#), [AVG_TIMER_UPDATE](#), [MAX_TIMER_UPDATE](#)

These columns aggregate all update operations.

- [COUNT_DELETE](#), [SUM_TIMER_DELETE](#), [MIN_TIMER_DELETE](#), [AVG_TIMER_DELETE](#), [MAX_TIMER_DELETE](#)

These columns aggregate all delete operations.

The [table_io_waits_summary_by_table](#) table has these indexes:

- Unique index on ([OBJECT_TYPE](#), [OBJECT_SCHEMA](#), [OBJECT_NAME](#))

[TRUNCATE TABLE](#) is permitted for table I/O summary tables. It resets the summary columns to zero rather than removing rows. Truncating this table also truncates the [table_io_waits_summary_by_index_usage](#) table.

The [table_io_waits_summary_by_index_usage](#) Table

The [table_io_waits_summary_by_index_usage](#) table aggregates all table index I/O wait events, as generated by the [wait/io/table/sql/handler](#) instrument. The grouping is by table index.

The columns of [table_io_waits_summary_by_index_usage](#) are nearly identical to [table_io_waits_summary_by_table](#). The only difference is the additional group column, [INDEX_NAME](#), which corresponds to the name of the index that was used when the table I/O wait event was recorded:

- A value of [PRIMARY](#) indicates that table I/O used the primary index.
- A value of [NULL](#) means that table I/O used no index.
- Inserts are counted against [INDEX_NAME = NULL](#).

The [table_io_waits_summary_by_index_usage](#) table has these indexes:

- Unique index on ([OBJECT_TYPE](#), [OBJECT_SCHEMA](#), [OBJECT_NAME](#), [INDEX_NAME](#))

[TRUNCATE TABLE](#) is permitted for table I/O summary tables. It resets the summary columns to zero rather than removing rows. This table is also truncated by truncation of the [table_io_waits_summary_by_table](#) table. A DDL operation that changes the index structure of a table may cause the per-index statistics to be reset.

The `table_lock_waits_summary_by_table` Table

The `table_lock_waits_summary_by_table` table aggregates all table lock wait events, as generated by the `wait/lock/table/sql/handler` instrument. The grouping is by table.

This table contains information about internal and external locks:

- An internal lock corresponds to a lock in the SQL layer. This is currently implemented by a call to `thr_lock()`. In event rows, these locks are distinguished by the `OPERATION` column, which has one of these values:

```
read normal
read with shared locks
read high priority
read no insert
write allow write
write concurrent insert
write delayed
write low priority
write normal
```

- An external lock corresponds to a lock in the storage engine layer. This is currently implemented by a call to `handler::external_lock()`. In event rows, these locks are distinguished by the `OPERATION` column, which has one of these values:

```
read external
write external
```

The `table_lock_waits_summary_by_table` table has these grouping columns to indicate how the table aggregates events: `OBJECT_TYPE`, `OBJECT_SCHEMA`, and `OBJECT_NAME`. These columns have the same meaning as in the `events_waits_current` table. They identify the table to which the row applies.

`table_lock_waits_summary_by_table` has the following summary columns containing aggregated values. As indicated in the column descriptions, some columns are more general and have values that are the same as the sum of the values of more fine-grained columns. For example, columns that aggregate all locks hold the sum of the corresponding columns that aggregate read and write locks. In this way, aggregations at higher levels are available directly without the need for user-defined views that sum lower-level columns.

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`

These columns aggregate all lock operations. They are the same as the sum of the corresponding `xxx_READ` and `xxx_WRITE` columns.

- `COUNT_READ`, `SUM_TIMER_READ`, `MIN_TIMER_READ`, `AVG_TIMER_READ`, `MAX_TIMER_READ`

These columns aggregate all read-lock operations. They are the same as the sum of the corresponding `xxx_READ_NORMAL`, `xxx_READ_WITH_SHARED_LOCKS`, `xxx_READ_HIGH_PRIORITY`, and `xxx_READ_NO_INSERT` columns.

- `COUNT_WRITE`, `SUM_TIMER_WRITE`, `MIN_TIMER_WRITE`, `AVG_TIMER_WRITE`, `MAX_TIMER_WRITE`

These columns aggregate all write-lock operations. They are the same as the sum of the corresponding `xxx_WRITE_ALLOW_WRITE`, `xxx_WRITE_CONCURRENT_INSERT`, `xxx_WRITE_LOW_PRIORITY`, and `xxx_WRITE_NORMAL` columns.

- `COUNT_READ_NORMAL`, `SUM_TIMER_READ_NORMAL`, `MIN_TIMER_READ_NORMAL`, `AVG_TIMER_READ_NORMAL`, `MAX_TIMER_READ_NORMAL`

These columns aggregate internal read locks.

- `COUNT_READ_WITH_SHARED_LOCKS`, `SUM_TIMER_READ_WITH_SHARED_LOCKS`, `MIN_TIMER_READ_WITH_SHARED_LOCKS`, `AVG_TIMER_READ_WITH_SHARED_LOCKS`, `MAX_TIMER_READ_WITH_SHARED_LOCKS`

These columns aggregate internal read locks.

- `COUNT_READ_HIGH_PRIORITY`, `SUM_TIMER_READ_HIGH_PRIORITY`, `MIN_TIMER_READ_HIGH_PRIORITY`, `AVG_TIMER_READ_HIGH_PRIORITY`, `MAX_TIMER_READ_HIGH_PRIORITY`

These columns aggregate internal read locks.

- `COUNT_READ_NO_INSERT`, `SUM_TIMER_READ_NO_INSERT`, `MIN_TIMER_READ_NO_INSERT`, `AVG_TIMER_READ_NO_INSERT`, `MAX_TIMER_READ_NO_INSERT`

These columns aggregate internal read locks.

- `COUNT_READ_EXTERNAL`, `SUM_TIMER_READ_EXTERNAL`, `MIN_TIMER_READ_EXTERNAL`, `AVG_TIMER_READ_EXTERNAL`, `MAX_TIMER_READ_EXTERNAL`

These columns aggregate external read locks.

- `COUNT_WRITE_ALLOW_WRITE`, `SUM_TIMER_WRITE_ALLOW_WRITE`, `MIN_TIMER_WRITE_ALLOW_WRITE`, `AVG_TIMER_WRITE_ALLOW_WRITE`, `MAX_TIMER_WRITE_ALLOW_WRITE`

These columns aggregate internal write locks.

- `COUNT_WRITE_CONCURRENT_INSERT`, `SUM_TIMER_WRITE_CONCURRENT_INSERT`, `MIN_TIMER_WRITE_CONCURRENT_INSERT`, `AVG_TIMER_WRITE_CONCURRENT_INSERT`, `MAX_TIMER_WRITE_CONCURRENT_INSERT`

These columns aggregate internal write locks.

- `COUNT_WRITE_LOW_PRIORITY`, `SUM_TIMER_WRITE_LOW_PRIORITY`, `MIN_TIMER_WRITE_LOW_PRIORITY`, `AVG_TIMER_WRITE_LOW_PRIORITY`, `MAX_TIMER_WRITE_LOW_PRIORITY`

These columns aggregate internal write locks.

- `COUNT_WRITE_NORMAL`, `SUM_TIMER_WRITE_NORMAL`, `MIN_TIMER_WRITE_NORMAL`, `AVG_TIMER_WRITE_NORMAL`, `MAX_TIMER_WRITE_NORMAL`

These columns aggregate internal write locks.

- `COUNT_WRITE_EXTERNAL`, `SUM_TIMER_WRITE_EXTERNAL`, `MIN_TIMER_WRITE_EXTERNAL`, `AVG_TIMER_WRITE_EXTERNAL`, `MAX_TIMER_WRITE_EXTERNAL`

These columns aggregate external write locks.

The `table_lock_waits_summary_by_table` table has these indexes:

- Unique index on (`OBJECT_TYPE`, `OBJECT_SCHEMA`, `OBJECT_NAME`)

`TRUNCATE TABLE` is permitted for table lock summary tables. It resets the summary columns to zero rather than removing rows.

25.11.15.9 Socket Summary Tables

These socket summary tables aggregate timer and byte count information for socket operations:

- `socket_summary_by_event_name`: Aggregate timer and byte count statistics generated by the `wait/io/socket/*` instruments for all socket I/O operations, per socket instrument.

- `socket_summary_by_instance`: Aggregate timer and byte count statistics generated by the `wait/io/socket/*` instruments for all socket I/O operations, per socket instance. When a connection terminates, the row in `socket_summary_by_instance` corresponding to it is deleted.

The socket summary tables do not aggregate waits generated by `idle` events while sockets are waiting for the next request from the client. For `idle` event aggregations, use the wait-event summary tables; see [Section 25.11.15.1, “Wait Event Summary Tables”](#).

Each socket summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the `setup_instruments` table:

- `socket_summary_by_event_name` has an `EVENT_NAME` column. Each row summarizes events for a given event name.
- `socket_summary_by_instance` has an `OBJECT_INSTANCE_BEGIN` column. Each row summarizes events for a given object.

Each socket summary table has these summary columns containing aggregated values:

- `COUNT_STAR`, `SUM_TIMER_WAIT`, `MIN_TIMER_WAIT`, `AVG_TIMER_WAIT`, `MAX_TIMER_WAIT`

These columns aggregate all operations.

- `COUNT_READ`, `SUM_TIMER_READ`, `MIN_TIMER_READ`, `AVG_TIMER_READ`, `MAX_TIMER_READ`, `SUM_NUMBER_OF_BYTES_READ`

These columns aggregate all receive operations (`RECV`, `RECVFROM`, and `RECVMSG`).

- `COUNT_WRITE`, `SUM_TIMER_WRITE`, `MIN_TIMER_WRITE`, `AVG_TIMER_WRITE`, `MAX_TIMER_WRITE`, `SUM_NUMBER_OF_BYTES_WRITE`

These columns aggregate all send operations (`SEND`, `SENDTO`, and `SENDMSG`).

- `COUNT_MISC`, `SUM_TIMER_MISC`, `MIN_TIMER_MISC`, `AVG_TIMER_MISC`, `MAX_TIMER_MISC`

These columns aggregate all other socket operations, such as `CONNECT`, `LISTEN`, `ACCEPT`, `CLOSE`, and `SHUTDOWN`. There are no byte counts for these operations.

The `socket_summary_by_instance` table also has an `EVENT_NAME` column that indicates the class of the socket: `client_connection`, `server_tcpip_socket`, `server_unix_socket`. This column can be grouped on to isolate, for example, client activity from that of the server listening sockets.

The socket summary tables have these indexes:

- `socket_summary_by_event_name`:
 - Primary key on (`EVENT_NAME`)
- `socket_summary_by_instance`:
 - Primary key on (`OBJECT_INSTANCE_BEGIN`)
 - Index on (`EVENT_NAME`)

`TRUNCATE TABLE` is permitted for socket summary tables. Except for `events_statements_summary_by_digest`, it resets the summary columns to zero rather than removing rows.

25.11.15.10 Memory Summary Tables

The Performance Schema instruments memory usage and aggregates memory usage statistics, detailed by these factors:

- Type of memory used (various caches, internal buffers, and so forth)
- Thread, account, user, host indirectly performing the memory operation

The Performance Schema instruments the following aspects of memory use

- Memory sizes used
- Operation counts
- Low and high water marks

Memory sizes help to understand or tune the memory consumption of the server.

Operation counts help to understand or tune the overall pressure the server is putting on the memory allocator, which has an impact on performance. Allocating a single byte one million times is not the same as allocating one million bytes a single time; tracking both sizes and counts can expose the difference.

Low and high water marks are critical to detect workload spikes, overall workload stability, and possible memory leaks.

Memory summary tables do not contain timing information because memory events are not timed.

For information about collecting memory usage data, see [Memory Instrumentation Behavior](#).

Example memory event summary information:

```
mysql> SELECT * FROM memory_summary_global_by_event_name
WHERE EVENT_NAME = 'memory/sql/TABLE'\G
***** 1. row *****
          EVENT_NAME: memory/sql/TABLE
          COUNT_ALLOC: 1381
          COUNT_FREE: 924
SUM_NUMBER_OF_BYTES_ALLOC: 2059873
SUM_NUMBER_OF_BYTES_FREE: 1407432
          LOW_COUNT_USED: 0
          CURRENT_COUNT_USED: 457
          HIGH_COUNT_USED: 461
          LOW_NUMBER_OF_BYTES_USED: 0
CURRENT_NUMBER_OF_BYTES_USED: 652441
          HIGH_NUMBER_OF_BYTES_USED: 669269
```

Each memory summary table has one or more grouping columns to indicate how the table aggregates events. Event names refer to names of event instruments in the [setup_instruments](#) table:

- [memory_summary_by_account_by_event_name](#) has [USER](#), [HOST](#), and [EVENT_NAME](#) columns. Each row summarizes events for a given account (user and host combination) and event name.
- [memory_summary_by_host_by_event_name](#) has [HOST](#) and [EVENT_NAME](#) columns. Each row summarizes events for a given host and event name.
- [memory_summary_by_thread_by_event_name](#) has [THREAD_ID](#) and [EVENT_NAME](#) columns. Each row summarizes events for a given thread and event name.
- [memory_summary_by_user_by_event_name](#) has [USER](#) and [EVENT_NAME](#) columns. Each row summarizes events for a given user and event name.
- [memory_summary_global_by_event_name](#) has an [EVENT_NAME](#) column. Each row summarizes events for a given event name.

Each memory summary table has these summary columns containing aggregated values:

- [COUNT_ALLOC](#), [COUNT_FREE](#)

The aggregated numbers of calls to memory-allocation and memory-free functions.

- `SUM_NUMBER_OF_BYTES_ALLOC`, `SUM_NUMBER_OF_BYTES_FREE`

The aggregated sizes of allocated and freed memory blocks.

- `CURRENT_COUNT_USED`

The aggregated number of currently allocated blocks that have not been freed yet. This is a convenience column, equal to `COUNT_ALLOC - COUNT_FREE`.

- `CURRENT_NUMBER_OF_BYTES_USED`

The aggregated size of currently allocated memory blocks that have not been freed yet. This is a convenience column, equal to `SUM_NUMBER_OF_BYTES_ALLOC - SUM_NUMBER_OF_BYTES_FREE`.

- `LOW_COUNT_USED`, `HIGH_COUNT_USED`

The low and high water marks corresponding to the `CURRENT_COUNT_USED` column.

- `LOW_NUMBER_OF_BYTES_USED`, `HIGH_NUMBER_OF_BYTES_USED`

The low and high water marks corresponding to the `CURRENT_NUMBER_OF_BYTES_USED` column.

The memory summary tables have these indexes:

- `memory_summary_by_account_by_event_name`:
 - Primary key on (`USER`, `HOST`, `EVENT_NAME`)
- `memory_summary_by_host_by_event_name`:
 - Primary key on (`HOST`, `EVENT_NAME`)
- `memory_summary_by_thread_by_event_name`:
 - Primary key on (`THREAD_ID`, `EVENT_NAME`)
- `memory_summary_by_user_by_event_name`:
 - Primary key on (`USER`, `EVENT_NAME`)
- `memory_summary_global_by_event_name`:
 - Primary key on (`EVENT_NAME`)

`TRUNCATE TABLE` is permitted for memory summary tables. It has these effects:

- In general, truncation resets the baseline for statistics, but does not change the server state. That is, truncating a memory table does not free memory.
- `COUNT_ALLOC` and `COUNT_FREE` are reset to a new baseline, by reducing each counter by the same value.
- Likewise, `SUM_NUMBER_OF_BYTES_ALLOC` and `SUM_NUMBER_OF_BYTES_FREE` are reset to a new baseline.
- `LOW_COUNT_USED` and `HIGH_COUNT_USED` are reset to `CURRENT_COUNT_USED`.
- `LOW_NUMBER_OF_BYTES_USED` and `HIGH_NUMBER_OF_BYTES_USED` are reset to `CURRENT_NUMBER_OF_BYTES_USED`.

In addition, each memory summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of

`memory_summary_global_by_event_name`. For details, see [Section 25.11.8, “Performance Schema Connection Tables”](#).

Memory Instrumentation Behavior

Memory instruments are listed in the `setup_instruments` table and have names of the form `memory/code_area/instrument_name`. Memory instrumentation is enabled by default. (Prior to 8.0.2, most memory instrumentation is disabled by default.)

Instruments named with the prefix `memory/performance_schema/` expose how much memory is allocated for internal buffers in the Performance Schema itself. The `memory/performance_schema/` instruments are built in, always enabled, and cannot be disabled at startup or runtime. Built-in memory instruments are displayed only in the `memory_summary_global_by_event_name` table.

To control memory instrumentation state at server startup, use lines like these in your `my.cnf` file:

- Enable:

```
[mysqld]
performance-schema-instrument='memory/%=ON'
```

- Disable:

```
[mysqld]
performance-schema-instrument='memory/%=OFF'
```

To control memory instrumentation state at runtime, update the `ENABLED` column of the relevant instruments in the `setup_instruments` table:

- Enable:

```
UPDATE setup_instruments SET ENABLED = 'YES'
WHERE NAME LIKE 'memory/%';
```

- Disable:

```
UPDATE setup_instruments SET ENABLED = 'NO'
WHERE NAME LIKE 'memory/%';
```

For memory instruments, the `TIMED` column in `setup_instruments` is ignored because memory operations are not timed.

Note

If disabled memory instrumentation is later enabled, accounting may result in an apparently negative allocation from missing an allocation operation but counting a free operation.

When a thread in the server executes a memory allocation that has been instrumented, these rules apply:

- If the thread is not instrumented or the memory instrument is not enabled, the memory block allocated is not instrumented.
- Otherwise (that is, both the thread and the instrument are enabled), the memory block allocated is instrumented.

For deallocation, these rules apply:

- If a thread is instrumented, and a memory block is not instrumented, the free operation is not instrumented; no statistics are changed.

- If a thread is not instrumented, and a memory block is instrumented, the free operation is instrumented, and statistics are changed.

For the per-thread statistics, the following rules apply.

When an instrumented memory block of size N is allocated, the Performance Schema makes these updates to memory summary table columns:

- `COUNT_ALLOC`: Increased by 1
- `CURRENT_COUNT_USED`: Increased by 1
- `HIGH_COUNT_USED`: Increased if `CURRENT_COUNT_USED` is a new maximum
- `SUM_NUMBER_OF_BYTES_ALLOC`: Increased by N
- `CURRENT_NUMBER_OF_BYTES_USED`: Increased by N
- `HIGH_NUMBER_OF_BYTES_USED`: Increased if `CURRENT_NUMBER_OF_BYTES_USED` is a new maximum

When an instrumented memory block is deallocated, the Performance Schema makes these updates to memory summary table columns:

- `COUNT_FREE`: Increased by 1
- `CURRENT_COUNT_USED`: Decreased by 1
- `LOW_COUNT_USED`: Decreased if `CURRENT_COUNT_USED` is a new minimum
- `SUM_NUMBER_OF_BYTES_FREE`: Increased by N
- `CURRENT_NUMBER_OF_BYTES_USED`: Decreased by N
- `LOW_NUMBER_OF_BYTES_USED`: Decreased if `CURRENT_NUMBER_OF_BYTES_USED` is a new minimum

For higher-level aggregates (global, by account, by user, by host), the same rules apply as expected for low and high water marks.

- `LOW_COUNT_USED` and `LOW_NUMBER_OF_BYTES_USED` are lower estimates. The value reported by the Performance Schema is guaranteed to be less than or equal to the lowest count or size of memory effectively used at runtime.
- `HIGH_COUNT_USED` and `HIGH_NUMBER_OF_BYTES_USED` are higher estimates. The value reported by the Performance Schema is guaranteed to be greater than or equal to the highest count or size of memory effectively used at runtime.

For lower estimates in summary tables other than `memory_summary_global_by_event_name`, it is possible for values to go negative if memory ownership is transferred between threads.

Here is an example of estimate computation; but note that estimate implementation is subject to change:

Thread 1 uses memory in the range from 1MB to 2MB during execution, as reported by the `LOW_NUMBER_OF_BYTES_USED` and `HIGH_NUMBER_OF_BYTES_USED` columns of the `memory_summary_by_thread_by_event_name` table.

Thread 2 uses memory in the range from 10MB to 12MB during execution, as reported likewise.

When these two threads belong to the same user account, the per-account summary estimates that this account used memory in the range from 11MB to 14MB. That

is, the `LOW_NUMBER_OF_BYTES_USED` for the higher level aggregate is the sum of each `LOW_NUMBER_OF_BYTES_USED` (assuming the worst case). Likewise, the `HIGH_NUMBER_OF_BYTES_USED` for the higher level aggregate is the sum of each `HIGH_NUMBER_OF_BYTES_USED` (assuming the worst case).

11MB is a lower estimate that can occur only if both threads hit the low usage mark at the same time.

14MB is a higher estimate that can occur only if both threads hit the high usage mark at the same time.

The real memory usage for this account could have been in the range from 11.5MB to 13.5MB.

For capacity planning, reporting the worst case is actually the desired behavior, as it shows what can potentially happen when sessions are uncorrelated, which is typically the case.

25.11.15.11 Error Summary Tables

The Performance Schema maintains summary tables for aggregating statistical information about server errors (and warnings). For a list of server errors, see [Section B.3, “Server Error Codes and Messages”](#).

Collection of error information is controlled by the `error` instrument, which is enabled by default. Timing information is not collected.

Each error summary table has three columns that identify the error:

- `ERROR_NUMBER` is the numeric error value. The value is unique.
- `ERROR_NAME` is the symbolic error name corresponding to the `ERROR_NUMBER` value. The value is unique.
- `SQLSTATE` is the SQLSTATE value corresponding to the `ERROR_NUMBER` value. The value is not necessarily unique.

For example, if `ERROR_NUMBER` is 1050, `ERROR_NAME` is `ER_TABLE_EXISTS_ERROR` and `SQLSTATE` is `42S01`.

Example error event summary information:

```
mysql> SELECT * FROM events_errors_summary_global_by_error
      WHERE SUM_ERROR_RAISED <> 0\G
***** 1. row *****
      ERROR_NUMBER: 1064
      ERROR_NAME: ER_PARSE_ERROR
      SQL_STATE: 42000
      SUM_ERROR_RAISED: 1
      SUM_ERROR_HANDLED: 0
      FIRST_SEEN: 2016-06-28 07:34:02
      LAST_SEEN: 2016-06-28 07:34:02
***** 2. row *****
      ERROR_NUMBER: 1146
      ERROR_NAME: ER_NO_SUCH_TABLE
      SQL_STATE: 42S02
      SUM_ERROR_RAISED: 2
      SUM_ERROR_HANDLED: 0
      FIRST_SEEN: 2016-06-28 07:34:05
      LAST_SEEN: 2016-06-28 07:36:18
***** 3. row *****
      ERROR_NUMBER: 1317
      ERROR_NAME: ER_QUERY_INTERRUPTED
      SQL_STATE: 70100
      SUM_ERROR_RAISED: 1
      SUM_ERROR_HANDLED: 0
      FIRST_SEEN: 2016-06-28 11:01:49
      LAST_SEEN: 2016-06-28 11:01:49
```

Each error summary table has one or more grouping columns to indicate how the table aggregates errors:

- `events_errors_summary_by_account_by_error` has `USER`, `HOST`, and `ERROR_NUMBER` columns. Each row summarizes events for a given account (user and host combination) and error.
- `events_errors_summary_by_host_by_error` has `HOST` and `ERROR_NUMBER` columns. Each row summarizes events for a given host and error.
- `events_errors_summary_by_thread_by_error` has `THREAD_ID` and `ERROR_NUMBER` columns. Each row summarizes events for a given thread and error.
- `events_errors_summary_by_user_by_error` has `USER` and `ERROR_NUMBER` columns. Each row summarizes events for a given user and error.
- `events_errors_summary_global_by_error` has an `ERROR_NUMBER` column. Each row summarizes events for a given error.

Each error summary table has these summary columns containing aggregated values:

- `SUM_ERROR_RAISED`

This column aggregates the number of times the error occurred.

- `SUM_ERROR_HANDLED`

This column aggregates the number of times the error was handled by an SQL exception handler.

- `FIRST_SEEN`, `LAST_SEEN`

Timestamp indicating when the error was first seen and most recently seen.

A `NULL` row in each error summary table is used to aggregate statistics for all errors that lie out of range of the instrumented errors. For example, if MySQL Server errors lie in the range from `M` to `N` and an error is raised with number `Q` not in that range, the error is aggregated in the `NULL` row. The `NULL` row is the row with `ERROR_NUMBER=0`, `ERROR_NAME=NULL`, and `SQLSTATE=NULL`.

The error summary tables have these indexes:

- `events_errors_summary_by_account_by_error`:
 - Primary key on (`USER`, `HOST`, `ERROR_NUMBER`)
- `events_errors_summary_by_host_by_error`:
 - Primary key on (`HOST`, `ERROR_NUMBER`)
- `events_errors_summary_by_thread_by_error`:
 - Primary key on (`THREAD_ID`, `ERROR_NUMBER`)
- `events_errors_summary_by_user_by_error`:
 - Primary key on (`USER`, `ERROR_NUMBER`)
- `events_errors_summary_global_by_error`:
 - Primary key on (`ERROR_NUMBER`)

`TRUNCATE TABLE` is permitted for error summary tables. It has these effects:

- For summary tables not aggregated by account, host, or user, truncation resets the summary columns to zero or `NULL` rather than removing rows.

- For summary tables aggregated by account, host, or user, truncation removes rows for accounts, hosts, or users with no connections, and resets the summary columns to zero or `NULL` for the remaining rows.

In addition, each error summary table that is aggregated by account, host, user, or thread is implicitly truncated by truncation of the connection table on which it depends, or truncation of `events_errors_summary_global_by_error`. For details, see [Section 25.11.8, “Performance Schema Connection Tables”](#).

25.11.15.12 Status Variable Summary Tables

The Performance Schema makes status variable information available in the tables described in [Section 25.11.14, “Performance Schema Status Variable Tables”](#). It also makes aggregated status variable information available in summary tables, described here. Each status variable summary table has one or more grouping columns to indicate how the table aggregates status values:

- `status_by_account` has `USER`, `HOST`, and `VARIABLE_NAME` columns to summarize status variables by account.
- `status_by_host` has `HOST` and `VARIABLE_NAME` columns to summarize status variables by the host from which clients connected.
- `status_by_user` has `USER` and `VARIABLE_NAME` columns to summarize status variables by client user name.

Each status variable summary table has this summary column containing aggregated values:

- `VARIABLE_VALUE`

The aggregated status variable value for active and terminated sessions.

The status variable summary tables have these indexes:

- `status_by_account`:
 - Primary key on (`USER`, `HOST`, `VARIABLE_NAME`)
- `status_by_host`:
 - Primary key on (`HOST`, `VARIABLE_NAME`)
- `status_by_user`:
 - Primary key on (`USER`, `VARIABLE_NAME`)

The meaning of “account” in these tables is similar to its meaning in the MySQL grant tables in the `mysql` system database, in the sense that the term refers to a combination of user and host values. They differ in that, for grant tables, the host part of an account can be a pattern, whereas for Performance Schema tables, the host value is always a specific nonpattern host name.

Account status is collected when sessions terminate. The session status counters are added to the global status counters and the corresponding account status counters. If account statistics are not collected, the session status is added to host and user status, if host and user status are collected.

Account, host, and user statistics are not collected if the `performance_schema_accounts_size`, `performance_schema_hosts_size`, and `performance_schema_users_size` system variables, respectively, are set to 0.

The Performance Schema supports `TRUNCATE TABLE` for status variable summary tables as follows; in all cases, status for active sessions is unaffected:

- `status_by_account`: Aggregates account status from terminated sessions to user and host status, then resets account status.

- `status_by_host`: Resets aggregated host status from terminated sessions.
- `status_by_user`: Resets aggregated user status from terminated sessions.

`FLUSH STATUS` adds the session status from all active sessions to the global status variables, resets the status of all active sessions, and resets account, host, and user status values aggregated from disconnected sessions.

25.11.16 Performance Schema Miscellaneous Tables

The following sections describe tables that do not fall into the table categories discussed in the preceding sections:

- `host_cache`: Information from the internal host cache
- `performance_timers`: Which event timers are available
- `threads`: Information about server threads

25.11.16.1 The `host_cache` Table

The `host_cache` table provides access to the contents of the host cache, which contains client host name and IP address information and is used to avoid DNS lookups. (See [Section 8.12.4.2, “DNS Lookup Optimization and the Host Cache”](#).) The `host_cache` table exposes the contents of the host cache so that it can be examined using `SELECT` statements. The Performance Schema must be enabled or this table is empty.

The `host_cache` table has these columns:

- `IP`

The IP address of the client that connected to the server, expressed as a string.

- `HOST`

The resolved DNS host name for that client IP, or `NULL` if the name is unknown.

- `HOST_VALIDATED`

Whether the IP-to-host name-to-IP DNS resolution was performed successfully for the client IP. If `HOST_VALIDATED` is `YES`, the `HOST` column is used as the host name corresponding to the IP so that calls to DNS can be avoided. While `HOST_VALIDATED` is `NO`, DNS resolution is attempted again for each connect, until it eventually completes with either a valid result or a permanent error. This information enables the server to avoid caching bad or missing host names during temporary DNS failures, which would affect clients forever.

- `SUM_CONNECT_ERRORS`

The number of connection errors that are deemed “blocking” (assessed against the `max_connect_errors` system variable). Only protocol handshake errors are counted, and only for hosts that passed validation (`HOST_VALIDATED = YES`).

- `COUNT_HOST_BLOCKED_ERRORS`

The number of connections that were blocked because `SUM_CONNECT_ERRORS` exceeded the value of the `max_connect_errors` system variable.

- `COUNT_NAMEINFO_TRANSIENT_ERRORS`

The number of transient errors during IP-to-host name DNS resolution.

- `COUNT_NAMEINFO_PERMANENT_ERRORS`

The number of permanent errors during IP-to-host name DNS resolution.

- [COUNT_FORMAT_ERRORS](#)

The number of host name format errors. MySQL does not perform matching of `Host` column values in the `mysql.user` table against host names for which one or more of the initial components of the name are entirely numeric, such as `1.2.example.com`. The client IP address is used instead. For the rationale why this type of matching does not occur, see [Section 6.2.4, “Specifying Account Names”](#).

- [COUNT_ADDRINFO_TRANSIENT_ERRORS](#)

The number of transient errors during host name-to-IP reverse DNS resolution.

- [COUNT_ADDRINFO_PERMANENT_ERRORS](#)

The number of permanent errors during host name-to-IP reverse DNS resolution.

- [COUNT_FCRDNS_ERRORS](#)

The number of forward-confirmed reverse DNS errors. These errors occur when IP-to-host name-to-IP DNS resolution produces an IP address that does not match the client originating IP address.

- [COUNT_HOST_ACL_ERRORS](#)

The number of errors that occur because no user from the client host can possibly log in. In such cases, the server returns `ER_HOST_NOT_PRIVILEGED` and does not even ask for a user name or password.

- [COUNT_NO_AUTH_PLUGIN_ERRORS](#)

The number of errors due to requests for an unavailable authentication plugin. A plugin can be unavailable if, for example, it was never loaded or a load attempt failed.

- [COUNT_AUTH_PLUGIN_ERRORS](#)

The number of errors reported by authentication plugins.

An authentication plugin can report different error codes to indicate the root cause of a failure. Depending on the type of error, one of these columns is incremented: [COUNT_AUTHENTICATION_ERRORS](#), [COUNT_AUTH_PLUGIN_ERRORS](#), [COUNT_HANDSHAKE_ERRORS](#). New return codes are an optional extension to the existing plugin API. Unknown or unexpected plugin errors are counted in the [COUNT_AUTH_PLUGIN_ERRORS](#) column.

- [COUNT_HANDSHAKE_ERRORS](#)

The number of errors detected at the wire protocol level.

- [COUNT_PROXY_USER_ERRORS](#)

The number of errors detected when a proxy user A is proxied to another user B who does not exist.

- [COUNT_PROXY_USER_ACL_ERRORS](#)

The number of errors detected when a proxy user A is proxied to another user B who does exist but for whom A does not have the `PROXY` privilege.

- [COUNT_AUTHENTICATION_ERRORS](#)

The number of errors caused by failed authentication.

- [COUNT_SSL_ERRORS](#)

The number of errors due to SSL problems.

- `COUNT_MAX_USER_CONNECTIONS_ERRORS`

The number of errors caused by exceeding per-user connection quotas. See [Section 6.3.6, “Setting Account Resource Limits”](#).

- `COUNT_MAX_USER_CONNECTIONS_PER_HOUR_ERRORS`

The number of errors caused by exceeding per-user connections-per-hour quotas. See [Section 6.3.6, “Setting Account Resource Limits”](#).

- `COUNT_DEFAULT_DATABASE_ERRORS`

The number of errors related to the default database. For example, the database did not exist or the user had no privileges for accessing it.

- `COUNT_INIT_CONNECT_ERRORS`

The number of errors caused by execution failures of statements in the `init_connect` system variable value.

- `COUNT_LOCAL_ERRORS`

The number of errors local to the server implementation and not related to the network, authentication, or authorization. For example, out-of-memory conditions fall into this category.

- `COUNT_UNKNOWN_ERRORS`

The number of other, unknown errors not accounted for by other columns in this table. This column is reserved for future use, in case new error conditions must be reported, and if preserving the backward compatibility and table structure of the `host_cache` table is required.

- `FIRST_SEEN`

The timestamp of the first connection attempt seen from the client in the `IP` column.

- `LAST_SEEN`

The timestamp of the last connection attempt seen from the client in the `IP` column.

- `FIRST_ERROR_SEEN`

The timestamp of the first error seen from the client in the `IP` column.

- `LAST_ERROR_SEEN`

The timestamp of the last error seen from the client in the `IP` column.

The `host_cache` table has these indexes:

- Primary key on (`IP`)
- Index on (`HOST`)

`FLUSH HOSTS` and `TRUNCATE TABLE host_cache` have the same effect: They clear the host cache. This also removes rows from the `host_cache` table (because it is the visible representation of the cache) and unblocks any blocked hosts (see [Section B.5.2.5, “Host ‘host_name’ is blocked”](#).) `FLUSH HOSTS` requires the `RELOAD` privilege. `TRUNCATE TABLE` requires the `DROP` privilege for the `host_cache` table.

25.11.16.2 The `performance_timers` Table

The `performance_timers` table shows which event timers are available:

```
mysql> SELECT * FROM performance_timers;
```

TIMER_NAME	TIMER_FREQUENCY	TIMER_RESOLUTION	TIMER_OVERHEAD
CYCLE	2389029850	1	72
NANOSECOND	1000000000	1	112
MICROSECOND	1000000	1	136
MILLISECOND	1036	1	168
TICK	105	1	2416

The timers in `setup_timers` that you can use are those that do not have `NULL` in the other columns. If the values associated with a given timer name are `NULL`, that timer is not supported on your platform.

The `performance_timers` table has these columns:

- `TIMER_NAME`

The name by which to refer to the timer when configuring the `setup_timers` table.

- `TIMER_FREQUENCY`

The number of timer units per second. For a cycle timer, the frequency is generally related to the CPU speed. For example, on a system with a 2.4GHz processor, the `CYCLE` may be close to 2400000000.

- `TIMER_RESOLUTION`

Indicates the number of timer units by which timer values increase. If a timer has a resolution of 10, its value increases by 10 each time.

- `TIMER_OVERHEAD`

The minimal number of cycles of overhead to obtain one timing with the given timer. The Performance Schema determines this value by invoking the timer 20 times during initialization and picking the smallest value. The total overhead really is twice this amount because the instrumentation invokes the timer at the start and end of each event. The timer code is called only for timed events, so this overhead does not apply for nontimed events.

The `performance_timers` table has these indexes:

- None

`TRUNCATE TABLE` is not permitted for the `performance_timers` table.

25.11.16.3 The threads Table

The `threads` table contains a row for each server thread. Each row contains information about a thread and indicates whether monitoring and historical event logging are enabled for it:

```
mysql> SELECT * FROM threads\G
***** 1. row *****
      THREAD_ID: 1
        NAME: thread/sql/main
         TYPE: BACKGROUND
PROCESSLIST_ID: NULL
PROCESSLIST_USER: NULL
PROCESSLIST_HOST: NULL
PROCESSLIST_DB: NULL
PROCESSLIST_COMMAND: NULL
```

```

PROCESSLIST_TIME: 80284
PROCESSLIST_STATE: NULL
PROCESSLIST_INFO: NULL
PARENT_THREAD_ID: NULL
    ROLE: NULL
    INSTRUMENTED: YES
    HISTORY: YES
CONNECTION_TYPE: NULL
THREAD_OS_ID: 489803
...
***** 4. row *****
    THREAD_ID: 51
        NAME: thread/sql/one_connection
        TYPE: FOREGROUND
    PROCESSLIST_ID: 34
    PROCESSLIST_USER: isabella
    PROCESSLIST_HOST: localhost
    PROCESSLIST_DB: performance_schema
PROCESSLIST_COMMAND: Query
PROCESSLIST_TIME: 0
PROCESSLIST_STATE: Sending data
PROCESSLIST_INFO: SELECT * FROM threads
PARENT_THREAD_ID: 1
    ROLE: NULL
    INSTRUMENTED: YES
    HISTORY: YES
CONNECTION_TYPE: SSL/TLS
THREAD_OS_ID: 755399
...

```

When the Performance Schema initializes, it populates the `threads` table based on the threads in existence then. Thereafter, a new row is added each time the server creates a thread.

The `INSTRUMENTED` and `HISTORY` column values for new threads are determined by the contents of the `setup_actors` table. For information about how to use the `setup_actors` table to control these columns, see [Section 25.4.6, “Pre-Filtering by Thread”](#).

Removal of rows from the `threads` table occurs when threads end. For a thread associated with a client session, removal occurs when the session ends. If a client has auto-reconnect enabled and the session reconnects after a disconnect, the session becomes associated with a new row in the `threads` table that has a different `PROCESSLIST_ID` value. The initial `INSTRUMENTED` and `HISTORY` values for the new thread may be different from those of the original thread: The `setup_actors` table may have changed in the meantime, and if the `INSTRUMENTED` or `HISTORY` value for the original thread was changed after the row was initialized, the change does not carry over to the new thread.

The `threads` table columns with names having a prefix of `PROCESSLIST_` provide information similar to that available from the `INFORMATION_SCHEMA.PROCESSLIST` table or the `SHOW PROCESSLIST` statement. Thus, all three sources provide thread-monitoring information. Use of `threads` differs from use of the other two sources in these ways:

- Access to `threads` does not require a mutex and has minimal impact on server performance. `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST` have negative performance consequences because they require a mutex.
- `threads` provides additional information for each thread, such as whether it is a foreground or background thread, and the location within the server associated with the thread.
- `threads` provides information about background threads, so it can be used to monitor activity the other thread information sources cannot.
- You can enable or disable thread monitoring (that is, whether events executed by the thread are instrumented) and historical event logging. To control the initial `INSTRUMENTED` and `HISTORY` values for new foreground threads, use the `setup_actors` table. To control these aspects of existing threads, set the `INSTRUMENTED` and `HISTORY` columns of `threads` table rows. (For more

information about the conditions under which thread monitoring and historical event logging occur, see the descriptions of the `INSTRUMENTED` and `HISTORY` columns.)

For these reasons, DBAs who perform server monitoring using `INFORMATION_SCHEMA.PROCESSLIST` or `SHOW PROCESSLIST` may wish to monitor using the `threads` table instead.

Note

For `INFORMATION_SCHEMA.PROCESSLIST` and `SHOW PROCESSLIST`, information about threads for other users is shown only if the current user has the `PROCESS` privilege. That is not true of the `threads` table; all rows are shown to any user who has the `SELECT` privilege for the table. Users who should not be able to see threads for other users should not be given that privilege.

The `threads` table has these columns:

- `THREAD_ID`

A unique thread identifier.

- `NAME`

The name associated with the thread instrumentation code in the server. For example, `thread/sql/one_connection` corresponds to the thread function in the code responsible for handling a user connection, and `thread/sql/main` stands for the `main()` function of the server.

- `TYPE`

The thread type, either `FOREGROUND` or `BACKGROUND`. User connection threads are foreground threads. Threads associated with internal server activity are background threads. Examples are internal `InnoDB` threads, “binlog dump” threads sending information to slaves, and slave I/O and SQL threads.

- `PROCESSLIST_ID`

For threads that are displayed in the `INFORMATION_SCHEMA.PROCESSLIST` table, this is the same value displayed in the `ID` column of that table. It is also the value displayed in the `Id` column of `SHOW PROCESSLIST` output, and the value that `CONNECTION_ID()` would return within that thread.

For background threads (threads not associated with a user connection), `PROCESSLIST_ID` is `NULL`, so the values are not unique.

- `PROCESSLIST_USER`

The user associated with a foreground thread, `NULL` for a background thread.

- `PROCESSLIST_HOST`

The host name of the client associated with a foreground thread, `NULL` for a background thread.

Unlike the `HOST` column of the `INFORMATION_SCHEMA.PROCESSLIST` table or the `Host` column of `SHOW PROCESSLIST` output, the `PROCESSLIST_HOST` column does not include the port number for TCP/IP connections. To obtain this information from the Performance Schema, enable the socket instrumentation (which is not enabled by default) and examine the `socket_instances` table:

```
mysql> SELECT * FROM setup_instruments WHERE NAME LIKE 'wait/io/socket%';
+-----+-----+-----+-----+
| NAME                                     | ENABLED | TIMED |
```

```

| wait/io/socket/sql/server_tcpip_socket | NO      | NO      |
| wait/io/socket/sql/server_unix_socket  | NO      | NO      |
| wait/io/socket/sql/client_connection   | NO      | NO      |
+-----+-----+-----+
3 rows in set (0.01 sec)

mysql> UPDATE setup_instruments SET ENABLED='YES' WHERE NAME LIKE 'wait/io/socket%';
Query OK, 3 rows affected (0.00 sec)
Rows matched: 3  Changed: 3  Warnings: 0

mysql> SELECT * FROM socket_instances\G
***** 1. row *****
EVENT_NAME: wait/io/socket/sql/client_connection
OBJECT_INSTANCE_BEGIN: 140612577298432
  THREAD_ID: 31
  SOCKET_ID: 53
    IP: ::ffff:127.0.0.1
    PORT: 55642
    STATE: ACTIVE
...

```

- [PROCESSLIST_DB](#)

The default database for the thread, or [NULL](#) if there is none.

- [PROCESSLIST_COMMAND](#)

For foreground threads, the type of command the thread is executing on behalf of the client, or [Sleep](#) if the session is idle. For descriptions of thread commands, see [Section 8.14, “Examining Thread Information”](#). The value of this column corresponds to the [COM_xxx](#) commands of the client/server protocol and [Com_xxx](#) status variables. See [Section 5.1.7, “Server Status Variables”](#)

Background threads do not execute commands on behalf of clients, so this column may be [NULL](#).

- [PROCESSLIST_TIME](#)

The time in seconds that the thread has been in its current state.

- [PROCESSLIST_STATE](#)

An action, event, or state that indicates what the thread is doing. For descriptions of [PROCESSLIST_STATE](#) values, see [Section 8.14, “Examining Thread Information”](#). If the value is [NULL](#), the thread may correspond to an idle client session or the work it is doing is not instrumented with stages.

Most states correspond to very quick operations. If a thread stays in a given state for many seconds, there might be a problem that bears investigation.

- [PROCESSLIST_INFO](#)

The statement the thread is executing, or [NULL](#) if it is not executing any statement. The statement might be the one sent to the server, or an innermost statement if the statement executes other statements. For example, if a [CALL](#) statement executes a stored procedure that is executing a [SELECT](#) statement, the [PROCESSLIST_INFO](#) value shows the [SELECT](#) statement.

- [PARENT_THREAD_ID](#)

If this thread is a subthread (spawned by another thread), this is the [THREAD_ID](#) value of the spawning thread.

- [ROLE](#)

Unused.

- [INSTRUMENTED](#)

Whether events executed by the thread are instrumented. The value is `YES` or `NO`.

- For foreground threads, the initial `INSTRUMENTED` value is determined by whether the user account associated with the thread matches any row in the `setup_actors` table. Matching is based on the values of the `PROCESSLIST_USER` and `PROCESSLIST_HOST` columns.

If the thread spawns a subthread, matching occurs again for the `threads` table row created for the subthread.

- For background threads, `INSTRUMENTED` is `YES` by default. `setup_actors` is not consulted because there is no associated user for background threads.
- For any thread, its `INSTRUMENTED` value can be changed during the lifetime of the thread.

For monitoring of events executed by the thread to occur, these things must be true:

- The `thread_instrumentation` consumer in the `setup_consumers` table must be `YES`.
- The `threads.INSTRUMENTED` column must be `YES`.
- Monitoring occurs only for those thread events produced from instruments that have the `ENABLED` column set to `YES` in the `setup_instruments` table.

- `HISTORY`

Whether to log historical events for the thread. The value is `YES` or `NO`.

- For foreground threads, the initial `HISTORY` value is determined by whether the user account associated with the thread matches any row in the `setup_actors` table. Matching is based on the values of the `PROCESSLIST_USER` and `PROCESSLIST_HOST` columns.

If the thread spawns a subthread, matching occurs again for the `threads` table row created for the subthread.

- For background threads, `HISTORY` is `YES` by default. `setup_actors` is not consulted because there is no associated user for background threads.
- For any thread, its `HISTORY` value can be changed during the lifetime of the thread.

For historical event logging for the thread to occur, these things must be true:

- The appropriate history-related consumers in the `setup_consumers` table must be enabled. For example, wait event logging in the `events_waits_history` and `events_waits_history_long` tables requires the corresponding `events_waits_history` and `events_waits_history_long` consumers to be `YES`.
- The `threads.HISTORY` column must be `YES`.
- Logging occurs only for those thread events produced from instruments that have the `ENABLED` column set to `YES` in the `setup_instruments` table.

- `CONNECTION_TYPE`

The protocol used to establish the connection, or `NULL` for background threads. Permitted values are `TCP/IP` (TCP/IP connection established without SSL), `SSL/TLS` (TCP/IP connection established with SSL), `Socket` (Unix socket file connection), `Named Pipe` (Windows named pipe connection), and `Shared Memory` (Windows shared memory connection).

- `THREAD_OS_ID`

The thread or task identifier as defined by the underlying operating system, if there is one:

- When a MySQL thread is associated with the same operating system thread for its lifetime, `THREAD_OS_ID` contains the operating system thread ID.
- When a MySQL thread is not associated with the same operating system thread for its lifetime, `THREAD_OS_ID` contains `NULL`. This is typical for user sessions when the thread pool plugin is used (see [MySQL Enterprise Thread Pool](#)).

For Windows, `THREAD_OS_ID` corresponds to the thread ID visible in Process Explorer (<https://technet.microsoft.com/en-us/sysinternals/bb896653.aspx>).

For Linux, `THREAD_OS_ID` corresponds to the value of the `gettid()` function. This value is exposed, for example, using the `perf` or `ps -L` commands, or in the `proc` file system (`/proc/[pid]/task/[tid]`). For more information, see the `perf-stat(1)`, `ps(1)`, and `proc(5)` man pages.

The `threads` table has these indexes:

- Primary key on (`THREAD_ID`)
- Index on (`NAME`)
- Index on (`PROCESSLIST_ID`)
- Index on (`PROCESSLIST_USER`, `PROCESSLIST_HOST`)
- Index on (`PROCESSLIST_HOST`)
- Index on (`THREAD_OS_ID`)

`TRUNCATE TABLE` is not permitted for the `threads` table.

25.11.16.4 The `user_defined_functions` Table

The `user_defined_functions` table contains a row for each user-defined function (UDF) registered by a server component or plugin, or by a `CREATE FUNCTION` statement. This table was added in MySQL 8.0.2.

`user_defined_functions` has these columns:

- `UDF_NAME`

The UDF name. The value is `NULL` if the function was registered by a `CREATE FUNCTION` statement and is in the process of unloading.

- `UDF_RETURN_TYPE`

The UDF return value type. The value is one of `int`, `decimal`, `real`, `char`, or `row`.

- `UDF_TYPE`

The UDF type. The value is one of `function` (scalar) or `aggregate`.

- `UDF_LIBRARY`

The UDF library file. The value is `NULL` if the UDF was registered using a server component service rather than by a `CREATE FUNCTION` statement.

- `UDF_USAGE_COUNT`

The current UDF usage count.

The `user_defined_functions` table has these indexes:

- Primary key on (`UDF_NAME`)

`TRUNCATE TABLE` is not permitted for the `user_defined_functions` table.

25.12 Performance Schema Option and Variable Reference

Table 25.3 Performance Schema Variable Reference

Name	Cmd-Line	Option File	System Var	Status Var	Var Scope	Dynamic
<code>performance_schema</code>	Yes	Yes	Yes		Global	No
<code>Performance_schema_accounts_lost</code>				Yes	Global	No

25.13 Performance Schema Command Options

Performance Schema parameters can be specified at server startup on the command line or in option files to configure Performance Schema instruments and consumers. Runtime configuration is also possible in many cases (see [Section 25.4, “Performance Schema Runtime Configuration”](#)), but startup configuration must be used when runtime configuration is too late to affect instruments that have already been initialized during the startup process.

Performance Schema consumers and instruments can be configured at startup using the following syntax. For additional details, see [Section 25.3, “Performance Schema Startup Configuration”](#).

- `--performance-schema-consumer-consumer_name=value`

Configure a Performance Schema consumer. Consumer names in the `setup_consumers` table use underscores, but for consumers set at startup, dashes and underscores within the name are equivalent. Options for configuring individual consumers are detailed later in this section.

- `--performance-schema-instrument=instrument_name=value`

Configure a Performance Schema instrument. The name may be given as a pattern to configure instruments that match the pattern.

The following items configure individual consumers:

- `--performance-schema-consumer-events-stages-current=value`

Configure the `events-stages-current` consumer.

- `--performance-schema-consumer-events-stages-history=value`

Configure the `events-stages-history` consumer.

- `--performance-schema-consumer-events-stages-history-long=value`

Configure the `events-stages-history-long` consumer.

- `--performance-schema-consumer-events-statements-current=value`

Configure the `events-statements-current` consumer.

- `--performance-schema-consumer-events-statements-history=value`

Configure the `events-statements-history` consumer.

- `--performance-schema-consumer-events-statements-history-long=value`

Configure the `events-statements-history-long` consumer.

- `--performance-schema-consumer-events-transactions-current=value`

Configure the Performance Schema `events-transactions-current` consumer.

- `--performance-schema-consumer-events-transactions-history=value`

Configure the Performance Schema `events-transactions-history` consumer.

- `--performance-schema-consumer-events-transactions-history-long=value`

Configure the Performance Schema `events-transactions-history-long` consumer.

- `--performance-schema-consumer-events-waits-current=value`

Configure the `events-waits-current` consumer.

- `--performance-schema-consumer-events-waits-history=value`

Configure the `events-waits-history` consumer.

- `--performance-schema-consumer-events-waits-history-long=value`

Configure the `events-waits-history-long` consumer.

- `--performance-schema-consumer-global-instrumentation=value`

Configure the `global-instrumentation` consumer.

- `--performance-schema-consumer-statements-digest=value`

Configure the `statements-digest` consumer.

- `--performance-schema-consumer-thread-instrumentation=value`

Configure the `thread-instrumentation` consumer.

25.14 Performance Schema System Variables

The Performance Schema implements several system variables that provide configuration information:

```
mysql> SHOW VARIABLES LIKE 'perf%';
```

Variable_name	Value
<code>performance_schema</code>	ON
<code>performance_schema_accounts_size</code>	-1
<code>performance_schema_digests_size</code>	10000
<code>performance_schema_events_stages_history_long_size</code>	10000
<code>performance_schema_events_stages_history_size</code>	10
<code>performance_schema_events_statements_history_long_size</code>	10000
<code>performance_schema_events_statements_history_size</code>	10
<code>performance_schema_events_transactions_history_long_size</code>	10000
<code>performance_schema_events_transactions_history_size</code>	10
<code>performance_schema_events_waits_history_long_size</code>	10000
<code>performance_schema_events_waits_history_size</code>	10
<code>performance_schema_hosts_size</code>	-1
<code>performance_schema_max_cond_classes</code>	80
<code>performance_schema_max_cond_instances</code>	-1
<code>performance_schema_max_digest_length</code>	1024

Performance Schema System Variables

performance_schema_max_file_classes	50
performance_schema_max_file_handles	32768
performance_schema_max_file_instances	-1
performance_schema_max_index_stat	-1
performance_schema_max_memory_classes	320
performance_schema_max_metadata_locks	-1
performance_schema_max_mutex_classes	220
performance_schema_max_mutex_instances	-1
performance_schema_max_prepared_statements_instances	-1
performance_schema_max_program_instances	-1
performance_schema_max_rwlock_classes	40
performance_schema_max_rwlock_instances	-1
performance_schema_max_socket_classes	10
performance_schema_max_socket_instances	-1
performance_schema_max_sql_text_length	1024
performance_schema_max_stage_classes	150
performance_schema_max_statement_classes	192
performance_schema_max_statement_stack	10
performance_schema_max_table_handles	-1
performance_schema_max_table_instances	-1
performance_schema_max_table_lock_stat	-1
performance_schema_max_thread_classes	50
performance_schema_max_thread_instances	-1
performance_schema_session_connect_attrs_size	512
performance_schema_setup_actors_size	-1
performance_schema_setup_objects_size	-1
performance_schema_users_size	-1

Performance Schema system variables can be set at server startup on the command line or in option files, and many can be set at runtime. See [Section 25.12, “Performance Schema Option and Variable Reference”](#).

The Performance Schema automatically sizes the values of several of its parameters at server startup if they are not set explicitly. For more information, see [Section 25.3, “Performance Schema Startup Configuration”](#).

Performance Schema system variables have the following meanings:

- [performance_schema](#)

Command-Line Format	<code>--performance-schema=#</code>	
System Variable	Name	performance_schema
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	boolean
	Default	ON

The value of this variable is [ON](#) or [OFF](#) to indicate whether the Performance Schema is enabled. By default, the value is [ON](#). At server startup, you can specify this variable with no value or a value of [ON](#) or 1 to enable it, or with a value of [OFF](#) or 0 to disable it.

Even when the Performance Schema is disabled, it continues to populate the [global_variables](#), [session_variables](#), [global_status](#), and [session_status](#) tables. This occurs as necessary to permit the results for the [SHOW VARIABLES](#) and [SHOW STATUS](#) statements to be drawn from those tables, depending on the setting of the [show_compatibility_56](#) system variable. The Performance Schema also populates some of the replication tables when disabled.

- [performance_schema_accounts_size](#)

Command-Line Format	<code>--performance-schema-accounts-size=#</code>
----------------------------	---

System Variable	Name	<code>performance_schema_accounts_size</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	<code>-1 (autoscaled)</code>
	Min Value	<code>-1 (autoscaled)</code>
	Max Value	<code>1048576</code>

The number of rows in the `accounts` table. If this variable is 0, the Performance Schema does not maintain connection statistics in the `accounts` table or status variable information in the `status_by_account` table.

- `performance_schema_digests_size`

Command-Line Format	<code>--performance-schema-digests-size=#</code>	
System Variable	Name	<code>performance_schema_digests_size</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	<code>-1 (autosized)</code>
	Min Value	<code>-1</code>
	Max Value	<code>1048576</code>

The maximum number of rows in the `events_statements_summary_by_digest` table. If this maximum is exceeded such that a digest cannot be instrumented, the Performance Schema increments the `Performance_schema_digest_lost` status variable.

For more information about statement digesting, see [Section 25.9, “Performance Schema Statement Digests”](#).

- `performance_schema_error_size`

Command-Line Format	<code>--performance-schema-error-size</code>	
System Variable	Name	<code>performance_schema_error_size</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	<code>number of server error codes</code>
	Min Value	<code>0</code>

	Max Value	1048576
--	------------------	---------

The number of instrumented server error codes. The default value is the actual number of server error codes. Although the value can be set anywhere from 0 to its maximum, the intended use is to set it to either its default (to instrument all errors) or 0 (to instrument no errors).

Error information is aggregated in summary tables; see [Section 25.11.15.11, “Error Summary Tables”](#). If an error occurs that is not instrumented, information for the occurrence is aggregated to the `NULL` row in each summary table; that is, to the row with `ERROR_NUMBER=0`, `ERROR_NAME=NULL`, and `SQLSTATE=NULL`.

- [performance_schema_events_stages_history_long_size](#)

Command-Line Format	<code>--performance-schema-events-stages-history-long-size=#</code>	
System Variable	Name	performance_schema_events_stages_history_long_size
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	-1 (autosized)

The number of rows in the `events_stages_history_long` table.

- [performance_schema_events_stages_history_size](#)

Command-Line Format	<code>--performance-schema-events-stages-history-size=#</code>	
System Variable	Name	performance_schema_events_stages_history_size
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	-1 (autosized)

The number of rows per thread in the `events_stages_history` table.

- [performance_schema_events_statements_history_long_size](#)

Command-Line Format	<code>--performance-schema-events-statements-history-long-size=#</code>	
System Variable	Name	performance_schema_events_statements_history_long_size
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	-1 (autosized)

- [performance_schema_events_statements_history_size](#)

Command-Line Format	<code>--performance-schema-events-statements-history-size=#</code>	
System Variable	Name	performance_schema_events_statements_history_size
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	-1 (autosized)

The number of rows per thread in the `events_statements_history` table.

- [performance_schema_events_transactions_history_long_size](#)

Command-Line Format	<code>--performance-schema-events-transactions-history-long-size=#</code>	
System Variable	Name	performance_schema_events_transactions_history_long_size
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	-1 (autosized)

The number of rows in the `events_transactions_history_long` table.

- [performance_schema_events_transactions_history_size](#)

Command-Line Format	<code>--performance-schema-events-transactions-history-size=#</code>	
System Variable	Name	performance_schema_events_transactions_history_size
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	-1 (autosized)

The number of rows per thread in the `events_transactions_history` table.

- [performance_schema_events_waits_history_long_size](#)

Command-Line Format	<code>--performance-schema-events-waits-history-long-size=#</code>	
System Variable	Name	performance_schema_events_waits_history_long_size
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	-1 (autosized)

The number of rows in the `events_waits_history_long` table.

- `performance_schema_events_waits_history_size`

Command-Line Format	<code>--performance-schema-events-waits-history-size=#</code>	
System Variable	Name	<code>performance_schema_events_waits_history_size</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	-1 (autosized)

The number of rows per thread in the `events_waits_history` table.

- `performance_schema_hosts_size`

Command-Line Format	<code>--performance-schema-hosts-size=#</code>	
System Variable	Name	<code>performance_schema_hosts_size</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	-1 (autoscaled)
	Min Value	-1 (autoscaled)
	Max Value	1048576

The number of rows in the `hosts` table. If this variable is 0, the Performance Schema does not maintain connection statistics in the `hosts` table or status variable information in the `status_by_host` table.

- `performance_schema_max_cond_classes`

Command-Line Format	<code>--performance-schema-max-cond-classes=#</code>	
System Variable	Name	<code>performance_schema_max_cond_classes</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	80

The maximum number of condition instruments.

- `performance_schema_max_cond_instances`

Command-Line Format	<code>--performance-schema-max-cond-instances=#</code>	
System Variable	Name	<code>performance_schema_max_cond_instances</code>

	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	-1 (autoscaled)

The maximum number of instrumented condition objects.

- [performance_schema_max_digest_length](#)

Command-Line Format	<code>--performance-schema-max-digest-length=#</code>	
System Variable	Name	performance_schema_max_digest_length
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	1024
	Min Value	0
	Max Value	1048576

The maximum number of bytes available for storage of normalized statement digest values in the Performance Schema. This variable is related to [max_digest_length](#); see the description of that variable in [Section 5.1.5, “Server System Variables”](#)

For more information about statement digesting, see [Section 25.9, “Performance Schema Statement Digests”](#).

- [performance_schema_max_file_classes](#)

Command-Line Format	<code>--performance-schema-max-file-classes=#</code>	
System Variable	Name	performance_schema_max_file_classes
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	80

The maximum number of file instruments.

- [performance_schema_max_file_handles](#)

Command-Line Format	<code>--performance-schema-max-file-handles=#</code>	
System Variable	Name	performance_schema_max_file_handles
	Variable Scope	Global
	Dynamic Variable	No

Permitted Values	Type	integer
	Default	32768

The maximum number of opened file objects.

The value of `performance_schema_max_file_handles` should be greater than the value of `open_files_limit`: `open_files_limit` affects the maximum number of open file handles the server can support and `performance_schema_max_file_handles` affects how many of these file handles can be instrumented.

- `performance_schema_max_file_instances`

Command-Line Format	<code>--performance-schema-max-file-instances=#</code>	
System Variable	Name	<code>performance_schema_max_file_instances</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	-1 (autoscaled)

The maximum number of instrumented file objects.

- `performance_schema_max_index_stat`

Command-Line Format	<code>--performance-schema-max-index-stat=#</code>	
System Variable	Name	<code>performance_schema_max_index_stat</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	-1 (autosized)

The maximum number of indexes for which the Performance Schema maintains statistics. If this maximum is exceeded such that index statistics are lost, the Performance Schema increments the `Performance_schema_index_stat_lost` status variable. The default value is autosized using the value of `performance_schema_max_table_instances`.

- `performance_schema_max_memory_classes`

Command-Line Format	<code>--performance-schema-max-memory-classes=#</code>	
System Variable	Name	<code>performance_schema_max_memory_classes</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	320

The maximum number of memory instruments.

- `performance_schema_max_metadata_locks`

Command-Line Format	<code>--performance-schema-max-metadata-locks=#</code>	
System Variable	Name	<code>performance_schema_max_metadata_locks</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	<code>-1 (autoscaled)</code>

The maximum number of metadata lock instruments. This value controls the size of the `metadata_locks` table. If this maximum is exceeded such that a metadata lock cannot be instrumented, the Performance Schema increments the `performance_schema_metadata_lock_lost` status variable.

- `performance_schema_max_mutex_classes`

Command-Line Format	<code>--performance-schema-max-mutex-classes=#</code>	
System Variable	Name	<code>performance_schema_max_mutex_classes</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values (8.0.0)	Type	integer
	Default	<code>200</code>
Permitted Values (>= 8.0.1, <= 8.0.2)	Type	integer
	Default	<code>220</code>
Permitted Values (>= 8.0.3)	Type	integer
	Default	<code>250</code>

The maximum number of mutex instruments.

- `performance_schema_max_mutex_instances`

Command-Line Format	<code>--performance-schema-max-mutex-instances=#</code>	
System Variable	Name	<code>performance_schema_max_mutex_instances</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	<code>-1 (autoscaled)</code>

The maximum number of instrumented mutex objects.

- `performance_schema_max_prepared_statements_instances`

Command-Line Format	<code>--performance-schema-max-prepared-statements-instances=#</code>	
System Variable	Name	<code>performance_schema_max_prepared_statements_instances</code>

	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	-1 (autoscaled)

The maximum number of rows in the `prepared_statements_instances` table. If this maximum is exceeded such that a prepared statement cannot be instrumented, the Performance Schema increments the `Performance_schema_prepared_statements_lost` status variable. The default value of this variable is autosized based on the value of the `max_prepared_stmt_count` system variable.

- `performance_schema_max_rwlock_classes`

Command-Line Format	<code>--performance-schema-max-rwlock-classes=#</code>	
System Variable	Name	<code>performance_schema_max_rwlock_classes</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	40

The maximum number of rwlock instruments.

- `performance_schema_max_program_instances`

Command-Line Format	<code>--performance-schema-max-program-instances=#</code>	
System Variable	Name	<code>performance_schema_max_program_instances</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	-1 (autoscaled)

The maximum number of stored programs for which the Performance Schema maintains statistics. If this maximum is exceeded, the Performance Schema increments the `Performance_schema_program_lost` status variable.

- `performance_schema_max_rwlock_instances`

Command-Line Format	<code>--performance-schema-max-rwlock-instances=#</code>	
System Variable	Name	<code>performance_schema_max_rwlock_instances</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	-1 (autoscaled)

The maximum number of instrumented rlock objects.

- [performance_schema_max_socket_classes](#)

Command-Line Format	<code>--performance-schema-max-socket-classes=#</code>	
System Variable	Name	performance_schema_max_socket_classes
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	10

The maximum number of socket instruments.

- [performance_schema_max_socket_instances](#)

Command-Line Format	<code>--performance-schema-max-socket-instances=#</code>	
System Variable	Name	performance_schema_max_socket_instances
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	-1 (autoscaled)

The maximum number of instrumented socket objects.

- [performance_schema_max_sql_text_length](#)

Command-Line Format	<code>--performance-schema-max-sql-text-length=#</code>	
System Variable	Name	performance_schema_max_sql_text_length
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	1024
	Min Value	0
	Max Value	1048576

The maximum number of bytes used to store SQL statements in the `SQL_TEXT` column of the `events_statements_current`, `events_statements_history`, and `events_statements_history_long` statement event tables. Any bytes in excess of `performance_schema_max_sql_text_length` are discarded and do not appear in the `SQL_TEXT` column. Statements differing only after that many initial bytes are indistinguishable in this column.

Decreasing the `performance_schema_max_sql_text_length` value reduces memory use but causes more statements to become indistinguishable if they differ only at the end. Increasing the value increases memory use but permits longer statements to be distinguished.

- `performance_schema_max_stage_classes`

Command-Line Format	<code>--performance-schema-max-stage-classes=#</code>	
System Variable	Name	<code>performance_schema_max_stage_classes</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	150

The maximum number of stage instruments.

- `performance_schema_max_statement_classes`

Command-Line Format	<code>--performance-schema-max-statement-classes=#</code>	
System Variable	Name	<code>performance_schema_max_statement_classes</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	-1 (autosized)

The maximum number of statement instruments. The default value is calculated at server build time based on the number of commands in the client/server protocol and the number of SQL statement types supported by the server.

This variable should not be changed, unless to set it to 0 to disable all statement instrumentation and save all memory associated with it. Setting the variable to nonzero values other than the default has no benefit; in particular, values larger than the default cause more memory to be allocated than is needed.

- `performance_schema_max_statement_stack`

Command-Line Format	<code>--performance-schema-max-statement-stack=#</code>	
System Variable	Name	<code>performance_schema_max_statement_stack</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	10

The maximum depth of nested stored program calls for which the Performance Schema maintains statistics. When this maximum is exceeded, the Performance Schema increments the `performance_schema_nested_statement_lost` status variable for each stored program statement executed.

- `performance_schema_max_table_handles`

Command-Line Format	<code>--performance-schema-max-table-handles=#</code>	
System Variable	Name	<code>performance_schema_max_table_handles</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	<code>-1 (autoscaled)</code>

The maximum number of opened table objects. This value controls the size of the `table_handles` table. If this maximum is exceeded such that a table handle cannot be instrumented, the Performance Schema increments the `Performance_schema_table_handles_lost` status variable.

- `performance_schema_max_table_instances`

Command-Line Format	<code>--performance-schema-max-table-instances=#</code>	
System Variable	Name	<code>performance_schema_max_table_instances</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	<code>-1 (autoscaled)</code>

The maximum number of instrumented table objects.

- `performance_schema_max_table_lock_stat`

Command-Line Format	<code>--performance-schema-max-table-lock-stat=#</code>	
System Variable	Name	<code>performance_schema_max_table_lock_stat</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	<code>-1 (autosized)</code>

The maximum number of tables for which the Performance Schema maintains lock statistics. If this maximum is exceeded such that table lock statistics are lost, the Performance Schema increments the `Performance_schema_table_lock_stat_lost` status variable.

- `performance_schema_max_thread_classes`

Command-Line Format	<code>--performance-schema-max-thread-classes=#</code>	
System Variable	Name	<code>performance_schema_max_thread_classes</code>
	Variable Scope	Global
	Dynamic Variable	No

Permitted Values	Type	integer
	Default	50

The maximum number of thread instruments.

- [performance_schema_max_thread_instances](#)

Command-Line Format	<code>--performance-schema-max-thread-instances=#</code>	
System Variable	Name	performance_schema_max_thread_instances
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	-1 (autoscaled)

The maximum number of instrumented thread objects. The value controls the size of the [threads](#) table. If this maximum is exceeded such that a thread cannot be instrumented, the Performance Schema increments the [Performance_schema_thread_instances_lost](#) status variable.

The [max_connections](#) system variable affects how many threads can run in the server. [performance_schema_max_thread_instances](#) affects how many of these running threads can be instrumented.

The [variables_by_thread](#) and [status_by_thread](#) tables contain system and status variable information only about foreground threads. If not all threads are instrumented by the Performance Schema, this table will miss some rows. In this case, the [Performance_schema_thread_instances_lost](#) status variable will be greater than zero.

- [performance_schema_session_connect_attrs_size](#)

Command-Line Format	<code>--performance-schema-session-connect-attrs-size=#</code>	
System Variable	Name	performance_schema_session_connect_attrs_size
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	-1 (autosized)
	Min Value	-1
	Max Value	1048576

The amount of preallocated memory per thread reserved to hold connection attribute key/value pairs. If the aggregate size of connection attribute data sent by a client is larger than this amount, the Performance Schema truncates the attribute data, increments the [Performance_schema_session_connect_attrs_lost](#) status variable, and writes a message to the error log indicating that truncation occurred if the [log_warnings](#) system variable is greater than zero. A [_truncated](#) attribute is also added to the session attributes with a value indicating how many bytes were lost, if the attribute buffer has sufficient space. This enables the Performance Schema to expose per-connection truncation information in the connection attribute tables. This information can be examined without having to check the error log.

The default value of `performance_schema_session_connect_attrs_size` is autosized at server startup. This value may be small, so if truncation occurs (`performance_schema_session_connect_attrs_lost` becomes nonzero), you may wish to set `performance_schema_session_connect_attrs_size` explicitly to a larger value.

Although the maximum permitted `performance_schema_session_connect_attrs_size` value is 1MB, the effective maximum is 64KB because the server imposes a limit of 64KB on the aggregate size of connection attribute data it will accept. If a client attempts to send more than 64KB of attribute data, the server rejects the connection. For more information, see [Section 25.11.9, “Performance Schema Connection Attribute Tables”](#).

- `performance_schema_setup_actors_size`

Command-Line Format	<code>--performance-schema-setup-actors-size=#</code>	
System Variable	Name	<code>performance_schema_setup_actors_size</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	<code>-1 (autoscaled)</code>

The number of rows in the `setup_actors` table.

- `performance_schema_setup_objects_size`

Command-Line Format	<code>--performance-schema-setup-objects-size=#</code>	
System Variable	Name	<code>performance_schema_setup_objects_size</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	<code>-1 (autoscaled)</code>

The number of rows in the `setup_objects` table.

- `performance_schema_users_size`

Command-Line Format	<code>--performance-schema-users-size=#</code>	
System Variable	Name	<code>performance_schema_users_size</code>
	Variable Scope	Global
	Dynamic Variable	No
Permitted Values	Type	integer
	Default	<code>-1 (autoscaled)</code>
	Min Value	<code>-1 (autoscaled)</code>
	Max Value	<code>1048576</code>

The number of rows in the `users` table. If this variable is 0, the Performance Schema does not maintain connection statistics in the `users` table or status variable information in the `status_by_user` table.

25.15 Performance Schema Status Variables

The Performance Schema implements several status variables that provide information about instrumentation that could not be loaded or created due to memory constraints:

```
mysql> SHOW STATUS LIKE 'perf%';
+-----+-----+
| Variable_name | Value |
+-----+-----+
| Performance_schema_accounts_lost | 0 |
| Performance_schema_cond_classes_lost | 0 |
| Performance_schema_cond_instances_lost | 0 |
| Performance_schema_file_classes_lost | 0 |
| Performance_schema_file_handles_lost | 0 |
| Performance_schema_file_instances_lost | 0 |
| Performance_schema_hosts_lost | 0 |
| Performance_schema_locker_lost | 0 |
| Performance_schema_mutex_classes_lost | 0 |
| Performance_schema_mutex_instances_lost | 0 |
| Performance_schema_rwlock_classes_lost | 0 |
| Performance_schema_rwlock_instances_lost | 0 |
| Performance_schema_socket_classes_lost | 0 |
| Performance_schema_socket_instances_lost | 0 |
| Performance_schema_stage_classes_lost | 0 |
| Performance_schema_statement_classes_lost | 0 |
| Performance_schema_table_handles_lost | 0 |
| Performance_schema_table_instances_lost | 0 |
| Performance_schema_thread_classes_lost | 0 |
| Performance_schema_thread_instances_lost | 0 |
| Performance_schema_users_lost | 0 |
+-----+-----+
```

Performance Schema status variables have the following meanings:

- `Performance_schema_accounts_lost`
The number of times a row could not be added to the `accounts` table because it was full.
- `Performance_schema_cond_classes_lost`
How many condition instruments could not be loaded.
- `Performance_schema_cond_instances_lost`
How many condition instrument instances could not be created.
- `Performance_schema_digest_lost`
The number of digest instances that could not be instrumented in the `events_statements_summary_by_digest` table. This can be nonzero if the value of `performance_schema_digests_size` is too small.
- `Performance_schema_file_classes_lost`
How many file instruments could not be loaded.
- `Performance_schema_file_handles_lost`
How many file instrument instances could not be opened.
- `Performance_schema_file_instances_lost`

How many file instrument instances could not be created.

- `Performance_schema_hosts_lost`

The number of times a row could not be added to the `hosts` table because it was full.

- `Performance_schema_index_stat_lost`

The number of indexes for which statistics were lost. This can be nonzero if the value of `performance_schema_max_index_stat` is too small.

- `Performance_schema_locker_lost`

How many events are “lost” or not recorded, due to the following conditions:

- Events are recursive (for example, waiting for A caused a wait on B, which caused a wait on C).
- The depth of the nested events stack is greater than the limit imposed by the implementation.

Events recorded by the Performance Schema are not recursive, so this variable should always be 0.

- `Performance_schema_memory_classes_lost`

The number of times a memory instrument could not be loaded.

- `Performance_schema_metadata_lock_lost`

The number of metadata locks that could not be instrumented in the `metadata_locks` table. This can be nonzero if the value of `performance_schema_max_metadata_locks` is too small.

- `Performance_schema_mutex_classes_lost`

How many mutex instruments could not be loaded.

- `Performance_schema_mutex_instances_lost`

How many mutex instrument instances could not be created.

- `Performance_schema_nested_statement_lost`

The number of stored program statements for which statistics were lost. This can be nonzero if the value of `performance_schema_max_statement_stack` is too small.

- `Performance_schema_prepared_statements_lost`

The number of prepared statements that could not be instrumented in the `prepared_statements_instances` table. This can be nonzero if the value of `performance_schema_max_prepared_statements_instances` is too small.

- `Performance_schema_program_lost`

The number of stored programs for which statistics were lost. This can be nonzero if the value of `performance_schema_max_program_instances` is too small.

- `Performance_schema_rwlock_classes_lost`

How many rwlock instruments could not be loaded.

- `Performance_schema_rwlock_instances_lost`

How many rwlock instrument instances could not be created.

- `Performance_schema_session_connect_attrs_longest_seen`

In addition to the connection attribute size-limit check performed by the Performance Schema against the value of the `performance_schema_session_connect_attrs_size` system variable, the server performs a preliminary check, imposing a limit of 64KB on the aggregate size of connection attribute data it will accept. If a client attempts to send more than 64KB of attribute data, the server rejects the connection. Otherwise, the server considers the attribute buffer valid and tracks the size of the longest such buffer in the `Performance_schema_session_connect_attrs_longest_seen` status variable. If this value is larger than `performance_schema_session_connect_attrs_size`, DBAs may wish to increase the latter value, or, alternatively, investigate which clients are sending large amounts of attribute data.

For more information about connection attributes, see [Section 25.11.9, “Performance Schema Connection Attribute Tables”](#).

- `Performance_schema_session_connect_attrs_lost`

The number of connections for which connection attribute truncation has occurred. For a given connection, if the client sends connection attribute key/value pairs for which the aggregate size is larger than the reserved storage permitted by the value of the `performance_schema_session_connect_attrs_size` system variable, the Performance Schema truncates the attribute data and increments `Performance_schema_session_connect_attrs_lost`. If this value is nonzero, you may wish to set `performance_schema_session_connect_attrs_size` to a larger value.

For more information about connection attributes, see [Section 25.11.9, “Performance Schema Connection Attribute Tables”](#).

- `Performance_schema_socket_classes_lost`

How many socket instruments could not be loaded.

- `Performance_schema_socket_instances_lost`

How many socket instrument instances could not be created.

- `Performance_schema_stage_classes_lost`

How many stage instruments could not be loaded.

- `Performance_schema_statement_classes_lost`

How many statement instruments could not be loaded.

- `Performance_schema_table_handles_lost`

How many table instrument instances could not be opened. This can be nonzero if the value of `performance_schema_max_table_handles` is too small.

- `Performance_schema_table_instances_lost`

How many table instrument instances could not be created.

- `Performance_schema_table_lock_stat_lost`

The number of tables for which lock statistics were lost. This can be nonzero if the value of `performance_schema_max_table_lock_stat` is too small.

- `Performance_schema_thread_classes_lost`

How many thread instruments could not be loaded.

- `Performance_schema_thread_instances_lost`

The number of thread instances that could not be instrumented in the `threads` table. This can be nonzero if the value of `performance_schema_max_thread_instances` is too small.

- `performance_schema_users_lost`

The number of times a row could not be added to the `users` table because it was full.

For information on using these variables to check Performance Schema status, see [Section 25.7, “Performance Schema Status Monitoring”](#).

25.16 The Performance Schema Memory-Allocation Model

The Performance Schema uses this memory allocation model:

- May allocate memory at server startup
- May allocate additional memory during server operation
- Never free memory during server operation (although it might be recycled)
- Free all memory used at shutdown

The result is to relax memory constraints so that the Performance Schema can be used with less configuration, and to decrease the memory footprint so that consumption scales with server load. Memory used depends on the load actually seen, not the load estimated or explicitly configured for.

Several Performance Schema sizing parameters are autoscaled and need not be configured explicitly unless you want to establish an explicit limit on memory allocation:

```
performance_schema_accounts_size
performance_schema_hosts_size
performance_schema_max_cond_instances
performance_schema_max_file_instances
performance_schema_max_index_stat
performance_schema_max_metadata_locks
performance_schema_max_mutex_instances
performance_schema_max_prepared_statements_instances
performance_schema_max_program_instances
performance_schema_max_rwlock_instances
performance_schema_max_socket_instances
performance_schema_max_table_handles
performance_schema_max_table_instances
performance_schema_max_table_lock_stat
performance_schema_max_thread_instances
performance_schema_users_size
```

For an autoscaled parameter, configuration works like this:

- With the value set to -1 (the default), the parameter is autoscaled:
 - The corresponding internal buffer is empty initially and no memory is allocated.
 - As the Performance Schema collects data, memory is allocated in the corresponding buffer. The buffer size is unbounded, and may grow with the load.
- With the value set to 0:
 - The corresponding internal buffer is empty initially and no memory is allocated.
- With the value set to $N > 0$:
 - The corresponding internal buffer is empty initially and no memory is allocated.
 - As the Performance Schema collects data, memory is allocated in the corresponding buffer, until the buffer size reaches N .

- Once the buffer size reaches *N*, no more memory is allocated. Data collected by the Performance Schema for this buffer is lost, and any corresponding “lost instance” counters are incremented.

To see how much memory the Performance Schema is using, check the instruments designed for that purpose. The Performance Schema allocates memory internally and associates each buffer with a dedicated instrument so that memory consumption can be traced to individual buffers. Instruments named with the prefix `memory/performance_schema/` expose how much memory is allocated for these internal buffers. The buffers are global to the server, so the instruments are displayed only in the `memory_summary_global_by_event_name` table, and not in other `memory_summary_by_XXX_by_event_name` tables.

This query shows the information associated with the memory instruments:

```
SELECT * FROM memory_summary_global_by_event_name
WHERE EVENT_NAME LIKE 'memory/performance_schema/%';
```

25.17 Performance Schema and Plugins

Removing a plugin with `UNINSTALL PLUGIN` does not affect information already collected for code in that plugin. Time spent executing the code while the plugin was loaded was still spent even if the plugin is unloaded later. The associated event information, including aggregate information, remains readable in `performance_schema` database tables. For additional information about the effect of plugin installation and removal, see [Section 25.7, “Performance Schema Status Monitoring”](#).

A plugin implementor who instruments plugin code should document its instrumentation characteristics to enable those who load the plugin to account for its requirements. For example, a third-party storage engine should include in its documentation how much memory the engine needs for mutex and other instruments.

25.18 Using the Performance Schema to Diagnose Problems

The Performance Schema is a tool to help a DBA do performance tuning by taking real measurements instead of “wild guesses.” This section demonstrates some ways to use the Performance Schema for this purpose. The discussion here relies on the use of event filtering, which is described in [Section 25.4.2, “Performance Schema Event Filtering”](#).

The following example provides one methodology that you can use to analyze a repeatable problem, such as investigating a performance bottleneck. To begin, you should have a repeatable use case where performance is deemed “too slow” and needs optimization, and you should enable all instrumentation (no pre-filtering at all).

1. Run the use case.
2. Using the Performance Schema tables, analyze the root cause of the performance problem. This analysis will rely heavily on post-filtering.
3. For problem areas that are ruled out, disable the corresponding instruments. For example, if analysis shows that the issue is not related to file I/O in a particular storage engine, disable the file I/O instruments for that engine. Then truncate the history and summary tables to remove previously collected events.
4. Repeat the process at step 1.

At each iteration, the Performance Schema output, particularly the `events_waits_history_long` table, will contain less and less “noise” caused by nonsignificant instruments, and given that this table has a fixed size, will contain more and more data relevant to the analysis of the problem at hand.

At each iteration, investigation should lead closer and closer to the root cause of the problem, as the “signal/noise” ratio will improve, making analysis easier.

5. Once a root cause of performance bottleneck is identified, take the appropriate corrective action, such as:
 - Tune the server parameters (cache sizes, memory, and so forth).
 - Tune a query by writing it differently,
 - Tune the database schema (tables, indexes, and so forth).
 - Tune the code (this applies to storage engine or server developers only).
6. Start again at step 1, to see the effects of the changes on performance.

The `mutex_instances.LOCKED_BY_THREAD_ID` and `rwlock_instances.WRITE_LOCKED_BY_THREAD_ID` columns are extremely important for investigating performance bottlenecks or deadlocks. This is made possible by Performance Schema instrumentation as follows:

1. Suppose that thread 1 is stuck waiting for a mutex.
2. You can determine what the thread is waiting for:

```
SELECT * FROM events_waits_current WHERE THREAD_ID = thread_1;
```

Say the query result identifies that the thread is waiting for mutex A, found in `events_waits_current.OBJECT_INSTANCE_BEGIN`.

3. You can determine which thread is holding mutex A:

```
SELECT * FROM mutex_instances WHERE OBJECT_INSTANCE_BEGIN = mutex_A;
```

Say the query result identifies that it is thread 2 holding mutex A, as found in `mutex_instances.LOCKED_BY_THREAD_ID`.

4. You can see what thread 2 is doing:

```
SELECT * FROM events_waits_current WHERE THREAD_ID = thread_2;
```

25.18.1 Query Profiling Using Performance Schema

The following example demonstrates how to use Performance Schema statement events and stage events to retrieve data comparable to profiling information provided by `SHOW PROFILES` and `SHOW PROFILE` statements.

The `setup_actors` table can be used to limit the collection of historical events by host, user, or account to reduce runtime overhead and the amount of data collected in history tables. The first step of the example shows how to limit collection of historical events to a specific user.

Performance Schema displays event timer information in picoseconds (trillionths of a second) to normalize timing data to a standard unit. In the following example, `TIMER_WAIT` values are divided by 1000000000000 to show data in units of seconds. Values are also truncated to 6 decimal places to display data in the same format as `SHOW PROFILES` and `SHOW PROFILE` statements.

1. Limit the collection of historical events to the user that will run the query. By default, `setup_actors` is configured to allow monitoring and historical event collection for all foreground threads:

```
mysql> SELECT * FROM performance_schema.setup_actors;
+-----+-----+-----+-----+-----+
| HOST | USER | ROLE | ENABLED | HISTORY |
+-----+-----+-----+-----+-----+
| %    | %    | %    | YES     | YES     |
+-----+-----+-----+-----+-----+
```

Update the default row in the `setup_actors` table to disable historical event collection and monitoring for all foreground threads, and insert a new row that enables monitoring and historical event collection for the user that will run the query:

```
mysql> UPDATE performance_schema.setup_actors SET ENABLED = 'NO', HISTORY = 'NO'
WHERE HOST = '%' AND USER = '%';

mysql> INSERT INTO performance_schema.setup_actors (HOST,USER,ROLE,ENABLED,HISTORY)
VALUES('localhost','test_user','%','YES','YES');
```

Data in the `setup_actors` table should now appear similar to the following:

```
mysql> SELECT * FROM performance_schema.setup_actors;
+-----+-----+-----+-----+-----+
| HOST      | USER      | ROLE | ENABLED | HISTORY |
+-----+-----+-----+-----+-----+
| %         | %         | %    | NO      | NO      |
| localhost | test_user | %    | YES     | YES     |
+-----+-----+-----+-----+-----+
```

2. Ensure that statement and stage instrumentation is enabled by updating the `setup_instruments` table. Some instruments may already be enabled by default.

```
mysql> UPDATE performance_schema.setup_instruments SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME LIKE '%statement/%';

mysql> UPDATE performance_schema.setup_instruments SET ENABLED = 'YES', TIMED = 'YES'
WHERE NAME LIKE '%stage/%';
```

3. Ensure that `events_statements_*` and `events_stages_*` consumers are enabled. Some consumers may already be enabled by default.

```
mysql> UPDATE performance_schema.setup_consumers SET ENABLED = 'YES'
WHERE NAME LIKE '%events_statements_%';

mysql> UPDATE performance_schema.setup_consumers SET ENABLED = 'YES'
WHERE NAME LIKE '%events_stages_%';
```

4. Under the user account you are monitoring, run the statement that you want to profile. For example:

```
mysql> SELECT * FROM employees.employees WHERE emp_no = 10001;
+-----+-----+-----+-----+-----+-----+
| emp_no | birth_date | first_name | last_name | gender | hire_date |
+-----+-----+-----+-----+-----+-----+
| 10001  | 1953-09-02 | Georgi    | Facello   | M      | 1986-06-26 |
+-----+-----+-----+-----+-----+-----+
```

5. Identify the `EVENT_ID` of the statement by querying the `events_statements_history_long` table. This step is similar to running `SHOW PROFILES` to identify the `Query_ID`. The following query produces output similar to `SHOW PROFILES`:

```
mysql> SELECT EVENT_ID, TRUNCATE(TIMER_WAIT/1000000000000,6) as Duration, SQL_TEXT
FROM performance_schema.events_statements_history_long WHERE SQL_TEXT like '%10001%';
+-----+-----+-----+
| event_id | duration | sql_text |
+-----+-----+-----+
```

```
+-----+-----+-----+
|      31 | 0.028310 | SELECT * FROM employees.employees WHERE emp_no = 10001 |
+-----+-----+-----+
```

- Query the `events_stages_history_long` table to retrieve the statement's stage events. Stages are linked to statements using event nesting. Each stage event record has a `NESTING_EVENT_ID` column that contains the `EVENT_ID` of the parent statement.

```
mysql> SELECT event_name AS Stage, TRUNCATE(TIMER_WAIT/1000000000000,6) AS Duration
FROM performance_schema.events_stages_history_long WHERE NESTING_EVENT_ID=31;
```

Stage	Duration

Chapter 26 MySQL sys Schema

Table of Contents

26.1 Prerequisites for Using the sys Schema	3095
26.2 Using the sys Schema	3096
26.3 sys Schema Progress Reporting	3097
26.4 sys Schema Object Reference	3098
26.4.1 sys Schema Object Index	3098
26.4.2 sys Schema Tables and Triggers	3102
26.4.3 sys Schema Views	3104
26.4.4 sys Schema Stored Procedures	3143
26.4.5 sys Schema Stored Functions	3162

MySQL 8.0 includes the `sys` schema, a set of objects that helps DBAs and developers interpret data collected by the Performance Schema. `sys` schema objects can be used for typical tuning and diagnosis use cases. Objects in this schema include:

- Views that summarize Performance Schema data into more easily understandable form.
- Stored procedures that perform operations such as Performance Schema configuration and generating diagnostic reports.
- Stored functions that query Performance Schema configuration and provide formatting services.

For new installations, the `sys` schema is installed by default during data directory initialization if you use `mysqld` with the `--initialize` or `--initialize-insecure` option. If this is not desired, you can drop the `sys` schema manually after initialization if it is unneeded.

`mysql_upgrade` returns an error if a `sys` schema exists but has no `version` view, on the assumption that absence of this view indicates a user-created `sys` schema. To upgrade in this case, remove or rename the existing `sys` schema first.

`sys` schema objects have a `DEFINER` of `'mysql.sys'@'localhost'`. Use of the dedicated `mysql.sys` account avoids problems that occur if a DBA renames or removes the `root` account.

26.1 Prerequisites for Using the sys Schema

Before using the `sys` schema, the prerequisites described in this section must be satisfied.

The `sys` schema requires MySQL 5.6 or higher.

Because the `sys` schema provides an alternative means of accessing the Performance Schema, the Performance Schema must be enabled for the `sys` schema to work. See [Section 25.3, “Performance Schema Startup Configuration”](#).

For full access to the `sys` schema, a user must have these privileges:

- `SELECT` on all `sys` tables and views
- `EXECUTE` on all `sys` stored procedures and functions
- `INSERT` and `UPDATE` for the `sys_config` table, if changes are to be made to it
- Additional privileges for certain `sys` schema stored procedures and functions, as noted in their descriptions; for example, the `ps_setup_save()` procedure

It is also necessary to have privileges for the objects underlying the `sys` schema objects:

- `SELECT` on any Performance Schema tables accessed by `sys` schema objects, and `UPDATE` for any tables to be updated using `sys` schema objects

- `PROCESS` for the `INFORMATION_SCHEMA INNODB_BUFFER_PAGE` table

Certain Performance Schema instruments and consumers must be enabled and (for instruments) timed to take full advantage of `sys` schema capabilities:

- All `wait` instruments
- All `stage` instruments
- All `statement` instruments
