

MySQL Connector/C++ Developer Guide

Abstract

This manual describes how to install and configure MySQL Connector/C++, the C++ interface for communicating with MySQL servers, and how to use it to develop database applications.

For notes detailing the changes in each release of Connector/C++, see [MySQL Connector/C++ Release Notes](#).

For legal information, see the [Legal Notices](#).

For help with using MySQL, please visit either the [MySQL Forums](#) or [MySQL Mailing Lists](#), where you can discuss your issues with other MySQL users.

For additional documentation on MySQL products, including translations of the documentation into other languages, and downloadable versions in variety of formats, including HTML and PDF formats, see the [MySQL Documentation Library](#).

Licensing information. This product may include third-party software, used under license. If you are using a *Commercial* release of MySQL Connector/C++, see [this document](#) for licensing information, including licensing information relating to third-party software that may be included in this Commercial release. If you are using a *Community* release of MySQL Connector/C++, see [this document](#) for licensing information, including licensing information relating to third-party software that may be included in this Community release.

This software or hardware and documentation may provide access to or information about content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services unless otherwise set forth in an applicable agreement between you and Oracle. Oracle Corporation and its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services, except as set forth in an applicable agreement between you and Oracle.

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc>.

Access to Oracle Support

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info> or visit <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs> if you are hearing impaired.

This documentation is NOT distributed under a GPL license. Use of this documentation is subject to the following terms:

You may create a printed copy of this documentation solely for your own personal use. Conversion to other formats is allowed as long as the actual content is not altered or edited in any way. You shall not publish or distribute this documentation in any form or on any media, except if you distribute the documentation in a manner similar to how Oracle disseminates it (that is, electronically for download on a Web site with the software) or on a CD-ROM or similar medium, provided however that the documentation is disseminated together with the software on the same medium. Any other use, such as any dissemination of printed copies or use of this documentation, in whole or in part, in another publication, requires the prior written consent from an authorized representative of Oracle. Oracle and/or its affiliates reserve any and all rights to this documentation not expressly granted above.

Chapter 1 Introduction to Connector/C++

MySQL Connector/C++ is a MySQL database connector for C++. It lets you develop C++ applications that connect to the MySQL Server.

For notes detailing the changes in each release of Connector/C++, see [MySQL Connector/C++ Release Notes](#).

MySQL Connector/C++ Benefits

MySQL Connector/C++ offers the following benefits for C++ users compared to the MySQL C API (MySQL client library):

- Convenience of pure C++; no C function calls required
- Supports JDBC 4.0, an industry standard API
- Supports the object-oriented programming paradigm
- Reduces development time
- Licensed under the GPL with the FLOSS License Exception
- Available under a commercial license upon request

JDBC Compatibility

Connector/C++ is compatible with the JDBC 4.0 API. Connector/C++ does not implement the entire JDBC 4.0 API, but does feature the following classes:

- [Connection](#)
- [DatabaseMetaData](#)
- [Driver](#)
- [PreparedStatement](#)
- [ResultSet](#)
- [ResultSetMetaData](#)
- [Savepoint](#)
- [Statement](#)

The JDBC 4.0 API defines approximately 450 methods for the classes just mentioned. Connector/C++ implements approximately 80% of these.

Platform Support and Prerequisites

MySQL Connector/C++ requires:

- MySQL 5.1 or higher
- Microsoft Visual Studio 2013 on Windows

To see which platforms are supported, visit the [Connector/C++ downloads page](#).

Chapter 2 How to Get Connector/C++

Connector/C++ distributions are available in binary and source formats. To obtain a distribution, visit the [Connector/C++ downloads page](#).

MySQL Connector/C++ Binary Distributions

Binary distributions are available for these platforms:

Microsoft Windows:

- MSI installer package
- Without installer (a Zip file)

Unix and Unix-like platforms:

- Compressed GNU TAR archive ([tar.gz](#))

MySQL Connector/C++ Source Distributions

Source packages use compressed GNU TAR file ([tar.gz](#)) format and can be used on any supported platform.

MySQL Connector/C++ Source Repository

The latest development sources are available through [Launchpad](#).

The Connector/C++ code repository uses Bazaar. To check out the latest source code, use the [bzd](#) command-line tool:

```
shell> bzd branch lp:~mysql/mysql-connector-cpp/trunk .
```

Chapter 3 Installing Connector/C++ from a Binary Distribution

To obtain a Connector/C++ binary package, visit the [Connector/C++ downloads page](#).

Note

It is important that the tools you use to build your Connector/C++ applications are compatible with the tools used to build Connector/C++ itself. Ideally, build your applications with the same tools that were used to build the Connector/C++ binaries.

All Connector/C++ distributions include a [README](#) file that contains platform-specific notes. At the end of the [README](#) file, you will find the configuration options used to build the binaries. If you experience build-related issues on a platform, it may help to check the settings that were used to build the binary on that platform.

Developers using Microsoft Windows must satisfy the following requirements:

- Microsoft Visual Studio 2013.
- Your applications should use the same linker configuration as Connector/C++. For example, use one of [/MD](#), [/MDd](#), [/MT](#), or [/MTd](#).

To use a different compiler version, release configuration, or runtime library, compile Connector/C++ from source using your desired settings and build your applications using these same settings. To avoid issues, ensure that the three variables of compiler version, runtime library, and runtime linker configuration settings are the same for your applications and Connector/C++ itself.

Archive Package

Unpack the distribution archive into an appropriate directory. If you plan to use a dynamically linked version of Connector/C++, make sure that your system can reference the [libmysqlclient](#) MySQL client library (Connector/C++ is linked against and thus requires the MySQL client library). Consult your operating system documentation on how to modify and expand the search path for libraries. If you cannot modify the library search path, it may help to copy your application, the Connector/C++ library and the MySQL client library into the same directory. Most systems search for libraries in the current directory.

Windows users can choose between two binary packaging formats:

- Windows MSI Installer ([.msi](#) file): To use the MSI Installer, launch it and follow the prompts in the screens it presents to install Connector/C++ in the location of your choosing.
- Zip archive without installer ([.zip](#) file): To use a Zip archive, unpack it in the directory where you intend to install it using [WinZip](#) or another tool that can read [.zip](#) files.

Windows MSI Installer

Using the MSI Installer may be the easiest solution. The MSI Installer does not require any administrative permissions because it simply copies files.

The MSI Installer begins by presenting a welcome screen.

Figure 3.1 MSI Installer Welcome Screen

The MSI Installer overview screen enables you to select the type of installation to perform. The “Typical” installation consists of all required header files and the Release libraries. The “Custom” installation enables you to install additional Debug versions of the connector libraries. The “Complete” installation installs everything in the distribution.

Figure 3.2 MSI Installer Overview Screen

If you select a “Custom” installation, the MSI Installer presents a Custom Setup screen that enables you to select which features to install and where to install them.

Figure 3.3 MSI Installer Custom Setup Screen

Chapter 4 Installing Connector/C++ from Source

Table of Contents

4.1 Source Installation System Prerequisites	9
4.2 Obtaining and Unpacking a Connector/C++ Source Distribution	9
4.3 Installing Connector/C++ from Source on Unix and Unix-Like Systems	10
4.4 Installing Connector/C++ from Source on Windows	11
4.5 Troubleshooting Connector/C++ Source Installation Problems	14
4.6 Dynamically Linking Connector/C++ Against the MySQL Client Library	14
4.7 Connector/C++ Source-Configuration Options	15

This chapter describes how to install Connector/C++ using a source distribution.

4.1 Source Installation System Prerequisites

To install Connector/C++ from source, the following system requirements must be satisfied:

- To compile Connector/C++, the MySQL client library (MySQL C API) must be installed. Connector/C++ is based on the MySQL client library and is linked against it.

Typically, the MySQL client library is installed when the MySQL Server is installed. However, check your operating system documentation for other installation options. Alternatively, you can install the client library by installing Connector/C.

You must use either a General Availability version of MySQL 5.7 (5.7.9 or higher) or Connector/C 6.1.8 or higher. Set the `MYSQL_DIR` CMake option appropriately at configuration time as necessary.

- You must have the cross-platform build tool `CMake` 2.6.2, or newer, and `GLib` 2.2.3 or newer. Check the `README` file included with the distribution for platform-specific notes.
- The Boost C++ libraries are required to build Connector/C++ (but not to use it). Boost 1.56.0 or newer must be installed. To obtain Boost and its installation instructions, visit [the official site](#). After Boost is installed, tell the build system where the Boost files are located by defining the `BOOST_ROOT` option when you invoke `CMake`. For example:

```
shell> cmake . -DBOOST_ROOT=/usr/local/boost_1_56_0
```

Adjust the path as necessary to match your installation.

4.2 Obtaining and Unpacking a Connector/C++ Source Distribution

To obtain a Connector/C++ source package, visit the [Connector/C++ downloads page](#).

A Connector/C++ source distribution is packaged as a compressed `tar` file or Zip archive, denoted here as `PACKAGE.tar.gz` or `PACKAGE.zip`. A source distribution in `tar` file or Zip archive format can be used on any supported platform.

To unpack a compressed `tar` file, use this command in the intended installation directory:

```
shell> tar zxvf PACKAGE.tar.gz
```

After unpacking the distribution, build it using the appropriate instructions for your platform later in this section.

To unpack a Zip archive, use [WinZip](#) or another tool that can read `.zip` files. After unpacking the distribution, build it using the appropriate instructions for your platform later in this section.

To check out the Connector/C++ code from the source code repository located on GitHub at <https://github.com/mysql/mysql-connector-cpp>, use the following command:

```
shell> git clone https://github.com/mysql/mysql-connector-cpp
```

4.3 Installing Connector/C++ from Source on Unix and Unix-Like Systems

To install Connector/C++ from source, your system must satisfy the requirements outlined in [Section 4.1, “Source Installation System Prerequisites”](#).

1. Change location to the top-level directory of the source distribution:

```
shell> cd /path/to/mysql-connector-cpp
```

2. Run `CMake` to build a `Makefile`:

```
shell> cmake .
-- Check for working C compiler: /usr/local/bin/gcc
-- Check for working C compiler: /usr/local/bin/gcc -- works
[...]
-- Generating done
-- Build files have been written to: /path/to/mysql-connector-cpp/
```

To use configuration values different from the defaults, use the options described at [Section 4.7, “Connector/C++ Source-Configuration Options”](#).

On non-Windows systems, `CMake` checks to see whether the `MYSQL_CONFIG_EXECUTABLE` `CMake` option is set. If not, `CMake` tries to locate `mysql_config` in the default locations.

If you have any problems with the configuration process, check the troubleshooting instructions given in [Section 4.5, “Troubleshooting Connector/C++ Source Installation Problems”](#).

3. Use `make` to build Connector/C++. First make sure you have a clean build, then build the connector:

```
shell> make clean
shell> make
[ 1%] Building CXX object »
driver/CMakeFiles/mysqlcppconn.dir/mysql_connection.o
[ 3%] Building CXX object »
driver/CMakeFiles/mysqlcppconn.dir/mysql_constructed_resultset.o
[...]
[100%] Building CXX object examples/CMakeFiles/statement.dir/statement.o
Linking CXX executable statement
```

If all goes well, you will find the Connector/C++ library in the `driver` directory.

4. Install the header and library files:

```
shell> make install
```

Unless you have changed the location in the configuration step, `make install` copies the header files to the directory `/usr/local/include`. The header files copied are `mysql_connection.h` and `mysql_driver.h`.

Again, unless you have specified otherwise, `make install` copies the library files to `/usr/local/lib`. The files copied are the dynamic library `libmysqlcppconn.so`, and the static library `libmysqlcppconn-static.a`. The dynamic library file name extension might differ on your system (for example, `.dylib` on OS X).

After installing Connector/C++, you can carry out a quick test to check the installation. To do this, compile and run one of the example programs, such as [examples/standalone_example.cpp](#). This example is discussed in more detail later, but for now, you can use it to test whether the connector has been correctly installed. This procedure assumes that you have a working MySQL Server to which you can connect. It also assumes header and library locations of [/usr/local/include](#) and [/usr/local/lib](#), respectively; adjust these as necessary for your system.

1. Compile the example program. To do this, change location to the [examples](#) directory and enter this command:

```
shell> g++ -o test_install \
-I/usr/local/include -I/usr/local/include/cppconn \
-Wl,-Bdynamic standalone_example.cpp -lmysqlcppconn
```

2. Make sure the dynamic library which is used in this case can be found at runtime:

```
shell> export LD_LIBRARY_PATH=/usr/local/lib
```

On OS X, try this:

```
shell> export DYLD_LIBRARY_PATH=/usr/local/lib
```

3. Now run the program to test your installation, substituting the appropriate host, user, password, and database arguments for your system:

```
shell> ./test_install localhost root password database
```

You should see output similar to the following:

```
Connector/C++ standalone program example...
... running 'SELECT 'Welcome to Connector/C++' AS _message'
... MySQL replies: Welcome to Connector/C++
... say it again, MySQL
...MySQL replies: Welcome to Connector/C++
... find more at http://www.mysql.com
```

If you see any errors, take note of them and go through the troubleshooting procedures in [Section 4.5, "Troubleshooting Connector/C++ Source Installation Problems"](#).

4.4 Installing Connector/C++ from Source on Windows

To install Connector/C++ from source, your system must satisfy the requirements outlined in [Section 4.1, "Source Installation System Prerequisites"](#).

Note

On Windows, `mysql_config` is not present, so `CMake` attempts to retrieve the location of MySQL from the environment variable `$ENV{MYSQL_DIR}`. If `MYSQL_DIR` is not set, `CMake` checks for MySQL in the following locations: `$ENV{ProgramFiles}/MySQL/*/include` and `$ENV{SystemDrive}/MySQL/*/include`.

Consult the `CMake` manual or check `cmake --help` to find out which build systems are supported by your `CMake` version:

```
C:\> cmake --help
cmake version 2.6-patch 2
```

Usage

[...]

Generators

The following generators are available on this platform:

Borland Makefiles	= Generates Borland makefiles.
MSYS Makefiles	= Generates MSYS makefiles.
MinGW Makefiles	= Generates a make file for use with mingw32-make.
NMake Makefiles	= Generates NMake makefiles.
Unix Makefiles	= Generates standard UNIX makefiles.
Visual Studio 6	= Generates Visual Studio 6 project files.
Visual Studio 7	= Generates Visual Studio .NET 2002 project files.
Visual Studio 7 .NET 2003	= Generates Visual Studio .NET 2003 project files.
Visual Studio 8 2005	= Generates Visual Studio .NET 2005 project files.
Visual Studio 8 2005 Win64	= Generates Visual Studio .NET 2005 Win64 project files.
Visual Studio 9 2008	= Generates Visual Studio 9 2008 project files.
Visual Studio 9 2008 Win64	= Generates Visual Studio 9 2008 Win64 project files.

[...]

It is likely that your [CMake](#) binary supports more compilers, known by [CMake](#) as *generators*, than can actually be used to build Connector/C++. We have built the connector using the following generators:

- Microsoft Visual Studio 2013
- NMake

[CMake](#) makes it easy for you to try other compilers. However, you may experience compilation warnings or errors, or linking issues not detected by Visual Studio. Patches are gratefully accepted to fix issues with other compilers.

For troubleshooting and configuration hints, see [Section 4.5, "Troubleshooting Connector/C++ Source Installation Problems"](#).

Use these steps to build Connector/C++:

1. Change location to the top-level directory of the source distribution:

```
C:\> cd C:\path_to_mysql_cpp
```

2. Run [CMake](#) to generate build files for your generator.

To use configuration values different from the defaults, use the options described at [Section 4.7, "Connector/C++ Source-Configuration Options"](#).

Visual Studio

```
C:\>cmake -G "Visual Studio 12 2013"
-- Check for working C compiler: cl
-- Check for working C compiler: cl -- works
-- Detecting C compiler ABI info
-- Detecting C compiler ABI info - done

NMake

```
C:\> cmake -G "NMake Makefiles"
-- The C compiler identification is MSVC
-- The CXX compiler identification is MSVC
[...]
```

3. Use your compiler to build Connector/C++.

Visual Studio

Open the newly generated project files in the Visual Studio GUI or use a Visual Studio command line to build the driver. The project files contain a variety of different configurations, debug and nondebug versions among them.

For example, to use the command line, execute commands like these to build the distribution and create a Zip package:

```
C:\> devenv MYSQLCPPCONN.sln /build RelWithDebInfo

C:\> cpack -G ZIP --config CPackConfig.cmake -C RelWithDebInfo
CPack: Create package using ZIP
CPack: Install projects
CPack: - Install project: MYSQLCPPCONN
CPack: Create package
CPack: - package: C:/opt/build/mysql-connector-c++-1.1.5/mysql-connector-c++-1.1.7-win32.zip generated
```

NMake

```
C:\>nmake

Microsoft (R) Program Maintenance Utility Version 9.00.30729.01
Copyright (C) Microsoft Corporation. All rights reserved.

Scanning dependencies of target mysqlcppconn
[ 2%] Building CXX object driver/CMakeFiles/mysqlcppconn.dir/mysql_connection.obj
mysql_connection.cpp
[...]
```

4.5 Troubleshooting Connector/C++ Source Installation Problems

If you encounter problems building Connector/C++, try these troubleshooting strategies:

1. For configuration or compilation problems, check your `CMake` options (MySQL installation path, debug version, and so forth):

```
shell> cmake -L
[...]
```

CMAKE_BACKWARDS_COMPATIBILITY:STRING=2.4
 CMAKE_BUILD_TYPE:STRING=
 CMAKE_INSTALL_PREFIX:PATH=/usr/local
 EXECUTABLE_OUTPUT_PATH:PATH=
 LIBRARY_OUTPUT_PATH:PATH=
 MYSQLCPPCONN_GCOV_ENABLE:BOOL=0
 MYSQLCPPCONN_TRACE_ENABLE:BOOL=0
 MYSQL_CONFIG_EXECUTABLE:FILEPATH=/usr/local/mysql/bin/mysql_config

For example, if your MySQL Server installation path is not `/usr/local/mysql` and you want to build a debug version of the Connector/C++, use this command:

```
shell> cmake \
  -DCMAKE_BUILD_TYPE=Debug \
  -DMYSQL_CONFIG_EXECUTABLE=/path/to/my/mysql/server/bin/mysql_config .
```

2. Use `cmake -L` to verify that your settings were changed:

```
shell> cmake -L
[...]
```

CMAKE_BACKWARDS_COMPATIBILITY:STRING=2.4
 CMAKE_BUILD_TYPE:STRING=Debug
 CMAKE_INSTALL_PREFIX:PATH=/usr/local
 EXECUTABLE_OUTPUT_PATH:PATH=
 LIBRARY_OUTPUT_PATH:PATH=
 MYSQLCPPCONN_GCOV_ENABLE:BOOL=0
 MYSQLCPPCONN_TRACE_ENABLE:BOOL=0
 MYSQL_CONFIG_EXECUTABLE=/path/to/my/mysql/server/bin/mysql_config

Proceed by executing a `make clean` command followed by a `make` command, as described previously.

4.6 Dynamically Linking Connector/C++ Against the MySQL Client Library

Note

This section refers to dynamic linking of Connector/C++ to the client library, not dynamic linking of applications to Connector/C++. Precompiled binaries of Connector/C++ use static binding with the client library by default.

An application that uses Connector/C++ can be either statically or dynamically linked to the Connector/C++ libraries. Connector/C++ is usually statically linked to the underlying MySQL client library (or to Connector/C; unless otherwise stated, reference to the MySQL client library is also taken to include Connector/C, which is a separately packaged, standalone version of the MySQL client library).

As of Connector/C++ 1.1.0, it is also possible to dynamically link to the underlying MySQL client library, although this capability is not enabled by default. To dynamically link Connector/C++ to the client library, enable `MYSQLCLIENT_STATIC_LINKING` when building Connector/C++ from source:

```
shell> rm CMakeCache.txt
shell> cmake . -DMYSQLCLIENT_STATIC_LINKING=1
```

```

shell> make clean
shell> make
shell> make install

```

Now, when creating a connection in your application, Connector/C++ will select and load a client library at runtime. It will choose the client library by searching defined locations and environment variables depending on the host operating system. It is also possible when creating a connection in an application to define an absolute path to the client library to load at runtime. This can be convenient if you have defined a standard location from which you want the client library to be loaded. This is sometimes done to circumvent possible conflicts with other versions of the client library that may be located on the system.

4.7 Connector/C++ Source-Configuration Options

Connector/C++ recognizes the [CMake](#) options described in this section.

Table 4.1 Connector/C++ Source-Configuration Option Reference

Formats	Description	Default	Introduced
BOOST_ROOT	The Boost source directory		
CMAKE_BUILD_TYPE	Type of build to produce	RelWithDebInfo	
CMAKE_ENABLE_C++11	Whether to enable C++11 support	OFF	1.1.6
CMAKE_INSTALL_PREFIX	Installation base directory	/usr/local	
MYSQLCLIENT_NO_THREADS	Whether to link against single-threaded MySQL client library	OFF	
MYSQLCLIENT_STATIC_LINKING	Whether to statically link to the MySQL client library	OFF	
MYSQLCPPCONN_GCOV_ENABLE	Whether to enable gcov support	OFF	
MYSQLCPPCON_TRACE_ENABLE	Whether to enable tracing functionality	OFF	
MYSQL_CFLAGS	C compiler flags		
MYSQL_CONFIG_EXECUTABLE	Path to the mysql_config program	\${MYSQL_DIR}/bin/mysql_config	
MYSQL_CXXFLAGS	C++ compiler flags		
MYSQL_CXX_LINKAGE	Whether MySQL client library needs C++ linking	ON	
MYSQL_DIR	MySQL Server or Connector/C installation directory		
MYSQL_EXTRA_LIBRARIES	Extra link libraries		
MYSQL_INCLUDE_DIR	The MySQL header file directory	\${MYSQL_DIR}/include	
MYSQL_LIB_DIR	The MySQL client library directory	\${MYSQL_DIR}/lib	
MYSQL_LINK_FLAGS	Extra link flags		
USE_SERVER_CXXFLAGS	Use MySQL Server CXXFLAGS value rather than system default	OFF	1.1.7

- [-DBOOST_ROOT=dir_name](#)

The directory where the Boost sources are installed.

- [-DCMAKE_BUILD_TYPE=type](#)

The type of build to produce:

- [RelWithDebInfo](#): Enable optimizations and generate debugging information. This is the default Connector/C++ build type.
- [Debug](#): Disable optimizations and generate debugging information.
- [-DCMAKE_ENABLE_C++11=bool](#)

Whether to enable C++11 support. The default is [OFF](#).

This option was added in Connector/C++ 1.1.6.

- [-DCMAKE_INSTALL_PREFIX=dir_name](#)

The installation base directory.

- [-DMYSQLCLIENT_NO_THREADS=bool](#)

Whether to link against a single-threaded [libmysqlclient](#) MySQL client library. In MySQL 5.5 and higher, the value of this option makes no difference because [libmysqlclient](#) is always multi-threaded.

- [-DMYSQLCLIENT_STATIC_LINKING=bool](#)

Whether to statically link to the MySQL client library. The default is [OFF](#) (use dynamic linking to the client library). For more information, see [Section 4.6, “Dynamically Linking Connector/C++ Against the MySQL Client Library”](#).

- [-DMYSQLCPPCONN_GCOV_ENABLE=bool](#)

Whether to enable [gcov](#) support.

- [-DMYSQLCPPCON_TRACE_ENABLE=VALUE_TYPE](#)

Whether to enable tracing functionality. For information about tracing, see [Chapter 9, Connector/C++ Debug Tracing](#).

- [-DMYSQL_CFLAGS=flags](#)

C compiler flags.

- [-DMYSQL_CONFIG_EXECUTABLE=file_name](#)

The path to the [mysql_config](#) program.

On non-Windows systems, [CMake](#) checks to see whether the [MYSQL_CONFIG_EXECUTABLE](#) [CMake](#) option is set. If not, [CMake](#) tries to locate [mysql_config](#) in the default locations.

- [-DMYSQL_CXXFLAGS=flags](#)

C++ compiler flags.

- [-DMYSQL_CXX_LINKAGE=bool](#)

Whether the MySQL client library needs C++ linking.

- [-DMYSQL_DIR=dir_name](#)

The directory where MySQL Server or Connector/C is installed.

- [-DMYSQL_EXTRA_LIBRARIES=flags](#)

Any needed additional link libraries.

- `-DMYSQL_INCLUDE_DIR=dir_name`

The directory where the MySQL header files are installed.

- `-DMYSQL_LIB_DIR=dir_name`

The directory where the MySQL client library is installed.

- `-DMYSQL_LINK_FLAGS=flags`

Any needed additional link flags.

- `-DUSE_SERVER_CXXFLAGS=bool`

Use MySQL Server `CXXFLAGS` values rather than the system default value.

This option was added in Connector/C++ 1.1.7.

Chapter 5 Building Connector/C++ Windows Applications with Microsoft Visual Studio

Connector/C++ is available as a static or dynamic library to use with your application. This section describes how to link the library to your application.

Note

To avoid potential crashes, the build configuration of Connector/C++ should match the build configuration of the application using it. For example, do not use the release build of Connector/C++ with a debug build of the client application.

Static Library

The Connector/C++ static library file is `mysqlcppconn-static.lib`. You link this library statically with your application. Also link against the files `libmysql.dll` and `libmysql.lib`. At runtime, the application will require access to `libmysql.dll`.

Dynamic Library

The Connector/C++ dynamic library file is `mysqlcppconn.dll`. To build your client application, link it with the file `mysqlcppconn.lib`. At runtime, the application will require access to the files `mysqlcppconn.dll` and `libmysql.dll`.

Building a Connector/C++ Application with Microsoft Visual Studio

The initial steps for building an application to use either the static or dynamic library are the same. Some additional steps vary, depend on whether you are building your application to use the [static](#) or [dynamic](#) library.

1. Select **File, New, Project** from the main menu.

Figure 5.1 Creating a New Project

2. In the wizard, select **Visual C++, Win32**. From **Visual Studio Installed Templates**, select the application type **Win32 Console Application**. Enter a name for the application, then click **OK**, to move to the Win32 Application Wizard.

Figure 5.2 The New Project Dialog Box

3. In the Win32 Application Wizard, click **Application Settings** and ensure the defaults are selected. The radio button **Console application** and the check box **Precompiled headers** are selected. Click **Finish** to close the wizard.

Figure 5.3 The Win32 Application Wizard

4. From the drop down list box on the toolbar, change from the default **Debug** build to the **Release** build.

Figure 5.4 Selecting the Release Build

5. From the main menu select **Project, Properties**. This can also be accessed using the hot key **ALT + F7**.

Figure 5.5 Selecting Project Properties from the Main Menu

6. Under **Configuration Properties**, open the tree view.
7. Select **C++, General** in the tree view.

Figure 5.6 Setting Properties

8. Ensure that Visual Studio can find the MySQL include directory. This directory includes header files that can optionally be installed when installing MySQL Server.

Figure 5.7 MySQL Include Directory

```
C:\mysql\include>dir
Volume in drive C has no label.
Volume Serial Number is 9484-B7C3

Directory of C:\mysql\include

10/12/2008  13:56    <DIR>          .
10/12/2008  13:56    <DIR>          ..
15/11/2008  06:53             10,935  config-win.h

15/11/2008  06:53             1,107  sslopt-vars.h
15/11/2008  06:53             1,501  typelib.h
               32 File(s)              325,486 bytes
                3 Dir(s)      4,091,248,640 bytes free

C:\mysql\include>
```

9. In the **Additional Include Directories** text field, add the MySQL `include/` directory.

Figure 5.8 Select Directory Dialog

10. Also set the location of additional libraries that Visual Studio needs to build the application. These are located in the MySQL `lib/opt` directory, a subdirectory of the MySQL Server installation directory.

Figure 5.9 Typical Contents of MySQL lib/opt Directory

11. In the tree view, open **Linker**, **General**, **Additional Library Directories**.

Figure 5.10 Additional Library Directories

12. Add the `lib/opt` directory into the **Additional Library Directories** text field. This enables the library file `libmysql.lib` to be found.

Figure 5.11 Additional Library Directories Dialog

Static Build

The remaining steps depend on whether you are building an application to use the Connector/C++ static or dynamic library. If you are building your application to use the dynamic library, see [Dynamic Build](#). If you are building your application to use the static library, carry out the following steps:

1. Open **Linker, Input, Additional Dependencies**.

Figure 5.12 Additional Dependencies

2. Enter `mysqlcppconn-static.lib` and `libmysql.lib`.

Figure 5.13 Adding Additional Dependencies

3. By default `CPPCONN_PUBLIC_FUNC` is defined to declare functions to be compatible with an application that calls a DLL. If you are building an application to call the static library, ensure that function prototypes are compatible with this. In this case, define `CPPCONN_PUBLIC_FUNC` to be an empty string, so that functions are declared with the correct prototype.

In the **Project, Properties** tree view, under **C++, Preprocessor**, enter `CPPCONN_PUBLIC_FUNC=` into the **Preprocessor Definitions** text field.

Figure 5.14 Setting the CPPCONN_PUBLIC_FUNC Define**Note**

Make sure you enter `CPPCONN_PUBLIC_FUNC=` and not `CPPCONN_PUBLIC_FUNC`, so that it is defined as an empty string.

Dynamic build

If you are building an application to use the Connector/C++ dynamically linked library, carry out these steps:

1. Under **Linker, Input**, add `mysqlcppconn.lib` into the **Additional Dependencies** text field.
2. `mysqlcppconn.dll` must be in the same directory as the application executable, or somewhere on the system's path, so that the application can access the Connector/C++ Dynamic Linked Library at runtime.

Copy `mysqlcppconn.dll` to the same directory as the application. Alternatively, extend the `PATH` environment variable using `SET PATH=%PATH%;C:\path\to\cpp`. Alternatively, you can copy `mysqlcppconn.dll` to the Windows installation Directory, typically `c:\windows`.

Chapter 6 Building Connector/C++ Linux Applications with NetBeans

This section describes how to build Connector/C++ applications for Linux using the NetBeans IDE.

Figure 6.1 The NetBeans IDE

Note

To avoid potential crashes, the build configuration of Connector/C++ should match the build configuration of the application using it. For example, do not use the release build of Connector/C++ with a debug build of the client application.

1. Create a new project. Select **File, New Project**. Choose a **C/C++ Application** and click **Next**.
2. Give the project a name and click **Finish**. A new project is created.
3. In the **Projects** tab, right-click **Source Files** and select **New**, then **Main C++ File...**
4. Change the filename, or simply select the defaults and click **Finish** to add the new file to the project.
5. Now add some working code to your main source file. Explore your Connector/C++ installation and navigate to the [examples](#) directory.
6. Select a suitable example, such as [standalone_example_docs1.cpp](#). Copy all the code in this file, and use it to replace the code in your existing main source file. Amend the code to reflect the connection properties required for your test database. You now have a working example that will access a MySQL database using Connector/C++.

7. At this point, NetBeans shows some errors in the source code. Direct NetBeans to the necessary header files to include. Select **File, Project Properties** from the main menu.
8. In the **Categories:** tree view panel, navigate to **Build, C++ Compiler**.
9. In the **General** panel, select **Include Directories**.
10. Click the ... button.
11. Click **Add**, then navigate to the directory where the Connector/C++ header files are located. This is `/usr/local/include` unless you have installed the files to a different location. Click **Select**. Click **OK**.

Figure 6.2 Setting the Header Include Directory

12. Click **OK** again to close the **Project Properties** dialog.

At this point, you have created a NetBeans project containing a single C++ source file. You have also ensured that the necessary include files are accessible. Before continuing, decide whether your project is to use the Connector/C++ static or dynamic library. The project settings are slightly different in each case, because you link against a different library.

Using the Static Library

To use the static Connector/C++ library, link against two library files, `libmysqlcppconn-static.a` and `libmysqlclient.a`. The locations of the files depend on your setup, but typically the former are in `/usr/local/lib` and the latter in `/usr/lib`. The file `libmysqlclient.a` is not part of Connector/C++, but is the MySQL client library file distributed with MySQL Server. (Remember, the MySQL client library is an optional component as part of the MySQL Server installation process.) The MySQL client library is also available as part of the Connector/C distribution.

1. Set the project to link the necessary library files. Select **File, Project Properties** from the main menu.

2. In the **Categories:** tree view, navigate to **Linker**.
3. In the **General** panel, select **Additional Library Directories**. Click the ... button.
4. Select and add the `/usr/lib` and `/usr/local/lib` directories.
5. In the same panel, add the two library files required for static linking as discussed earlier. The properties panel should then look similar to the following screenshot.

Figure 6.3 Setting the Static Library Directories and File Names

6. Click **OK** to close the **Project Properties** dialog.

Using the Dynamic Library

To use the Connector/C++ dynamic library, link your project with a single library file, `libmysqlcppconn.so`. The location of this file depends on how you configured your installation of Connector/C++, but typically is `/usr/local/lib`.

1. Set the project to link the necessary library file. Select **File, Project Properties** from the main menu.
2. In the **Categories:** tree view, navigate to **Linker**.
3. In the **General** panel, select **Additional Library Directories**. Click the ... button.
4. Select and add the `/usr/local/lib` directories.
5. In the same panel, add the library file required for static linking as discussed earlier. The properties panel should look similar to the following screenshot.

Figure 6.4 Setting the Dynamic Library Directory and File Name

6. Click OK to close the Project Properties dialog.

After configuring your project, build it by selecting **Run, Build Main Project** from the main menu. You then run the project using **Run, Run Main Project**.

On running the application, you should see a screen similar to the following (this is actually the static version of the application shown):

Figure 6.5 The Example Application Running

```
dist/Debug/GNU-Linux-x86/test_static
Running 'SELECT 'Hello World!' AS _message'...
... MySQL replies: Hello World!
... MySQL says it again: Hello World!
[Press Enter to close window]
```

Note

The preceding settings and procedures were carried out for the default [Debug](#) configuration. To create a [Release](#) configuration, select that configuration before setting the Project Properties.

Chapter 7 Getting Started with Connector/C++: Usage Examples

Table of Contents

7.1 Connecting to MySQL	36
7.2 Running a Simple Query	37
7.3 Fetching Results	37
7.4 Using Prepared Statements	38
7.5 Complete Example 1	38
7.6 Complete Example 2	39

Source distributions of Connector/C++ include an [examples](#) directory that contains usage examples that explain how to use the following classes:

- [Connection](#)
- [Driver](#)
- [PreparedStatement](#)
- [ResultSet](#)
- [ResultSetMetaData](#)
- [Statement](#)

The examples cover:

- Using the [Driver](#) class to connect to MySQL
- Creating tables, inserting rows, fetching rows using (simple) statements
- Creating tables, inserting rows, fetching rows using prepared statements
- Hints for working around prepared statement limitations
- Accessing result set metadata

Several examples in this document are only code snippets, not complete programs. These snippets provide a brief overview on the API. For complete programs, check the [examples](#) directory of your Connector/C++ installation. Please also read the [README](#) file in that directory. To test the example code, edit the [examples.h](#) file in the [examples](#) directory to add your connection information, then rebuild the code by issuing a [make](#) command.

The example programs in the [examples](#) directory include:

- [connect.cpp](#):
How to create a connection, insert data, and handle exceptions.
- [connection_meta_schemaobj.cpp](#):
How to obtain metadata associated with a connection object, such as a list of tables or databases, the MySQL version, or the connector version.
- [debug_output.cpp](#):
How to activate and deactivate the Connector/C++ debug protocol.

- [exceptions.cpp](#):

A closer look at the exceptions thrown by the connector and how to fetch error information.

- [prepared_statements.cpp](#):

How to execute Prepared Statements, including an example showing how to handle SQL statements that cannot be prepared by the MySQL Server.

- [resultset.cpp](#):

How to use a cursor to fetch data and iterate over a result set.

- [resultset_meta.cpp](#):

How to obtain metadata associated with a result set, such as the number of columns and column types.

- [resultset_types.cpp](#):

Result sets returned from metadata methods. (This is more a test than an example.)

- [standalone_example.cpp](#):

Simple standalone program not integrated into regular [CMake](#) builds.

- [statements.cpp](#):

How to execute SQL statements without using Prepared Statements.

- [cpp_trace_analyzer.cpp](#):

This example shows how to filter the output of the [debug trace](#). Please see the inline comments for further documentation. This script is unsupported.

7.1 Connecting to MySQL

To establish a connection to MySQL Server, retrieve an instance of [sql::Connection](#) from a [sql::mysql::MySQL_Driver](#) object. A [sql::mysql::MySQL_Driver](#) object is returned by [sql::mysql::get_mysql_driver_instance\(\)](#).

```
sql::mysql::MySQL_Driver *driver;
sql::Connection *con;

driver = sql::mysql::get_mysql_driver_instance();
con = driver->connect("tcp://127.0.0.1:3306", "user", "password");

delete con;
```

Make sure that you free [con](#), the [sql::Connection](#) object, as soon as you do not need it any more. But do not explicitly free [driver](#), the connector object. Connector/C++ takes care of freeing that.

Note

[get_mysql_driver_instance\(\)](#) calls [get_driver_instance\(\)](#), which is not thread-safe. Either avoid invoking these methods from within multiple threads at once, or surround the calls with a mutex to prevent simultaneous execution in multiple threads.

These methods can be used to check the connection state or reconnect:

- [sql::Connection::isValid\(\)](#) checks whether the connection is alive

- `sql::Connection::reconnect()` reconnects if the connection has gone down

7.2 Running a Simple Query

To run simple queries, you can use the `sql::Statement::execute()`, `sql::Statement::executeQuery()`, and `sql::Statement::executeUpdate()` methods. Use the method `sql::Statement::execute()` if your query does not return a result set or if your query returns more than one result set. See the [examples](#) directory for more information.

```
sql::mysql::MySQL_Driver *driver;
sql::Connection *con;
sql::Statement *stmt;

driver = sql::mysql::get_mysql_driver_instance();
con = driver->connect("tcp://127.0.0.1:3306", "user", "password");

stmt = con->createStatement();
stmt->execute("USE " EXAMPLE_DB);
stmt->execute("DROP TABLE IF EXISTS test");
stmt->execute("CREATE TABLE test(id INT, label CHAR(1))");
stmt->execute("INSERT INTO test(id, label) VALUES (1, 'a')");

delete stmt;
delete con;
```

Note

You must free the `sql::Statement` and `sql::Connection` objects explicitly using `delete`.

7.3 Fetching Results

The API for fetching result sets is identical for (simple) statements and prepared statements. If your query returns one result set, use `sql::Statement::executeQuery()` or `sql::PreparedStatement::executeQuery()` to run your query. Both methods return `sql::ResultSet` objects. By default, Connector/C++ buffers all result sets on the client to support cursors.

```
// ...
sql::Connection *con;
sql::Statement *stmt;
sql::ResultSet *res;
// ...
stmt = con->createStatement();
// ...

res = stmt->executeQuery("SELECT id, label FROM test ORDER BY id ASC");
while (res->next()) {
    // You can use either numeric offsets...
    cout << "id = " << res->getInt(1); // getInt(1) returns the first column
    // ... or column names for accessing results.
    // The latter is recommended.
    cout << ", label = '" << res->getString("label") << "'" << endl;
}

delete res;
delete stmt;
delete con;
```

Note

In the preceding code snippet, column indexing starts from 1.

Note

You must free the `sql::Statement`, `sql::Connection`, and `sql::ResultSet` objects explicitly using `delete`.

Cursor usage is demonstrated in the examples contained in the download package.

7.4 Using Prepared Statements

If you are not familiar with Prepared Statements in MySQL, take a look at the source code comments and explanations in the file `examples/prepared_statement.cpp`.

`sql::PreparedStatement` is created by passing an SQL query to `sql::Connection::prepareStatement()`. As `sql::PreparedStatement` is derived from `sql::Statement`, you will feel familiar with the API once you have learned how to use (simple) statements (`sql::Statement`). For example, the syntax for fetching results is identical.

```
// ...
sql::Connection *con;
sql::PreparedStatement *prep_stmt
// ...

prep_stmt = con->prepareStatement("INSERT INTO test(id, label) VALUES (?, ?)");

prep_stmt->setInt(1, 1);
prep_stmt->setString(2, "a");
prep_stmt->execute();

prep_stmt->setInt(1, 2);
prep_stmt->setString(2, "b");
prep_stmt->execute();

delete prep_stmt;
delete con;
```

Note

You must free the `sql::PreparedStatement` and `sql::Connection` objects explicitly using `delete`.

7.5 Complete Example 1

The following code shows a complete example of how to use Connector/C++.

```
/* Copyright 2008, 2010, Oracle and/or its affiliates. All rights reserved.

*/

/* Standard C++ includes */
```

```

#include <stdlib.h>
#include <iostream>

/*
   Include directly the different
   headers from cppconn/ and mysql_driver.h + mysql_util.h
   (and mysql_connection.h). This will reduce your build time!
*/
#include "mysql_connection.h"

#include <cppconn/driver.h>
#include <cppconn/exception.h>
#include <cppconn/resultset.h>
#include <cppconn/statement.h>

using namespace std;

int main(void)
{
    cout << endl;
    cout << "Running 'SELECT 'Hello World!' »
        AS _message'..." << endl;

    try {
        sql::Driver *driver;
        sql::Connection *con;
        sql::Statement *stmt;
        sql::ResultSet *res;

        /* Create a connection */
        driver = get_driver_instance();
        con = driver->connect("tcp://127.0.0.1:3306", "root", "root");
        /* Connect to the MySQL test database */
        con->setSchema("test");

        stmt = con->createStatement();
        res = stmt->executeQuery("SELECT 'Hello World!' AS _message");
        while (res->next()) {
            cout << "\t... MySQL replies: ";
            /* Access column data by alias or column name */
            cout << res->getString("_message") << endl;
            cout << "\t... MySQL says it again: ";
            /* Access column data by numeric offset, 1 is the first column */
            cout << res->getString(1) << endl;
        }
        delete res;
        delete stmt;
        delete con;

    } catch (sql::SQLException &e) {
        cout << "# ERR: SQLException in " << __FILE__;
        cout << "(" << __FUNCTION__ << ") on line " <<
            << __LINE__ << endl;
        cout << "# ERR: " << e.what();
        cout << " (MySQL error code: " << e.getErrorCode();
        cout << ", SQLState: " << e.getSQLState() << " )" << endl;
    }

    cout << endl;

    return EXIT_SUCCESS;
}

```

7.6 Complete Example 2

The following code shows a complete example of how to use Connector/C++.

```

/* Copyright 2008, 2010, Oracle and/or its affiliates. All rights reserved.

This program is free software; you can redistribute it and/or modify

```

it under the terms of the GNU General Public License as published by the Free Software Foundation; version 2 of the License.

#include "mysql_connection.h"

#include <cppconn/driver.h>
#include <cppconn/exception.h>
#include <cppconn/resultset.h>
#include <cppconn/statement.h>
#include <cppconn/prepared_statement.h>

using namespace std;

int main(void)
{
    cout << endl;
    cout << "Let's have MySQL count from 10 to 1..." << endl;

    try {
        sql::Driver *driver;
        sql::Connection *con;
        sql::Statement *stmt;
        sql::ResultSet *res;
        sql::PreparedStatement *pstmt;

        /* Create a connection */
        driver = get_driver_instance();
        con = driver->connect("tcp://127.0.0.1:3306", "root", "root");
        /* Connect to the MySQL test database */
        con->setSchema("test");

        stmt = con->createStatement();
        stmt->execute("DROP TABLE IF EXISTS test");
        stmt->execute("CREATE TABLE test(id INT)");
        delete stmt;

        /* '?' is the supported placeholder syntax */
        pstmt = con->prepareStatement("INSERT INTO test(id) VALUES (?)");
        for (int i = 1; i <= 10; i++) {
            pstmt->setInt(1, i);
            pstmt->executeUpdate();
        }
        delete pstmt;

        /* Select in ascending order */
        pstmt = con->prepareStatement("SELECT id FROM test ORDER BY id ASC");
        res = pstmt->executeQuery();
```

```
/* Fetch in reverse = descending order! */
res->afterLast();
while (res->previous())
    cout << "\t... MySQL counts: " << res->getInt("id") << endl;
delete res;

delete pstmt;
delete con;

} catch (sql::SQLException &e) {
    cout << "# ERR: SQLException in " << __FILE__;
    cout << "(" << __FUNCTION__ << ") on line " <<
        << __LINE__ << endl;
    cout << "# ERR: " << e.what();
    cout << " (MySQL error code: " << e.getErrorCode();
    cout << ", SQLState: " << e.getSQLState() << "
        << endl;
}

cout << endl;

return EXIT_SUCCESS;
}
```

Chapter 8 Connector/C++ Tutorials

8.1 Prerequisites and Background Information	43
8.2 Calling Stored Procedures with <code>Statement</code> Objects	44
8.2.1 Using a <code>Statement</code> for a Stored Procedure That Returns No Result	45
8.2.2 Using a <code>Statement</code> for a Stored Procedure That Returns an Output Parameter	46
8.2.3 Using a <code>Statement</code> for a Stored Procedure That Returns a Result Set	47
8.3 Calling Stored Procedures with <code>PreparedStatement</code> Objects	49
8.3.1 Using a <code>PreparedStatement</code> for a Stored Procedure That Returns No Result	49
8.3.2 Using a <code>PreparedStatement</code> for a Stored Procedure That Returns an Output Parameter	50
8.3.3 Using a <code>PreparedStatement</code> for a Stored Procedure That Returns a Result Set	51

The following tutorials illustrate various aspects of using MySQL Connector/C++. Also consult the examples in [Chapter 7, *Getting Started with Connector/C++: Usage Examples*](#).

8.1 Prerequisites and Background Information

This section describes the prerequisites that must be satisfied before you work through the remaining tutorial sections, and shows how to set up the framework code that serves as the basis for the tutorial applications.

These tutorials refer to tables and sample data from the `world` database, which you can download from the “Example Databases” section of the [MySQL Documentation](#) page.

Each tutorial application uses a framework consisting of the following code. The examples vary at the line that says `/* INSERT TUTORIAL CODE HERE! */` within the `try` block, which is replaced for each application with the application-specific code.

```
#include <stdlib.h>
#include <iostream>
#include <sstream>
#include <stdexcept>
/* uncomment for applications that use vectors */
/*#include <vector>*/

#include "mysql_connection.h"

#include <cppconn/driver.h>
#include <cppconn/exception.h>
#include <cppconn/resultset.h>
#include <cppconn/statement.h>
#include <cppconn/prepared_statement.h>

#define EXAMPLE_HOST "localhost"
#define EXAMPLE_USER "worlduser"
#define EXAMPLE_PASS "worldpass"
#define EXAMPLE_DB "world"

using namespace std;

int main(int argc, const char **argv)
{
    string url(argc >= 2 ? argv[1] : EXAMPLE_HOST);
    const string user(argc >= 3 ? argv[2] : EXAMPLE_USER);
    const string pass(argc >= 4 ? argv[3] : EXAMPLE_PASS);
    const string database(argc >= 5 ? argv[4] : EXAMPLE_DB);

    cout << "Connector/C++ tutorial framework..." << endl;
    cout << endl;
```

```
try {
    /* INSERT TUTORIAL CODE HERE! */
} catch (sql::SQLException &e) {
    /*
        MySQL Connector/C++ throws three different exceptions:

        - sql::MethodNotImplementedException (derived from sql::SQLException)
        - sql::InvalidArgumentException (derived from sql::SQLException)
        - sql::SQLException (derived from std::runtime_error)
    */
    cout << "# ERR: SQLException in " << __FILE__;
    cout << "(" << __FUNCTION__ << ") on line " << __LINE__ << endl;
    /* what() (derived from std::runtime_error) fetches error message */
    cout << "# ERR: " << e.what();
    cout << " (MySQL error code: " << e.getErrorCode();
    cout << ", SQLState: " << e.getSQLState() << " )" << endl;

    return EXIT_FAILURE;
}

cout << "Done." << endl;
return EXIT_SUCCESS;
}
```

To try the framework code as a standalone program, use this procedure:

1. Copy and paste the framework code to a file such as [framework.cpp](#). Edit the `#define` statements to reflect your connection parameters (server, user, password, database). Also, because the file contains those parameters, set its access mode to be readable only to yourself.
2. Compile the framework. For example, on OS X, the command might look like this (enter the command on one line):

```
shell> g++ -o framework
-I/usr/local/include -I/usr/local/include/cppconn
framework.cpp -lmysqlcppconn
```

Adapt the command as necessary for your system. A similar command is needed for the tutorial applications that follow.

3. To run the framework, enter the following:

```
shell> ./framework
```

You will see a simple message:

```
Connector/C++ tutorial framework...
Done.
```

You are now ready to continue to the tutorials.

8.2 Calling Stored Procedures with [Statement](#) Objects

A stored procedure can be called using a [Statement](#) or [PreparedStatement](#) object. This section shows how to call stored procedures using [Statement](#) objects. To see how to use [PreparedStatement](#) objects, see [Section 8.3, "Calling Stored Procedures with PreparedStatement Objects"](#).

The following list describes different types of stored procedures that you can construct and call, along with example stored procedures that illustrate each type:

1. A stored procedure that returns no result. For example, such a stored procedure can log non-critical information, or change database data in a straightforward way.

The following procedure adds a country to the **world** database, but does not return a result:

```
CREATE PROCEDURE add_country (IN country_code CHAR(3),
                             IN country_name CHAR(52),
                             IN continent_name CHAR(30))
BEGIN
    INSERT INTO Country(Code, Name, Continent)
    VALUES (country_code, country_name, continent_name);
END;
```

2. A stored procedure that returns one or more values using output parameters. For example, such a procedure can indicate success or failure, or retrieve and return data items.

The following procedures use an output parameter to return the population of a specified country or continent, or the entire world:

```
CREATE PROCEDURE get_pop (IN country_name CHAR(52),
                         OUT country_pop BIGINT)
BEGIN
    SELECT Population INTO country_pop FROM Country
    WHERE Name = country_name;
END;
```

```
CREATE PROCEDURE get_pop_continent (IN continent_name CHAR(30),
                                    OUT continent_pop BIGINT)
BEGIN
    SELECT SUM(Population) INTO continent_pop FROM Country
    WHERE Continent = continent_name;
END;
```

```
CREATE PROCEDURE get_pop_world (OUT world_pop BIGINT)
BEGIN
    SELECT SUM(Population) INTO world_pop FROM Country;
END;
```

3. A stored procedure that returns one or more result sets. The procedure can execute one or more queries, each of which returns an arbitrary number of rows. Your application loops through each result set to display, transform, or otherwise process each row in it.

This procedure returns several result sets:

```
CREATE PROCEDURE get_data ()
BEGIN
    SELECT Code, Name, Population, Continent FROM Country
    WHERE Continent = 'Oceania' AND Population < 10000;
    SELECT Code, Name, Population, Continent FROM Country
    WHERE Continent = 'Europe' AND Population < 10000;
    SELECT Code, Name, Population, Continent FROM Country
    WHERE Continent = 'North America' AND Population < 10000;
END;
```

Enter and test the stored procedures manually to ensure that they will be available to your C++ applications. (Select **world** as the default database before you create them.) You are now ready to start writing applications using Connector/C++ that call stored procedures.

8.2.1 Using a **Statement** for a Stored Procedure That Returns No Result

This example shows how to call a stored procedure that returns no result set.

1. Make a copy of the tutorial framework code:

```
shell> cp framework.cpp sp_scenario1.cpp
```

2. Add the following code to the **try** block of the tutorial framework:

```
sql::Driver* driver = get_driver_instance();
std::auto_ptr<sql::Connection> con(driver->connect(url, user, pass));
con->setSchema(database);
std::auto_ptr<sql::Statement> stmt(con->createStatement());

// We need not check the return value explicitly. If it indicates
// an error, Connector/C++ generates an exception.
stmt->execute("CALL add_country('ATL', 'Atlantis', 'North America')");
```

3. Compile the program as described in [Section 8.1, "Prerequisites and Background Information"](#).
4. Run the program:

```
shell> ./sp_scenario1
```

5. Using the **mysql** command-line client or other suitable program, check the **world** database to determine that it has been updated correctly. You can use this query:

```
mysql> SELECT Code, Name, Continent FROM Country WHERE Code='ATL';
+-----+-----+-----+
| Code | Name      | Continent |
+-----+-----+-----+
| ATL  | Atlantis  | North America |
+-----+-----+-----+
```

The code in this application simply invokes the **execute** method, passing to it a statement that calls the stored procedure. The procedure itself returns no value, although it is important to note there is always a return value from the **CALL** statement; this is the **execute** status. Connector/C++ handles this status for you, so you need not handle it explicitly. If the **execute** call fails for some reason, it raises an exception that the **catch** block handles.

8.2.2 Using a **Statement** for a Stored Procedure That Returns an Output Parameter

This example shows how to handle a stored procedure that returns an output parameter.

1. Make a copy of the tutorial framework code:

```
shell> cp framework.cpp sp_scenario2.cpp
```

2. Add the following code to the **try** block of the tutorial framework:

```
sql::Driver* driver = get_driver_instance();
std::auto_ptr<sql::Connection> con(driver->connect(url, user, pass));
con->setSchema(database);
std::auto_ptr<sql::Statement> stmt(con->createStatement());

stmt->execute("CALL get_pop('Uganda', @pop)");

std::auto_ptr<sql::ResultSet> res(stmt->executeQuery("SELECT @pop AS _reply"));
while (res->next())
    cout << "Population of Uganda: " << res->getString("_reply") << endl;
```

```
stmt->execute("CALL get_pop_continent('Asia', @pop)");

res.reset(stmt->executeQuery("SELECT @pop AS _reply"));
while (res->next())
    cout << "Population of Asia: " << res->getString("_reply") << endl;

stmt->execute("CALL get_pop_world(@pop)");

res.reset(stmt->executeQuery("SELECT @pop AS _reply"));
while (res->next())
    cout << "Population of World: " << res->getString("_reply") << endl;
```

3. Compile the program as described in [Section 8.1, "Prerequisites and Background Information"](#).
4. Run the program:

```
shell> ./sp_scenario2
Connector/C++ tutorial framework...

Population of Uganda: 21778000
Population of Asia: 3705025700
Population of World: 6078749450
Done.
```

In this scenario, each stored procedure sets the value of an output parameter. This is not returned directly to the `execute` method, but needs to be obtained using a subsequent query. If you were executing the SQL statements directly, you might use statements similar to these:

```
CALL get_pop('Uganda', @pop);
SELECT @pop;
CALL get_pop_continent('Asia', @pop);
SELECT @pop;
CALL get_pop_world(@pop);
SELECT @pop;
```

In the C++ code, a similar sequence is carried out for each procedure call:

1. Execute the **CALL** statement.
2. Obtain the output parameter by executing an additional query. The query produces a **ResultSet** object.
3. Retrieve the data using a **while** loop. The simplest way to do this is to use a `getString` method on the **ResultSet**, passing the name of the variable to access. In this example `_reply` is used as a placeholder for the variable and therefore is used as the key to access the correct element of the result dictionary.

Although the query used to obtain the output parameter returns only a single row, it is important to use the **while** loop to catch more than one row, to avoid the possibility of the connection becoming unstable.

8.2.3 Using a **Statement** for a Stored Procedure That Returns a Result Set

This example shows how to handle result sets produced by a stored procedure.

Note

This scenario requires MySQL 5.5.3 or higher. The client/server protocol does not support fetching multiple result sets from stored procedures prior to 5.5.3.

1. Make a copy of the tutorial framework code:

```
shell> cp framework.cpp sp_scenario3.cpp
```

2. Add the following code to the [try](#) block of the tutorial framework:

```
sql::Driver* driver = get_driver_instance();
std::auto_ptr<sql::Connection> con(driver->connect(url, user, pass));
con->setSchema(database);
std::auto_ptr<sql::Statement> stmt(con->createStatement());

stmt->execute("CALL get_data()");
std::auto_ptr< sql::ResultSet > res;
do {
    res.reset(stmt->getResultSet());
    while (res->next()) {
        cout << "Name: " << res->getString("Name")
            << " Population: " << res->getInt("Population")
            << endl;
    }
} while (stmt->getMoreResults());
```

3. Compile the program as described in [Section 8.1, "Prerequisites and Background Information"](#).
4. Run the program:

```
shell> ./sp_scenario3
Connector/C++ tutorial framework...

Name: Cocos (Keeling) Islands Population: 600
Name: Christmas Island Population: 2500
Name: Norfolk Island Population: 2000
Name: Niue Population: 2000
Name: Pitcairn Population: 50
Name: Tokelau Population: 2000
Name: United States Minor Outlying Islands Population: 0
Name: Svalbard and Jan Mayen Population: 3200
Name: Holy See (Vatican City State) Population: 1000
Name: Anguilla Population: 8000
Name: Atlantis Population: 0
Name: Saint Pierre and Miquelon Population: 7000
Done.
```

The code is similar to the examples shown previously. The code of particular interest here is:

```
do {
    res.reset(stmt->getResultSet());
    while (res->next()) {
        cout << "Name: " << res->getString("Name")
            << " Population: " << res->getInt("Population")
            << endl;
    }
} while (stmt->getMoreResults());
```

The [CALL](#) is executed as before, but this time the results are returned into multiple [ResultSet](#) objects because the stored procedure executes multiple [SELECT](#) statements. In this example, the output shows that three result sets are processed, because there are three [SELECT](#) statements in the stored procedure. Each result set returns more than one row.

The results are processed using this code pattern:

```
do {
    Get Result Set
    while (Get Result) {
        Process Result
```

```
}
} while (Get More Result Sets);
```

Note

Use this pattern even if the stored procedure executes only a single `SELECT` and produces only one result set. This is a requirement of the underlying protocol.

8.3 Calling Stored Procedures with `PreparedStatement` Objects

This section shows how to call stored procedures using prepared statements. It is recommended that, before working through it, you first work through the previous tutorial [Section 8.2, “Calling Stored Procedures with `Statement` Objects”](#). That section shows the stored procedures required by the applications in this section.

8.3.1 Using a `PreparedStatement` for a Stored Procedure That Returns No Result

This example shows how to call a stored procedure that returns no result set.

1. Make a copy of the tutorial framework code:

```
shell> cp framework.cpp ps_scenario1.cpp
```

2. Add the following code to the `try` block of the tutorial framework:

```
vector<string> code_vector;
code_vector.push_back("SLD");
code_vector.push_back("DSN");
code_vector.push_back("ATL");

vector<string> name_vector;
name_vector.push_back("Sealand");
name_vector.push_back("Disneyland");
name_vector.push_back("Atlantis");

vector<string> cont_vector;
cont_vector.push_back("Europe");
cont_vector.push_back("North America");
cont_vector.push_back("Oceania");

sql::Driver * driver = get_driver_instance();

std::auto_ptr< sql::Connection > con(driver->connect(url, user, pass));
con->setSchema(database);

std::auto_ptr< sql::PreparedStatement > pstmt;

pstmt.reset(con->prepareStatement("CALL add_country(?,?,?)"));
for (int i=0; i<3; i++)
{
    pstmt->setString(1,code_vector[i]);
    pstmt->setString(2,name_vector[i]);
    pstmt->setString(3,cont_vector[i]);

    pstmt->execute();
}
```

Also, uncomment `#include <vector>` near the top of the code, because vectors are used to store sample data.

3. Compile the program as described in [Section 8.1, "Prerequisites and Background Information"](#).
4. Run the program:

```
shell> ./ps_scenario1
```

5. You can check whether the database has been updated correctly by using this query:

```
mysql> SELECT Code, Name, Continent FROM Country
-> WHERE Code IN('DSN','ATL','SLD');
+-----+-----+-----+
| Code | Name      | Continent |
+-----+-----+-----+
| ATL  | Atlantis  | Oceania   |
| DSN  | Disneyland| North America |
| SLD  | Sealand   | Europe    |
+-----+-----+-----+
```

The code is relatively simple, as no processing is required to handle result sets. The procedure call, `CALL add_country(?,?,?)`, is made using placeholders for input parameters denoted by `'?'`. These placeholders are replaced by the appropriate data values using the `PreparedStatement` object's `setString` method. The `for` loop is set up to iterate 3 times, as there are three data sets in this example. The same `PreparedStatement` is executed three times, each time with different input parameters.

8.3.2 Using a `PreparedStatement` for a Stored Procedure That Returns an Output Parameter

This example shows how to handle a stored procedure that returns an output parameter.

1. Make a copy of the tutorial framework code:

```
shell> cp framework.cpp ps_scenario2.cpp
```

2. Add the following code to the `try` block of the tutorial framework:

```
vector<string> cont_vector;
cont_vector.push_back("Europe");
cont_vector.push_back("North America");
cont_vector.push_back("Oceania");

sql::Driver * driver = get_driver_instance();

std::auto_ptr< sql::Connection > con(driver->connect(url, user, pass));
con->setSchema(database);

std::auto_ptr< sql::Statement > stmt(con->createStatement());
std::auto_ptr< sql::PreparedStatement > pstmt;
std::auto_ptr< sql::ResultSet > res;

pstmt.reset(con->prepareStatement("CALL get_pop_continent(?,@pop)"));

for (int i=0; i<3; i++)
{
    pstmt->setString(1,cont_vector[i]);
    pstmt->execute();
    res.reset(stmt->executeQuery("SELECT @pop AS _population"));
    while (res->next())
        cout << "Population of "
              << cont_vector[i]
              << " is "
              << res->getString("_population") << endl;
}
```

Also, uncomment `#include <vector>` near the top of the code, because vectors are used to store sample data.

3. Compile the program as described in [Section 8.1, "Prerequisites and Background Information"](#).
4. Run the program:

```
shell> ./ps_scenario2
Connector/C++ tutorial framework...

Population of Europe is 730074600
Population of North America is 482993000
Population of Oceania is 30401150
Done.
```

In this scenario a `PreparedStatement` object is created that calls the `get_pop_continent` stored procedure. This procedure takes an input parameter, and also returns an output parameter. The approach used is to create another statement that can be used to fetch the output parameter using a `SELECT` query. Note that when the `PreparedStatement` is created, the input parameter to the stored procedure is denoted by `'?'`. Prior to execution of the prepared statement, it is necessary to replace this placeholder by an actual value. This is done using the `setString` method:

```
pstmt->setString(1, cont_vector[i]);
```

Although the query used to obtain the output parameter returns only a single row, it is important to use the `while` loop to catch more than one row, to avoid the possibility of the connection becoming unstable.

8.3.3 Using a `PreparedStatement` for a Stored Procedure That Returns a Result Set

This example shows how to handle result sets produced by a stored procedure.

Note

This scenario requires MySQL 5.5.3 or higher. The client/server protocol does not support fetching multiple result sets from stored procedures prior to 5.5.3.

1. Make a copy of the tutorial framework code:

```
shell> cp framework.cpp ps_scenario3.cpp
```

2. Add the following code to the `try` block of the tutorial framework:

```
sql::Driver * driver = get_driver_instance();

std::auto_ptr< sql::Connection > con(driver->connect(url, user, pass));
con->setSchema(database);

std::auto_ptr< sql::PreparedStatement > pstmt;
std::auto_ptr< sql::ResultSet > res;

pstmt.reset(con->prepareStatement("CALL get_data()"));
res.reset(pstmt->executeQuery());

for(;;)
{
    while (res->next()) {
        cout << "Name: " << res->getString("Name")
```

```
        << " Population: " << res->getInt("Population")
        << endl;
    }
    if (pstmt->getMoreResults())
    {
        res.reset(pstmt->getResultSet());
        continue;
    }
    break;
}
```

3. Compile the program as described in [Section 8.1, "Prerequisites and Background Information"](#).
4. Run the program:

```
shell> ./ps_scenario3
```

5. Make a note of the output generated.

The code executes the stored procedure using a [PreparedStatement](#) object. The standard [do/while](#) construct is used to ensure that all result sets are fetched. The returned values are fetched from the result sets using the [getInt](#) and [getString](#) methods.

Chapter 9 Connector/C++ Debug Tracing

Although a debugger can be used to debug a specific instance of your application, you may find it beneficial to enable the debug traces of the connector. Some problems happen randomly which makes them difficult to debug using a debugger. In such cases, debug traces and protocol files are more useful because they allow you to trace the activities of all instances of your program.

DTrace is a very powerful technology to trace any application without having to develop an extra trace module for your application. DTrace is currently available on Solaris, OS X, and FreeBSD.

Connector/C++ can write two trace files:

1. A trace file generated by the MySQL client library
2. A trace file generated internally by Connector/C++

The first trace file can be generated by the underlying MySQL client library ([libmysqlclient](#)). To enable this trace, the connector calls the [mysql_debug\(\)](#) C API function internally. Because only debug versions of the MySQL client library are capable of writing a trace file, compile Connector/C++ against a debug version of the library to use this trace. The trace shows the internal function calls and the addresses of internal objects as shown here:

```
>mysql_stmt_init
| >_mymalloc
| | enter: Size: 816
| | exit: ptr: 0x68e7b8
| <_mymalloc | >init_alloc_root
| | enter: root: 0x68e7b8
| | >_mymalloc
| | | enter: Size: 2064
| | | exit: ptr: 0x68eb28
| [...]

```

The second trace is the Connector/C++ internal trace. It is available with debug and nondebug builds of the connector as long as you have enabled the tracing module at compile time. By default, tracing functionality is not available and calls to trace functions are removed by the preprocessor. To enable the tracing module, use `cmake -DMYSQLCPPCONN_TRACE_ENABLE=1`.

Compiling the connector with tracing functionality enabled causes two additional tracing function calls per each connector function call. For example:

```
| INF: Tracing enabled
| <MySQL_Connection::setClientOption
| >MySQL_Prepared_Statement::setInt
| | INF: this=0x69a2e0
| | >MySQL_Prepared_Statement::checkClosed
| | <MySQL_Prepared_Statement::checkClosed
| | <MySQL_Prepared_Statement::setInt
| [...]

```

Run your own benchmark to find out how much this will impact the performance of your application.

A simple test using a loop running 30,000 [INSERT](#) SQL statements showed no significant real-time impact. The two variants of this application using a trace enabled and trace disabled version of the connector performed equally well. The runtime measured in real time was not significantly impacted as long as writing a debug trace was not enabled. However, there will be a difference in the time spent in the application. When writing a debug trace, the I/O subsystem may become a bottleneck.

In summary, use connector builds with tracing enabled carefully. Trace-enabled versions may cause higher CPU usage even if the overall runtime of your application is not impacted significantly.

The example from [examples/debug_output.cpp](#) demonstrates how to activate the debug traces in your program. Currently they can only be activated through API calls. The traces are controlled on a per-connection basis. You can use the [setClientOption\(\)](#) method of a connection object to activate and deactivate trace generation. The MySQL client library trace always writes its trace to a file, whereas the connector writes protocol messages to the standard output.

```
sql::Driver *driver;
int on_off = 1;

/* Using the Driver to create a connection */
driver = get_driver_instance();
std::auto_ptr< sql::Connection > con(driver->connect(host, user, pass));

/*
Activate debug trace of the MySQL client library (C API)
Only available with a debug build of the MySQL client library!
*/
con->setClientOption("libmysql_debug", "d:t:0,client.trace");

/*
Connector/C++ tracing is available if you have compiled the
driver using cmake -DMYSQLCPPCONN_TRACE_ENABLE:BOOL=1
*/
con->setClientOption("clientTrace", &on_off);
```

Chapter 10 Connector/C++ Usage Notes

Connector/C++ is compatible with the JDBC 4.0 API. See the [JDBC overview](#) for information on JDBC 4.0. Please also check the [examples](#) directory of the download package.

- The Connector/C++ `sql::DataType` class defines the following JDBC standard data types: `UNKNOWN`, `BIT`, `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INTEGER`, `BIGINT`, `REAL`, `DOUBLE`, `DECIMAL`, `NUMERIC`, `CHAR`, `BINARY`, `VARCHAR`, `VARBINARY`, `LONGVARCHAR`, `LONGVARBINARY`, `TIMESTAMP`, `DATE`, `TIME`, `GEOMETRY`, `ENUM`, `SET`, `SQLNULL`.

Connector/C++ does not support the following JDBC standard data types: `ARRAY`, `BLOB`, `CLOB`, `DISTINCT`, `FLOAT`, `OTHER`, `REF`, `STRUCT`.

- `DatabaseMetaData::supportsBatchUpdates()` returns `true` because MySQL supports batch updates in general. However, the Connector/C++ API provides no API calls for batch updates.
- Two non-JDBC methods let you fetch and set unsigned integers: `getUInt64()` and `getUInt()`. These are available for `ResultSet` and `PreparedStatement`:
 - `ResultSet::getUInt64()`
 - `ResultSet::getUInt()`
 - `PreparedStatement::setUInt64()`
 - `PreparedStatement::setUInt()`

The corresponding `getLong()` and `setLong()` methods have been removed.

- The `DatabaseMetaData::getColumnNames()` method has 23 columns in its result set, rather than the 22 columns defined by JDBC. The first 22 columns are as described in the JDBC documentation, but column 23 is new:

23. `IS_AUTOINCREMENT`: A string which is “YES” if the column is an auto-increment column, “NO” otherwise.

- Connector/C++ may return different metadata for the same column, depending on the method you call.

Suppose that you have a column that accepts a character set and a collation in its specification and you specify a binary collation, such as:

```
VARCHAR(20) CHARACTER SET utf8 COLLATE utf8_bin
```

The server sets the `BINARY` flag in the result set metadata of this column. The `ResultSetMetaData::getColumnTypeName()` method uses the metadata and reports, due to the `BINARY` flag, that the column type name is `BINARY`, as illustrated here:

```
mysql> CREATE TABLE varbin (a VARCHAR(20) CHARACTER SET utf8 COLLATE utf8_bin);
Query OK, 0 rows affected (0.00 sec)

mysql> select * from varbin;
Field  1:  `a`
Catalog:  `def`
Database:  `test`
Table:     `varbin`
Org_table: `varbin`
Type:      VAR_STRING
Collation: latin1_swedish_ci (8)
Length:    20
Max_length: 0
Decimals:  0
```

```

Flags:      BINARY

0 rows in set (0.00 sec)

mysql> SELECT * FROM INFORMATION_SCHEMA.COLUMNS WHERE TABLE_NAME='varbin'\G
***** 1. row *****
      TABLE_CATALOG: NULL
      TABLE_SCHEMA: test
      TABLE_NAME: varbin
      COLUMN_NAME: a
      ORDINAL_POSITION: 1
      COLUMN_DEFAULT: NULL
      IS_NULLABLE: YES
      DATA_TYPE: varchar
CHARACTER_MAXIMUM_LENGTH: 20
CHARACTER_OCTET_LENGTH: 60
      NUMERIC_PRECISION: NULL
      NUMERIC_SCALE: NULL
CHARACTER_SET_NAME: utf8
COLLATION_NAME: utf8_bin
      COLUMN_TYPE: varchar(20)
      COLUMN_KEY:
      EXTRA:
      PRIVILEGES: select,insert,update,references
      COLUMN_COMMENT:
1 row in set (0.01 sec)

```

However, `INFORMATION_SCHEMA` gives no hint in its `COLUMNS` table that metadata will contain the `BINARY` flag. `DatabaseMetaData::getColumn()` uses `INFORMATION_SCHEMA` and will report the type name `VARCHAR` for the same column. It also returns a different type code.

- When inserting or updating `BLOB` or `TEXT` columns, Connector/C++ developers are advised not to use `setString()`. Instead, use the dedicated `setBlob()` API function.

The use of `setString()` can cause a `Packet too large` error message. The error occurs if the length of the string passed to the connector using `setString()` exceeds `max_allowed_packet` (minus a few bytes reserved in the protocol for control purposes). This situation is not handled in Connector/C++, because it could lead to security issues, such as extremely large memory allocation requests due to malevolently long strings.

If `setBlob()` is used, this problem does not arise because `setBlob()` takes a streaming approach based on `std::istream`. When sending the data from the stream to MySQL Server, Connector/C++ splits the stream into chunks appropriate for MySQL Server using the current `max_allowed_packet` setting.

Caution

When using `setString()`, it is not possible to set `max_allowed_packet` to a value large enough for the string prior to passing it to Connector/C++. That configuration option cannot be changed within a session.

This difference from the JDBC specification ensures that Connector/C++ is not vulnerable to memory flooding attacks.

- In general, Connector/C++ works with MySQL 5.0, but it is not completely supported. Some methods may not be available when connecting to MySQL 5.0. This is because the Information Schema is used to obtain the requested information. There are no plans to improve the support for 5.0 because the current GA version of MySQL Server is 5.6. Connector/C++ is primarily targeted at the MySQL Server GA version that is available on its release.

The following methods throw a `sql::MethodNotImplemented` exception when you connect to a MySQL server earlier than 5.1:

- `DatabaseMetaData::getCrossReference()`

- `DatabaseMetaData::getExportedKeys()`
- Connector/C++ includes a `Connection::getClientOption()` method that is not included in the JDBC API specification. The prototype is:

```
void getClientOption(const std::string & optionName, void * optionValue)
```

The method can be used to check the value of connection properties set when establishing a database connection. The values are returned through the `optionValue` argument passed to the method with the type `void *`.

Currently, `getClientOption()` supports fetching the `optionValue` of the following options:

- `metadataUseInfoSchema`
- `defaultStatementResultType`
- `defaultPreparedStatementResultType`

The `metadataUseInfoSchema` connection option controls whether to use the `Information_Schemata` for returning the metadata of `SHOW` statements:

- For `metadataUseInfoSchema`, interpret the `optionValue` argument as a boolean upon return.
- For `defaultStatementResultType` and `defaultPreparedStatementResultType`, interpret the `optionValue` argument as an integer upon return.

The connection property can be set either when establishing the connection through the connection property map, or using `void Connection::setClientOption(const std::string & optionName, const void * optionValue)` where `optionName` is assigned the value `metadataUseInfoSchema`.

Some examples:

```
bool isInfoSchemaUsed;
conn->getClientOption("metadataUseInfoSchema", (void *) &isInfoSchemaUsed);

int defaultStmtResType;
int defaultPStmtResType;
conn->getClientOption("defaultStatementResultType", (void *) &defaultStmtResType);
conn->getClientOption("defaultPreparedStatementResultType", (void *) &defaultPStmtResType);
```

- To get and set MySQL session variables, Connector/C++ supports the following `MySQL_Connection` methods, which are not found in the JDBC API standard:

```
std::string MySQL_Connection::getSessionVariable(const std::string & varname)
```

```
void MySQL_Connection::setSessionVariable(const std::string & varname, const std::string & value)
```

`getSessionVariable()` is equivalent to executing the following and fetching the first return value:

```
SHOW SESSION VARIABLES LIKE 'var_name'
```

You can use the `%` and `_` SQL pattern characters in `var_name`.

`setSessionVariable()` is equivalent to executing:

```
SET SESSION var_name = value
```

-
- Fetching the value of a column can sometimes return different values depending on whether the call is made from a Statement or Prepared Statement. This is because the protocol used to communicate with the server differs depending on whether a Statement or Prepared Statement is used.

To illustrate this, consider the case where a column has been defined as type `BIGINT`. The most negative `BIGINT` value is then inserted into the column. If a Statement and Prepared Statement are created that perform a `getUInt64()` call, then the results will be different in each case. The Statement returns the maximum positive value for `BIGINT`. The Prepared Statement returns 0.

The difference results from the fact that Statements use a text protocol, and Prepared Statements use a binary protocol. With the binary protocol in this case, a binary value is returned from the server that can be interpreted as an `int64`. In the preceding scenario, a very large negative value is fetched with `getUInt64()`, which fetches unsigned integers. Because the large negative value cannot be sensibly converted to an unsigned value, 0 is returned.

In the case of the Statement, which uses the text protocol, values are returned from the server as strings, and then converted as required. When a string value is returned from the server in the preceding scenario, the large negative value must be converted by the runtime library function `strtoul()`, which `getUInt64()` calls. The behavior of `strtoul()` is dependent upon the specific runtime and host operating system, so the results can be platform dependent. In the case, given a large positive value was actually returned.

Although it is very rare, there are some cases where Statements and Prepared Statements can return different values unexpectedly, but this usually only happens in extreme cases such as the one mentioned.

- The JDBC documentation [lists many fields](#) for the `DatabaseMetaData` class. JDBC also appears to [define certain values](#) for those fields. However, Connector/C++ does not define certain values for those fields. Internally enumerations are used and the compiler determines the values to assign to a field.

To compare a value with the field, use code such as the following, rather than making assumptions about specific values for the attribute:

```
// dbmeta is an instance of DatabaseMetaData
if (myvalue == dbmeta->attributeNoNulls) {
    ...
}
```

Usually `myvalue` will be a column from a result set holding metadata information. Connector/C++ does not guarantee that `attributeNoNulls` is 0. It can be any value.

- When programming stored procedures, JDBC has available an extra class, an extra abstraction layer for callable statements, the `CallableStatement` class. As this class is not present in Connector/C++, use the methods from the `Statement` and `PreparedStatement` classes to execute a stored procedure using `CALL`.

Chapter 11 Connector/C++ Known Bugs and Issues

Please report bugs through the MySQL Bug System. See [How to Report Bugs or Problems](#).

For notes detailing the changes in each release of Connector/C++, see [MySQL Connector/C++ Release Notes](#).

- When linking against a static library for 1.0.3 on Windows, define `CPPDBC_PUBLIC_FUNC` either in the compiler options (preferable) or with `/D "CPPCONN_PUBLIC_FUNC="`. You can also explicitly define it in your code by placing `#define CPPCONN_PUBLIC_FUNC` before the header inclusions.
- Generally speaking, C++ library binaries are less portable than C library binaries. Issues can be caused by name mangling, different Standard Template Library (STL) versions, and using different compilers and linkers for linking against the libraries than were used for building the library itself.

Even a small change in the compiler version can cause problems. If you obtain error messages that you suspect are related to binary incompatibilities, build Connector/C++ from source, using the same compiler and linker that you use to build and link your application.

Due to the variations between Linux distributions, compiler and linker versions and STL versions, it is not possible to provide binaries for each and every possible configuration. However, the Connector/C++ binary distributions contain a [README](#) file that describes the environment and settings used to build the binary versions of the libraries.

- To avoid potential crashes, the build configuration of Connector/C++ should match the build configuration of the application using it. For example, do not use the release build of Connector/C++ with a debug build of the client application.

Chapter 12 Connector/C++ Support

For general discussion of Connector/C++, please use the [C/C++ community forum](#) or join the [Connector/C++ mailing list](#).

Bugs can be reported at the [MySQL bug Web site](#).

For notes detailing the changes in each release of Connector/C++, see [MySQL Connector/C++ Release Notes](#).
